Proceedings 2002-2011

Forensic Pathology/ Biology

Forensic Pathology / Biology

AMERICAN ACADEMY OF FORENSIC SCIENCES
410 North 21st Street
Colorado Springs, CO 80904
www.aafs.org

The Proceedings of the American Academy of Forensic Sciences is an official publication of the American Academy of Forensic Sciences (AAFS) and includes various areas of the forensic sciences such as pathology, toxicology, physical anthropology, psychiatry, odontology, jurisprudence, criminalistics, questioned documents, digital sciences, engineering sciences and other disciplines. The proceedings herein are from the Pathology/Biology section for the years 2002 to 2011.

As with the Proceedings in which these abstracts were originally published, there is no implication or assertion that the AAFS, any of its sections, or any member of the AAFS have verified the statements and/or conclusions of the abstracts. The views expressed in this publication are not those of the AAFS or individual members. In short, the data and opinions appearing in the abstracts are the responsibility of the individual authors alone.

All contents copyright 2002-2011 by the AAFS. Unless stated otherwise, noncommercial reproduction of material contained herein is permitted by the AAFS provided that the copying is faithful to the original. No other reproduction of any form may be done without prior written permission from the AAFS. Printed in the United States of America.

Preface

The American Academy of Forensic Sciences (AAFS) is a multi-disciplinary professional organization created and maintained to provide leadership in the application of science to the legal system. A premier forensic science organization, its specific objectives are to promote professionalism, integrity, competency and education, and to foster scientific research, improvements in the practice of forensic science, and collaboration within the many fields of forensic science.

For sixty-three years, since its founding in 1948, the AAFS has served a distinguished and diverse membership. It comprises eleven different sections representing the broad range of expertise and interest of its members, now numbering over 6200. Included among them are physicians, attorneys, dentists, toxicologists, physical anthropologists, document examiners, psychiatrists, physicists, engineers, criminalists, educators, and digital evidence specialists. Representing all fifty US states, all ten Canadian provinces and 61 other countries from all corners of the world, AAFS members actively practice forensic science. In many cases, AAFS members also teach and conduct research in the field, producing hundreds of refereed publications and books.

The editors express gratitude to the past and present AAFS leadership, especially to the AAFS staff headed by Executive Director Anne Warren, to the AAFS Presidents since 1949, and to our section's directors and chair persons.

Academy Presidents

Robert E. Barsley, DDS, JD	2012-13		
Douglas H. Ubelaker, PhD	2011-12	Lowell J. Levine, DDS	1980-81
Joseph P. Bono, MA	2010-11	June K. Jones, MS	1979-80
Thomas L. Bohan, PhD, JD	2009-10	Kurt M. Dubowski, PhD	1978-79
Carol E. Henderson, JD	2008-09	B. Edward Whittaker, BS	1977-78
Bruce A. Goldberger, PhD	2007-08	James T. Weston, MD	1976-77
James G. Young, MD	2006-07	Robert J. Joling, JD	1975-76
Edmund R. Donoghue, MD	2005-06	David A. Crown, DCrim	1974-75
Ronald L. Singer, MS	2004-05	Morton F. Mason, PhD	1973-74
Kenneth E. Melson, JD	2003-04	Douglas M. Lucas, MSc, DSc	1972-73
Graham R. Jones, PhD	2002-03	Cyril H. Wecht, MD, JD	1971-72
Mary Fran Ernst, BLS	2001-02	Edwin C. Conrad, JD, PhD	1970-71
John D. McDowell, DDS, MS	2000-01	James W. Osterburg, MPA	1969-70
Patricia J. McFeeley, MD	1999-00	Maier I. Tuchler, MD	1968-69
Barry A.J. Fisher, MS, MBA.	1998-99	Charles S. Petty	1967-68
Michael A. Peat, PhD	1997-98	Jack L. Sachs, JD	1966-67

1961-1962		Joseph H. Davis, MD
1960-1961		E. H. Johnston, MD
1959-1960		Charles S. Petty, MD
1958-1959		Arthur E. O'Dea, MD
1957-1958		Frank P. Cleveland, MD
1956-1957		Samuel R. Gerber, MD, LLB
1955-1956		Russell S. Fisher, MD
1954-1955		Russell S. Fisher, MD
1953-1954		Geoffrey T. Mann, LLB, MD
1952-1953		William E.B. Hall, MD
1951-1952		William E.B. Hall, MD
1950-1951		Milton Helpern, MD

Our heartfelt thanks to the Academy Staff for managing the proceedings process that results in the highest standards of quality including Sonya Bynoe, Publications & Website Coordinator; Debbie Crockett, Finance Manager; Sondra Doolittle, Meetings & Exposition Manager; Phyllis Gilliam, Receptionist; Salena Grant, Assistant Meetings Manager; Cheryl Hunter, Membership Coordinator; Nancy Jackson, Director of

Development & Accreditation; Tracie McCray, Accounting Assistant; Christie Vigil, Membership Assistant; and Kimberly Wrasse, Executive Assistant.

This further acknowledges the excellent work of Pathology/Biology authors worldwide who are willing to share their work for education.

Victor W. Weedn, MD, JD
Gregory G. Davis, MD
Jeffery K. Tomberlin, PhD

Davis, MD, Jefferson County Medical Examiner's Office, 1515 6th Avenue, South, Room 220, Birmingham, AL 35233-1601</i>	12
The Use of Raman Spectroscopic Imaging in Cases of Ethylene Glycol Toxicity	<i>Victor W. Weedn, MD, Maryland State Office of the Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Mary G. Ripple, MD, 68 Bluebird Road, Port Deposit, MD 21904; Sara Nedley, MS, ChemImage, 7301 Penn Avenue, Pittsburgh, PA 15208; and David R. Fowler, MD, and Kristin A. Johnson, MD*, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	12
Death From Severe Anorectal Injury of a Jet Ski Passenger	<i>Dennis Rhee, MD*, and Lynn A. Salzberger, MD, Southwest Institute of Forensic Sciences, 5230 Southwestern Medical Avenue, Dallas, TX 75235</i>	13

Sudden Unexpected Infant Death: Peripheral Retinal Hemorrhages Associated With Accidental Positional Asphyxiation (Wedging)	<i>Stephen Lenfest, MD*, Wake Forest University Baptist Medical Center Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157; Candace H. Schoppe, MD, Wake Forest University School of Medicine, Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157; Constance A. Stanton, MD, Department of Pathology, Wake Forest University Health Sciences, Medical Center Boulevard, Winston Salem, NC 27157; Donald R. Jason, JD, Wake Forest University School of Medicine, Medical Center Boulevard, Winston-Salem, NC 27157-1072; and Patrick E. Lantz, MD, Wake Forest University Health Sciences, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072</i>	13
Antiepileptic Drug Intoxication: Report of One Case and a Forensic Pathologist's Approach	<i>Ana R. Pereira, MD*, Ladeira das Alpenduradas nº13A, Coimbra, 3030- 167, PORTUGAL; Paula C. Oliveira, MD*, Konara Gunathilake, MD, Bruno M. Santos, MSc, Paula Proenca, PharmD, and Miguel Franco, MSc, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; Maria C. Mendonça, PhD, Instituto Nacional de Medicina Legal, Largo Sé Nova, Coimbra, 3000, PORTUGAL; and Duarte N.P. Vieira, PhD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL</i>	14
Are Peripapillary Intrascleral Hemorrhages Pathognomonic for Abusive Head Trauma?	<i>Candace H. Schoppe, MD*, Wake Forest University Baptist Medical Center, Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157; Constance A. Stanton, MD, Department of Pathology, Wake Forest University Health Sciences, Medical Center Boulevard, Winston Salem, NC 27157; and Patrick E. Lantz, MD, Wake Forest University of Health Science, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072</i>	15
The Correlation of Serum Stress Hormone Levels With Cause and Circumstance of Death	<i>Robert C. Shaler, PhD*, 30 Spring Street, Flemington, NJ 08822; Dominic Flaim, PMFS, Pennsylvania State University, 107 Whitmore Lab, State College, PA 16802; and Thomas Andrew, MD, Office of the State Chief Medical Examiner, 246 Pleasant Street, Concord, NH 03301</i>	15
Stippling Mimics — Differentiating Pseudostippling From Stippling: A Report of Four Cases	<i>Jeffery G. Gofson, MD*, and Wendy M. Gunther, MD*, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046</i>	16
DNA Extraction From Paraffin Blocks: Organ Selection and Pre-Embedding Fixation Times – Practical Implications for Forensic Pathologists	<i>Alex John, MD*, Harris County Institute of Forensic Sciences, 1885 Old Spanish trail, Houston, TX 77054; Dwayne A. Wolf, PhD, Harris County Medical Examiner's Office, JAJ Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054; Jennifer Petrash, MS, Shahida Flores, BS, Dustin Foley, MS, Lisa Gefrides, MS, and Roger Kahn, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX</i>	16

The Potential Value of Bone Marrow Analysis for Forensic Purposes: Evaluation of Needle Aspiration and Biopsy Taken From the Sternum	<i>Biagio Solarino, PhD*, Lucia Tattoli, PhD, Eloisa Maselli, MD, and Maria C. Romanelli, MD, Section of Legal Medicine, University of Bari, Piazza Giulio Cesare, 11, Bari, 70122, ITALY; Michael Tsokos, PhD, Institute of Legal Medicine and Forensic Sciences, University of Berlin, Turmstr. 21, Building L, 10559, Berlin, 10559, GERMANY; Alessandro Dell Erba, PhD, Section of Legal Medicine, University of Bari, Piazza Giulio Cesare, 11, Bari, 70122, ITALY; and Mario Delia, PhD, Hematology Section, University of Bari, Piazza Giulio Cesare, 11, Bari, 70122, ITALY</i>	17
2009 H1N1 Fatalities: The New Mexico Experience	<i>Erin G. Brooks, MD*, Office of the Medical Investigator, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131; Clare H. Cunliffe, MD, Office of Medical Investigator, 700 Camino de Salud Northeast, Albuquerque, NM 87106; Catherine Avery, Chad Smelser, MD, and Deborah Thompson, MD, New Mexico Department of Health, 1190 South Saint Francis Drive, Santa Fe, NM 87502; and Kurt B. Nolte, MD, Office of Medical Investigator, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131-0001</i>	17
The Potential Use of Aquatic Invertebrate for Postmortem Submersion Interval (PMSI) Determination	<i>Simona Corrado, MD*, Sezione di Medicina Legale, Bari, 70100, ITALY; Lucio Rositani, PhD, Laboratory of Marine Biology, Molo Pizzoli, Bari, 70100, ITALY; Maurizio Scarpa, MD, Piazza G. Cesare 11 Università di Bari, Bari, 70100, ITALY; and Francesco Introna, PhD, Section of legal Medicine - DiMIMP, Piazza Giulio Cesare n.11, Bari, 70124, ITALY</i>	18
Epidemic Outbreak of Meningococcal Meningitis in a Nursery: Two Fatal Cases of Waterhouse-Friderichsen Syndrome	<i>Alessandro Bonsignore, MD*, Francesca Fossati, MD, Federica Portunato, MD, Francesco Ventura, PhD, and Francesco De Stefano, MD, Department of Legal and Forensic Medicine, University of Genova, Via de Toni 12, Genova, 16132, ITALY</i>	18
Postmortem Animal Injuries: A Forensic Pathologist's Perspective	<i>Ana R. Pereira, MD*, Ladeira das Alpenduradas nº13A, Coimbra, 3030-167, PORTUGAL; Bruno M. Santos, MSc, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; Carmen Barbu, MD, Instituto de Medicina Legal de Sf. Gheorghe, Romania, Bucharest, ROMANIA; Pedro A. Rezende, MSc, Jardim Carriço Videira, Porto, PORTUGAL; Paula C. Oliveira, MD*, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; Jorge C. Santos, PhD, South Branch National Institute of Legal Medicine, R. Manuel Bento de Sousa, nº 3, 1150-219 Lisboa, Lisboa, PORTUGAL; and Duarte N.P. Vieira, PhD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL</i>	19
Neck Findings in Hanging and Strangulation Cases That Underwent Autopsy in Adana, Turkey	<i>Ahmet Hilal, MD*, Necmi Cekin, MD, Mete K. Gulmen, PhD, and Kemal C. Yildirim, MD, Cukurova University School of Medicine, Department of Forensic Medicine, Balcali, Adana, 01330, TURKEY</i>	20

Evaluation of Cardiac Conduction System Pathologies in Sudden Deaths in Adana Region	Mete K. Gulmen, PhD*, Cukurova University School of Medicine, Department of Forensic Medicine, Adana, 01330, TURKEY; Ramazan Karanfil, MD, Kahramanmaraş Sutcu Imam University, School of Medicine, Department of Forensic Medicine, Kahramanmaraş, 46100, TURKEY; and Ahmet Hilal, MD, and Necmi Cekin, MD, Cukurova University School of Medicine, Department of Forensic Medicine, Balcalı, Adana, 01330, TURKEY	20
A Peculiar Fatal Lightning Strike Inside a Cottage	Federica Portunato, MD*, Manuela Botto, MD, and Alessandro Bonsignore, MD, University of Genova, Department of Legal and Forensic Medicine, Via de' Toni 12, Genova, I-16132, ITALY; and Francesco Ventura, MD, University of Genova, Department of Forensic Pathology, Via de' Toni, 12, Genova, 16132, ITALY	21
Enterobacter Cloacae Peritonitis Secondary to Hemorrhagic Cystitis in a Long-Term Substance Abuser	Elena Bulakhtina, MD*, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222; Zhuo Wang, MD, Conemaugh Valley Memorial Hospital, 1020 Franklin Street, Johnstown, PA 15905; Todd M. Luckasevic, DO, Baiyang Xu, MD, and Abdulrezak M. Shakir, MD, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222; and Karl E. Williams, MD, MPH, Allegheny County Medical Examiner's Office, 542 Fourth Avenue, Pittsburgh, PA 15219	21
Two Suicidal Deaths From Head Injuries Caused by Unusual Sharp Force Instruments and Review of the Literature	Patricia A. Aronica-Pollak, MD*, and Mary G. Ripple, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Juan C. Troncoso, MD, Department of Pathology, Johns Hopkins University School of Medicine, 600 North Wolfe Street, Baltimore, MD 21287; Kyle C. Shaw, MBBS, District 5 Medical Examiner's Office, 809 Pine Street, Leesburg, FL 34748; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201	22
Iatrogenic Laceration of a Pulmonary Angiomatoid Lesion: Fatal Complication or Medical Error?	Paolo Fais, MD*, and Giovanni Cecchetto, MD, Via Faloppio 50, Padova, 35121, ITALY; Guido Viel, MD, University of Padua, Via Faloppio 50, PADOVA, 35121, ITALY; Rossella Snenghi, MD, and Rafael Boscolo-Berto, MD, Via Faloppio 50, Padova, 35121, ITALY; Andrea Zuin, MD, Via Giustiniani 2, Padova, ITALY; and Massimo Montisci, PhD, Via Faloppio 50, Padova, 35121, ITALY	23
Pedestrian Fatalities in Maryland: How Many, Who, When, Where, Why, How, and Ways to Prevent Them	Ana Rubio, PhD*, Carol H. Allan, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201	23
Sudden Cardiac Death in an Athlete: A Case Report	Damien Mauillon, MD*, Service de Médecine Légale, Centre Hospitalier Universitaire, 4 rue Larrey, Angers Cedex 9, 49933, FRANCE; Nathalie Jousset, MD, Centre Hospitalier Universitaire, 4 rue Larrey, Angers Cedex 9, 49933, FRANCE; Paul Fornes, PhD, Hospital Robert Debre, Avenue du General Koeing, Reims, 51100, FRANCE; and Clotilde Rouge-Maillart, PhD, Centre Hospitalier Universitaire, Service de Médecine Légale, 4 rue Larrey, Angers Cedex 9, 49933, FRANCE	24
Myocarditis With Giant Cells in an Infant: A Case Report and Review of the Literature	Tera A. Jones, MD*, Douglas County Coroner's Office, 4000 Justice Way, Castle Rock, CO 80109	24

Massive Systemic Fat Embolism Detected by Postmortem Imaging and Biopsy	<i>Patricia M. Flach, MD; Steffen G. Ross, MD; Garyfalia Ampanozi, MD; Stephan A. Boliger, MD; Gary M. Hatch, MD; Michael Thali, MD; and Tanja Germerott, MD, Institut of Forensic Medicine, University of Bern- Virtopsy, Buehlstrasse 20, Bern 3012 SWITZERLAND</i>	25
Radiocarbon and Stable Isotope Results of Fingernails of Breastfed Mother-Infant Pairs to Investigate Deviation of Year-of-Birth Determinations Due to Diet	<i>Kaelyn M. Ormsby, BS*, and Guaciara M. Santos, PhD, KCC-AMS Preparation Laboratory, University of California, Irvine, B321 Croul Hall, Irvine, CA 92697; and Benjamin T. Fuller, PhD, Max Planck Institute for Evolutionary Anthropology, Department of Human Evolution, Deutscher Platz 6, Leipzig, D-04103, GERMANY</i>	25
The Effect of Cultural Cranial Deformation on Neurological Development: A Beneficial or Disadvantageous Practice?	<i>Anna Williams, PhD*, and Mitzi A. Richards, MSc, Cranfield University, Defence Academy of the UK, Shrivenham, SN6 8LA, UNITED KINGDOM</i>	26
Morphological Identification of Right Ventricular Ischemia Determining Right Heart Failure in Cases of Fatal Pulmonary Thromboembolism	<i>Tony Fracasso, MD*, University Center of Legal Medicine, CMU - CURML, Rue Michel-Servet 1, Geneva, 1211, SWITZERLAND; Heidi Pfeiffer, PhD, University Hospital Münster, Röntgenstr 23, Münster, 48149, GERMANY; Cristina Sauerland, University of Münster, Domagstr 9, Münster, 48149, GERMANY; and Andreas Schmeling, PhD, University Hospital Münster, Röntgenstr. 23, Münster, 48149, GERMANY</i>	27
Autopsy Performance in Transfusion Recipient Fatalities Reported to the United States Food and Drug Administration (FDA) During Fiscal Year 2008	<i>Stephen L. Sgan, MD*, District 2 Medical Examiner's Office, PO Box 14389, Tallahassee, FL 32317</i>	27
A Case of Atypical Chronic Subdural Hematoma: A Spontaneous Rupture of Dural Lymphoma Nodule?	<i>Renaud Clement, MD*, 1 Rue Gaston Veil, Nantes, FRANCE</i>	28
A Comparison of Trauma Associated With Manual and Automated Cardiopulmonary Resuscitation	<i>Deborrah C. Pinto, PhD*, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Kathryn Haden-Pinneri, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054; and Jennifer C. Love, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054</i>	28
Sudden Unexpected Death Associated With Undiagnosed Lymphocytic Thyroiditis: Report of a Case and Literature Review	<i>Silvia Tambuschio, PhD*, University of Verona, via Rezzonico, 24, 35131, Padova, ITALY; Jennifer Pascali, PhD, University of Verona, Piazzale L.A. Scuro 10, Verona, IL 37100, ITALY; Andrea Galassi, MD, S.Bortolo Vicenza Hospital, via Rodolfi 37, Vicenza, IL, ITALY; Federica Alessandrini, PhD, Università Politecnica delle Marche, via Conca 6 Torrette, Ancona, IL 60126, ITALY; and Fiorella Calabrese, MD, University of Padova, via A.Gabelli61, Padova, 35121, ITALY</i>	29
The Pattern of Immunoreactivity for von Willebrand Factor in a Variety of Thrombotic States	<i>Stacey A Simons, MD*, Miami Dade County Medical Examiner Department, Number One on Bob Hope Drive, Miami, FL 33136; Paul E. Swanson, MD, University of Washington Division of Anatomic Pathology, 1959 Northeast Pacific Street, Seattle, WA 98195; and Aldo J. Fusaro, DO, King County Medical Examiner's Office, 908 Jefferson Street, Seattle, WA 98104</i>	30

Giant Cell Myocarditis as a Cause of Sudden or Unexpected Death: A Report of Two Cases and a Review of the Literature	<i>Steven M. White, PhD*, Mitra B. Kalelkar, MD, and James A. Filkins, JD, PhD, Office of the Medical Examiner, County of Cook, 2121 West Harrison Street, Chicago, IL 60612</i>	30
Death Due to Atrial Septum Defect Repaired by Transcatheter Closure: Who Failed?	<i>Eugenio Di Stefano, MD*, Via Raffaello N°9, Palermo, 90100, ITALY; Filippo Maria Cascino, MD*, Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via del Vespro 129, Palermo, 90127, ITALY; and Graziana Farina, MD, Roberto Guarino, MD, Nunzia Albano, MD, and Emiliano Maresi, Via Del Vespro 127, Palermo, 90100, ITALY</i>	31
Dissecting Intramural Hematoma of the Esophagus: A Rare Case of Sudden Death	<i>Cristoforo Pomara, PhD*, University of Foggia, Department of Forensic Pathology, Viale Degli Aviatori 1, Foggia, 71100, ITALY; Alessandra De Salvia, PhD, University of Verona, Department of Forensic Pathology, Policlinico G. B. Rossi, Verona, 71100, ITALY; Antonio Nieddu, MD, University of Sassari, Department of Forensic Pathology, Sassari, Sassari, ITALY; and Stefano D'Errico, PhD, University of Foggia, Department of Forensic Pathology, Viale Degli Aviatori, Foggia, 71100, ITALY</i>	31
Anaphylactic Shock and Postmortem Exam – A Systematic Approach	<i>César L. Santos, MD*, and Beatriz S. Silva, MD, Portuguese National Institute of Legal Medicine, Delegação do Centro do INML, IP, Largo da Sé Nova, 3000-213, Coimbra, PORTUGAL; and Duarte N.P. Vieira, PhD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL</i>	32
Spontaneous Pulmonary Arterial Dissection: A Case Report	<i>Margherita Neri, PhD*, Stefania Bello, MD, Raffaella Bisceglia, MD, and Carmela Fiore, MD, Department of Forensic Pathology, University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY</i>	32
Inherited Cardiac Diseases and Molecular Autopsy: Perspectives and Limitations	<i>Katarzyna Michaud, MD*, Centre Universitaire Romand de, Medecine Legale, Rue du Bugnon 21, Lausanne, 1005, SWITZERLAND; Florence Fellmann, PhD, University Service of Medical Genetics, Lausanne, 1010, SWITZERLAND; and Patrice Mangin, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND</i>	33
Sudden, Unexpected Death Due to Glioblastoma: Three Fatal Cases	<i>Irene Riezzo, PhD*, University of Foggia, Osp D'Avanzo, Department of Forensic Pathology, Viale Degli Aviatori, I, Foggia, 71100, ITALY; Santina Cantatore, Benedetta Di Battista, MD, Ruggero Parente, MD, and Francesco Ventura, MD, University of Genova, Department of Forensic Pathology, Via de' Toni, 12, Genova, 16132, ITALY</i>	34
Postmortem Tryptase Levels of Anaphylactic and Non-Anaphylactic Deaths	<i>Marc D. Bollmann, MD*, Centre Universitaire Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND; Olaf Drummer, Noel W.F. Woodford, MD, Victorian Institute of Forensic Medicine, 57-83 Kavanagh Street, Southbank, Victoria, 3006, AUSTRALIA; Bettina Schrag, MD, University Center of Legal Medicine Lausanne-Geneva, Bugnon 21, Lausanne, 1011, SWITZERLAND; and Dimitri Gerostamoulos, Victorian Institute of Forensic Medicine, 57-83 Kavanagh Street, Southbank, Victoria, 3006, AUSTRALIA</i>	35

Murder-Suicide in Fulton County, Georgia: 1992-2006	<i>Randy L. Hanzlick, MD*, and Stacey L. Smith, MD, Fulton County Medical Examiner's Office, 430 Pryor Street Southeast, Atlanta, GA 30312</i>	35
Homicidal Deaths in the Western Suburbs of Paris: A 15-Year-Study With Special Focus on Survival Time	<i>Jérôme Cros, MD, AP-HP, Jean-Claude Alvarez, PharmD, AP-HP, Raymond Poincaré Hospital, 104, Bd Raymond Poincaré, Garches, F- 92380, FRANCE; Emilie Sbidian, MD, AP-HP, Department of Clinical Research and Public Health, Henri Mondor Hospital, 51 av du Maréchal de Tassigny, Créteil, F-94010, FRANCE; and Philippe Charlier, PhD, AP-HP, and Geoffroy Lorin de la Grandmaison, PhD*, AP-HP, Raymond Poincaré Hospital, 104, Bd Raymond Poincaré, Garches, F-92380, FRANCE</i>	36
Pattern of Limb Lesions in Suicidal Hanging: A Criteria Tool in the Distinction of Suspicious Cases	<i>Anne Desjarlais, BSc*, 7101 De La Roche, Montreal, QC H2S2E6, CANADA; Anny Sauvageau, MD, Office of the Chief Medical Examiner, 7007 - 116 Street, Edmonton, AB T6H 5R8, CANADA; and Jean-Pierre Guay, PhD, University of Montreal, CP 6128, Succ. Centre-ville, Montréal, QC H2S 2E7, CANADA</i>	36
Decubitus Ulcers and Ligature Marks as Evidence in a Homicide Case	<i>Miran Coklo, PhD, Valter Stemberg, PhD, Drazen Cuculic, PhD*, and Alan Bosnar, PhD, Rijeka University School of Medicine, Department of Forensic Medicine, Brace Branchetta 20, Rijeka, 51000, CROATIA</i>	37
Soccer Scams, Search Engines, Scientists, and Slaughter: Investigating a Complex Double Homicide in North-East England	<i>Stuart J. Hamilton, MB ChB*, 9 Troon Close, Consett, DH8 5XF, UNITED KINGDOM</i>	37
Death Certification of "Suicide by Cop"	<i>Amber R. Neitzel, BS*, 550 East Van Buren Street, Phoenix, AZ 85004; and James R. Gill, MD, Office of the Chief Medical Examiner, 520 First Avenue, New York, NY 10016</i>	38
Study of Lethal and Non-Lethal Filmed Hangings: New Insight Into the Pathophysiology of Hanging	<i>Anny Sauvageau, MD*, Office of the Chief Medical Examiner, 7007 - 116 Street, Edmonton, AB T6H 5R8, CANADA</i>	38
Pitfalls in the Interpretation of the Hyoid and Thyroid Fractures in Strangulation: The Importance of Anatomical Variations	<i>João S. Pinheiro, MS*, Instituto Nacional de Medicina Legal, Delegação do Centro, Largo da Sé Nova, Coimbra, 3000, PORTUGAL; and Anny Sauvageau, MD, Office of the Chief Medical Examiner, 7007 - 116 Street, Edmonton, AB T6H 5R8, CANADA</i>	39
A Comparison Study of Homicides Between Beijing, China and the State of Maryland, United States	<i>Lin Chang, MD*, China University of Political Science and Law, 116 Lugu Road, Shijingshan District, Beijing, 100040, PEOPLES REPUBLIC OF CHINA; Li Liu, MD, Beijing Municipal Public Security Bureau, No.1 Qinghe Longgang Road Haidian District, Beijing, 100192, PEOPLES REPUBLIC OF CHINA; and Xiang Zhang, MD, David R. Fowler, MD, Eleanor J. Thomas, and Ling Li, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	39
Blood at the Scene of Death Due to Hanging: Artifact or Antemortem	<i>Surendra K. Kumar, MD*, Army College of Medical Sciences, Delhi Cantonment, New Delhi, 110010, INDIA</i>	40
The Influence of the Meteorological Factors on Occurrence of the Suicide Cases	<i>Zalina Muzaferova*, Main Bureau of Forensic Medicine, Mirakhmedov Street, 143, Tashkent, UZBEKISTAN</i>	40
Complex Suicide: An Unusual Case With Six Methods Applied	<i>Stojan Petkovic, PhD*, Miljen Maletin, MD, MSc, and Maja Durendic-Brenesel, PhD, Klinicki Centar Vojvodine, Department of Forensic Medicine, Clinical Center of Vojvodina, Hajduk Veljkova 5-7, Novi Sad, 21000, SERBIA AND MONTENEGRO</i>	41

Bitten by Snake Shot: Attempted Homicide and Successful Suicide With Multiple Gunshot Wounds	<i>Todd M. Luckasevic, DO*, and Baiyang Xu, MD, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222; and Abdulrezak M. Shakir, MD, and Karl E. Williams, MD, MPH, Office of the Medical Examiner - Allegheny County, 542 Fourth Avenue, Pittsburgh, PA 15219</i>	41
Survived Strangulation: A Case Report	<i>Paula C. Oliveira, MD*, Portuguese National Institute of Legal Medicine, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; Ana R. Pereira, MD*, Ladeira das Alpenduradas nº13A, Coimbra, 3030-167, PORTUGAL; Rosario L. Silva, MD, and Graca Santos Costa, MD, Portuguese National Institute of Legal Medicine, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; and Duarte N.P. Vieira, PhD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL</i>	42
Cause of Sudden Death Due to Cardiac Rhabdomyoma in an 11-Month-Old Baby	<i>Sabina Di Donato, PhD*, University of Foggia, Department of Forensic Pathology, Viale Aviatori, 1, Foggia, 71100, ITALY; Michele Nolè, A.O.R. "San Carlo" Hospital, Via Potito Petrone, 6, Potenza, 85100, ITALY; Irene Riezzo, PhD, University of Foggia, Osp D'Avanzo, Department of Forensic Pathology, Viale degli Aviatori, 1, Foggia, 71100, ITALY; Sara Vita, MD, University of Foggia, Department of Forensic Pathology, Viale Aviatori, 1, Foggia, 71100, ITALY; and Rocco A.G. Maglietta, MD, San Carlo Hospital Potenza, Section of Legal Medicine, via P. Petrone n.6, Potenza, 85100, ITALY</i>	42
Suicide by Table Saw — A Slice of Interpretation	<i>Jeffrey Racette, MD*, Baiyang Xu, MD, Todd M. Luckasevic, DO, Allegheny County Medical Examiner Office, 1520 Penn Avenue, Pittsburgh, PA 15222; and Abdulrezak M. Shakir, MD, Allegheny County and Karl E. Williams, MD, Office of the Medical Examiner - Allegheny County, 542 Fourth Avenue, Pittsburgh, PA 15219</i>	43
The Significance of Gross Adrenal Hemorrhage — Undiagnosed Waterhouse-Friderichsen Syndrome: A Case Series	<i>Lee M. Tormos, MD*, Medical and Forensic Autopsy, Pathology and Laborat Medicine, 171 Ashley Avenue, Suite 309, MSC908, Charleston, SC 29425-9080; and Cynthia A. Schndl, PhD, Medical University of South Carolina, 171 Ashley Avenue, Suite 309, MSC-908, Charleston, SC 29425</i>	43
Metastatic Calcification of AV-Node as a Cause of Complete Heart Block and Death	<i>Joseph K. White, DO*, University of Colorado Denver School of Medicine, 660 Bannock Street, Denver, CO 80204; and Amy Martin, MD, Denver Office of the Medical Examiner, 660 Bannock Street, Denver, CO 80204</i>	44
Postmortem Interval and Cardiac Troponin Effect	<i>Ziya Kir, MD, and Coskun Yorulmaz, MD*, Istanbul University Cerrahpasa School of Medicine, Department of Forensic Medicine, Cerrahpasa, Istanbul, 34099, TURKEY; Murat Bolayirli, MD, Istanbul University Cerrahpasa School of Medicine, Department of Biochemistry, Cerrahpasa, Istanbul, 34099, TURKEY; Haluk Ince, PhD, Council of Forensic Medicine, Chairperson of the Counsil of Forensic Medicine, Istanbul, 34197, TURKEY; and Mete K. Gulmen, PhD, Cukurova University School of Medicine, Department of Forensic Medicine, Adana, 01330, TURKEY</i>	44

Ante- and Postmortem In-Human Cocaine Packs Detected by Computed Tomography	<i>Patricia Mildred Flach, MD*, and Steffen G. Ross, MD, Institute of Forensic Medicine, Center of Forensic Imaging "Viropsy", Buehlstrasse 20, Bern, 3012, SWITZERLAND; Garyfália Ampanozi, MD, Ulrich Preiss, MD, Tanja Germerott, MD, Gary M. Hatch, MD, and Michael Thali, MD, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND; and Michael Patak, MD, University of Bern, Radiology, Freiburgstrasse, Bern, 3010, SWITZERLAND</i>	45
Decomposition in a Closed Vehicle Environment in Southern Ontario	<i>Shari L. Forbes, PhD*, Helene LeBlanc, PhD*, Katelynn Perrault, BSc, and Alicia Buetter, BSc, University of Ontario Institute of Technology, 2000 Simcoe Street North, Oshawa, ON L1H7K4, CANADA</i>	45
Child Abusive Head Trauma in Portugal	<i>Agostinho Santos, PhD*, North Branch of the National Institute of Legal Medicine, Jardim Carrilho Videira, Porto, 4050-167, PORTUGAL; Liliana Santos, MD, Jardim Carrilho Videira, Porto, 4050-167, PORTUGAL; Teresa Magalhães, PhD, North Branch of the National Institute of Legal Medicine, Jardim Carrilho Videira, Porto, 4050-167, PORTUGAL; Francisco Corte-Real, PhD, Center Branch National Institute of Legal Medicine, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; Jorge C. Santos, PhD, South Branch National Institute of Legal Medicine, R. Manuel Bento de Sousa, nº 3, Lisboa, 1150-219, PORTUGAL; and Duarte N.P. Vieira, PhD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL</i>	46
Gravesoil Microbial Community Structure During Carcass Decomposition	<i>Amy E. Maile, BS*, and David O. Carter, PhD, University of Nebraska, Lincoln, Department of Entomology, 202 Entomology Hall, Lincoln, NE 68583-0816; and Rhae A. Drijber, PhD, University of Nebraska-Lincoln, Department of Agronomy and Horticulture, 279 Plant Sciences Hall, Lincoln, NE 68583-0915</i>	47
Laceration of the Inferior Vena Cava Following Blunt Abdominal Trauma in a Case of Child Abuse	<i>Carlos F. Chavez-Arias, MD*, Puerto Rico Institute of Forensic Sciences, PO BOX 11878, Caparra Heights Station, San Juan, PR 00922-1878; and Javier G. Serrano, MD, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921</i>	47
Inferior Vena Cava Compression: A Possible Mechanism for Arrest Related Death	<i>Jeffrey D. Ho, MD, Hennepin County Medical Center, Department of Emergency Medicine, 701 Park Avenue South, Minneapolis, MN 55415; Donald M. Dawes, MD*, Lompoc Valley Medical Center, 1515 East Ocean Avenue, Lompoc, CA 93436; and Johanna C. Moore, MD, and James R. Miner, MD, Hennepin County Medical Center, Department of Emergency Medicine, 701 Park Avenue South, 1431 Lakeview Avenue South, Minneapolis, MN 55415</i>	48
Intra-Abdominal Hemorrhage Associated to an Intrapartum Rupture of the Umbilical Cord: A Case Report	<i>Carlos F. Chavez-Arias, MD*, Puerto Rico Institute of Forensic Sciences, PO BOX 11878, Caparra Heights Station, San Juan, PR 00922-1878; and Javier G. Serrano, MD, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921</i>	48

Aortic Aneurysm Rupture Into the Lung With Formation of Pseudoaneurysm	<i>Carlos F. Chavez-Arias, MD, Puerto Rico Institute of Forensic Sciences, PO BOX 11878, Caparra Heights Station, San Juan, PR 00922-1878; and Javier G. Serrano, MD*, and Edda Rodriguez, MD, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921</i>	49
Is DNA Purified From Forensic Autopsy Material Suitable for Molecular Biological Studies?	<i>Iana Lesnikova, PhD*, Department of Forensic Pathology of University of Aarhus, Denmark, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Jakob Hansen, PhD, Department of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; and Jytte B. Lundemose, Department of Forensic Pathology, University of Aarhus, Denmark, Brendstrupgaardsvej 100, Aarhus N, AK 8200, DENMARK</i>	50
Evaluation of a New Approach for Estimating the Postmortem Interval Based on the Direct Skin Surface Analysis Using FTIR Spectroscopy	<i>Liliana Santos, MD*, Jardim Carrilho Videira, Porto, 4050-167, PORTUGAL; João Lopes, PhD, Faculty of Pharmacy, Rua Aníbal Cunha 164, Porto, 4050-047, PORTUGAL; Agostinho Almeida, PhD, 2REQIMTE, Department of Chemistry-Physics, Faculty, Rua Aníbal Cunha 164, Porto, 4050-047, PORTUGAL; and Agostinho Santos, PhD, and Teresa Magalhães, PhD, North Branch of the National Institute of Legal Medicine, Jardim Carrilho Videira, Porto, 4050-167, PORTUGAL</i>	50
Unusual Style Cut Throat Injury: A Case Report	<i>Suresh K. Shetty, MD*, Kasturba Medical College, Light House Hill Road, Mangalore, 575001, INDIA</i>	51
Mass Fatality Management: A Multi-National Perspective	<i>Ann H. Ross, PhD, North Carolina State University, Department of Sociology & Anthropology, Campus Box 8107, Raleigh, NC 27695-8107; and Jason H. Byrd, PhD*, Maples Center for Forensic Medicine, University of Florida, 4800 Southwest 35th Drive, Gainesville, FL 32608</i>	51
Improving Evidence and Victim Recovery Protocols at the Mass Fatality Incident	<i>Dennis C. Dirkmaat, PhD*, Luis L. Cabo-Pérez, MS, Michael W. Kenyhercz, MS, Allison M. Nesbitt, MS, Alexandra R. Klales, MS, and Erin Chapman, MS, Mercyhurst College, Department of Applied Forensic Sciences, 501 East 38th Street, Erie, PA 16546</i>	51
Telluric Movements of Death: The Cemetery of Gargano's Mafia Inside the Ravine of Zazzano (Foggia, Italy)	<i>Cristoforo Pomara, PhD*, and Gianpaolo Di Peri, MD, University of Foggia, Department of Forensic Pathology, Viale Degli Aviatori, Foggia, 71100, ITALY; Giuseppe Guglielmi, PhD MD, University of Foggia, Department of Radiology, Viale Pinto, Foggia, 71100, ITALY; Emilio Nuzzolese, DDS, PhD, Viale J.F. Kennedy 77, Bari, 70124, ITALY; and Stefano Derrico, PhD, University of Foggia, Department of Forensic Pathology, Via Luigi Pinto, 1, Foggia, 71100, ITALY</i>	52
Use of Multidetector Computed Tomography (MDCT) in the Evaluation of Gunshot Wounds	<i>Edward L. Mazuchowski, PhD*, and Philip J. Berran, JD, Office of the Armed Forces Medical Examiner, 1413 Research Boulevard, Building 102, Rockville, MD 20850; and Howard T. Harcke, MD, Armed Forces Institute of Pathology, 6825 16th Street Northwest, Washington, DC 20306</i>	53
Gunshot Wounds Covered by Different Textiles: Determination of GSR Through Micro-CT Analysis	<i>Giovanni Cecchetto, MD*, Alessandro Amagliani, MD, Guido Viel, MD, and Paolo Fais, MD, University of Padua, Via Falloppio 50, Padova, 35121, ITALY; Giampietro Feltrin, MD, Via Giustiniani 2, Padova, 35121, ITALY;</i>	53

	<i>Santo Davide Ferrara, PhD, University of Padua - Section of Legal Medicine and Forensic Toxicology, Via Falloppio 50, Padua, 35121, ITALY; and Massimo Montisci, PhD, University of Padua, Via Falloppio 50, Padova, 35121, ITALY;</i>	
Child Abuse vs. Cachexia: Do Healing and Acute Rib Fractures Trump a Diagnosis of Probable Cardiac Dysrhythmia Due to Electrolyte Abnormalities	<i>Steven A. Symes, PhD, Mercyhurst College, 501 East 38th Street, Erie, PA 16546-0001; and Dianne R. Vertes, PhD, MD, Erie County Medical Examiner's Office, 462 Grider Street, Buffalo, NY 14215</i>	54
The Identification of French Victims in the Massive Earthquake on January 12, 2010 in Haiti	<i>Stephane Malbranque, MD*, French-DVI, Chu Fort-De-France, Hop. La Meynard, BP 632, Fort-De-France cedex, 97261, MARTINIQUE</i>	54
Comparison of Methods for Measuring Decomposition of Submerged Carrion in Fresh Water	<i>Michael K. Humphreys, MS*, Yolo County Sheriff/Coroner Office, 2500 East Gibson Road, Woodland, CA 95616; Edward Panacek, MD, MPH, University of California - Davis, Department of Emergency Medicine, 4150 V Street, Patient Support Services Building, Suite 2100, Sacramento, CA 95817; William Green, MD, California Clinical Forensic Medical Training Center, University of California - Davis Medical Center, 3671 Business Drive, Sacramento, CA 95820; and Elizabeth A. Albers, MD, Sacramento County Coroner's Office, 4800 Broadway, Sacramento, CA 95820</i>	55
Fatal Sexual Violence Against Women: Normative, Baseline Studies of Postmortem Genital Anatomy — What Can We Say About Normal?	<i>Sharon R. Crowley, MN*, FCNS, 122 Emeline Avenue, Santa Cruz, CA 95060</i>	56
The Effects of Household Chemicals on Blow Fly Oviposition and Development Using Human Cadavers	<i>Kristi N. Bugajski, MS*, 929 King Street, Lafayette, IN 47905; and Ralph E. Williams, PhD, Purdue University Department of Entomology, 901 West State Street, West Lafayette, IN 47907</i>	57
Mass Disaster Procedures: Forensic Pathology and Genetic Techniques Used to Locate Nine Missing People in the Calabria Region (Southern Italy)	<i>Paola A. Magni, MS, F.E.LAB ASL TO1, c/o Civico Obitorio di Torino, Via Bertani 112/A, Torino, 10137, ITALY; Giulio Di Mizio, PhD*, Policlinico Universitario Camp, Germaneto, Edificio Clinico, Sec. Foren Med, Viale Europa, Catanzaro, 88100, ITALY; Federica Colosimo, MD, Magna Graecia University of Catanzaro, Viale Europa Loc. Germaneto, Catanzaro, 88100, ITALY; Sergio Schiavone, PhD*, RIS Carabinieri, S.S. 114 Km 3,400, Messina, 98128, ITALY; Carlo G. Romano, MSc, RIS Carabinieri, S.S. 114 Km 6,400, Messina, 98128, ITALY; Ciro Di Nunzio, Institute of Legal Medicine, School of Medicine, Magna Graecia University, Viale Europa Germaneto, Catanzaro, 88100, ITALY; Ian Dadour, PhD, Centre for Forensic Science, University of Western Australia, 35 Stirling Highway, Nedlands, 6009, AUSTRALIA; and Pietrantonio Ricci, MD, Università degli Studi Magna Graecia Catanzaro, Viale Europa - Località Germaneto, Catanzaro, ITALY</i>	57
Variance in Growth Rates of Calliphora vomitoria on Different Tissue Types: Mass Raised vs. Single Raised	<i>Bridget R. McSweeney, BA*, 1629 South Shenandoah Street, Los Angeles, CA 90035; and Tal Simmons, PhD, School of Forensic & Investigative Sciences, University of Central Lancashire, Preston, PR1 2HE, UNITED KINGDOM</i>	58

Identification of Two Homicide Victims and Linking of Separate Crimes Solved by Radiographic Discovery of a Healed Bullet Wound.	<i>William C. Rodriguez III, PhD*, and Laura A. Regan, PhD, Armed Forces Medical Examiner System, 1413 Research Boulevard, Building 102, Rockville, MD 20850; and Humphrey H. Germaniuk, MD, Trumbull County Coroner's Office, 1863 East Market Street, Warren, OH 44483</i>	58
Utilizing Multi-Detector Computerized Tomography to Evaluate Concrete-Encased Human Remains	<i>Robert A. Kurtzman, DO, Community Hospital, 2021 North 12th Street, Grand Junction, CO 81501; and Casey P. Bitting, BS*, 1700 Bassett Street, #2114, Denver, CO 80202</i>	59
Use of Multidetector Computed Tomography (MDCT) in the Medicolegal Investigation of Human Remains After a Natural Disaster	<i>Howard T. Harcke, MD*, Armed Forces Institute of Pathology, 6825 16th Street Northwest, Washington, DC 20306; and Edward L. Mazuchowski, PhD, and Philip J. Berran, JD, Office of the Armed Forces Medical Examiner, 1413 Research Boulevard, Building 102, Rockville, MD 20850</i>	60
Evaluation of the Randox Whole Blood Drugs of Abuse (DOA) Microchip Arrays for Use With Alternative Postmortem Samples as a Rapid Near-Body Screen	<i>Poppy McLaughlin, MSc*, Bournemouth University, Fern Barrow, Talbot Campus, Poole, BH12 5BB, UNITED KINGDOM; Derrick J. Pounder, MB, University of Dundee, Department of Forensic Medicine, Dundee, DD1 4HN, UNITED KINGDOM; and Michael D. Osselton, Bournemouth University, Fern Barrow, Talbot Campus, Poole, BH12 5BB, UNITED KINGDOM</i>	60
Postmortem Vitreous Beta-Hydroxybutyrate: Interpretation in a Forensic Setting	<i>Michael Heninger, MD*, Fulton County Medical Examiner's Office, 430 Pryor Street, Atlanta, GA 30312</i>	61
The Rising Trend of Ecstasy and Mimic Drugs Among Teenagers in Santa Clara County, California — A Guide and Awareness for Medical Examiners, Coroners, and Toxicologists	<i>Larry Silveira, MS*, Santa Clara County Department of Alcohol and Drug Services, 2101 Alexian Drive, Suite 110, San Jose, CA 95116; and Michelle A. Jorden, MD, Santa Clara Medical Examiner, 850 Thornton Way, San Jose, CA 95128</i>	61
Laboratory Variation and Postmortem Redistribution in the Interpretation of Postmortem Fentanyl Levels	<i>Clarissa Krinsky, MD*, University of New Mexico School Of Medicine, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131; and Sarah Lathrop, PhD, DVM, and Ross E. Zumwalt, MD, University of New Mexico, Office of Medical Investigator, MSC 11 6030, 1 University of New Mexico, Albuquerque, NM 87131-0001</i>	62
Toxicology and Pathology of 149-Methadone-Related Deaths	<i>Sébastien Prat, MD*, Service de Médecine Légale, Hôpital Trousseau, Centre Régional Hospitalier Universitaire de Tours, Tours, FRANCE; Patrice Mangin, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND; Marc Augsburger, PhD, University Center of Legal Medicine, Bugnon 21, Lausanne, 1010, SWITZERLAND; and Katarzyna Michaud, MD, Centre Universitaire Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, 1005, SWITZERLAND</i>	62
Deaths in Unlicensed Alcohol Rehabilitation Facilities	<i>Lawrence Nguyen, MD, Los Angeles County Department of Coroner, 1104 North Mission Road, Los Angeles, CA 90033; and Christopher B. Rogers, MD*, Los Angeles County Medical Examiner's Office, 1104 North Mission Road, Los Angeles, CA 90033</i>	63

Was This Drug Overdose Due to Intravenous Injection or Oral Ingestion of Heroin — Can You Tell?	<i>Johan A. Duflou, MM*, Department of Forensic Medicine, PO Box 90, Glebe, Sydney, 2037, AUSTRALIA; Shane Darke, PhD, National Drug and Alcohol Research Centre, University of New South Wales, Sydney, 2052, AUSTRALIA; and Jennifer Easson, BSc, Division of Analytical Laboratories, Sydney West Area Health Service, Joseph Street, Lidcombe, 2141, AUSTRALIA</i>	63
First Reported Case of Bromo-Dragonfly Fatality in the United States, San Jose, California, County of Santa Clara	<i>Michelle A. Jorden, MD*, Santa Clara Medical Examiner, 850 Thorton Way, San Jose, CA 95128; Lee M. Blum, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Joseph Corvo, BS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090</i>	64
Sudden Unexpected Infant Death: Lymphocytic Meningoencephalitis With Multiple Retinal Hemorrhages	<i>Patrick E. Lantz, MD*, Wake Forest University, School of Medicine, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072; Amy M. Durso, MD, Professional Pathology Services, One Science Court, Suite 200, Columbia, SC 29203; and Ryan T. Mott, MD, Department of Pathology/Wake Forest University Health Sciences, Medical Center Buolevard, Winston Salem, NC 27157-1072</i>	64
Parietal Pseudofracture in Children Suggesting Non-Accidental Trauma: A Report of Two Cases and Review of the Literature	<i>Pauline Saint-Martin, MD*, and Camille Rerolle, MD, Hopital Troussseau, Service de Medecine Legale, CHRU TOURS, TOURS, 37000, FRANCE; Thierry Lefrancq, MD, Le Vauban, BP 549, 16 rue Clerget, NEVERS, 58009, FRANCE; and Patrick O. Byrne, MD, Service de Medecine Legale, Hopital Troussseau, CHRU TOURS, TOURS, 37000, FRANCE</i>	65
Methadone and Cocaine Related Death in A Young Boy: A Case Report	<i>Francesco Ausania, MD, Institute of Forensic Medicine, Catholic University, School of Medicine, Ro, largo Francesco Vito 1, Rome, ITALY; Massimo Senati, PhD, Largo Francesco Vito 1, Rome, ITALY; Nadia Fucci, PhD, largo francesco vito 1, Rome, ITALY; Antonio Oliva, PhD*, Institute of Forensic Medicine, Catholic University, School of Medicine, Ro, Largo Francesco Vito 1, Rome, ITALY; and Pietrantonio Ricci, PhD, Università degli Studi Magna Grecia Catanzaro, Viale Europa - Località Germaneto, Catanzaro, ITALY</i>	66
Sudden Death Due to Dengue Fever in an 8-Month-Old Baby	<i>Mohd Shafie Bin Othman, MD*, Forensic Department Hospital Raja Permaisuri Bainun, Jalan Hospital 30450, Ipoh, 31350, MALAYSIA; and Santina Cantatore, Dania De Carlo, MD, and Margherita Neri, PhD, Department Forensic Pathology, University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY</i>	66
Sudden Death in the First Year of Life: The Importance of Pancreatic Histomorphological Analysis	<i>Francesco Paolo Busardo, MD*, Institute of Legal Medicine, Via Del Vespro, 129, Palermo, 90100, ITALY; Stefania Zerbo, MD, Institute of Legal Medicine, Via Del Vespro, 127, Palermo, 90100, ITALY; Antonina Argo, Via Del Vespro 127, Palermo, 90100, ITALY; Liliya Gutsul, MD, Instituto, Via Del Vespro, 127, Palermo, 90100, ITALY; Paolo Procaccianti, Palermo University, Via Del Vespro, N. 127, Palermo, 90100, ITALY; and Emiliano Maresi, Via Del Vespro 127, Palermo, 90100, ITALY</i>	67

Isolated Coronary Anomalies and Sudden Death in the Young	<i>Emiliano Maresi*, and Livio Milone, PhD, Via Del Vespro, N. 127, Palermo, 90100, ITALY; Paola Pugnetti, MD, Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via Del Vespro, n. 129, Palermo, 90127, ITALY; Francesco P. Busardo, MD, Institute of Legal Medicine, Via Del Vespro, 129, Palermo, 90127, ITALY; Nunzia Albano, MD, Pierangela Fleres, MD, Via Del vespro 127, Palermo, 90100, ITALY; and Paolo Procaccianti, Palermo University, Via Del Vespro, n. 127, Palermo, 90100, ITALY</i>	68
Pathologic and Anthropologic Manifestations of Documented Repetitive Blunt Trauma in a Child Abuse Case	<i>Pramod Gumpeni, MD*, Jason M. Wiersema, PhD, and Luis A. Sanchez, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054</i>	68
Pregnancy, Caesarean, and Pheochromocytoma: A Case Report With a Fatal Outcome	<i>Isabelle Plu, PhD*, Denis Barrès, MD, and Dominique Lecomte, PhD, Institut Médico-Légal, 2 place Mazas, Paris, 75012, FRANCE</i>	69
Infant Death Evaluation: What is the Constellation of Abusive Injuries?	<i>M.G.F. Gilliland, MD*, Brody School of Medicine at East Carolina University, Pathology & Lab Medicine, Brody 7S-10, Greenville, NC 27858-4354</i>	69
Utility of Whole Body Postmortem Computed Tomography Imaging in Detection of Elder Abuse: Comparison With and Potential Substitution for Standard Autopsy	<i>Zabiullah Ali, MD*, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Barry Daly, MD, and Nancy Knight, PhD, University of Maryland Medical Center, Radiology Department, 22 South Greene Street, Baltimore, MD 21201; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	70
Findings of the Examinations of Suspected Animal Cruelty Cases Submitted to the Birmingham Jefferson County Animal Control	<i>Ubicelio Martin-Orozco, EDV*, Ciudad Juarez Autonomous University, Benjamin Franklin# PRONAF Zone, Juarez, 32315, MEXICO; Barbara Benhart, DVM, Jefferson County Animal Control, 6227 5th Avenue North, Birmingham, AL 35212; and Elizabeth A. Gardner, PhD, University of Alabama Department of Justice, UBOB 210, 1530 3rd Avenue, South, Birmingham, AL 35294-4562</i>	71
Fatal Tiger Attack on a Zoo Patron: Patterns and Types of Injuries in Large Predatory Cats	<i>Ellen Moffatt, MD*, City & County of San Francisco Office of the Medical Examiner, 850 Bryant Street, San Francisco, CA 94103; Gregory L. Mar, DDS*, Hall of Justice, 850 Bryant Street, Room 442, San Francisco, CA 94103; Duane E. Spencer, DDS*, 1855 San Miguel Drive, Suite 9, Walnut Creek, CA 94596-5282; John K. Berk, DDS, 20652 Redwood Road, Castro Valley, CA 94546; James D. Wood, DDS, 102 South Main Street, Cloverdale, CA 95425; Freeland Dunker, DVM, California Academy of Sciences, Steinhart Aquarium, 55 Music Concourse Drive, San Francisco, CA 94118; and Jacqueline Jencek, DVM, San Francisco Zoological Society, 1 Zoo Road, San Francisco, CA 94132-1098</i>	71
The Utility of Skeletal Examination in Recognition of Occult Skeletal Injury	<i>Jason M. Wiersema, PhD*, Jennifer C. Love, PhD, Sharon M. Derrick, PhD, and Luis A. Sanchez, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054</i>	71

Interpretation of Anogenital Findings in Forensic Autopsy: Problems and Challenges	<i>Patrícia Jardim, MD*, José M. Fernandes, MD, Dina Almeida, MD, Liliana Santos, MD, MSc, Agostinho Santos, PhD, and Teresa Magalhães, PhD, North Branch of the National Institute of Legal Medicine, Jardim Carrilho Videira, 4050-167, Porto, PORTUGAL</i>	72
When Lightning Strikes: 17 Fatal Lightning Strikes in New Mexico	<i>Alice J. Briones, DO*, 1107 Canvasback Lane, Denton, MD 21629; and Michelle B. Aurelius, MD, Office of the Medical Investigator, MSC 11 6030, 1 University of New Mexico, Albuquerque, NM 87131</i>	73
Drag Racing of Snowmobiles on Asphalt: A Novel Cause for Sudden Violent Death	<i>Abraham T. Philip, MD*, Brian P. Ehret, and Robert Stoppacher, MD, Onondaga County Medical Examiner's Office, 100 Elizabeth Blackwell Street, Syracuse, NY 13210</i>	73
Blast Overpressure After Tire Explosion: A Fatal Case	<i>Stefano Derrico, PhD*, University of Foggia, Department of Forensic Pathology, Via Luigi Pinto, 1, Foggia, 71100, ITALY; Gabriela Perilli, MD, University of Foggia, Department of Forensic Pathology, Viale Degli Aviatori 1, Foggia, 71100, ITALY; Umberto Volpe, Bari, Bari, , ITALY; Natascha Pascale, MD, University of Foggia, Department of Forensic Pathology, Viale Degli Aviatori, Foggia, 71100, ITALY; and Irene Riezzo, PhD, University of Foggia, Osp D'Avanzo, Department of Forensic Pathology, Viale Degli Aviatori, 1, Foggia, 71100, ITALY</i>	74
TASER® XREP™: A Case Study	<i>Ogbonna Chinwah, MD*, Department of the Coroner, 1104 North Mission Road, Los Angeles, CA 90033; and Christopher B. Rogers, MD, and Lakshmanan Sathyavagiswaran, MD, Los Angeles County Medical Examiner's Office, 1104 North Mission Road, Los Angeles, CA 90033</i>	74
3D in Forensics: TIM Synthetic MRI and Virtobot – Forensic Imaging Workflow of the Future	<i>Michael Thali, MD*, VIRTOPSY Team, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND</i>	75
Transition to Digital in the Forensic Morgue: Lessons Learned on the Pathway to Greater Efficiency	<i>Jason M. Wiersema, PhD*, Diane Logan, MBA, and Luis A. Sanchez, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054</i>	75
Postmortem Computed Tomography as a Valuable Tool for Diagnosing Trauma Prior to Medicolegal Autopsy	<i>Seija Ylijoki-Soerensen, MD*, Department of Forensic Medicine, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Iana Lesnikova, MD, Department of Forensic Pathology of University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Lars Uhrenholt, PhD, Institute of Forensic Medicine, Department of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; and Annie Vesterby, MD, DMSc, Institute of Forensic Medicine, University of Aarhus, Brendstrupgårdsvæj 100, 8200 Aarhus N, DK-8000, DENMARK</i>	76
Traumatic Injuries in Fatal Tire Explosions	<i>Chris Milroy, MD*, University of Ottawa, The Ottawa Hospital, 501 Smyth Road, Box 117, 4th Floor CCW, Ottawa, ON K1H 8L6, CANADA; and Alison Edgecombe, MD, The University of Ottawa, Department of Pathology and Laboratory Medicine, PO Box 117, 4th Floor CCW, 501 Smyth Road, Ottawa, ON, CANADA</i>	77

2010

Retinal and Optic Nerve Sheath Hemorrhages Are Not Pathognomonic of Abusive Head Injury	<i>Evan Matsches, MD*, Southwestern Institute of Forensic Sciences, 5230 Southwestern Medical Avenue, Dallas, TX 75235</i>	78
Child Abuse vs. Accidental Falls: Judicial Outcomes in Alleged Child Abuse	<i>James A.J. Ferris, MD*, Department of Forensic Pathology, LabPlus, 85 Park Road, Grafton, PO Box 110031, Auckland, NEW ZEALAND</i>	78
Pediatric Deaths in Harris County	<i>Kathryn H. Haden-Pinneri, MD*, and Sharon M. Derrick, PhD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	78
What Is the Frequency of Finding Lethal Injury When a SIDS-Like Death Is Reported?	<i>M.G.F. Gilliland, MD*, Brody School of Medicine at East Carolina University, Pathology & Lab Medicine, Brody 7S-10, Greenville, NC 27858-4354</i>	79
Cardiac Channelopathies Linked to Sudden Infant Death Syndrome/Sudden Unexplained Death Syndrome	<i>Dawei Wang, PhD*, and Donald Siegel, PhD, New York City Office of the Chief Medical Examiner, 421 East 26 Street, New York, NY ; and Yingying Tang, MD, PhD, Mechthild K. Prinz, PhD, and Barbara A. Sampson, MD, PhD, Office of Chief Medical Examiner, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016</i>	80
Fatal Acute Intracranial Injury With Subdural Hematoma and Retinal Hemorrhages in an Infant Due to Stairway Fall	<i>Patrick E. Lantz, MD*, Department of Pathology, Wake Forest University, School of Medicine, Medical Center Boulevard, Winston- Salem, NC 27157-1072; and Daniel E. Couture, MD, Department of Neurosurgery, Wake Forest University School of Medicine, Medical Center Boulevard, Winston Salem, NC 27157</i>	80
Morbidity and Mortalities Related to TV Tip Over	<i>Marvin S. Platt, MD, JD*, 5050 La Jolla Boulevard, Apartment 2G, San Diego, CA 92109; and Christina Stanley, MD, San Diego County Medical Examiner's Office, 5555 Overland Avenue, Suite 1411, San Diego, CA 92123</i>	81
Hanging Deaths in Children: An Investigation of Manner of Death	<i>Julie Adams, DO*, 1234 Big Bend Crossing Drive, Valley Park, MO 63088</i>	81
Does a Draft Really Influence Postmortem Body Cooling?	<i>Michał R. Kaliszak, PhD*, Medical University of Gdańsk, Debowa 23, Gdańsk, 80-286, POLAND</i>	82
Forensic Medicine in Dubai, United Arab Emirates	<i>Fawzi A. Benomran, MD*, Dubai Police, Dubai Medical College, PO Box 39844, Dubai, UNITED ARAB EMIRATES</i>	82
Injuries to Abdominal Organs in Fatal Road Traffic Crash Victims	<i>Lars Uhrenholt, PhD*, Louise Moller Andersen, and Freja Gaborit, Department of Forensic Medicine, Faculty of Health Sciences, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK</i>	83
Case Example: Cerebral Dural Venous Sinus Thrombosis Following a Motor Vehicle Accident	<i>Ariel Goldschmidt, MD*, Jackson County Medical Examiner's Office, 1700 Forum Boulevard, Apartment 509, Columbia, MO 65203; Adrian Baron, MD, and Megan Minnear, BS, 660 East 24th Street, Kansas City, MO 64108</i>	83
A Death Due to Subinvolution of the Uteroplacental Arteries: A Case Report and Literature Review	<i>Ruth E. Kohlmeier, MD*, El Paso County Coroner's Office, 2743 East Las Vegas Street, Colorado Springs, CO 80906; and Norma J. Farley, MD, Valley Forensics, 200 South 10th Street, McAllen, TX 78501</i>	84

Case Studies of Cranial Trepanation in Apulia (Southern Italy) Through Forensic Imaging	<i>Emilio Nuzzolese, DDS, PhD*, Ambulatorio Nuzzolese, viale J.F. Kennedy 77, Bari, 70124, ITALY; Sandro Sublimi Saponetti, BSc, and Vito Scattarella, BS, Department of Animal and Environmental Biology, Università degli Studi di Bari, Bari, 70100, ITALY; and Marino Capece, MD, Imaging Department, ASL BA, Monopoli, 70100, ITALY; Nunzio Di Nunno, PhD, Università del Salento, Lecce, 73100, ITALY</i>	84
Systemic Lupus Erythematosus and Fatal Cardiac Failure Due to Pancarditis in a Young Man	<i>Irene Riezzo, MD*, Stefania Bello, MD, Margherita Neri, PhD, and Cristoforo Pomara, PhD, Department of Forensic Pathology University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY</i>	85
Autopsy Investigation and Bayesian Approach to Coronary Artery Disease (CAD) in Victims of Motor Vehicle Accidents	<i>Antonio Oliva, PhD*, and Sara Meriglioli, PhD, Institute of Forensic Medicine, Catholic University, School of Medicine, Largo Francesco Vito 1, Rome, ITALY; Jose Flores, MD, Montreal Heart Institute, University, Montreal, Quebec, Canada, Montreal, CANADA; Francesca Cittadini, PhD, Sara Partemi, MD, and Vincenzo L. Pascali, PhD, Institute of Forensic Medicine, Catholic University, largo Francesco Vito 1, Rome, ITALY; and Ramon Brugada, MD, Montreal Heart Institute, Montreal Quebec, Canada, Montreal, CANADA</i>	86
An Unusual “In-Custody” Death	<i>Brian Drewry, BS*, Iowa and Jerri McLemore, MD, Iowa Office of the State Medical Examiner, 2250 South Ankeny Boulevard, Ankeny, IA 50023; Dennis Klein, MD, Iowa Department of Public Health, 2250 South Ankeny Boulevard, Ankeny, IA 50023</i>	86
Analysis of Female Firearm Homicides in King County, Washington 2000 - 2007	<i>Janaki Warushahennadi, MD*, and Richard C. Harruff, PhD, King County Medical Examiner’s Office, 325 Ninth Avenue, HMC Box 359792, Seattle, WA 98116</i>	86
Genetic Aspects of Sudden Death in Youth: A Retrospective Study of Familial Hypercholesterolemia	<i>Maiken K. Larsen, MD*, Department of Forensic Medicine, Brendstrupgårdsvej 100, DK-8200 Aarhus N, DENMARK; Peter H. Nissen, MSc, Department of Clinical Biochemistry, Aarhus University Hospital, Tage Hansens Gade, DK-8200 Aarhus N, DENMARK; Ingrid B. Kristensen, MD, Department of Forensic Medicine, Brendstrupgaardsvej 100, DK-8200 Aarhus N, DENMARK; Henrik K. Jensen, MSc, Department of Cardiology, Aarhus University Hospital, Skejby, Brendstrupgaardsvej 100, DK-8200 Aarhus N, DENMARK; and Jytte B. Lundemose, PhD, Faculty of Health Sciences Aarhus University, Department of Forensic Medicine, Brendstrupgårdsvej 100, DK-8200 Århus N, , DENMARK</i>	87

An Unusual Death of a Masochist: Accident or Suicide?	<i>Biagio Solarino, PhD*, Sezione di Medicina Legale, Università degli Studi di Bari, P.zza Giulio Cesare, 11, Bari 70125, ITALY; Lucia Tattoli, MD, Sezione di Medicina Legale, University of Bari, Bari, ITALY; Ignazio Grattagliano, PsyD, Section of Forensic Psychiatry, University of Bari, Piazza Giulio Cesare, Bari 70124, ITALY; Claas T. Buschmann, MD, Institute of Legal Medicine and Forensic Sciences, Turmstrasse 22, Berlin 10439, GERMANY; Michael Tsokos, MD, Institute of Legal Medicine & Forensic Sciences, Turmstrasse 21, Haus L, Berlin 10559, GERMANY; and Giancarlo Di Vella, PhD, Sezione di Medicina Legale, DIMIMP, University of Bari, Policlinico, piazza G. Cesare, Bari 70121, ITALY</i>	88
Numerous Rhabdomyomata and Cortical Tubers in a Possible Case of SIDS	<i>Iyare Izevbaye, PhD*, State University of New York, Buffalo, 100 High Street, Buffalo, NY 14203; and Fazlollah Loghmanee, MD, Erie County Medical Examiner's Office, 111 Lehn Spring Drive, Williamsville, NY 14221-6920</i>	88
Fatal Subarachnoid Hemorrhage During Sexual Activity: A Case Report	<i>Federica Portunato*, Maria Celeste Landolfa, MD, Manuela Botto, MD, and Francesco De Stefano, MD, Department of Legal and Forensic Medicine, Via De Toni 12, Genova, I-16132, ITALY; and Francesco Ventura, MD, Department of Forensic Pathology, University of Genova, via de' Toni, 12, Genova, 16132, ITALY</i>	88
Occurrence of MRSA in the Peritoneal Cavity Following PEG Tube Insertion	<i>Nicole Singer, BS*, 206 South 13th Street Apartment 702, Philadelphia, PA 19107; and Fredric N. Hellman, MD, Office of the Medical Examiner, Fair Acres, Route 352, Lima, PA 19037</i>	89
Two Cases of Generalized Myxedema	<i>Meredith A. Lann, MD*, and Jeffrey J. Barnard, MD, Southwestern Institute of Forensic Sciences, 5230 Southwestern Medical Drive, Dallas, TX 75235</i>	90
Adipositas Cordis and Iatrogenic Death: Fatal Complication or Medical Error?	<i>Guido Viel, MD*, and Giovanni Cecchetto, MD, University of Padua, Via Falloppio 50, Padova, 35121, ITALY; Ann S. Schroder, MD, and Nadine Wilke, MD, Eppendorf-Hamburg, Hamburg, Germany; Massimo Montisci, PhD, Via Falloppio 50, Padova, ITALY; and Klaus Pueschel, PhD, Eppendorf-Hamburg, Hamburg, Germany</i>	90
Public Death From Orally Ingested Drugs During a One Year Period in Louisiana as Analyzed by a Single Forensic Toxicology Laboratory	<i>Gilbert E. Corrigan, PhD*, 11801 Hidden Lake, Saint Louis, MO 63138</i>	91
Complex Suicide: A Case Report	<i>Cristina G. Cordeiro, MD*, and Duarte N.P. Vieira, PhD, Instituto Nacional de Medicina Legal, IP, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL</i>	92
Fire Death of Two Lovers: An Immunohistochemical and Toxicological Study	<i>Paolo Fais, MD*, Guido Viel, MD, Massimo Montisci, PhD, Alessandro Nalesso, Silvano Zancaner, MD, and Giovanni Cecchetto, MD, University of Padua, Via Falloppio 50, Padova, 35121, ITALY</i>	92
Non-Traumatic Subdural Hematoma in Adults	<i>Carolyn H. Revercomb, MD*, and Sarah M. Colvin, MD, Office of the Chief Medical Examiner, District of Columbia, 1910 Massachusetts Avenue Southeast, Washington, DC 20003; and Marie L. Pierre-Louis, MD, 6404 Luzon Avenue, Northwest, Washington, DC 20012</i>	93

Accidental Carbon Monoxide Poisoning: A Review of Environmental and Cultural Risk Factors of Fatal Cases in King County	<i>Kristinza R. Woodard, MD*, University of Washington Pathology and Lab Medicine, 1959 Northeast Pacific Street, PO Box 356100, Seattle, WA 98195; and Richard C. Harruff, MD, PhD, King County Medical Examiner's Office, 325 9th Avenue, Box 359792, Seattle, WA 98104</i>	93
Differences in Scene Reenactment of Pediatric Death: Homicide Versus Others	<i>Marianna Sandomirsky, MD*, and Jane W. Turner, PhD, MD, St. Louis City Medical Examiner's Office, 1300 Clark Street, St. Louis, MO 63103</i>	94
Suicide by Multiple Gunshots From Automatic Weapons	<i>Paul Uribe, MD*, 7807 Mineral Springs Drive, Gaithersburg, MD 20877</i>	94
EBV (+) T-Cell Lymphoproliferative Disorder of Childhood Causing Sudden Death: A Case Report	<i>Mark A. Super, MD*, Sacramento County Coroner's Office, 4800 Broadway, Suite 100, Sacramento, CA 95820-1530; and Karimireddy J. Reddy, MD*, University of California, Davis, Department of Pathology, 4400 V Street, Sacramento, CA 95817</i>	95
Temporal Variation of Ethanol Related Firearm Deaths	<i>Rameen S. Starling-Roney, MD*, Anna Rubio, MD, Donna M. Vincenti, MD, and David R. Fowler, MD, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	95
Axonal Injury in Pediatric Head Trauma: A Study of the Interpretation of β-Amyloid Precursor Protein (β-APP) Expression in Trauma and Non-Trauma Cases	<i>Michael W. Johnson, MD, PhD*, and Anna Rubio, MD, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Juan Troncoso, MD, The Johns Hopkins University, School of Medicine, 558 Ross Building, 720 Rutland Avenue, Department of Neuropathology, Baltimore, MD 21205; and David R. Fowler, MD, and Ling Li, MD, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	96
Association of Retinal Hemorrhages With Fatal Head Injuries in Infant Monkeys	<i>Candace H. Schoppe, MD*, and Patrick E. Lantz, MD, Wake Forest University School of Medicine, Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157; Kurt A. Schoppe, MD, and Jonathan Burdette, MD, Wake Forest University School of Medicine, Department of Radiology, Medical Center Boulevard, Winston Salem, NC 27157; Keith G. Mansfield, DVM, Harvard Medical School, New England Primate Research Center, 1 Pine Hill Drive, Southborough, MA; and Constance A. Stanton, MD, Wake Forest University School of Medicine, Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157</i>	96
Postmortem Pulmonary Findings by Computed Tomography Compared With Conventional Autopsy	<i>Lene W. Boel, PhD*, Institute of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Lars Urenholt, PhD, Institute of Forensic Medicine, Department of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Rita Ullerup, Institute of Forensic Medicine, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; and Anne Grethe Jurik, DSc, Department of Radiology Aarhus University Hospital, Noerrebrogade 44, Aarhus C, 8000, DENMARK</i>	97

Forensic Imaging: Yes, We Scan! New Challenges for a Radiographer	<i>Alexendre Dominguez*, Haute Ecole Cantonale Vaudoise de la Santé, Avenue de Beaumont 21, Lausanne, SWITZERLAND; Francesco Doenz, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, Richard Dirnhofer, MD, and Beat Steger, Fumedica AG, Luzernerstrasse 91, Muri, SWITZERLAND; Barbara Sollberger, Department for Cardiovascular Surgery, University Hospital Bern, Hochschulstrasse 4, Bern, SWITZERLAND; Erich Gygax, Department for Cardiovascular Surgery, Hochschulstrasse 4, Bern, SWITZERLAND; Reto Meuli, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, 1011, SWITZERLAND; and Patrice Mangin, MD, PhD, and Silke Grabherr, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND</i>	98
Benefits and Limitations of Postmortem Multislice Computed Tomography as Adjunct to the Perinatal and Pediatric Autopsy	<i>Kerstin Aschenbroich, MD*, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND; Steffen G. Ross, MD, Institute of Forensic Medicine, Center of Forensic Imaging "Viropsy", Buehlstrasse 20, Bern, 3012, SWITZERLAND; Michael Thali, MD, MBA, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND; and Harald Bonell, MD, Institute of Diagnostic Radiology, Inselspital Bern, Bern, 3010, SWITZERLAND</i>	98
Multidetector Computed Tomographic (MDCT) Autopsy in Suicide by Gunshot to the Head	<i>Theodore Harcke, MD, Craig T. Mallak, JD, MD, and Terrill Top, MD*, Armed Forces Institute of Pathology, 1413 Research Boulevard, Rockville, MD 21771</i>	99
Classification of Asphyxia: The Need for Standardization	<i>Anny Sauvageau, MD*, Office of the Chief Medical Examiner, 7007, 116 Street, Edmonton, AB T6H 5R8, CANADA</i>	99
Discrimination of Falls and Blows in Blunt Head Trauma: A Multi-Criteria Approach	<i>Anny Sauvageau, MD*, Office of the Chief Medical Examiner, 7007, 116 Street, Edmonton, AB T6H 5R8, CANADA</i>	100
Glioblastoma – Cause of Sudden Death on an Apparently Healthy Woman	<i>Jerónimo F.S. Silva*, National Institute of Legal Medicine - Portugal, Bairro de Santa Justa, 10, Coimbra, 3000-356, PORTUGAL</i>	100
Stab Wounds, Incised Wounds, or Blunt Trauma With Single or Multiple Weapons – How to Read Soft Tissue and Bone Injuries	<i>João S. Pinheiro, MS*, Rosario L. Silva, MD, and Claudia Marques, MD, Instituto Nacional Medicina Legal, Delegação do Centro, Largo da Sé Nova, Coimbra, 3000, PORTUGAL; José Elísio P.A. de Campos e Sousa, MD, Largo da Sé Nova, Coimbra, 3000-213 COIMBRA, PORTUGAL; and Francisco C. Real, PhD, Instituto Nacional Medicina Legal, Delegação do Centro, Largo da Sé Nova, Coimbra, 3000, PORTUGAL</i>	101

Sudden Infant Death Syndrome and Infant Mortality in Serbia	<i>Djordje M. Alempijevic, PhD*, Faculty of Medicine University of Belgrade, Institute of Forensic Medicine, 31a Deligradska Street, Belgrade, 11000, SERBIA AND MONTENEGRO; Ana Milenkovic, and Nikola Vukelic, Faculty of Medicine University of Belgrade, 8 Drive Subotica Street, Belgrade, 11000, SERBIA AND MONTENEGRO; and Dragan S. Jecmenica, PhD, Snezana Pavlekic, PhD, Aleksandra V. Nedeljkov, MD, and Branimir V. Aleksandric, PhD, Institute of Forensic Medicine, Faculty of Medicine, University of Belgrade, 31a Deligradska Street, Belgrade, 11000, SERBIA AND MONTENEGRO</i>	101
Fatty Versus Fibrofatty Involvement of the Myocardium in Sudden Death and Heart Failure	<i>Lise A.M. Matzke, MSc*, and William M. Elliott, PhD, UBC-James Hogg iCAPTURE, University of British Columbia/Providence Health Care, Saint Paul's Hospital Room 166, 1081 Burrard Street, Vancouver, V6H 1P9, CANADA; Crystal Leung, BMLSc, James Hogg iCapture Centre for Cardiovascular and Pulmonary Research, Saint Paul's Hospital, Room 166 1081 Burrard Street, Vancouver, V6Z 1Y6, CANADA; Carol Lee, MD, 2165 Fraserview Drive, Vancouver, V5P 2N2, CANADA; Charles Lee, MD, Vancouver General Hospital, Department of Forensic Pathology, 855 West 12th Avenue, Room 1352, Vancouver, BC V5Z 1M9, CANADA; Bruce M. McManus, PhD, James Hogg iCAPTURE Centre, Saint Paul's Hospital, 1081 Burrard Street, Vancouver, V6H 1P9, CANADA; and Michael Allard, MD, James Hogg iCapture Centre for Cardiovascular and Pulmonary Research, 1081 Burrard Street, Vancouver, BC V6Z 1Y6, CANADA</i>	101
A Homicide Due to an Atypical Asphyxiation Tool: A Rolling Pin	<i>Margherita Neri, PhD*, Santina Cantatore, Gabriela Perilli, MD, and Irene Riezzo, MD, Department of Forensic Pathology, University of Foggia, viale degli Aviatori, 1, Foggia, 71100, ITALY</i>	102
Use of Volatile Organic Compounds and Chemometric Procedures to Determine Postmortem Interval	<i>John W. McIlroy, BS*, Michigan State University, Chemistry Building, East Lansing, MI 48824; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824</i>	103
Comparison of Drug-Related Deaths in Tarrant County, Texas, With Law Enforcement Seizures of Illicit Substances Over a Similar Time Frame	<i>Lucile B. Tennant, JD*, Marc A. Krouse, MD, and Nizam Peerwani, MD, Tarrant County Medical Examiner's Office, 200 Feliks Gwozdz Place, Fort Worth, TX 76104-4919</i>	103
Nocturnal Oviposition of Blow Flies (Diptera: Calliphoridae) in the Lower Mainland of British Columbia, Canada	<i>Jaime S. Prevolesek, BSc*, and Gail S. Anderson, PhD, Simon Fraser University, School of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA</i>	104

Blood Aspiration as a Vital Sign Detected by CT Imaging and Postmortem CT Guided Biopsy	<i>Laura Filograna, MD*, and Steffen G. Ross, MD, Institute of Forensic Medicine Center of Forensic Imaging "Viropsy", Buehlstrasse 20, Berne, AL 3012, SWITZERLAND; Stephan Bolliger, MD, and Tanja Germerott, MD, University of Berne Institute of Forensic Medicine, Buehlstrasse 20, Bern, AL 3012, SWITZERLAND; Patricia M. Flach, MD, Institute of Forensic Medicine Bern / Viropsy, Buehlstrasse 20, Bern, SWITZERLAND; and Michael Thali, MD, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND</i>	104
Brain Tissue Responses After Traumatic Brain Injury in Animal Models	<i>Kazuhiko Kibayashi, MD*, Ken-ichiro Nakao, MS, and Ryo Shimada, PhD, Department of Legal Medicine, School of Medicine, Tokyo Women's Medical University, 8-1 Kawada-cho, Shinjuku-ku, Tokyo, 162- 8666, JAPAN</i>	105
Determination of Procalcitonin, C-Reactive Protein, Tumor Necrosis Factor-Alpha, Interleukin-6, and Interleukin-8 Levels in Serum, Vitreous Humor, and Cerebrospinal Fluid as Markers of Sepsis	<i>Cristian Palmiere, MD*, Bettina Schrag, Marc D. Bollmann, MD, and Patrice Mangin, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND</i>	105
Sudden Death Due to Mesothelioma of the Atrio-Ventricular Node	<i>Géraldine Maulean, MD*, Alain Tabib, PhD, Daniel Malicier, and Laurent Fanton, PhD, Institut of Legal Medicine, 12 Avenue Rockefeller, Lyon, 69008, FRANCE</i>	106
Accidental Drowning Deaths in a Coastal Region of South India – A Ten Year Study	<i>Tanuj Kanchan, MD*, Kasturba Medical College, Department of Forensic Medicine, Light House Hill Road, Mangalore, 575 001, INDIA</i>	107
Sudden Death From Atypical Pneumonia in a Healthy Adolescent	<i>Sabina Di Donato, MD*, Ospedale San Carlo - U.O. Medicina Legale, Via Potito Petrone, s.n.c., Potenza, 85100, ITALY; Margherita Neri, PhD, Department Forensic Pathology, University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY; and Rocco A. Maglietta, MD, C.R.O.B. - Rionero in Vulture (Pz), via Padre Pio, 1, Rionero in Vulture (Pz), 85100, ITALY</i>	107
Viropsy Project - Postmortem Needle Biopsy of the Lungs: A Feasible Tool for the Study of Fat Embolism as Vital Reaction	<i>Laura Filograna, MD*, Institute of Forensic Medicine, Centre of Forensic Imaging and Viropsy, Buehlstrasse, 20, Berne, SWITZERLAND; Stephan Bolliger, MD, University of Berne Institute of Forensic Medicine, Buehlstrasse 20, Bern, AL 3012, SWITZERLAND; Danny Spendlove, MD, Institute of Forensic Medicine, Centre of Forensic Imaging and Viropsy, Buehlstrasse, 20, Berne, AL 3012, SWITZERLAND; and Ulrich Preiss, MD, and Michael Thali, MD, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND</i>	108
Cerebral Artery Thrombosis After Penetrating Oral Trauma: An Exceptional Autopsy Case	<i>Renaud Clement, MD*, 1 Rue Gaston Veil, Nantes, 44093, FRANCE</i>	108
Does Embalming Impact Vitreous Glucose Levels?	<i>Stephany Fiore, MD*, County of Sacramento, Coroner's Office, 4800 Broadway, Suite 100, Sacramento, CA 95820-1530; and Charlotte A. Wacker, MS*, University of California, Davis Body Donation Program, 4800 Broadway, Suite 100, Sacramento, CA 95820</i>	109

Analysis of an Unusual Misfire of a Common Handgun	<i>Janaki Warushahennadi, MD*, King County Medical Examiner's Office, 325 9th Avenue, HMC Box 359792, Seattle, WA 98104; Brian J. Smelser, BS, Washington State Patrol Crime Laboratory, Washington State Patrol, 2203 Airport Way South, Building A Suite 250, Seattle, WA 98134; Richard T. Wyant, MS, Washington State Patrol CLD, 2203 Airport Way, South, Suite 250, Seattle, WA 98134; and Timothy L. Williams, MD, King County Medical Examiner's Office, 325 - 9th Avenue, Box 359792, Seattle, WA 98104-2499</i>	109
Fatal Cardiac Perforation During Percutaneous Treatment in Iliac Artery Occlusion	<i>Alessandro Bonsignore, MD*, Massimo Gallo, MD, Francesco Ventura, PhD, and Francesco De Stefano, MD, Department of Legal and Forensic Medicine, University of Genova, Via De Toni 12, Genova, 16132, ITALY</i>	109
Swiss Virtobot (Virtual Autopsy) Documentation and Analysis: Work Flow and Procedure	<i>Steffen G. Ross, MD, Institute of Forensic Medicine Center of forensic imaging "Virtopsy", Buehlstrasse 20, Bern, AE 3012, SWITZERLAND; Lars Ebert, University Bern, IRM, Buehlstrasse 20, Bern, AE 3012, SWITZERLAND; Silvio Näther, Institute of Forensic Medicine, Centre of Forensic Imaging, Bühlstrasse 20, Bern, 3012, SWITZERLAND; and Stephan Bolliger, MD, and Michael Thali, MD*, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND</i>	110
Mortuary Management in the Aftermath of the 2009 Australian Bush Fires	<i>Jodie J. Leditschke, PhD*, Victorian Institute of Forensic Medicine, 57- 83 Kavanagh Street, Southbank, Melbourne, 3006, AUSTRALIA</i>	110
A Uniform Protocol to Address the Rapidly Accumulating Unidentified Human Remains and Missing Persons in the United States — A Nation's Silent Mass Disaster	<i>Marzena H. Mulawka, MFS*, Forensic Sciences Program, National University, 11255 North Torrey Pines Road, La Jolla, CA 92037-1011; Ismail M. Sebetan, MD, PhD, 12752 Via Nieve, San Diego, CA 92130; and Paul Stein, PhD, 25757 Bellemore Drive, Ramona, CA 92065</i>	111
Request for Uniform Autopsy Protocols on Certain Drowning Victims	<i>Gerald N. Nance, BA*, National Center for Missing and Exploited Children (NCMEC), 699 Prince Street, Alexandria, VA 22314</i>	112
MAPS: How a Statewide Pharmaceutical Database Improves Death Investigation	<i>Shawn A. Silver*, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909; Joyce L. deJong, DO, Sparrow Health Systems, Forensic Pathology, 1322 East Michigan Avenue, Suite 118, Lansing, MI 48909; and Philip R. Croft, MD, Michael A. Markey, MD, and Michelle P. Elieff, MD, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909</i>	112
Death Investigation and Organ and Tissue Donation in Clark County, Nevada	<i>Alane Olson, MD*, Clark County Coroner's Office, 1704 Pinto Lane, Las Vegas, NV 89106</i>	113
Fatal Sexual Violence Database for Postmortem Genital Examinations With Colposcopy	<i>Sharon R. Crowley, MN*, FCNS, 122 Emeline Avenue, Santa Cruz, CA 95060</i>	113
Grant Solicitations: New Opportunities for Medical Examiners and Coroners – Tips on the Process	<i>Marcella F. Fierro, MD*, Fierro Forensics, 8702 Berwickshire Drive, Henrico, VA 23229-7833</i>	114

Development of Standard Operating Procedures for Conducting Arthropod Succession Studies: Improving Postmortem Estimates Through Ecology	<i>Jeffery K. Tomberlin, PhD*, Department of Entomology, TAMU 2475, College Station, TX 77843-2475; and Jason H. Byrd, PhD*, Maples Center for Forensic Medicine, University of Florida, 4800 Southwest 35th Drive, Gainesville, FL 32608</i>	114
Using Biolog EcoPlates™ as an Economical Approach to Determining Postmortem Body Dump Sites Through Microbial Community Level Physiological Profiling	<i>M. Eric Benbow, PhD*, University of Dayton, Department of Biology, 300 College Park, Dayton, OH 45469-2320; Jeffery K. Tomberlin, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843- 2475; Tawni L. Crippen, PhD, Southern Plains Agricultural Research Center, Agricultural Research Service, U.S. Department of Agriculture, College Station, TX 77845; Andrew Lewis, BS, University of Dayton, Department of Biology, 300 College Park, Dayton, OH 45469-2320; and Jennifer Pechal, MS, TAMU 2475, Texas A&M University, College Station, TX 77843-2475</i>	115
Microbes Associated With Decomposing Remains Regulate Insect Colonization	<i>Jeffery K. Tomberlin, PhD*, Department of Entomology, TAMU 2475, College Station, TX 77843-2475; M. Eric Benbow, PhD*, University of Dayton, Department of Biology, 300 College Park, Dayton, OH 45469- 2320; Tawni Crippen, PhD, 2881 F&B Road, College Station, TX 77843; Charity Owings, BS, 2475 TAMU, College Station, TX 77845; Francisco I. Ortiz, BS, 1818 South 2nd Street, Apartment 62, Waco, TX 76706; and Jill C. Ross, BS, 110 Hillview Avenue, Millersville, PA 17551</i>	115
Lower Temperature Threshold for Black Soldier Fly (Diptera: Stratiomyidae) Egg and Adult Eclosion	<i>Leslie A. Holmes, BS*, and Sherah L. Van Laerhoven, PhD, University of Windsor, Department of Biology, 401 Sunset Avenue, Room 119 Bio, Windsor, ON N9B 3P4, CANADA; and Jeffery K. Tomberlin, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475</i>	116
Colonization Behavior of Forensically Important Blow Fly Species: Implications for Postmortem Interval Estimations	<i>Jennifer Y. Rosati, BSc*, and Sherah L. Van Laerhoven, PhD, University of Windsor, Department of Biology, 401 Sunset Avenue, Room 119 Bio, Windsor, ON N9B 3P4, CANADA</i>	116
Petechia in Hanging: A Retrospective Study of Contributing Variables	<i>Renaud Clement, MD*, 1 Rue Gaston Veil, Nantes, 44093, FRANCE; and Anny Sauvageau, MD, Office of the Chief Medical Examiner, 7007 116 Street, Edmonton, AB T6H 5R8, CANADA</i>	117
Fractures of the Neck Structures in Suicidal Hangings: A Retrospective Study on Contributing Variables	<i>Anny Sauvageau, MD*, Office of the Chief Medical Examiner, 7007, 116 Street, Edmonton, AB T6H 5R8, CANADA; and Renaud Clement, MD, 1 Rue Gaston Veil, Nantes, 44093, FRANCE</i>	117
Precision of Autopsy Body Length Measurements	<i>William Oliver, MD, MPA*, Leone Lisa, MA, and Colleen Tetterton, PA, Brody School of Medicine at East Carolina University, Division of Forensic Pathology, Department of Pathology and Laboratory Medicine, 7S-10 Brody Medical Sciences Building, Greenville, NC 27858</i>	118
“Goodness Gracious Great Balls of Fire”: Genital Thermal Injuries From Airbag Exhaust	<i>William S. Smock, MD*, University of Louisville Hospital, Department of Emergency Medicine, 530 South Jackson Street, Louisville, KY 40202</i>	119

Histologic Diagnosis of Amniotic Fluid Embolism: Providing Context Through Immunohistochemistry	<i>Philip R. Croft, MD, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909-7980; Michael A. Markey, MD*, Sparrow Forensic Services, Sparrow Hospital, 1215 East Michigan Avenue, Lansing, MI 48912; Joyce L. deJong, DO, Sparrow Health Systems, Forensic Pathology, 1322 East Michigan Avenue, Suite 118, Lansing, MI 48909; and Michelle P. Elieff, MD, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909</i>	119
Utility of Large Bowel Examination in Medicolegal Death Investigation	<i>Michael R. Condron, MD*, and Mary L. Anzalone, MD, Harris County Medical Examiner, 1885 Old Spanish Trail, Houston, Texas 77054; and Dwayne A. Wolf, MD, PhD, Harris County Medical Examiner, JAJ Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054</i>	120
Detection of KCNQ1 Genetic Variations by High Resolution Melting Analysis for the Diagnosis of Channelopathies in Postmortem Investigations	<i>Audrey Farrugia, MD*, Christine Keyser, PhD, and Bertrand Ludes, MD, PhD, Institut de Medecine Legale, 11 rue Humann, Strasbourg Cedex, 67085, FRANCE</i>	120
Cardioinhibitory Reflex Cardiac Arrest – Myth or Reality?: A Systematic Review From Cases	<i>Bettina Schrag*, Rue du Bugnon 21, Lausanne, SWITZERLAND</i>	121
Differentiation of Bullet Type Based on Analysis of Gunshot Residue Using Inductively Coupled Plasma Mass Spectrometry	<i>Ruth N. Udey, BS*, Michigan State University, 209 Biochemistry, East Lansing, MI 48824; Brian C. Hunter, MD, 630 South Saginaw Street, Flint, MI 48502; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 506 Baker Hall, East Lansing, MI 48824</i>	121
Vehicular Emissions Systems and Their Effects on Suicides and Attempted Suicides by Carbon Monoxide	<i>Mark E. Goodson, PE*, 1500 Spencer Road, Denton, TX 76205-5105</i>	122
Pseudostrangulation	<i>Thomas W. Young, MD*, Heartland Forensic Pathology, LLC, 12717 Oakmont Drive, Kansas City, MO 64145</i>	123
Investigation and Autopsy Procedures in Cases Involving Conducted Energy Devices (CEDs) in the State of Maryland	<i>Mary G. Ripple, MD*, David R. Fowler, MD, and Ling Li, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	123
Postmortem CT-Angiography Using Angiofil®	<i>Silke Grabherr*, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1011, SWITZERLAND; Francesco Doenz, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, , SWITZERLAND; Alexandre Dominguez, Haute Ecole Cantonale Vaudoise de la Santé, Filière Technique en Radiologie Médicale, Avenue du Beaumont 21, Lausanne, , SWITZERLAND; Richard Dirnhofer, and Beat Steger, Fumedica AG, Luzernerstrasse 91, Muri, 5630, SWITZERLAND; Barbara Sollberger, and Erich Gygax, Department for Cardiovascular Surgery, University Hospital Bern, Hochschulstrasse 4, Bern, 3012, SWITZERLAND; Reto Meuli, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, 1011, SWITZERLAND; and Patrice Mangin, MD, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND</i>	124

Radiological Interpretation of Postmortem CT-Angiography	<i>Francesco Doenz*, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, SWITZERLAND; Alexendre Dominguez, Haute Ecole Cantonale Vaudoise de la Santé, Avenue de Beaumont 21, Lausanne, SWITZERLAND; Richard Dirnhofer, and Beat Steger, Fumedica AG, Luzernerstrasse 91, Muri, SWITZERLAND; Erich Gygax, and Barbara Sollberger, Department for Cardiovascular Surgery, University Hospital Bern, Hochschulstrasse 4, Bern, SWITZERLAND; Reto Meuli, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, 1011, SWITZERLAND; and Patrice Mangin, PhD, and Silke Grabherr, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1011, SWITZERLAND</i>	124
Perfusion Technique for Postmortem CT-Angiography	<i>Erich Gygax*, and Barbara Sollberger, Department for Cardiovascular Surgery, University Hospital Bern, Hochschulstrasse 4, Bern, SWITZERLAND; Alexandre Dominguz, Haute Ecole Cantonale Vaudoise de la Santé, Avenue de Beaumont 21, Lausanne, SWITZERLAND; Richard Dirnhofer, and Beat Steger, Fumedica AG, Luzernerstrasse 91, Muri, SWITZERLAND; Francesco Doenz, and Reto Meuli, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, 1011, SWITZERLAND; and Patrice Mangin, PhD, and Silke Grabherr, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1011, SWITZERLAND</i>	125
The Role of Microscopic Postmortem Study in Explaining Traffic-Crash Related Neck Injury: A Case Review	<i>Lars Uhrenholt, PhD*, Institute of Forensic Medicine, Department of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; and Michael Freeman, PhD, 205 Liberty Street, Northeast, Suite B, Salem, OR 97301</i>	126
Lethal Consequences Arising From the Rupture of an Undetected Large Ductus Arteriosus Aneurysm During a T-12 Kyphoplasty Procedure	<i>William J. Bonner, BA*, 1100 South Broad Street, Unit 402B, Philadelphia, PA 19146; and Fredric N. Hellman, MD, Office of the Medical Examiner, Fair Acres, Route 352, Lima, PA 19037</i>	127
Exploring the Potential for Nocturnal Colonization of Fresh Cadavers by Carrion Flies in the Central United States	<i>Timothy E. Huntington, PhD*, Concordia University Nebraska, 800 North Columbia Avenue, Seward, NE 68434; and Leon G. Higley, PhD, University of Nebraska, 706 Hardin Hall, Lincoln, NE 68583-0987</i>	127
Suicide by Extraordinarily Numerous Blade Wounds	<i>Dollett T. White, MD*, and Leszek Chrostowski, MD, Hillsborough County Medical Examiner Department, 11025 North 46th Street, Tampa, FL 33617</i>	128
A DNA Database for Species Identification of Forensically Important Flesh Flies (Diptera: Sarcophagidae) in the Continental United States	<i>Trevor I. Stamper, PhD*, 3516 State Route 222, Batavia, OH 45103- 9708; Alice E. Timm, PhD, Department of Biological Sciences, University of Cincinnati, Cincinnati, OH 45221-006; Gregory A. Dahlem, PhD, Department of Biological Sciences, Northern Kentucky University, Highland Heights, KY 41099; and Ronald W. DeBry, PhD, Department of Biological Sciences, University of Cincinnati, Cincinnati, OH 45221-0006</i>	128

NMR and Bioinformatic Studies on the Metabolic Effects of Acetaminophen in Rat's and Human's in Urine: A Metabonomic Approach	<i>Joshua R. McMillen, BS*, 4715 Garden Ranch Drive, Apartment 308, Colorado Springs, CO 80918</i>	129
A Cold Case: A Forensic Review Nine Years After the Crime	<i>Luigi Saravo, PhD, Reparto Carabinieri Investigazioni Scientifiche, Viale Tor di Quinto 151, Roma, 00190, ITALY; Gennaro Aprea, PhD, Università degli Studi di Napoli "Federico II", Complesso Monte Sant'Angelo, Via Cinthia, Napoli, 80126, ITALY; and Paola A. Magni, MS*, F.E.LAB ASL TO1, c/o Civico Obitorio di Torino, Via Bertani 112/A, Torino, 10137, ITALY</i>	129
Dead Men in Wells: How Forensic Science Was Used to Solve a Crime in an Aquatic Environment	<i>Paola A. Magni, MS*, F.E.LAB ASL TO1, c/o Civico Obitorio di Torino, Via Bertani 112/A, Torino, 10137, ITALY; and Mario A. Apostol, PhD, SC Medicina Legale ASL TO4, Via C. Bertetti 10A, Torre Canavese (TO), 10100, ITALY</i>	129
Fatal Rescue Burns	<i>Tanuj Kanchan, MD*, Manipal University, Department of Forensic Medicine, Kasturba Medical College, Light House Hill Road, Mangalore, 575001, INDIA</i>	130
Sports Tool as a Weapon of Assault: A Case Report	<i>B. Suresh K. Shetty, MD*, Kasturba Medical College, Light House Hill Road, Mangalore, 575001, INDIA</i>	130
Unusual Case of Blunt Chest Trauma Without Rib Fractures Leading to a Major Pulmonary Laceration	<i>Javier Serrano, MD*, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921; and Carlos F. Chavez-Arias, MD, Puerto Rico Institute of Forensic Sciences, PO Box 11878, Caparra Heights Station, San Juan, PR 00922-1878</i>	131
Postmortem Analysis of Vitamin D Using Liquid Chromatography Tandem Mass Spectroscopy	<i>Geza Bodor, PhD, Denver VA Medical Center, 1055 Clermont Street, Denver, CO 80220; John Carver, JD, City and County of Denver, 660 Bannock Street, Denver, CO 80204; and Amy Martin, MD, and Michael A. Burson, PhD*, City and County of Denver, Office of the Medical Examiner, 660 Bannock Street, Denver, CO 80204</i>	131
An Unusual Case of Homicide by Knife, Screwdriver, and a Kitchen Fork	<i>Sabina Di Donato, MD*, Ospedale San Carlo - U.O. Medicina Legale, Via Potito Petrone, s.n.c., Potenza, 85100, ITALY; Aldo Di Fazio, Section of legal medicine - Matera Hospital, via Montescaglioso n.5, Matera, 75100, ITALY; and Rocco Maglietta, CROB Rionero in Vulture (Potenza), via Padre Pio n. 1, Rionero in Vulture (Pz), 85028, ITALY</i>	132
Love and a Bullet: Autoerotic Accident or Intentional Suicide?	<i>Kelly L. Rose, MD*, and Kim A. Collins, MD, Fulton County Medical Examiner's Office, 430 Pryor Street Southwest, Atlanta, GA 30312</i>	132
Laryngeal and Hyoid Bone Trauma Resulting From Forces Other Than Compression of the Neck	<i>Carlos F. Chavez-Arias, MD*, Puerto Rico Institute of Forensic Sciences, PO Box 11878, Caparra Heights Station, San Juan, PR 00922-1878; Dario Sanabria, MD, Puerto Rico Institute of Forensic Sciences, Department of Pathology, PO Box 11878, Caparra Heights Station, San Juan, PR 00922-1878; and Javier Serrano, MD, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921</i>	133

The Evolving Distribution of Cause and Manner of Death in HIV Positive Medical Legal Cases: Links Between ART and Traditional Categories of Chronic Disease	<i>Sharon M. Derrick, PhD*, Harris County Medical Examiner's Office, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	134
Death in a Wine Vat	<i>Romano La Harpe, MD*, Sandra E. Burkhardt, MD, and Kebede Shiferaw, MD, Institut de Medecine Legale, 9 Av de Champel (CMU), Geneva, 1206, SWITZERLAND</i>	134
Nailing the Diagnosis: Features of Fatal Injury Inflicted By Unusual Projectiles and Firearms	<i>Hilary S. McElligott, MD*, Cook County Office of the Medical Examiner, 2121 West Harrison Street, Chicago, IL 60612-3705</i>	135
Please, Don't Get Angry! Two Fatal Cases of Emotional Stress-Related Death in Left Ventricular Apical Ballooning Syndrome (Tako Tsubo Cardiomyopathy)	<i>Stefano D. Errico, MD*, Benedetta Di Battista, MD, Carmela Fiore, MD, and Cristoforo Pomara, MD, PhD, Department of Forensic Pathology, University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY</i>	135
A Case of Anaphylactoid Syndrome of Pregnancy	<i>Jennifer L. Shuttlesworth, MD*, Ana E. Lopez, MD, and Luis A. Sanchez, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	136
Pheochromocytoma Causing Unexpected Death – Two Unusual Presentations	<i>Jacqueline L. Parai, MD*, Ontario Forensic Pathology Services, Division of Anatomical Pathology, The Ottawa Hospital, 501 Smyth Road, Box 117 4th Floor, Ottawa, ON K1H 8L6, CANADA; and Iris Teo, MD, Itrat Ahmed, MD, and Christopher M. Milroy, MD, The Ottawa Hospital, 501 Smyth Road, Box 117 4th Floor, Ottawa, ON K1H 8L6, CANADA</i>	137
Digital UV/IR Photography for Tattoo Evaluation in Mummified Remains	<i>William Oliver, MD, MPA*, and Leone Lisa, MA, Brody School of Medicine at East Carolina University, Department of Pathology and Laboratory Medicine, Division of Forensic Pathology, 7S-10 Brody Medical Sciences Building, Greenville, NC 27858</i>	137
Undiagnosed, Untreated Acute Promyelocytic Leukemia Presenting as Suspicious Sudden Death	<i>Pauline Saint-Martin, MD*, and Patrick O Byrne, MD, Service de Medecine Legale, CHRU Tours, Tours, 37000, FRANCE; Jean Michel Gaulier, PhD, Service de Pharmacologie et Toxicologie, CHRU Dupuytren, 2 avenue Martin Luther King, Limoges, 87042, FRANCE; and Sophie Martin Dupont, MD, Agnès Peyclit, MD, and François Paraf, PhD, Service de Medecine Legale, CHRU Dupuytren, 2 Avenue Martin Luther King, LIMOGES, 87042, FRANCE</i>	138
Death of a Bodybuilder: A Case Report of Mixed Drug Overdose With Lethal Gamma-Hydroxybutyrate Level	<i>Wendy M. Gunther, MD*, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046</i>	139
Hara-Kiri or Homicide?	<i>Wendy M. Gunther, MD*, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046</i>	139
Two Cases of Novel Influenza A (H1N1) Virus (“Swine Flu”) Infection: Clinical Presentations, Autopsy Protocol With Findings, and Review of Literature	<i>Abraham T. Philip, MD*, Onondaga County Medical Examiner's Office, 100 Elizabeth Blackwell Street, Syracuse, NY 13210; Kerry Whiting, BS, and Sanjay Mukhopadhyay, MD, State University of New York - Upstate Medical University, 766 Irving Avenue, Syracuse, NY 13210; and Robert Stoppacher, MD, Onondaga County Medical Examiner's Office, 100 Elizabeth Blackwell Street, Syracuse, NY 13210</i>	140

An Unusual Case of “Piggyback” Sandwiched Projectiles Caused by a Round- Nose Bullet Shot Through a Door	<i>Geoffrey P. Smith, MD, Kelly L. Rose, MD*, and Randy L. Hanzlick, MD, Fulton County Medical Exam Center, 430 Pryor Street, Southwest, Atlanta, GA 30312</i>	141
Newborn Kidnapping by Crude Cesarean Section	<i>Todd M. Luckasevic, DO*, Laine L. Frazier, BS, Abdulrezak M. Shakir, MD, Baiyang Xu, MD, and Karl E. Williams, MD, MPH, Allegheny County Medical Examiner’s Office, 1520 Penn Avenue, Pittsburgh, PA 15222</i>	141
An Unusual Case of Accidental Poisoning: Fatal Methadone Inhalation	<i>Cristian Palmiere, MD*, Christophe Brunel, MD, Frank Sporkert, MD, and Patrice Mangin, MD, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND</i>	141
Fatalities Occurring With Ingestion of Ibogaine	<i>James R. Gill, MD*, Office of Chief Medical Examiner, 520 First Avenue, New York, NY 10016; and Kenneth R. Alper, MD, New York University School of Medicine, 403 East 34th street, 4th Floor EPC, New York, NY 10016</i>	142
Acetaminophen Induced Death of a Fetus With Maternal Survival: An Unusual Case of a Suicide Attempt Resulting in Fetal Death	<i>Jeffrey K. Racette, MD*, Todd M. Luckasevic, DO, Baiyang Xu, MD, Abdulrezak M. Shakir, MD, and Karl E. Williams, MD, MPH, Allegheny County Medical Examiner’s Office, 1520 Penn Avenue, Pittsburgh, PA 15222</i>	143

2009		
Exertional Collapse in a Youth With Hemoglobin SE	<i>Elise F. Arbefeville, MD*, and Vernard I. Adams, MD, Hillsborough County Medical Examiner Department, 401 South Morgan Street, Tampa, FL 33602</i>	144
Machinery-Related Occupational Death: The Relevance of Workplace Investigation and Antemortem Radiological Data in Forensic Reconstruction	<i>Giovanni Cecchetto, MD*, Via Faloppio 50, Padova, 35121, ITALY; Guido Viel, MD, and Federica De Lotto, MD, University of Padua, Via Faloppio 50, Padova, 35121, ITALY; Renzo Manara, MD, Istituto di Neuroradiologia, Padova, 35121, ITALY; Massimo Montisci, PhD, Via Faloppio 50, Padova, 35121, ITALY; and Silvano Zancaner, MD, Sede di Medicina Legale - Università degli Studi di Padova, Via Faloppio 50, Padova, 35121, ITALY</i>	144
Impetigo Contagiosa Simulating Non-Accidental Injuries in a Pregnant Woman Using Intravenous Drug	<i>Fleres Pierangela*, Institute of Legal Medicine, Via del Vespro, n. 127, Palermo, 90100, ITALY; Farina Graziana, MD, Institute of Legal Medicine of Palermo, Via del Vespro, n. 129, Palermo, 90100, ITALY; Antonina Argo, via Narbone n. 13, Palermo, , ITALY; Paola Pugnetti, Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via del Vespro, n. 129, Palermo, 90127, ITALY; Paolo Procaccianti, Palermo University, Via del Vespro, n. 127, Palermo, 90100, ITALY; and Emiliano Maresi, Via del Vespro, n. 127, Palermo, 90100, ITALY</i>	145
HPLC Analysis of Benzocaine in “Green Products”	<i>Harminder S. Bhawara, PhD*, fsl, S/O Shri A.S. Bhawara, Shanti Nagar, Near Ram Mandir, Raipur (C.G), INDIA</i>	145
Child Deaths Due to Television Falls With Injury Patterns That Mimic Child Abuse	<i>Evan Matshes, MD, c/o Dr. Amy Gruszecki, Southwestern Institute, of Forensic Sciences, 5230 Medical Center Drive, Dallas, TX 75235; Reade A. Quinton, MD, University of Texas Southwestern, Department of Pathology, 5323 Harry Hines Boulevard, Dallas, TX 75390; and Amy C. Gruszecki, DO, and Jeremy Deisch, MD*, Southwestern Institute, of Forensic Sciences, 5230 Medical Center Drive, Dallas, TX</i>	146
Application of Forensic Engineering for the Reconstruction of Manner of Death: A Nautical Accident	<i>Daniele Gibelli, MD*, Istituto di Medicina Legale e delle Assicurazioni di Milano, V. Mangiagalli, 37, Milan, ITALY; Angela Cantatore, BE, and Remo Sala, BE, Politecnico di Milano, P.zza Leonardo da Vinci, Milan, ITALY; and Salvatore Andreola, MD, and Cristina Cattaneo, PhD, Istituto di Medicina Legale e delle Assicurazioni di Milano, V. Mangiagalli, 37, Milan, ITALY</i>	146
Homicide, Suicide, and the Missing Mother: The Mysterious and Tragic Deaths of a Latino Family	<i>William C. Rodriguez III, PhD*, Armed Forces Medical Examiner, 1413 Research Boulevard, Building 102, Rockville, MD 20850; and Carroll Allen, Donna Vicente, and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	147
Sudden Death in Epilepsy: A Review of 51 Consecutive Cases	<i>Rudy J. Castellani, MD*, University of Maryland, Department of Pathology, 22 South Greene Street Baltimore, MD 21201; Heather F. Grothous, BS, Michigan State University College of Osteopathic Medicine, A306 East Fee Hall, East Lansing, MI 48824; Philip R. Croft, MD, 1215 East Michigan Avenue, Lansing, MI 48909-7980; Michael A. Markey, MD, Sparrow Forensic Services, Sparrow Hospital, 1215 East Michigan Ave, Lansing, MI 48909-7980; and Joyce L. de Jong, DO, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909</i>	148

Spontaneous Coronary Artery Dissection – An Isolated Eosinophilic Vasculitis?: Report of Two Sudden Death Cases	<i>Dario Sanabria, MD*, Puerto Rico Institute of Forensic Sciences, Department of Pathology, PO Box 11878, Caparra Heights Station, San Juan, 00922-1878; Carlos F. Chavez-Arias, MD, Puerto Rico Institute of Forensic Sciences, PO Box 11878, Caparra Heights Station, San Juan, 00922-1878; Lee M. Tormos, MD, Instituto de Ciencias Forenses, PO Box 11878, Caparra Heights Station, San Juan, 00926; and Jose Rodriguez-Orengo, PhD, Puerto Rico Institute of Forensic Sciences, PO Box 11878, San Juan, 00922-1878</i>	148
Fibromuscular Dysplasia of Pulmonary Arteries: Report of Two Cases	<i>Stefania Zerbo, MD*, and Rosa Liotta, MD, Institute of Legal Medicine, Via del Vespro, 127, Palermo, 90100, ITALY; Antonina Argo, PhD, Via Narbone n.13, Palermo, ITALY; Cettina Sortino, Via del Vespro, 129, Palermo, ITALY; Antonino Bonifacio, MD, Institute of Legal Medicine, Via del Vespro, n. 127, Palermo, 90100, ITALY; Eugenia Di Stefano, Via Raffaello n.9, Palermo, ITALY; and Emiliano Maresi, PhD, Via del Vespro, 127, Palermo, 90100, ITALY</i>	149
Sudden Death From Arteritis Involving a Surgically Repaired Coronary Artery - Right Atrium Fistula	<i>Marc A. Krouse, MD*, Tarrant County Medical Examiner, 200 Feliks Gwozdz Place, Fort Worth, TX 76104-4919</i>	149
Ephemeral Petechial-Like Spots in a Victim of a House Fire	<i>Russell T. Alexander, MD*, and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	150
Forensic Identification of Microbial Mixtures Via ESI-TOF Mass Spectrometry	<i>Joshua K. Stone, BS*, and Raleigh W. Parrott, MS, Federal Bureau of Investigation, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135; Jason D. Bannan, PhD, and Bruce Budowle, PhD, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA; and James M. Robertson, PhD, and Brian A. Eckenrode, PhD, Federal Bureau of Investigation, CFSRU, Federal Bureau of Investigation Academy, Building 12, Quantico, VA 22135</i>	150
Environmental Scanning Electron Microscopy and Other Techniques in Cutting Crime Investigation: Case Report and Review of the Literature	<i>Paolo Fais, MD*, and Giovanni Cecchetto, MD, Via Faloppio 50, Padova, ITALY; Guido Viel, MD, University of Padua, Via Faloppio 50, PADOVA, 0 35121, ITALY; Attilio Cecchetto, PhD, Istituto Anatomia Patologica, Via Gabelli 61, Padova, 35121, ITALY; Claudio Furlan, MD, Via Faloppio, Padova, ITALY; and Massimo Montisci, PhD, Via Faloppio 50, Padova, ITALY</i>	151
Exploration of Non-Cardiogenic Pulmonary Edema With Chronic Opiate Use: Case Studies and Scientific Review	<i>Marrah E. Lachowicz, MFS*, University of California Davis, One Shields Avenue, UCDSOM, Tupper Hall 4112, Davis, CA 95616-8643</i>	151
Is Toxicological Analysis Necessary in Postmortem External Examinations?	<i>D. Kimberley Molina, MD*, Bexar County, Medical Examiner's Office, 7337 Louis Pasteur Drive, San Antonio, TX 78229; and Meredith A. Lann, MD*, UCDHSC, AIP - Department of Pathology, 12605 East 16th Avenue, Room 3026, Aurora, CO 80045</i>	152
TASER® Wound Progression in Two Deployment Modes	<i>Donald M. Dawes, MD*, Lompoc Valley Medical Center, 518 East Hickory Avenue, Lompoc, CA 93436; and Jeffrey D. Ho, MD, Hennepin County Medical Center, 701 Park Avenue South, Department of Emergency Medicine, Minneapolis, MN 55415</i>	152

Rat Bite Fever: A Fatal Case of <i>Streptobacillus moniliformis</i> Infection in a 14-Month-Old Boy	<i>Priya Banerjee, MD*, The Johns Hopkins Hospital Department of Pathology, 600 North Wolfe Street, Carnegie/Pathology 401, Baltimore, MD 21287; and David R. Fowler, MD, and Zabiullah Ali, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	153
Contributions From Forensic Imaging to the Investigation of Fatal Upper Cervical Fractures	<i>Lars Uhrenholt, PhD, and Lene W. Boel, PhD*, University of Aarhus, Institute of Forensic Medicine, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK</i>	153
Contributions From Forensic Imaging to the Investigation of Fatal Upper Cervical Fractures	<i>Asser H. Thomsen, MD*, Lars Uhrenholt, PhD, and Annie Vesterby, MD, DMSc, Institute of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, DK-8000, DENMARK</i>	154
An Unsolved Cold Case in Iowa: A Probable Case of Dragging	<i>Dawnie W. Steadman, PhD*, Binghamton University, SUNY, Department of Anthropology, Binghamton University, PO Box 6000, Binghamton, NY 13902-6000; Dennis Klein, MD, Iowa Department of Public Health, 321 East 12th Street, Des Moines, IA 50319-0075; and Blythe Bloemendaal, BA, Lyon County Sheriff's Office, 410 South Boone, Rock Rapids, IA 51246</i>	154
An Unusual Death Involving a Sensory Deprivation Tank	<i>Meredith A. Lann, MD*, University of Colorado at Denver Health Sciences Center, AIP - Department of Pathology, 12605 East 16th Avenue, Room 3026, Aurora, CO 80045; and Amy Martin, MD, Denver Office of the Medical Examiner, 660 Bannock Street, Denver, CO 80204</i>	155
Preliminary Analyses of Carrion Colonization of Necrophagous Flies (Diptera: Calliphoridae) in Central Oklahoma	<i>JeAnna R. Redd, BS*, University of Central Oklahoma, 100 North University Drive, Evans Hall 101 (Box 208), Edmond, Oklahoma 73034; and Wayne D. Lord, PhD, Forensic Science Institute, University of Central Oklahoma, 100 North University Drive, Edmond, OK 73034</i>	155
Two Fatal Cases of Hidden Pneumonia in Young People	<i>Francesco Ventura, MD, and Alessandro Bonsignore, MD*, Department of Forensic Pathology, University of Genova, Via De Toni, 12, 16132, Genova, 16132, ITALY; Raffaella Gentile, MD, Department of Clinical Pathology, University of Genova, Largo Rosanna Benzi, 10, Genova, 16132, ITALY; and Francesco De Stefano, MD, Department of Forensic Pathology, University of Genova, Via De Toni, 12, Genova, 16132, ITALY</i>	156
Methodologies for Heteroplasmy Identification	<i>Simona Ricci, MD*, Department of Legal Medicine, Viale Regina Elena 336, Roma, ITALY</i>	157
Internal Validation of Quantifiler™ DUO DNA Quantification Kit and AmpFlSTR® Yfiler™ PCR Amplification Kit	<i>María J. Illescas, BS*, Virginia Commonwealth University, 1000 West Cary Street, PO Box 842012, Richmond, VA 23284-2012; Fernando Mercedes, MS*, Institute of Forensic Science of Puerto Rico, Calle Maga Esq. Casia, Urb. Reparto Metropolitano, San Juan, PR 00922; Tracey Dawson Cruz, PhD*, 1000 West Cary Street, PO Box 842012, Virginia Commonwealth University, Richmond, VA 23284; and Carmen A. Tirado, MS*, Institute of Forensic Science of Puerto Rico, Calle Maga Esq. Casia, Urb. Reparto Metropolitano, San Juan, PR 00922</i>	157
The Effect of Clothing on Scavenger Visits and Decomposition	<i>Amanda J. Marshall, BS*, Jennifer R. Simon, BS*, and Phillip L. Watson, PhD*, Ferris State University, Department of Biology, 2004 ASC, 808 Campus Drive, Big Rapids, MI 49307</i>	158

Foreign Bodies: Three Cases of Projectile Maintenance Without Complications	<i>Duarte N.P. Vieira, PhD*, Carlos Abreu, MD, and Cristina Cordeiro, MSci, Instituto Nacional de Medicina Legal, Largo da Sé Nova, Coimbra, LB 3000-213, PORTUGAL</i>	158
The Persistence of an Elevated Concentration of Ninhydrin-Reactive Nitrogen in Grave Soil	<i>Brianna F. Anderson*, and Jessica D. Wilkerson, University of Nebraska-Lincoln, 202 Entomology Hall, PO Box 830816, Lincoln, NE 68583-0816; and David O. Carter, PhD, University of Nebraska, Lincoln, Department of Entomology, 202 Plant Industry Building, Lincoln, NE 68583-0816</i>	158
The Application of DNA Identification Technology to Large Wildlife Carnivore Attacks on Humans	<i>Jeff Rodzen, PhD, California Department of Fish and Game Wildlife Forensic Laboratory, 1701 Nimbus Road, Rancho Cordova, CA 95670; Elizabeth Thompson, BS*, Orange County Sheriff-Coroner Department, Forensic Science Services, 320 North Flower Street, Santa Ana, CA 92703; James D. Banks, BS, and Erin Meredith, MS, California Department of Fish and Game Wildlife Forensic Laboratory, 1701 Nimbus Road, Rancho Cordova, CA 95670; Hailu Kinde, DVM, California Animal Health and Food Safety Laboratory System, 105 Carousel Mall, San Bernardino, CA 92401; Joseph J. Halka, MD, Orange County Sheriff-Coroner Department, Forensic Science Center, 1071 West Santa Ana Boulevard, Santa Ana, CA 92703; and Pennie Laferty, MS, and John M. Hartmann, MBA, Orange County Sheriff- Coroner Department, Forensic Science Services, 320 North Flower Street, Santa Ana, CA 92703</i>	159
Sudden Unexplained Death Due to Disseminated Malaria	<i>Ritesh G. Menezes, MD*, Kasturba Medical College, Mangalore, India, Department of Forensic Medicine, Light House Hill Road, Mangalore, Karnataka 575001, INDIA</i>	159
Chloride Levels of Sphenoid Sinus Fluid in Salt and Fresh Water Drownings on the Island of Oahu, Hawaii	<i>Nicole Stalter, MSFS*, Chaminade University, 3140 Waialae Avenue, Forensic Science Department, Honolulu, HI 96816; Gayle Suzuki, MD, and Erin Mitsunaga, BA, Honolulu Medical Examiner, 835 Iwilei Road, Honolulu, HI 96817; and M. Lee Goff, PhD, Forensic Sciences Program, Chaminade University of Honolulu, 3140 Waialae Avenue, Honolulu, HI 96816-1578</i>	159
Recovery of Transplantable Organs After Cardiac Arrest in France	<i>Nathalie Jousset, MD*, Arnaud Gaudin, MD, Damien Mauillon, MD, and Clotilde G. Rougé-Maillart, MD, CHU, Service de Médecine Légale, 4 rue Larrey, Angers, 49000, FRANCE</i>	160

Veterinary Forensic Science: Documentation, Processing, and Interpretation of Physical Evidence at Scenes of Animal Crimes	<i>Jason H. Byrd, PhD*, University of Florida, Department of Agriculture & Consumer Services, University of Florida, PO Box 147100, Gainesville, FL 32614-7100; Kenneth F. Cohrn, DDS*, Heritage Dental of Central Florida, 422 Teague Trail, Lady Lake, FL 32159; Jeffery K. Tomberlin, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475; David W. Hall, PhD*, David Hall Consultant, Inc., 3666 NW 13th Place, Gainesville, FL 32605; John J. Schultz, PhD*, University of Central Florida, Department of Anthropology, PO Box 25000, Orlando, FL 32816; Melinda Merck, DVM*, ASPCA, 6175 Hickory Flat Highway Suite 110-2, Canton, GA 30115; and Randall Lockwood, PhD*, ASPCA, 2214 Tulip Drive, Falls Church, VA 22046; Micah Flores, BSc*, Texas A&M, 2475 TAMU, College Station, TX 77840</i>	160
Natural Causes of Sudden Unexpected Infant Death: A Seven Year Retrospective Forensic Autopsy Study in Hubei, China	<i>Ling Li, MD*, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201; Lan Zhou, BM, Department of Forensic Medicine, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, 430030, PEOPLES REPUBLIC OF CHINA; Xiang Zhang, MD*, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Liang Lui, MD, Tongji Medical College, 13 Hong Kon Road, Wuhan, Hubei 430030, PEOPLES REPUBLIC OF CHINA; Lin Chang, MD, Key Laboratory of Evidence Science, China University of Political Science and Law, Beijing, MD 100040, PEOPLES REPUBLIC OF CHINA; Guangzhao Huang, BM, Department of Forensic Medicine, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, MD 430030, PEOPLES REPUBLIC OF CHINA; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	161
Biomedical Engineering in Root Cause Analysis – Example: Assessing Infant Apnea-Related Deaths	<i>Bruce H. Barkalow, PhD*, William E. Grant, MA, and Farrah J. Curran, BS, B.H. Barkalow, PC, 490 Quarterline St., Newaygo, MI 49337-9125</i>	161
In Utero Traumatic Head Injuries During a Motor Vehicle Collision: Case-Report and Review of the Literature	<i>Sean A. Swiatkowski, DO*, 1 Middlebridge Court, Silver Spring, MD 20906; Anna Rubio, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Michael Johnson, MD, and Juan C. Troncoso, MD, Johns Hopkins University School of Medicine, 111 Penn Street, Baltimore, MD 21201; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	162
Return of an Old Acquaintance - A Case of Septic Abortion	<i>Karen B. Looman, DO*, Hamilton County Coroner's Office, 3159 Eden Avenue, Cincinnati, OH 45219</i>	162

Fatal Rupture of Splenic Artery Aneurysm in a Pregnant Woman With Portal Hypertension	<i>Slobodan Savic, MD, PhD*, School of Medicine, University of Belgrade, Institute of Forensic Medicine, Deligradska 31a, Belgrade, 11000, SERBIA AND MONTENEGRO; Djordje Alempijevic, PhD, Institute of Forensic Medicine, Faculty of Medicine, 31 A Deligradska St., Belgrade, 11000, SERBIA AND MONTENEGRO; Irina Damjanjuk, MD, Institute of Forensic Medicine, Belgrade, OR 11000, SERBIA AND MONTENEGRO; Stojan Petkovic, MD PhD, Klinicki Centar Vojvodina, Department of Forensic Medicine, Clinical Center of Vojvodina, Hajduk Veljkova 5-7, Novi Sad, 21000, SERBIA AND MONTENEGRO; and Radmila Stevanovic, MD, Institute of Pathology, School of Medicine, University of Belgrade, 8 Dr Subotica St., Belgrade, 11000, SERBIA AND MONTENEGRO</i>	163
How Often is Pre-Existing Disease Found in Child Deaths?	<i>M.G. Gilliland, MD*, Brody School of Medicine at East Carolina University, Pathology & Laboratory Medicine, Brody Building, Greenville, NC 27858-4354</i>	163
Lymphogenic Cardiomyopathy: A Possible Cause of Non-Immune Fetal Hydrops	<i>Antonio Bonifacio, MD*, Stefania Zerbo, MD, Cettina Sortino, Pierangela Fleres, MD, and Emiliano Maresi, PhD, Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via del Vespro, n. 129, Palermo, 90127, ITALY</i>	164
Prolonged Survival Time Following Duodenal Transection in a Child With Abdominal Trauma	<i>Lauren E. Moser, MD*, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Mary G. Ripple, MD, 68 Bluebird Road, Port Deposit, MD 21904; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	165
Role of Scene Reconstruction in the Medicolegal Investigation of Sudden Unexpected Infant Deaths	<i>Richard C. Harruff, PhD, and Pamela S. Ulmer, DO*, King County Medical Examiner's Office, 325 9th Avenue, HMC Box 359792, Seattle, WA 98104-2499</i>	165
Death by INR: A Case of Vitamin K Deficiency Bleeding Masquerading as Shaken Baby Syndrome	<i>O.C. Smith, MD*, Conscience and Science in Medicine, LLC 9639 Rosemark Road, Atoka, TN 38004; and Jennifer Griffith, MS, Lani Collins, MS, and Linda Willford, PhD, The University of Tennessee Clinical Laboratory Sciences, 930 Madison Avenue, Memphis, TN 38163</i>	166

Malicious Use of Nonprescription Cough and Cold Medications in Children	<i>Jody L. Green, PhD*, Denver Health Rocky Mountain Poison & Drug Center, 777 Bannock Street, MC 0180, Denver, CO 80204; William Banner, PhD, Oklahoma Poison Control Center, 4822 East 112th Street, Tulsa, OK 74137; Randall Bond, MD, Cincinnati Drug & Poison Information Center, 660 Lincoln Avenue, Cincinnati, OH 45206; Ralph Kauffman, MD, University of Missouri-Kansas City, Department of Pediatrics, 2919 NW 86th Terrace, Kansas City, MO 64154; Anthony Manoguerra, PharmD, University of California at San Diego, School of Pharmacy, 9500 Gilman Drive, MC 0657, La Jolla, CA 92093; Robert B. Palmer, PhD, Toxicology Associates, 2555 South Downing Street, Suite 260, Denver, CO 80210; Ian M. Paul, MD, Penn State College of Medicine, 500 University Drive, HMC; Pediatrics; H085, Hershey, PA 17033; Barry Rumack, MD, University of Colorado, Anshutz Medical Campus, Denver, CO 80045; David C. Winston, PhD, Forensic Science Center, 2825 East District Street, Tucson, AZ 85714; and Richard C. Dart, PhD, Denver Health Rocky Mountain Poison & Drug Center, 777 Bannock Street, MC 0180, Denver, CO 80204</i>	167
Wrongful Convictions and Pediatric Forensic Pathology: The Canadian Experience	<i>Jeffrey R. Manishen, BA*, Ross & McBride LLP, 1 King Street West, 10th Floor, PO Box 907, Hamilton, L8N 3P6, CANADA</i>	167
The Possibilities and Limitations of Neuropathology in Exhumation Autopsies	<i>Jan E. Leestma, MD*, 1440 North Kingbury Street, Suite 210, Chicago, IL 60622</i>	168
Pathology/Odontology: The Team Approach to a Forensic Autopsy	<i>John E. Filippi, DDS*, 1325 North 127th Avenue, Omaha, NE 68154; and Mary H. Dudley, MD*, Jackson County Medical Examiner's Office, 660 East 24th Street, Kansas City, MO 64108</i>	168
Making the Best of Death	<i>Chantal Ferraro, PhD*, Long Island University, Sociology/Anthropology, CW Post, Brookville, NY 11548; and O. C. Smith, MD, Conscience and Science in Medicine, Atoka, TN 38004</i>	168
Building the Communication/Language for Collaboration Between the Forensic Pathologist and Funeral Director/Embalmer	<i>Vincent E. Hill, MD*, Mortuary Medical Services, 3003 Van Ness Street, North West, Suite 106, Washington, DC 20008</i>	169
Sickle Cell Trait Associated Deaths: A Case Series With a Spectrum of Clinical Presentations	<i>Christopher Wilson, MBBS, Jon R. Thogmartin, MD*, Noel A. Palma, MD, and Susan S. Ignacio, MD, Medical Examiner's Office, District 6, 10900 Ulmerton Road, Largo, FL 33778; Barbara C. Wolf, MD, and Wendy A. Lavezzi, MD, Office of the Medical Examiner, District 5, 809 Pine Street, Leesburg, FL 34748; and Mark J. Shuman, MD, Miami Dade County, Medical Examiner Department, Number One on Bob Hope Road, Miami, FL 33136</i>	169
Commotio Cordis: A Forensic Science Perspective	<i>Ariel Goldschmidt, MD*, Steven T. Hensley, and Mary H. Dudley, MD, Jackson County Medical Examiner's Office, 660 East 24th Street, Kansas City, MO 64108</i>	170
Corpora Amylacea and Sudden Death: A Case of Adult Polyglucosan Body Disease Diagnosed at Forensic Autopsy	<i>Timothy L. Williams, MD*, and R. Ross Reichard, MD, New Mexico Office of the Medical Investigator, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131-0001</i>	170

Trends in Forensic Investigations Into the Missing: Observations From the ICRC	<i>Morris Tidball-Binz, MD*, Ute Hofmeister, MA, and Shuala M. Drawdy, MA, International Committee of the Red Cross, 19 Avenue de la Paix, Geneva, 1202, SWITZERLAND</i>	171
Evidence-Based, Medical-Legal Documentation of the Postmortem Anogenital Examination	<i>Sharon R. Crowley, MN*, FCNS, 122 Emeline Avenue, Santa Cruz, CA 95060</i>	171
Postmortem Recognition of Sickle Cell Trait	<i>Kathryn H. Haden-Pinneri, MD*, and Sara Nunez-Doyle, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	172
An Angel Dies on the Needle: Fatality After Injection Sclerotherapy for Prolapse Rectum in a Child	<i>Abraham T. Philip, MD*, Onondaga County Medical Examiner, 100 Elizabeth Blackwell Street, Syracuse, NY 13210; and Jeanna M. Marraffa, PharmD, Upstate New York Poison Center, 250 Harrison Street, Syracuse, NY 1302</i>	173
MDMA Neurotoxicity	<i>Irene Riezzo, MD, Viale Degli Aviatori, 1, Department of Forensic Pathology, University of Foggia, Foggia, 71100, ITALY; Vittorio Fineschi, PhD, Chair Forensic Pathology, University of Foggia, Ospedale Colonnello D'Avanzo, Foggia, I-71100, ITALY; Carmela Fiore, MD, and Stefano Derrico, MD, University of Foggia, Department of Forensic Pathology, Viale Degli Aviatori 1, Foggia, 71100, ITALY; and Steven B. Karch, MD*, PO Box 5139, Berkeley, CA 94705-0139</i>	174
Levorphanol, Dextromethorphan, and a Case of (Probable) Mistaken Identity	<i>Philip Croft, MD*, Sparrow Health Systems, 1215 East Michigan Avenue, Lansing, MI 48912; Joyce L. de Jong, DO, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909; Michael A. Markey, MD, Sparrow Hospital, Sparrow Forensic Services, 1215 East Michigan Avenue, Lansing, MI 48909; and Michael Smith, PhD, Sparrow Health Systems, 1215 East Michigan Avenue, Lansing, MI 48912</i>	174
Fentanyl-Related Drug Deaths in Virginia (2000-2006)	<i>William T. Gormley, PhD*, Office of the Chief Medical Examiner, 400 East Jackson Street, Richmond, VA 23219; and Anna Noller, PhD, Virginia Department of Health, Office of the Chief Medical Examiner, 400 East Jackson Street, Richmond, VA 23219</i>	175
Deaths Involving Stress	<i>Jeffery J. Gofton, MD, 901 North Stonewall, Oklahoma City, OK 73117-1218; and Wendy M. Gunther, MD*, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046</i>	175
Investigation of Acute Oxymorphone (Opana® ER) and Ethyl Alcohol Intoxication	<i>Andrew W. Sexton, DO*, 24 Regency Park Drive, Agawam, MA 01001</i>	176
Deaths During Police Chases	<i>Jeffery J. Gofton, MD*, 901 North Stonewall, Oklahoma City, OK 73117-1218; and Wendy M. Gunther, MD*, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046</i>	176
Variations on a Theme: Inhalant Abuse Related Fatalities in Central New York — An 11 Year Review	<i>Abraham T. Philip, MD*, Onondaga County Medical Examiner's Office, 100 Elizabeth Blackwell Street, Syracuse, NY 13210</i>	177

A New Framework for Guiding Research in Forensic Entomology: Improving the Science Relevant to PMI Estimates	<i>M. Eric Benbow, PhD*, University of Dayton, Department of Biology, 300 College Park, Dayton, OH 45469-2320; and Jeffery K. Tomberlin, PhD, and Rachel Mohr, MS, Department of Entomology, Texas A&M University, 2475 TAMU, College Station, TX 77843</i>	177
The Activity of <i>Calliphora vicina</i> (Diptera: Calliphoridae) Can Alter the Morphology and Presumptive Chemistry of High Impact Bloodstains	<i>Amanda Fujikawa, BS*, University of Nebraska-Lincoln, 202 Entomology Hall, Lincoln, NE 68583-0816; Larry Barksdale, MA, Lincoln Police Department, 575 South 10th Street, Lincoln, NE 68508; and David O. Carter, PhD, University of Nebraska-Lincoln, Department of Entomology, 202 Entomology Hall, Lincoln, NE 68583-0816</i>	178
Rehydrating Dried Blow Fly Larvae to Reclaim Their Usefulness in Forensic Investigations	<i>Michelle R. Sanford, MS*, Jennifer L. Pechal, MS, and Jeffery K. Tomberlin, PhD, 2475 TAMU, Department of Entomology, Texas A&M University, College Station, TX 77843</i>	179
Patterns of Adult Blow Fly Attraction to Carrion Over Time	<i>Rachel M. Mohr, MS*, and Jeffery K. Tomberlin, PhD, Department of Entomology, Texas A&M University, 2475 TAMU, College Station, TX 77843-2475</i>	179
The Effect of Soil Compaction on Pupation Depth of <i>Lucilia sericata</i> in Soil	<i>Jonathan A. Cammack, BS*, and Peter H. Adler, PhD, Department of Entomology, Soils, and Plant Sciences, Clemson University, 114 Long Hall Box 345315, Clemson, SC 29634; Jeffery K. Tomberlin, PhD, Department of Entomology, Texas A&M University, TAMU 2475, College Station, TX 77843-2475; Yuji Arai, PhD, Department of Entomology, Soils, and Plant Sciences, Clemson University, 270 Poole Agriculture Center, Clemson, SC 29634; and William C. Bridges Jr., PhD, Department of Applied Economics and Statistics, Clemson University, 243 Barre Hall, Clemson, SC 29634</i>	180
Feeding Patterns of American (<i>Periplaneta americana</i>) and German (<i>Blattella germanica</i>) Cockroaches on Pig Skin	<i>Lindsay A. Bright*, 1500 Olympia Way #12, College Station, TX 77840; and Jeffery K. Tomberlin, PhD, and Roger Gold, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475</i>	180
Attraction of Two Forensically Important Fly Species: <i>Chrysomya rufifacies</i> (Macquart) and <i>Cochliomyia macellaria</i> (Fabricius) to Inter- and Intraspecific Eggs	<i>Adrienne L. Brundage, MS*, Texas A&M University, 2001 Cobblestone Lane, Bryan, TX 77807; and Jeffery K. Tomberlin, PhD, Texas A&M University, Department of Entomology, TAMU 2475, College Station, TX 77843-2475</i>	181
Effects of Resource Age and Sterilization on the Attraction of <i>Cochliomyia macellaria</i> (Fabricius) and <i>Chrysomya rufifacies</i> (Macquart)	<i>Francisco I. Ortiz, BS*, 1818 South 2nd Street, Apartment 62, Waco, TX 76706; and Jeffery K. Tomberlin, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475</i>	181
Factors Affecting the Rate of Decomposition of Pig (<i>Sus scrofa</i>) Carcasses During a Period of Drought in Southern-Western Australia	<i>R. Christopher O'Brien, MFS*, Faculty of Science, UOIT, Oshawa, ON L1H 7K4, CANADA; Ian Dadour, PhD, Centre for Forensic Science, University of Western Australia, 35 Stirling Highway, Nedlands, 6009, AUSTRALIA; Jan Meyer, PhD, Mailbag M309, 35 Stirling Highway, Crawley, 6009, AUSTRALIA; and Shari Forbes, PhD, University of Ontario Institute of Technology, 2000 Simcoe Street North, Oshawa, L1H7K4, CANADA</i>	182

Associative Learning of <i>Cochliomyia macellaria</i> in Response to Larval Resource: Inter- and Intraspecific Resource Interaction, and Presence of Inter- and Intraspecific Larvae on a Resource	<i>Stacy A. Boatright, BS*, 2304 Cornell, College Station, TX 77840; and Jeffery K. Tomberlin, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475</i>	182
Attraction and Repellance of Blow Flies to Intra- and Interspecific Fecal Bacteria	<i>Melinda K. Dooley*, and Jeffery K. Tomberlin, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475; and Adrienne L. Brundage, MS, 2001 Cobblestone Lane, Bryan, TX 77807</i>	183
Three Dimensional Polygonal Model Visualization of <i>Lucilia sericata</i> From SEM and Stereomicroscopic Data	<i>Jeffrey R. Christiansen, BS*, Halff Associates, 1201 North Bowser Road, Richardson, TX 75081; and Jeffery K. Tomberlin, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475</i>	184
An Unusual Case of Homicidal Chest Trauma Using a Golf Club as a Weapon	<i>Carlos F. Chavez-Arias, MD, Puerto Rico Institute of Forensic Sciences, PO Box 11878, Caparra Heights Station, San Juan, Puerto Rico 00922-1878; Javier Serrano, MD*, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921; Dario Sanabria, MD, Puerto Rico Institute of Forensic Sciences, Department of Pathology, PO Box 11878, Caparra Heights Station, San Juan, Puerto Rico 00922-1878; and Jose F. Rodriguez, PhD, Institute of Forensic Science of Puerto Rico, Calle Maga Esq. Casia, Urb. Reparto Metropolitano, San Juan, PR 00922</i>	184
Non-Chemical Suffocation Deaths in Forensic Setting: A Six Year Retrospective Study of Environmental Suffocation, Smothering, Choking, Traumatic, and Positional Asphyxia	<i>Silvia Tambuscio, MD*, Legal Medicine for the Court of Padova, Via Rezzonico, 24, Padova, LA 35131, ITALY; and Anny Sauvageau, MD, Lab de Sciences Judiciaires et de Medecine Legale, 1701, Parthenais Street, 12th Floor, Montreal, Quebec H2K 3S7, CANADA</i>	185
Death by Electrocution: Unusual Findings in a "Love Nest"	<i>Sandra Cornetta, MD*, Sezione di Meidcina Legale - Università di Bari, piazza Giulio Cesare, 11, Bari, 70124, ITALY; Fiorenza Zotti, PhD, Section of Legal Medicine, Place G. Cesare, Bari, 70124, ITALY; Roberto Gagliano-Candela, AS, University of Bari, Cattedra Tossicologia Forense, Policlinico, Piazza G. Cesare 11, Bari, 70124, ITALY; Andrea Marzullo, MD, Sezione di Anatomia Patologica - Università di Bari, piazza Giulio Cesare, n.11, Bari, 70124, ITALY; and Alessandro D. Erba, Sezione di Medicina Legale - Università di Bari, piazza Giulio Cesare, n.11, via Prospero Petroni, n.37, Bari, 70124, ITALY</i>	185
A Fatal Case Due to a Pitchfork Penetrating Head Injury	<i>Margherita Neri, PhD*, Santina Cantatore, and Cristoforo Pomara, PhD, Department of Forensic Pathology University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY</i>	186
Head Injury Associated With Posterior Distraction of the Spine in a 4.5 Months Old Baby: Analysis of the Lesional Mechanisms	<i>Audrey Farrugia, MD, Annie Geraut, MD*, Bertrand Ludes, MD, PhD, and Jean Sebastien Raul, MD, PhD, Medico-Legal Institute, 11 Rue Humann, Strasbourg, 67065, FRANCE</i>	186
Genetic Testing of Sudden Cardiac Death Victims: From a Forensic to a Multidisciplinary Approach	<i>Katarzyna Michaud, MD*, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1005, SWITZERLAND; and Bernice Elger, PhD, Centre Universitaire Romand de Médecine Légale, 1211 Genève, Rue Michel-Servet 1, Genève, SWITZERLAND</i>	187

Unexpected Death of 24-Year-Old Male With a Phenotype Strongly Suggestive of Lujan-Fryns Syndrome	<i>Stojan Petkovic, PhD*, Department of Forensic Medicine, Clinical Center of Vojvodina, Hajduk Veljkova 5-7, Novi Sad, 21000, SERBIA AND MONTENEGRO; Branislav Budakov, MD PhD, Hajduk Veljkova 3, Novi Sad, 21000 SERBIA AND MONTENEGRO; Slobodan Savic, PhD, School of Medicine, University of Belgrade, Institute of Forensic Medicine, Deligradska 31a, Belgrade, 11000, SERBIA AND MONTENEGRO; and Isidora Samoilik, MD, Department of Pharmacology and Toxicology, Faculty of Medicine, Hajduk Veljkova 3, Novi Sad, 21000, SERBIA AND MONTENEGRO</i>	187
Fatal Air Embolism During Hemodialysis	<i>B.G. Brogdon, MD*, University of South Alabama Medical Center, Department of Radiology, 2451 Fillingim Street, Mobile, AL 36617; and LeRoy Riddick, MD*, University of South Alabama Medical Center, Department of Pathology, 2451 Fillingim Street, Mobile, AL 36609</i>	188
Traffic Accident Deaths? The Importance of Autopsy	<i>Duarte N.P. Vieira, PhD*, Instituto Nacional, de Medicina Legal, Coimbra, 3000-213, PORTUGAL; Cristina Cordeiro, MSci, Instituto Nacional de Medicina Legal, Largo da Sé Nova, Coimbra, FL, PORTUGAL; and Helena Garcia, MD, CEDAP, Av. Calouste Gulbenkian, Coimbra, 3000, PORTUGAL</i>	189
Undiagnosed Preeclampsia-Eclampsia Leading to Maternal Death	<i>William J. Bonner, BA*, 1100 South Broad Street, Unit 402B, Philadelphia, PA 19146; John E. Tomaszewski, MD, Department of Pathology and Laboratory Medicine, Hospital of the University of Pennsylvania, 3400 Spruce Street, Philadelphia, PA 19104; and Fredric N. Hellman, MD, Office of the Medical Examiner, Fair Acres, Rte 352, Lima, PA 19037</i>	189
Rupture of the Left Ventricle Due to Blunt Trauma - A Pediatric Case Study	<i>Francois Paysant, MD*, Chu, Hopital Michallon, BP 217, 38043 Grenoble Cedex 9, Grenoble, FRANCE</i>	189
Postmortem Examination of Coronary Artery Stents Using a Hand-Held Rotary Tool	<i>Christopher Tape, MD*, and Patrick E. Lantz, MD, Department of Pathology, Wake Forest University, SOM, Medical Center Boulevard, Winston-Salem, NC 27157-1072</i>	189
Detection of Wild Game DNA in Maggot Tissue	<i>Jill C. Ross, BS*, and John R. Wallace, PhD, Department of Biology, Millersville University, Millersville, PA 17551; and Jane E. Huffman, PhD, Northeast Wildlife DNA Laboratory, East Stroudsburg University, East Stroudsburg, PA 18301</i>	190
Conversion of the Wyoming State Crime Laboratory From FM-BIO Slab Gel Technology to the AB 3130 Genetic Analyzer for CODIS and Casework Sample Analysis	<i>Timmy L. Neece, BS, BA*, 1239 9th Street, Apartment 1, Huntington, WV 25701</i>	190
A Rapid Penta STR Screening Method by Microchip Capillary Electrophoresis	<i>Maurice J. Aboud, BSc*, 10720 North West 66th Street, Apartment #113, Miami, FL 33178</i>	191
How Does Season Affect the Release of Ninhydrin - Reactive Nitrogen Into Grave Soil?	<i>Jessica D. Wilkerson*, and Brianna F. Anderson, University of Nebraska-Lincoln, 202 Entomology Hall, PO Box 830816, Lincoln, NE 68583-0816; and David O. Carter, PhD, University of Nebraska, Lincoln, Department of Entomology, 202 Plant Industry Building, Lincoln, NE 68583-0816</i>	191

Consumption of Fly Artifacts After Deposition and Translocation of Bloodstains by <i>Calliphora vicina</i> (Diptera: Calliphoridae)	<i>Becca Striman*</i> , 1347 North 37th Street, Lincoln, NE 68503; <i>Amanda Fujikawa</i> , BS, 202 Entomology Hall, University of Nebraska-Lincoln, Lincoln, NE 68583-0816; <i>Larry Barksdale</i> , MA, Lincoln Police Department, 575 South 10th Street, Lincoln, NE 68508; and <i>David O. Carter</i> , PhD, University of Nebraska, Lincoln, Department of Entomology, 202 Plant Industry Building, Lincoln, NE 68583-0816	192
Decomposition of Child-Sized Remains in Dumpsters	<i>Kevin M. Willis</i> , BS*, Washington County Sheriff's Office, 1535 Colfax Street, Blair, NE 68008	192
Inadvertent Administration of Lidocaine: Illustration of Two Cases	<i>Cettina Sortino*</i> , Via del Vespro 129, Palermo, ITALY; <i>Fleres Pierangela</i> , Insitute of Legal Medicine, Via del Vespro, n. 127, Palermo, Italia 90100, ITALY; <i>Paola Pugnetti</i> , Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via del Vespro, n. 129, Palermo, 90127, ITALY; <i>Antonino Bonifacio</i> , MD, Institute of Legal Medicine, Via del Vespro, n. 127, Palermo, 90100, ITALY; <i>Massimo Grillo</i> , and <i>Valentina Triolo</i> , Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via del Vespro, n. 129, Palermo, 90127, ITALY; and <i>Paolo Procaccianti</i> , PhD, Palermo University, Via del Vespro, n. 127, Palermo, 90100, ITALY	193
Asphyxia by Confinement: The Death of a Man Kidnapped and Segregated in a Small Underground Cistern	<i>Cettina Sortino*</i> , <i>Antonino Bonifacio</i> , MD, <i>Sergio Cinque</i> , MD, <i>Stefania Zerbo</i> , MD, <i>Livio Milone</i> , PhD, and <i>Paolo Proccianti</i> , PhD, Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via del Vespro, n. 129, Palermo, 90127, ITALY	194
50 Years Later: How Insect Evidence is Key in Turning Over a Wrongful Conviction in Canada's Most Notorious Case – <i>Regina v. Steven Truscott</i>	<i>Cettina Sortino*</i> , <i>Antonino Bonifacio</i> , MD, <i>Sergio Cinque</i> , MD, <i>Stefania Zerbo</i> , MD, <i>Livio Milone</i> , PhD, and <i>Paolo Proccianti</i> , PhD, Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via del Vespro, n. 129, Palermo, 90127, ITALY	194
First Insect Succession Study on a Human Cadaver in Texas	<i>Jennifer L. Pechal</i> , MS*, Texas A&M University, 2475 TAMU, College Station, TX 77843-2475; <i>Adrienne L. Brundage</i> , MS, 2001 Cobblestone Ln, Bryan, TX 77807; <i>Elizabeth T. Brandt</i> , BA, 232 Evans Liberal Arts, Anthropology Dept, 601 University Drive, San Marcos, TX 78666; <i>Connie L. Parks</i> , BS, 8802 Featherhill Road, Austin, TX 78737; <i>Jeffery K. Tomberlin</i> , PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475; and <i>Jerry Melbye</i> , PhD, Department of Anthropology, 601 University Drive, ELA 273, Texas State University- San Marcos, San Marcos, TX 78666-4616	195
Comparison of Biological Sensors to Detect Human Remains: Canine Versus Hymenopteran	<i>Glen C. Rains</i> , PhD*, University of Georgia, PO Box 748, Tifton, GA 31793; <i>Ben Alexander</i> , MS, Texas A&M University, TAMU 2475, College Station, TX 77843; <i>Jeffery K. Tomberlin</i> , PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475; and <i>Jerry Melbye</i> , PhD, Department of Anthropology, 601 University Drive, ELA 273, Texas State University-San Marcos, San Marcos, TX 78666-4616	195

Generating Development Data for Forensically Important Flies That Are Difficult to Rear in the Laboratory	<i>Anne E. Nichols, BS*, West Virginia University, 1367 Stewartstown Road, Apartment W-7, Morgantown, WV 26505; Neal H. Haskell, PhD, 425 Kannal Avenue, Rensselaer, IN 47978; and Jeffrey D. Wells, PhD, West Virginia University, Department of Biology, Life Sciences Building, Room 3135, 53 Campus Drive, PO Box 6057, Morgantown, WV 26506-6057</i>	196
Insect Pupal Cases as Decay-Resistant Reservoirs of Human Soft Tissue Radiocarbon Content	<i>Gregory W. Hodgins, DPhil*, University of Arizona, Department of Physics, 1118 East Fourth Street, Tucson, AZ 85721</i>	196
Reconstruction of Decay Processes of a Dead Child's Body in a Plastic Garbage Bag	<i>Heike Klotzbach, PhD*, Institute of Legal Medicine, Fürstengraben 23, D-07743 Jena, GERMANY</i>	197
Unusual Methods of Suicide in Chicago, Illinois, Cook County	<i>Michelle A. Jorden, MD*, James A. Filkins, MD, JD, PhD, and Tera A. Jones, MD, Cook County Medical Examiner Office, 2121 West Harrison Street, Chicago, IL 60612</i>	197
Mass Fatality Investigation Due to Combustible Dust Related Industrial Explosion and Fire	<i>J.C. Upshaw Downs, MD*, and Edmund R. Donoghue, MD, Regional Medical Examiner, Georgia Bureau Investigation, 925 A Mohawk Street, Savannah, GA 31419-1796</i>	198
Worker Fatalities by Hydrogen Sulfide Poisoning: Autopsy and Toxicological Findings	<i>Biagio Solarino, PhD*, Sezione di Medicina Legale, Università Degli Studi di Bari, P.zza Giulio Cesare, 11, Bari, 70125, ITALY; Giancarlo Di Vella, PhD, Sezione di Medicina Legale, DIMIMP, University of Bari, Policlinico, Piazza G. Cesare, Bari, 70121, ITALY; Lucia Tattoli, MD, Sezione di Medicina Legale, University of Bari, Bari, , ITALY; Claudia Liuzzi, MD, Sezione di Medicina Legale, Università Degli Studi di Bari, Bari, 70100, ITALY; Giuseppe Strisciullo, BES, University of Bari, Policlinico, Piazza G. Cesare, 11, Bari, 70124, ITALY; and Roberto Gagliano-Candela, PhD, University of Bari, Cattedra Tossicologia Forense, Policlinico, Piazza G. Cesare 11, Bari, 70124, ITALY</i>	199
Suicide by Hanging in Harris County, Texas	<i>Sara Nunez-Doyle, MD*, and Sharon M. Derrick, PhD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	199
Death in a Tanker Truck	<i>Christopher B. Rogers, MD*, Los Angeles County, Medical Examiner's Office, 1104 North Mission Road, Los Angeles, CA 90033; John Kades, BA, Los Angeles County, Department of Coroner, 1104 North Mission Road, Los Angeles, CA 90033; and Lakshmanan Sathyavagiswaran, MD, Los Angeles County, Medical Examiner's Office, 1104 North Mission Road, Los Angeles, CA 90033</i>	200
Agonal Sequences in Eight Filmed Hangings: Analysis of Respiratory and Movement Responses to Asphyxia by Hanging	<i>Anny Sauvageau, MD*, Lab de Sciences Judiciaires, et de Medecine Legale, 1701, Parthenais St, 12th Fl, Montreal, QE H2K 3S7, CANADA; Romano La Harpe, MD, Institut de Medecine Legale, 9 Av de Champel (CMU), Geneva, 1206, SWITZERLAND; and Vernon J. Geberth, MS, MPS, P.H.I. Investigative Consultant Inc., PO Box 197, Garnerville, NY 10923</i>	200

Dead Victim Identification: Age Determination by Analysis of Bomb-Pulse Radiocarbon in Tooth Enamel	<i>Henrik Druid, PhD*, Department of Forensic Medicine, Karolinska Institutet, Retzius v. 3, Stockholm, SE-171 77, SWEDEN; Kanar Alkass, BSc, Department of Forensic Medicine, Retzius v 3, 171 77, Stockholm, SWEDEN; Kirsty Spalding, PhD, Department of Cell and Molecular Biology, Medical Nobel Institute, Karolinska Institutet, Stockholm, SWEDEN; and Bruce Buchholz, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550</i>	201
Postmortem Injury Detection in an Aviation Mishap: Computed Tomography Imaging Versus Autopsy	<i>David M. DeLonga, PhD*, Naval Medical Center Portsmouth, 6513 Harbour Pointe Drive, Suffolk, VA 23435; Angela D. Levy, MD, United States Army, Department of Radiology and Radiological Sciences, Uniform Services University of the Health Sciences, 4301 Jones Bridge Road, Bethesda, MD 20814; and Howard T. Harcke, MD, Department of Radiologic Pathology, Armed Forces Institute of Pathology, 3205 Coachman Road, Wilmington, DE 19803</i>	201
Usefulness of Systematic Histological Examination in Routine Forensic Autopsy	<i>Geoffroy Lorin de la Grandmaison, PhD*, AP-HP, Philippe Charlier, PhD, AP-HP, and Michel Durigon, PhD, AP-HP, 104 Boulevard Raymond Poincaré, Raymond Poincaré Hospital, Garches, F-92380, FRANCE</i>	202
Radiology Students and Morgues: A Mutually Beneficial Relationship	<i>Nancy S. Adams, BS*, 202 Milford Street, #155, Tupelo, MS 38801</i>	202
CT Autopsy Imaging in the State Medical Examiner Setting: Logistic Issues, Techniques, and Findings	<i>Kyle Shaw, MBBS*, David R. Fowler, MD, Zabiullah Ali, MD, and Jack M. Titus, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Mary G. Ripple, MD, 68 Bluebird Road, Port Deposit, MD 21904; Barry Daly, MD, Radiology Department, University of Maryland Medical Center, 22 South Greene Street, Baltimore, MD 21201; and Clint W. Sliker, MD, University of Maryland Medical Center, Diagnostic Imaging Department, 22 South Greene Street, Baltimore, MD 21201</i>	203
Intersecting Fractures of the Skull and Gunshot Wounds: Case Report and Literature Review	<i>Guido Viel, MD*, University of Padua, Via Falloppio 50, Padova, 35121, ITALY; Axel Gehl, MD, Department of Forensic Pathology - Institute of Le, Hamburg, GERMANY; Giovanni Cecchetto, MD, University of Padua, Via Falloppio 50, Padova, 35121, ITALY; Massimo Montisci, PhD, University of Padua, Via Falloppio 50, Padova, 35121, ITALY; and Jan P. Sperhake, MD, Department of Forensic Pathology - Institute of Le, Hamburg, GERMANY</i>	203
Sudden Cardiac Death Due to Atrophy and Fibrous and/or Fatty Substitution of Right Ventricle: Pathologic Substrates and Postmortem High Resolution MRI	<i>Massimo Grillo*, Department of Biotechnology and Legal Medicine – Section of Legal Medicine, Via del Vespro, n. 129, Palermo, 90127, ITALY; Pierangela Fleres, MD, and Cettina Sortino, Via del Vespro, n. 129, Palermo, , ITALY; Antonino Bonifacio, MD, Institute of Legal Medicine, Via del Vespro, n. 129, Palermo, 90127, ITALY; Livio Milone, PhD, Via del Vespro, n. 129, Palermo, 90127, ITALY; Paolo Procaccianti, PhD, Palermo University, Via del Vespro, n. 129, Palermo, 90100, ITALY; and Emiliano Maresi, PhD, Via del Vespro, n. 129, Palermo, 90127, ITALY</i>	204

Autopulse® Associated Injuries	<i>Kathryn H. Haden-Pinneri, MD*, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054; Dwayne A. Wolf, MD, PhD, Harris County Medical Examiner's Office, JAJ Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054; and Jennifer C. Love, PhD, and Roger A. Mitchell, Jr., MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	204
Migration of a Bullet in the Lumbosacral Spinal Canal: A Case Report and Review of the Literature	<i>Audrey Farrugia, MD*, Bertrand Ludes, PhD, Annie Geraut, MD, and Jean Sebastien Raul, PhD, Medicolegal Institute, 11 Rue Humann, Strasbourg, 67065, FRANCE</i>	205
Homicide-Suicide in Tours France: 2000-2007	<i>Pauline Saint-Martin, MD*, and Patrick O. Byrne, MD, Service de Medecine Legale, Hopital Troussseau, Centre Hospitalier Régional Universitaire de Tours, Tours, 37000, FRANCE</i>	205
Sudden Deaths Associated With Sexual Activity	<i>Albert Y. Chu, MD*, Sharon M. Derrick, PhD, and Luis A. Sanchez, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	206
Sex Killer: Sexually Related Trauma and Deaths - Forensic Aspects	<i>Gilles Tournel, PhD*, IML de Lille, 1, Place de Verdun, Faculté de Médecine, Lille, 59045, FRANCE; and Valery Hedouin, PhD, Cédric Houssaye, MD, Frédéric Grimopont, Antoine Stelandre, Anne Becart, PhD, Viviane Gnemmi, Sandrine Depret, MD, IML de Lille, Lille, 59045, FRANCE; and Didier Gosset, PhD, IML de Lille, Faculte de Medecine, Lille, 59045, FRANCE</i>	206
Conducted Electrical Weapons — A Review of the Medical Literature	<i>Donald M. Dawes, MD*, Lompoc Valley Medical Center, 518 East Hickory Ave, Lompoc, CA 93436; and Jeffrey D. Ho, MD*, Hennepin County Medical Center, 701 Park Avenue South, Department of Emergency Medicine, Minneapolis, MN 55415</i>	207

2008		
Decapitation Due to Car Accident: Description of a Case and Review of the Literature	<i>Francesco Ausania, MD, Antonio Oliva, MD, PhD*, Fidelia Cascini, MD, Massimo Senati, MD, Vincenzo L. Pascali, MD, PhD, and Francesca Cittadini, PhD, Catholic University, School of Medicine, Institute of Forensic Medicine, Largo Francesco Vito 1, Rome, ITALY</i>	208
Unusual Gunshot Wound Death of a Sex Offender on the Way to Jail in the World of CSI	<i>Karen B. Looman, DO*, Tidewater Office of the Chief Medical Examiner, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510</i>	208
The Effect of Clothing on Decomposition Rate: A Teaching Model	<i>Phillip L. Watson, PhD*, Ferris State University, 808 Campus Drive, 2004 ASC, Big Rapids, MI 49307</i>	209
Improved Estimation of Time Since Death With Multiple Protein Markers and Automated Analytical Methods	<i>Behnoush Memari, MS*, Kenneth G. Furton, PhD, and Alberto Sabucedo, Florida International University, 11200 South West 8th Street, Miami, FL 33199</i>	209
The Effect of Environmental Degradation on DNA With Respect to Time and Conditions	<i>Matt Buettner, BS*, Kerry Opel, BS, Bruce R. McCord, PhD, International Forensic Research Institute, Department of Chemistry, Florida International University 11200 SW 8th St, Miami, FL 33199; and Lee Jantz, PhD, 250 South Stadium Hall, Knoxville, TN 37996</i>	210
The Role of Scene Investigation in Uncovering Staged Suicides	<i>Jerri McLemore, MD, and Steven Tvrlik, BS*, Iowa Office of the State Medical Examiner, 2250 South Ankeny Boulevard, Ankeny, IA 50023</i>	210
Intrauterine Sudden Death: Study of the Fetal Morphological Substrates	<i>Emiliano Maresi*, Antonina Argo, Pierangela Fleres, Paolo Procaccianti, and Michele Spicola, Palermo University, Via del Vespro, n. 127, Palermo, 90100, ITALY</i>	211
Fatty Acid Methyl Ester Profiling of Bacterial Spores for Microbial Forensics	<i>Christopher Ehrhardt, PhD*, Counterterrorism and Forensic Science Research Unit, Federal Bureau of Investigation Academy, Building 12, Quantico, VA 22135; Mark Reimers, PhD, Alcon Laboratories, Inc., 6201 South Freeway, Fort Worth, TX 76134; Mathew Ducote, PhD, Midwest Research Institute, 1470 Treeland Boulevard South East, Palm Bay, FL 32909; James Robertson, PhD, Counterterrorism and Forensic Science Research Unit, Federal Bureau of Investigation Academy, Building 12, Quantico, VA 22135; and Jason Bannan, PhD, Federal Bureau of Investigation, Laboratory Division, 2501 Investigation Parkway, Quantico, VA 22135</i>	211
Suicidal Intoxication by Copper Sulphate	<i>Jerónimo Fonte Santa Silva*, Bairro de Santa Justa, 10, Coimbra, 3000-356, PORTUGAL</i>	212
Visceral Leishmaniasis in Turkey: Sociocultural Issues in Forensic Epidemiology	<i>Hüseyin Cakan, PhD*, and Vecdet Oz, PhD, Istanbul University, Institute of Forensic Sciences, Adli Tip Enstitusu, Cerrahpasa Kampusu, PK10, Istanbul, 34303, TURKEY; Mustafa Aslan, PhD, Istanbul University, Cerrahpasa Medical Faculty, Tip Fakultesi, Mikrobiyoloji ABD, Istanbul, 34303, TURKEY; T. Mehmet Karayel, BS, Ismail Cakir, PhD*, H. Bulent Uner, PhD*, and M. Yasar Iscan, Ph.D, Istanbul Univ, Istanbul Universitesi, Adli Tip Enstitusu, Cerrahpasa Kampusu, PK.10, 34303, Istanbul, 34098, TURKEY</i>	212

Child Abuse: Practical Case of Autopsical, Radiological, and Anatomopathological Studies	<i>Fabrice Dedouit, MD*, and Céline Guilbeau Frugier, MD, Caroline Capuani, and Annick Sevely, MD, Service de Neuroradiologie, Hôpital de Purpan, 1 Avenue du Professeur Jean Poulhès, TSA 50032, Toulouse Cedex 9, 31059, FRANCE; Philippe Otal, PhD, Hervé Rousseau, PhD, and Francis Joffre, PhD, Service de Radiologie Générale, Hôpital de Rangueil, 1 Avenue du Professeur Jean Poulhès, TSA 50032, Toulouse Cedex 9, AL 31059, FRANCE; Bernadette Delisle, PhD, Service d'anatomie Pathologique, Hôpital de Rangueil, 1 Avenue du Professeur Jean Poulhès, TSA 50032, Toulouse Cedex 9, 31059, FRANCE; and Daniel Rouge, PhD, and Norbert Telmon, PhD, Service de Médecine Légale, Hôpital de Rangueil, 1 Avenue du Professeur Jean Poulhès, TSA 50032, Toulouse Cedex 9, 31059, FRANCE</i>	213
Posterior Rib Fractures in Infants Associated With Cardiopulmonary Resuscitation	<i>Jolene R. Clouse, MD*, and Patrick E. Lantz, MD, Wake Forest University, School of Medicine, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072</i>	214
Role of Preoperative 3D-CT Reconstruction in Depressed Skull Fractures Treated With Craniectomy: A Case Report of Forensic Interest	<i>Guido Viel, MD*, and Giovanni Cecchetto, MD, University of Padua, Via Falloppio 50, Padova, 35121, ITALY; Renzo Manara, MD, Istituto di Neuroradiologia, Padova, ITALY; and Donata Favretto, PhD, and Massimo Montisci, PhD, University of Padua, Via Falloppio 50, Padova, 35121, ITALY</i>	215
Subway Train Related Fatalities in New York City: Accident vs. Suicide	<i>Peter T. Lin, MD*, and James R. Gill, MD, Office of Chief Medical Examiner, 520 First Avenue, New York, NY 10016</i>	216
Cardiovascular Trauma in Motor Vehicle Collisions: A 20 Year Retrospective Study and Review of the Literature	<i>Kelly L. Rose, MD*, and Kim A. Collins, MD, Medical University of South Carolina, Department of Pathology and Laboratory Medicine, 165 Ashley Avenue, Suite 309, PO Box 250908, Charleston, SC 29425</i>	216
Right Ventricular Lipomatosis and Fibrous Tissue in Cases of Non-Cardiac Deaths and Arrhythmogenic Right Ventricular Cardiomyopathy	<i>Carol Kaluen Lee, MD*, New Mexico Office of the Medical Investigator, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131-0001; Charles Lee, MD, Vancouver General Hospital, Department of Forensic Pathology, 855 West 12th Avenue, Room 1352, Vancouver, BC V5Z 1M9, CANADA; and Michael Allard, MD, James Hogg iCapture Centre for Cardiovascular and Pulmonary Research, Room 387, St. Paul's Hospital, 1081 Burrard Street, Vancouver, BC V6Z 1Y6, CANADA</i>	217

Sodium Channelopathies Linked to Sudden Cardiac Death (SCD) - What is the Meaning of Carrying a Genetic Mutation?	<i>Antonio Oliva, MD, PhD*, Catholic University, Italy, Largo Francesco Vito 1, Rome, 00168, ITALY; Preben Bjerregaard, MD, St Louis University Hospital, Cardiology Department, 3635 Vista Avenue, St. Louis, MO 63110; Kui Hong, MD, PhD, Nanchang University, Jiangxi Province, 235 Nanjing East Road, Jiangxi; Steven Evans, MD, Beth Israel Medical Center, Cardiology Division, First Avenue at 16th Street, New York, NY 10001; Kevin Vernooy, MD, PhD, Academic Hospital, Maastricht, Department of Cardiology, Maastricht, NETHERLANDS; Jorge McCormack, MD, Pediatric Cardiology Associates, Tampa, FL; Josep Brugada, MD, PhD, Hospital Clinic Barcelona, Arrhythmia Unit, Villaroel 32, Barcelona, SPAIN; Pedro Brugada, MD, PhD, Free University of Brussels, Department of Cardiology, Brussel, BELGIUM; Vincenzo L. Pascali, MD, PhD, Catholic University, Institute of Forensic Medicine, Largo f. Vito 1, Rome, ITALY; and Ramon Brugada, MD, Montreal Heart Institute, Montreal, CANADA</i>	217
SCN5A Gene Mutation Associated With Acute Myocardial Infarction	<i>Antonio Oliva, MD, PhD*, Catholic University, School of Medicine, Institute of Forensic Medicine, Largo Francesco Vito 1, Rome, ITALY; Dan Hu, MD, PhD, Masonic Medical Research Laboratory, 2150 Bleecker Street, Utica, NY 13501-1738; Sami Viskin, MD, PhD, Department of Cardiology, Tel-Aviv Sourasky Medical Center, 6 Weizmann Street, Utica, ISREAL; and Jonathan M. Cordeiro, PhD, Tabitha Carrier, BS, Hector Barajas-Martinez, PhD, Yuesheng Wu, MS, Elena Burashnikov, BS, Serge Sicouri, MD, and Ramon Brugada, MD, Masonic Medical Research Laboratory, 2150 Bleecker Street, Utica, NY 13501-1738; and Rafael Rosso, MD, Sackler School of Medicine, Tel-Aviv University, 6 Weizmann Street, Tel Aviv, ISREAL; and Alejandra Guerchicoff, PhD, Guido D. Pollevick, PhD, and Charles Antzelevitch, PhD, Masonic Medical Research Laboratory, 2150 Bleecker Street, Utica, NY 13501-1738</i>	218
Arrhythmogenic Right Ventricular Dysplasia/Cardiomyopathy a Not So Infrequent Cause of Sudden Death - A Danbury Hospital Five Year Experience (June 2002 - June 2007)	<i>Juan A. Merayo-Rodriguez, MD*, Frank Braza, and Jeffrey West, Danbury Hospital, 24 Hospital Avenue, 2 Tower Lab, Danbury, CT</i>	218
Sudden Cardiac Death in Professional Sports Persons: Natural vs. Anabolic Steroid Induced Lesions and Experimental Rabbit Model	<i>Laurent Fanton, MD*, Alain Tabib, MD, Stéphane Tilhet-Coartet, MD, Maire Joly, and Daniel Malivier, MD, Institut of Legal Medicine, 12 Avenue Rockefeller, Lyon, 69008, FRANCE</i>	218
Cocaine Induced Intracerebral Hemorrhage in a Patient With Cerebral Amyloid Angiopathy: A New Risk Factor for Stroke in Cocaine Users	<i>Daniel G.K. Phillips, MD*, University of Maryland, Baltimore, Department of Pathology, 22 South Greene Street, Baltimore, MD 21201; Joyce L. deJong, DO, and Michael A. Markey, MD, Sparrow Forensic Services, Sparrow Hospital, 1215 East Michigan Avenue, Lansing, MI 48909-7980; and Rudy J. Castellani, MD, University of Maryland, Department of Pathology, 22 South Greene Street, Baltimore, MD 21201</i>	219

Can Immunohistochemical Stains Aid to Rule Out Pitfalls in Suffocation Deaths?	<i>Antonina Argo*, Rosa Liotta, Emiliano Maresi, Stefania Zerbo, Rosaria Vitale, Pierangela Fleres, and Paolo Procaccianti, Via del Vespro, n. 127, Palermo, 90100, ITALY</i>	219
Alcohol Related Accidental Drowning in Virginia: An Epidemiological Review	<i>Shane Chittenden, DO*, Anna Noller, PhD, and Marnie Wood, MD*, Office Chief Medical Examiner, 400 East Jackson Street, Richmond, VA 23219</i>	220
Cytomegalovirus Enteritis With Profuse Gastrointestinal Bleeding Diagnosed at Autopsy: A Case Report and Review of the Literature	<i>Benjamin J. Havard, MD*, Kelly L. Rose, MD, and Kim A. Collins, MD, Medical University of South Carolina, Department of Pathology and Laboratory Medicine, 165 Ashley Avenue, Suite 309, PO Box 250908, Charleston, SC 29425</i>	220
Ethyl Chloride Toxicity in a Case of Unsuspecting Abuse	<i>Valerie S. Green, MD*, Stephen K Wilson, MD, Terry J. Danielson, PhD, Ashraf Mozayani, PhD, and Luis A. Sanchez, MD, Harris County, Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	220
Motorcycle Fatalities in the State of Vermont: 1995-2005	<i>Erin G. Brooks, MD*, University of Vermont, Fletcher Allen Health Care, Department of Pathology, 111 Colchester Avenue, Burlington, VT 05401-1473; and Steven L. Shapiro, MD, and Brittany N. Philbin, BS*, Vermont Office of the Chief Medical Examiner, 111 Colchester Avenue, Baird 1, Burlington, VT 05401</i>	221
Progressive Isolated Hypoglossal Nerve Palsy and Sudden Asphyxial Death	<i>Emiliano Maresi*, Antonina Argo, Massimo Grillo, Valentina Murgo, Filippo M. Cascino, and Paolo Procaccianti, Palermo University, Via del Vespro, n. 127, Palermo, 90100, ITALY</i>	222
Medico-Legal Importance of Posttraumatic Hypopituitarism	<i>Vladimir Zivkovic, MD, MSc, Djordje Alempijevic, MD, PhD, Slobodan Savic, MD, PhD*, Ivanka Baralic, Dragan Jecmenica, MD, PhD, and Branimir Aleksandric, University of Belgrade, School of Medicine Institute of Forensic Sciences, Faculty of Medicine, 31a Deligradska Street, Belgrade, 11000, SERBIA AND MONTENEGRO; and Vera Popovic, PhD, Institute of Endocrinology, Clinical Centre of Serbia, Dr. Subotic Street 13, Belgrade, , SERBIA AND MONTENEGRO</i>	222
Massive Fat Pulmonary Embolization Secondary to a Liposuction Procedure With Tumescent Technique Diagnosed Postmortem in an Embalmed and Buried Body	<i>Jose A. Garza-Leal, MD*, Alberto Montemayor-Martinez, MD*, and Magadalena Gomez*, Medfor-Lab S.A. DE C.V., Cholula 106, Colonia Mitras Centro, Monterrey, 64460, MEXICO</i>	222
Lethal Inhalation of Isomers of Butylene: A Case Report	<i>Giovanni Cecchetto, MD*, and Guido Viel, MD, University of Padua, Via Falloppio 50, Padova, 35121, ITALY; and Attilio Cecchetto, PhD, Istituto Anatomia Patologica, Via Gabelli 61, Padova, 35121, ITALY; Claudio Terranova, University of Padova, Section of Legal Medicine, via Falloppio n.50, Padova, 35121, ITALY; and Massimo Montisci, PhD, and Santo Davide Ferrara, PhD, University of Padua, Section of Legal Medicine and Forensic Toxicology, Via Falloppio 50, Padua, 35121, ITALY</i>	223

Lethal Neglect: A Case of Extreme Intrafamilial Child Torture	<i>Biagio Solarino, MD*, University of Bari, Sezione di Medicina Legale, Piazza Giulio Cesare, 11, Bari, 70100, ITALY; Vito Romano, MD, U.O.C. di Medicina Legale - Ospedale "Miulli", Acquaviva delle Fonti, (Bari), 70021, ITALY; Giuseppe Troccoli, MD, University of Bari, Department of Criminology and, Forensic Psychiatry, Largo Giordano Bruno 65, Bari, 70121, ITALY; Ignazio Grattagliano, PsyD, and Roberto Catanesi, MD, University of Bari, Section of Forensic Psychiatry, Piazza Giulio Cesare, Bari, 70125, ITALY</i>	223
Multiple Histories: A Statistically Significant Indicator of Non-Accidental Injury in Children	<i>M.G.F. Gilliland, MD*, Brody School of Medicine at ECU, Pathology & Lab Medicine, Brody Building, Greenville, NC 27858-4354</i>	224
Recognizing Classic Metaphyseal Lesions in Child Abuse: An Autopsy Technique	<i>Jennifer C. Love, PhD*, and Luis A. Sanchez, MD, Harris County, Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	224
Comprehensive Molecular Genetic Testing for the Cardiac Channelopathy Genes in 42 Cases of Sudden Infant Death and Sudden Unexplained Death in the City of New York Revealed High Mutation Rate	<i>Yingying Tang, MD, PhD*, Erik T. Bieschke, MS, Erin Labitzke, Jennifer D'Andrea, MSFS, Stacey Sainte-Marie, MSFS, Dawei Wang, Jean Jeudy, Yoonhee A. Kim, Stephanie Pack, Lucy En, Barbara A. Sampson, and Mechthild K. Prinz, PhD, Office of Chief Medical Examiner, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016</i>	225
Primitive Neuroectodermal Tumor (PNET) Masquerading as Non Accidental Head Trauma in an Infant: Lessons for Multiple Disciplines	<i>Michael J. Caplan, MD, and Kelly Rose, MD*, Medical University of South Carolina, Department of Pathology and Laboratory Medicine, 165 Ashley Avenue, Suite 309, PO Box 250908, Charleston, SC 29425</i>	225
Sudden Death of a 17-Year-Old Boy Due to Suspected Williams Syndrome - A Case Report	<i>Stojan Petkovic, MD*, Clinical Center Vojvodina, Institute of Forensic Medicine, Hajduk Veljkova 5, Novi Sad, 21000, SERBIA AND MONTENEGRO; Slobodan Savic, MD, PhD, University of Belgrade, School of Medicine, Institute of Forensic Medicine, Deligradska 31a, Belgrade, 11000, SERBIA AND MONTENEGRO; and Milan Simic, MD, PhD, Clinical Center Vojvodina, Institute of Forensic Medicine, Hajduk Veljkova 5, Novi Sad, 21000, SERBIA AND MONTENEGRO</i>	226
Sudden Cardiac Death in Professional Sports Persons: Natural vs. Anabolic Steroid Induced Lesions, and Experimental Rabbit Model	<i>Laurent Fanton, MD, Alain Tabib, MD, Stéphane Tilhet-Coartet, MD, Maire Joly, and Daniel Malicier, MD*, Institut Medico Legal, 12 Avenue Rockfeller, Lyon, 69007, FRANCE</i>	227
Cocaine Skin Popping: A Fatal Case	<i>Margherita Neri, MD*, and Carmela Fiore, MD, University of Foggia, Department of Forensic Pathology, Viale Pinto 1, Foggia, 71100, ITALY</i>	227
Erroneous Diagnosis of Cadmium Poisoning Based on Postmortem Toxicology	<i>Karl E. Williams, MD, MPH*, Office of the Medical Examiner, Allegheny County, 542 Fourth Avenue, Pittsburgh, PA 15219</i>	228
The Continued Role of Over the Counter Drugs in Drug Related Deaths	<i>Anna C. Noller, PhD*, and Marcella F. Fierro, MD, Office of the Chief Medical Examiner, 400 East Jackson Street, Richmond, VA 23219</i>	228

Exceptional Suicide by Sharp Force During Mefloquine Therapy: A Case of Drug Induced Psychosis?	<i>Clotilde G. Rougé-Maillart, MD*, and A. Tracqui, MD, Service de Médecine Légale, CHU, 4 rue Larrey, Angers, 49000, FRANCE; A. Le Bouil, MD, and A. Turcant, MD, Institut de Médecine Légale, Faculté de Médecine, Strasbourg, France; and M. Penneau, MD, PhD, Service de Médecine Légale, CHU, 4 rue Larrey, Angers, 49000, FRANCE</i>	229
Determination of β—Phenylethylamine Blood Levels in Carbon Monoxide Intoxicated-Related Fatalities	<i>Wen-Ling Lin*, and Kai-Ping Shaw, MD, PhD*, Institute of Forensic Medicine, Ministry of Justice, 166-1, Sect. 2, Keelung Road, Taipei (106), Taiwan, ROC</i>	229
The Development of a Model to Assess the Effects of Conducted Electrical Weapons in a Stressful State	<i>Amanda O. Esquivel, MS*, and Cynthia Bir, PhD, Wayne State University, 818 West Hancock, Detroit, MI 48201</i>	230
Exsanguination Due to Disruption of the Left Popliteal Artery and Vein Due to Posterior Dislocation of the Left Knee Prosthesis: A Case Report and Review of the Literature	<i>Wieslawa Tlomak, MD*, Milwaukee County Medical Examiner Office, 933 West Highland Avenue, Milwaukee, WI 53233</i>	230
What Lies Beneath: An Unusual Congenital Anomaly in an Assault Victim	<i>Kathryn H. Haden-Pinneri, MD*, Jason M. Wiersema, PhD, and Jennifer C. Love, PhD, Harris County, Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054-2098</i>	230
Forensic Pathology of the Rupture of an Enlarged Spleen	<i>Maurice G. Rogev, MBChB*, 11/1 Zamenhof Street, Tel Aviv, Jaffo 64373, ISRAEL</i>	231
Clinical and Pathological Spectrum of Fatty Cardiomyopathy in Sudden Cardiac Death	<i>Lise A.M. Matzke, MSc*, Michael Allard, MD, and Bruce M. McManus, James Hogg iCapture Centre for Cardiovascular and Pulmonary Research, St. Paul's Hospital, 1081 Burrard Street, Vancouver, BC V6H 1P9, CANADA; Carol K. Lee, MD, New Mexico Office of the Medical Investigator, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131-0001; and Charles Lee, MD, Vancouver General Hospital, Department of Forensic Pathology, 855 West 12th Avenue, Room 1352, Vancouver, BC V5Z 1M9, CANADA</i>	231
Sudden Death and Fatty Liver Disease	<i>Michael E. Archer, MA*, New York Forensics, Inc., 1039 Main Street, PO Box 28, Fishkill, NY 12524-0028; and Dennis J. Chute, MD, and Kari B. Reiber, MD, Office of the Medical Examiner, Dutchess County Department of Health, 387 Main Street, Poughkeepsie, NY 12601</i>	232
Hypertensive Heart Disease May Compound the Risk of Death From Medication and Contrast Media-Induced Anaphylactic Shock	<i>Ariel Goldschmidt, MD*, and Jane W. Turner, MD, St. Louis City Medical Examiner's Office, 1300 Clark Street, St. Louis, MO 63103</i>	232
Diffuse Axonal Injury in Medico-Legal Practice	<i>Djordje Alempijevic, MD, PhD, Dragan Jecmenica, MD, PhD, Vladimir Zivkovic, MD, Snezana Pavlekic, MD, PhD, and Slobodan Savic, MD, PhD*, University of Belgrade, School of Medicine, Institute of Forensic Medicine, 31a Deligradska Street, Belgrade, 11000, SERBIA AND MONTENEGRO</i>	233

Placental Site Trophoblastic Tumor (PSTT) With Lung Metastases as Cause of Death in a Young Patient: Autopsy Findings and Medico-Legal Implications	<i>Catia Colecchi, MD, Catholic University, Institute of Forensic Medicine, Rome, ITALY; Ezio Fulcheri, MD, University of Genova, Department of Pathology, Genova, ITALY; Sara Partemi, MD, and Fabio De Giorgio MD, Catholic University, School of Medicine, Institute of Forensic Medicine, Largo Francesco Vito 1, Rome, ITALY; Giovan Battista Serra, MD, Catholic University, Department of Obstetrics and Gynecology, Rome, ITALY; and Vincenzo L. Pascali, MD, PhD, and Antonio Oliva, MD, PhD*, Catholic University, School of Medicine, Institute of Forensic Medicine, Largo Francesco Vito 1, Rome, ITALY</i>	233
Identification of Human Body Fluids: Comparison Between Two Commercial Kits for Detection of Semen	<i>Simona Ricci, MD*, Department of Legal Medicine, Viale Regina Elena 336, Rome, ITALY; Fabio Verginelli, Department of Oncology and Neuroscience University "G.d'Annunzio" and Center of Excellence on Aging (Ce.S.I.), D.d'Annunzio Foundation, Chieti, ITALY; Andrea Mele, MD, Department of Legal Medicine University "Sapienza" Viale Regina Elena 336, Rome, ITALY; and Manuela Rosini, and Carla Vecchiotti, MD, PhD, Laboratory Genetic of the Department of Legal Medicine University "Sapienza", Viale Regina Elena 336 00161 Rome, ITALY</i>	234
A Brush With Death: Suicidal Ingestion of Toothpaste	<i>Rebecca Irvine, MD*, 808 Shire Street, South West, Albuquerque, NM 87121; and Susan Kunkle, PharmD, New Mexico Poison and Drug Information Center, MSC11 3060, 1 University of New Mexico, Albuquerque, NM 87131-0001</i>	235
Toxicological Implications in Heat Related Deaths in Phoenix, Arizona: Case Reports From the Office of the Medical Examiner	<i>Kimberly McCall-Tackett, BS*, Maricopa County, Forensic Science Center, 701 West Jefferson Street, Phoenix, AZ 85050; Ann L. Bucholtz, MD, 6643 East Sweetwater Avenue, Scottsdale, AZ 85254; Amy L. Lais, BS, Maricopa County Forensic Science Center, 701 West Jefferson Street, Phoenix, AZ 85007; and Norman A. Wade, MS, Office of the Medical Examiner, Forensic Science Center, 701 West Jefferson Street, Phoenix, AZ 85007</i>	235
Firearm Deaths by Law Enforcement in New York City	<i>James R. Gill, MD, Office of Chief Medical Examiner's Office, 520 First Avenue, New York, NY 10016; and Melissa Pasquale-Styles, MD*, New York City, Office of Chief Medical Examiner's Office, 599 Winthrop Street, Brooklyn, NY 11203</i>	236
Postmortem Genital Examinations With Colposcopy in the Evaluation of Fatal Sexual Violence Against Women	<i>Sharon R. Crowley, RN, MN*, 122 Emeline Avenue, Santa Cruz, CA 95060</i>	236
The Serial Killer of Elderly Women: Analysis of a Multi-Victim Homicide Investigation	<i>Carlo P. Campobasso, MD, PhD*, University of Molise, via De Sanctis, snc, Campobasso, 86100, ITALY; and Massimo F. Colonna, MD, Felice Carabellese, MD, Ignazio Grattagliano, PsyD, Chiara Candelli, MD, and Roberto Catanesi, MD, University of Bari, Section of Forensic Psychiatry, Piazza Giulio Cesare, Bari, 70124, ITALY</i>	237

One Entrance Wound, Three Bullets, and Four Pulls of the Trigger: An Unusual Case of a Suicidal Gunshot Wound of the Head	<i>Todd M. Luckasevic, DO*, Alleghey County, Office of the Medical Examiner, 542 Fourth Avenue, Pittsburgh, PA 15219; Kenneth Clark, MD, University of Pittsburgh Medical Center, 200 Lothrop Street, Pittsburgh, PA 15213; and Abdulrezak M. Shakir, MD, and Karl E. Williams, MD, MPH, Alleghey County, Office of the Medical Examiner, 542 Fourth Avenue, Pittsburgh, PA 15219</i>	237
Suicidal Shotgun Wound Using a Shotgun Barrel, a Shotgun Shell, and a BB	<i>Brian S. Linert, BS*, 2102 North Meridian Street, Apartment 9, Indianapolis, IN 46202; Janis Regnier, Portage Police Department, Portage, IN ; Barrett W. Doyle, Porter County Coroner's Office, Valparaiso, IN; and Joseph A. Prahlow, MD, South Bend Medical Foundation, 530 North Lafayette Boulevard, South Bend, IN 46601</i>	238
Characteristics of Suicidal Gunshot Wounds to the Mouth in Women	<i>Lakshmanan Sathyavagiswaran, MD*, Christopher B. Rogers, MD, Frances Hicks, and Donald Boger, MD, Los Angeles County, Medical Examiner's Office, 1104 North Mission Road, Los Angeles, CA 90033</i>	238
Victimization of Children, Adolescents, and Young Adults by Physical and/or Sexual Abuse in Northwestern Greece: A Three Year Study	<i>Vasilios S. Stoukas*, Telamonos 25, Anthoupoli, Peristeri, Athens, 12135, GREECE; Angeliki Tsiola, MD, Patras, GREECE; and Anastasia Varvarigou, MD, University of Patras, Medical School, GREECE</i>	239
Aneurysms and Old Lace: A Ruptured Splenic Artery Mycotic Aneurysm Masquerading as Arsenic Poisoning	<i>Sam Simmons, MD*, and Gregory J. Davis, MD, University of Kentucky, Medical Center, MS 117, 800 Rose Street, Lexington, KY 40536-0298</i>	239
Lymphocytic Hypophysitis Associated With Sudden Unexpected Death in a Young Woman	<i>Rudy J. Castellani, MD*, and Luis F. Gonzalez-Cuyar, MD, University of Maryland, Baltimore, Department of Pathology, 22 South Greene Street, Baltimore, MD 21201; Fabio Tavora, MD, Johns Hopkins Hospital, 600 North Wolfe Street, Baltimore, MD 21205 ; Kyle Shaw, MD, University of Maryland, Baltimore, Department of Pathology, 22 South Greene Street, Baltimore, MD 21201; and Joyce L. deJong, DO, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909</i>	240
Medico-Legal Aspects of Posttraumatic Gastroduodenal Ulcers	<i>Slobodan Savic, MD, PhD*, School of Medicine, University of Belgrade, Institute of Forensic Medicine, Deligradska 31a, Belgrade, YT 11000, SERBIA AND MONTENEGRO; Radmila Stevanovic, MD, MSc, Institute of Pathology, School of Medicine, University of Belgrade, 8 Dr Subotica Street, Belgrade, 11000, SERBIA AND MONTENEGRO; Djordje Alempijevic, MD, PhD, Institute of Forensic Medicine, 31a Deligradska Street, Belgrade, Serbia 11000, SERBIA AND MONTENEGRO; and Stojan Petkovic, MD, MSc, Clinical Center of Vojvodina, Institute of Forensic Medicine, 5 Hajduk Veljkova Street, Novi Sad, 21000, SERBIA AND MONTENEGRO</i>	240
Death Caused by Cardioinhibitory Reflex: Myth or Reality?	<i>Bettina Schrag, MD*, Béat Horisberger, MD, and Patrice Mangin, MD, PhD, University Lausanne, Institute of Legal Medicine, Rue du Bugnon 21, Lausanne, SWITZERLAND</i>	241
Ehlers-Danlos Syndrome Type IV (Vascular): An Atypical Presentation and Unexpected Diagnosis in a Medical Examiner Setting	<i>James L. Caruso, MD*, Armed Forces Medical Examiner System, U.S. Naval Hospital, Okinawa, Japan, PSC 482 Box 2560, FPO, AP 96362</i>	241

Mechanisms of Delayed Splenic Rupture: A New Hypothesis	<i>Sarathchandra Kodikara, MBBS, MD, DLM*, NIL, Department of Forensic Medicine, Faculty of Medici, Peradeniya, SRI LANKA; and Murugapillai Sivasubramanium, MBBS, MD, DLM, Teaching Hospital, Kegalle, Sri Lanka</i>	242
Death of a Vampire?: Case of Exhumation and Mutilation of a Corpse in Rural Romania	<i>William C. Rodriguez III, Ph.D. *, Office of the Armed Forces Medical Examiners Office, Armed Forces Institute of Pathology, 1413 Research Blvd. Building 102, Rockville, MD 20850</i>	243
Sickle Cell Disease and Sudden Death	<i>Michelle A. Jorden, MD*, Jennifer A. McReynolds, PhD, and Adrienne E. Segovia, MD, Cook County Medical Examiner, 2121 West Harrison Street, Chicago, IL 60612</i>	243
The Biochemical Alteration of Soil by Decomposition Products	<i>Shari L. Forbes, PhD*, University of Ontario Institute of Technology, 2000 Simcoe Street North, Oshawa, Ontario, LIH 7K4, CANADA; David O. Carter, PhD, University of Nebraska, Department of Entomology, 202 Plant Industry Building, Lincoln, NE 68583-0816; and Laura A. Benninger, BSc, University of Ontario Institute of Technology, 2000 Simcoe Street North, Oshawa, Ontario, LIH 7K4, CANADA</i>	244
A Cadaver Encased Within Concrete: A Case Report	<i>Gilles Tournel, MD, PhD*, Anne Becart-Robert, DDS, Benoît Bourel, PhD, Axelle Balgairies, Cédric Houssaye, Valéry Hedouin, PhD, and Didier Gosset, MD, PhD, Institut de Médecine Légale de Lille, 1, place de Verdun, Faculté de Médecine, Lille, 59045, FRANCE</i>	244
A Degloving Experiment to Suggest Postmortem Interval: Give the Anthropologist Some Hands From Freshwater	<i>Turhon A. Murad, PhD*, California State University, Department of Anthropology, 400 West First Street, Chico, CA 95929-0400</i>	245
Parasitic Wasps: Succession, Development, and Forensic Importance as PMI Indicators	<i>Sasha C. Voss, BSc*, and Ian Dadour, PhD, Centre for Forensic Science, University of Western Australia, 35 Stirling Highway, Nedlands, Western Australia 6009, AUSTRALIA</i>	246
Difficulties in Determining Sex From the Skull: Considering Conflicting Lines of Evidence	<i>Krista E. Latham, MS, MA*, Temple University, Anthropology Department, Philadelphia, PA 19122; Carlos J. Zambrano, MS, C.A. Pound Human ID Lab, 5231 North West 56th Court, Gainesville, FL 32653; and Laurel E. Freas, MA, 3425 South West 2nd Avenue, #246, Gainesville, FL 32607</i>	246
Molecular Genetic Testing in 323 Cases of Fatal Pulmonary Thromboembolism in the City of New York Revealed Racial Stratification	<i>Yingying Tang, MD, PhD*, Erik T. Bieschke, MS, Stacey Sainte-Marie, MSFS, Jean Jeudy, Yoonhee A. Kim, Stephanie Pack, Barbara A. Sampson, and Mechthild Prinz, PhD, Office of Chief Medical Examiner, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016</i>	247
The Pathologist's Role in Preserving Implanted Pacemakers and Cardiac Defibrillators or How Not to Get Shocked!	<i>Suzanne D. Parisian, MD*, Medical Device Assistance, Inc., 7117 North 3rd Street, Phoenix, AZ 85020; and Bruce H. Barkalow, PhD*, and William E. Grant, MA, B.H. Barkalow, P.C., 490 Quarterline Road, Newaygo, MI 49337-9125</i>	247

Postmortem Angiography in Support of Radiologic Assisted Autopsy	<i>H. Theodore Harcke, MD*, Armed Forces Institute of Pathology, 3205 Coachman Road, Wilmington, DE 19803; and Carol Solomon, MD, and Scott Luzi, MD, Office of the Chief Medical Examiner, 1413 Research Boulevard, Building 102, Rockville, MD 20850</i>	248
CSI Halifax in Miami: The Importance of Practical Courses in the Forensic Sciences	<i>Tanya R. Peckmann, PhD*, Saint Mary's University, Department of Anthropology, McNally South 208, 923 Robie Street, Halifax, Nova Scotia B3H 3C3, CANADA; and Dr. Bruce A. Hyma, MD, Miami-Dade County Medical Examiner's Office, 1 Bob Hope Road, Miami, FL 33136</i>	248
Can Renal Acute Tubular Necrosis Be Differentiated From Autolysis at Autopsy?	<i>Johan A. Duflou, MBChB, MMed*, and Linda Kocovski, BSc, Department of Forensic Medicine, PO Box 90, Glebe, 2037, AUSTRALIA</i>	248
The Effects of a New Level 1 Trauma Center on the Local Medical Examiner Office	<i>Martha J. Burt, MD, District 8, Medical Examiner Office, 606 South West 3rd Avenue, Gainesville, FL 32601; and Charlotte J. Stevens, BA*, 6417 South West 9th Avenue, Apartment A, Gainesville, FL 32607</i>	249
Mapping the Literature in Forensic Pathology and Legal Medicine: A Bibliometric Study of North-American Journals From 1980 to 2005	<i>Anny Sauvageau, MD*, A. Godin, S. Desnoyers, C. Kremer, MSc, and S. Racette, BSc, Lab de Sciences Judiciaires, et de Medecine Legale, 1701, Parthenais Street, 12th Floor, Montreal, PQ H2K 3S7, CANADA</i>	250
Purtscher Retinopathy Detected by Postmortem Monocular Indirect Ophthalmoscopy	<i>Patrick E. Lantz, MD*, Department of Pathology, Wake Forest University, SOM, Medical Center Boulevard, Winston-Salem, NC 27157-1072; Constance A. Stanton, MD, Department of Pathology, Wake Forest University of Health Sciences, Medical Center Boulevard, Winston Salem, NC 27157; and Marshall E. Tyler, Department of Ophthalmology, Wake Forest University of Health Sciences, Medical Center Boulevard, Winston Salem, NC 27157</i>	250
Sudden Death Due to a Cardiac Sarcoidosis: Histopathological Helping Evidences	<i>Irene Riezzo, MD*, and Stefano D'Errico, MD, University of Foggia, Department of Forensic Pathology, via Luigi Pinto, 1, Foggia, 71100, ITALY; and Francesco Ventura, MD, University of Genova, Department of Forensic Pathology, Via de' Toni, 12, Genova, 16132, ITALY</i>	251
A Diagnosis of Chagas Disease at Autopsy	<i>Ana E. Lopez, MD*, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054; L. Maximiliam Buja, MD, University of Texas-Houston Health Science Center, 7000 Fannin, Suite 1715, Houston, TX 77030; and Luis A. Sanchez, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	251
Dysplasia of the Atrioventricular Nodal Artery: A Case Report and Review of the Literature	<i>Clarissa Krinsky, MD*, 3908 Silver, South East, Albuquerque, NM 87108; Sam W. Andrews, MD, Office of Chief Medical Examiner, 4070 Bowness Road North West, Calgary, Alberta T3B 3R7, CANADA; and Rebecca Irvine, MD, 808 Shire Street, South West, Albuquerque, NM 87121</i>	252

Subaortic Aneurysm of the Left Ventricle Complicating Staphylococcal Endocarditis	<i>Pauline Saint-Martin, MD*, Service de Medecine Legale, Hopital Troussseau, Centre Hospitalier Regional Universitaire de Tours, Tours, 37000, FRANCE; Christopher B. Rogers, MD, and Eugene Carpenter, MD, Los Angeles County, Medical Examiner's Office, 1104 North Mission Road, Los Angeles, CA 90033; Michael C. Fishbein, MD, Department of Pathology and Laboratory Medicine, David Geffen School of Medicine at University of California, Los Angeles, CA 90095; and Lakshmanan Sathyavagiswaran, MD, Los Angeles County Medical Examiner's Office, 1104 North Mission Road, Los Angeles, CA 90033</i>	252
A Rare Case of Cardiac Failure Due to Hypertensive Crisis in Pheochromocytoma: A Methodological Approach for Diagnosis	<i>Stefano Derrico, MD*, Irene Riezzo, MD, and Cristoforo Pomara, MD, Department of Forensic Pathology, University of Foggia, via Luigi Pinto, 1, Foggia, Italy 71100, ITALY</i>	253
Arrhythmogenic Right Ventricular Dysplasia (ARVD): A Not So Rare Cause of Sudden Death in Young Adults	<i>Frank Braza, MD, PhD*, Juan A. Merayo-Rodriguez, MD, and Jeffrey West, Danbury Hospital, 24 Hospital Avenue, 2 Tower Lab, Danbury, CT 06810</i>	253
Cardiac Death in Anabolic Steroid Abuse: A Pathological and Toxicological Study	<i>Claudio Terranova*, and Massimo Montisci, PhD, University of Padova, Section of Legal Medicine, via Falloppio n.50, Padova - Italy, Padova, 35121, ITALY; Cristina Basso, and Gaetano Thiene, via Gabelli 61, Padova, 35121, ITALY; and Santo Davide Ferrara, PhD, University of Padua - Section of Legal Medicine and Forensic Toxicology, Via Falloppio 50, Padua, 35121, ITALY</i>	254
A “Café Coronary” in a 2-Year-Old: Case Report	<i>Jennifer L. Shuttlesworth, MD*, University of Texas Medical Branch, 301 University Boulevard, Route 0743, Galveston, TX 77555; and Stephen M. Pustilnik, MD, Galveston County Medical Examiner's Office, 6607 Highway 1764, Texas City, TX 77591</i>	255
Identification of Twenty Charred Victims of a Helicopter Accident, Africa	<i>Laurent Martrille, MS, MD*, Service de Medecine Legale, CHU Lapeyronie, 191 Avenue, du Doyen Gaston Giraud, Montpellier, CEDEX 5 34295, FRANCE; Charles Georget, DMD, Stéphane Chapenoire, MD, Jean Paul Tissier, MS, and Laurent Chartier, PhD, CTGN, IRCCN, 1 Boulevard T Sueur, Rosny Sous Bois, 93111, FRANCE; Didier Buiret, MS, SCIJ, 31 av Franklin Roosevelt, Ecully, 69134, FRANCE; Gérard De Lassus, MS, IJPN, Paris, 75000, FRANCE; and Eric Baccino, MD, 371, av du Doyen Gaston GIRAUD, 34295 Montpellier, Hopital Lapeyronie, Cedex 5, FRANCE</i>	255
Risk Factors for Pedestrian Deaths	<i>William T. Gormley, MD, PhD*, and Anna Noller, PhD, Office of the Chief Medical Examiner, Commonwealth of Virginia, 400 East Jackson Street, Richmond, VA, 23219</i>	256

Cervical Spine Injuries in Fatal Traffic Crash Victims: Microscopy and Diagnostic Imaging Findings	<i>Lars Uhrenholt, DC*, and Annie Vesterby Charles, DMSc, University of Aarhus, Institute of Forensic Medicine, Peter Sabroes Gade 15, Aarhus C, Europe 8000, DENMARK; Ellen Hauge, MD, PhD, Research Unit for Rheumatology and Bone Biology, Aarhus University Hospital, Aarhus Sygehus (NBG), Denmark; and Markil Gregersen, DMSc, University of Aarhus, Institute of Forensic Medicine, Peter Sabroes Gade 15, Aarhus C, Europe 8000, DENMARK</i>	256
Reconstruction of a Fatal Dragster Crash	<i>Michael J. Shkrum, MD*, London Health Sciences Centre, Department of Pathology, 339 Windermere Road, London, Ontario, N6A 5A5, CANADA; Kevin J. McClafferty, BESc*, Multi-Disciplinary Accident Research Team, Faculty of Engineering, University of Western Ontario, London, Ontario N6A 5B9, CANADA; and John R. Fernandes, MDCM, Forensic Pathology Unit, Hamilton Health Sciences, 237 Barton Street, East, Hamilton, Ontario L8L 2X2, CANADA</i>	257
Death Due to Aquatic Erotic Asphyxia - Accident or Homicide?	<i>Andrea Zaferes, BA*, PO Box 211, Hurley, NY 12443; and Kari B. Reiber, MD, and Dennis J. Chute, MD, Office of the Medical Examiner, Dutchess County Department of Health, 387 Main Street, Poughkeepsie, NY 12601</i>	257
Bear Facts Alaska: The Good, The Bad, and the U	<i>Kathleen Day, MA, MS*, University of Alaska, Anchorage, PO Box 670276, Chugiak, AK 99567; and Franc Fallico, MD, Office of the Chief Medical Examiner, State of Alaska, 4500 South Boniface Parkway, Anchorage, AK 99567</i>	258
Concussive Head Injury and Alcohol	<i>Jane Willman Turner, PhD, MD*, St. Louis University School of Medicine, 1402 South Grand Boulevard, St. Louis, MO 63104</i>	258
Preliminary Study and Potential Role of CT Imaging Autopsy in the Investigation of Death Due to Accidental Blunt Trauma	<i>Barry Daly, MD*, and Clint W. Sliker, MD, University of Maryland Medical Center, Diagnostic Imaging Department, 22 South Greene Street, Baltimore, MD 21201; Zabiullah Ali, MD, Dawn Zulauf, RN, and Jack M. Titus, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Mary G. Ripple, MD, 68 Bluebird Road, Port Deposit, MD 21904; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	258
Stairway Related Deaths: An Analysis of Autopsy Findings of Individuals Found Dead at the Bottom of a Stairway	<i>Joyce L. deJong, DO*, and Michael A. Markey, MD, Sparrow Forensic Services, Sparrow Hospital, 1215 East Michigan Avenue, Lansing, MI 48909-7980; and Rudy J. Castellani, MD, University of Maryland, Department of Pathology, 22 South Greene Street, Baltimore, MD 21201</i>	259
Discrimination of Falls and Blows in Blunt Head Trauma: Assessment of Predictability Through Combined Criteria	<i>Anny Sauvageau, MD*, S. Racette, BSc, and C. Kremer, MSc, Laboratoire de sciences judiciaires et de médecine légale, 1701 Parthenais Street, 12th Floor, Montreal, Quebec H2K 3S7, CANADA</i>	259
Unusual Death of a Transsexual (Identification of Damaging Means and Death Time)	<i>Alessandro Dell'Erba*, Sandra Cornetta, MD, Fiorenza Zotti, PhD, and Annalisa Addante, MD, PHD, Section of Legal Medicine, Place G. Cesare, BARI, 70124, ITALY</i>	260

2007		
Sudden Unexpected Death in a Case of Human Immunodeficiency Virus (HIV) and Mycobacterium Infection Diagnosed Postmortem	<i>Hydow Park, MD*, Atlantic County Medical Examiner's Office, 201 Shore Road, Northfield, NJ 08225-2319</i>	261
Assisted Suicide as Practiced in the French Part of Switzerland	<i>Sandra E. Burkhardt, MD*, Jerome Sobel, MD, and Romano La Harpe, MD, Institute of Forensic Medicine, 9, Avenue de Champel, Geneva, 1206, Switzerland</i>	261
Firearms Injuries: Beyond Entry and Exit Wounds	<i>Rosa Falamingo, MD, PhD, and Francesco Vinci, MD, Section of Legal Medicine (Di.M.I.M.P.) - University of Bari, Piazza Giulio Cesare, Policlinico, Bari, 70124, Italy; and Carlo P. Campobasso, MD, PhD*, Department of Health Sciences (Di.S.pe.S), University of Molise, via De Sanctis, snc, Campobasso, 86100, Italy</i>	261
The Mummified Corpse Found in a Domestic Setting	<i>Carlo P. Campobasso, MD, PhD*, Department of Health Sciences (Di.S.pe.S.), University of Molise, via De Sanctis, snc, Campobasso, Italy 86100, Italy; and Rosa Falamingo, MD, PhD, Domenica Laviola, MD, Claudia Liuzzi, MD, and Francesco Vinci, MD, Section of Legal Medicine (Di.M.I.M.P.) - University of Bari, Piazza Giulio Cesare, Policlinico, Bari, 70124, Italy</i>	262
Acute Hemorrhagic Leukoencephalopathy (Weston-Hurst Disease): A Natural Disease Presents as Head Trauma	<i>Kenneth D. Hutchins, MD*, Miami-Dade County Medical Examiner Department, Number 1 Bob Hope Road, Miami, FL 33136; and Lyla E. Perez, MD, Southern Regional Medical Examiner Office, 1175 DeHirsch Avenue, Woodbine, NJ 08270</i>	262
Weight That Kills: Adults With Natural Deaths are Heavier Than Those Dying Non-Naturally — A Cross-Sectional Study	<i>Ana Rubio, MD, PhD*, and David Reisz, BS, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Christopher Cox, PhD, Bloomberg School of Public Health, Johns Hopkins University, Monument Street, Baltimore, MD 21205; and David M. Fowler, MD, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	263
Forensic Science "Case Derived" Templates Formulated With Relational Database Software	<i>Gilbert E. Corrigan, MD, PhD*, East Baton Rouge Coroner's Office, 4030 T.B. Hearndon Drive, Baton Rouge, LA 70807; and Sarah P. Corrigan, MS, Jefferson Parish Forensic Laboratory, Jefferson Parish Government, Metairie, LA 70001</i>	263
Three Unusual Neuropathologic-Related Causes of Sudden Death	<i>Dennis J. Chute, MD*, and Kari Reiber, MD, Dutchess County Medical Examiner's Office, 387 Main Street, Poughkeepsie, NY 12601</i>	264
Ruptured Cerebral Artery Aneurysm Mimicking Home Invasion and Assault	<i>Albert Y. Chu, MD, MHS*, and Luis A. Sanchez, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	264
Checking In to Check Out: The New Mexico Experience of Suicide Occurring in Hotels	<i>Rebecca A. Irvine, MD*, University of New Mexico, Office of the Medical Investigator, MSC 11 6030, 1 University of New Mexico, Albuquerque, NM 87131-0001</i>	265
Liver Laceration as a Result of Resuscitation in an Adult Man	<i>Ellen G. Moffatt, MD*, Office of the Chief Medical Examiner, 850 Bryant Street, San Francisco, CA 94103</i>	265

The Epidemiology of Sudden Cardiac Death in Young Decedent Medical Examiner Cases	<i>Sharon M. Derrick, PhD*, Stacey A. Mitchell, MSN, RN, and Luis A. Sanchez, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	266
Significance of Blood Neopterine Measurement in Forensic Autopsy Cases	<i>Takaki Ishikawa, MD, PhD*, Department of Legal Medicine, Osaka City University Medical School, Asahimachi 1-4-3, Abeno, Osaka, 545-8585, Japan; Marianne Hamel, MD, PhD, Thomas Jefferson University Hospital, Department of Pathology, 132 South 10th Street, Suite 285 Main Building, Philadelphia, PA 19107; and Bao-Li Zhu, MD, PhD, and Hitoshi Maeda, MD, PhD, Department of Legal Medicine, Osaka City University Medical School, Asahimachi 1-4-3, Abeno, Osaka, 545-8585, Japan</i>	266
Evaluation of Nasoharyngeal Viral Swabs in Infants Dying of Natural Causes	<i>Wendy A. Stroh, DO*, and Deborah Kay, MD, Office of the Chief Medical Examiner, 400 East Jackson Street, Richmond, VA 23219</i>	267
Succession of Microfungi in Grave Soil	<i>Shari L. Forbes, PhD*, University of Ontario Institute of Technology, 2000 Simcoe Street North, Oshawa, Ontario LIH 7K4, Canada; Trevor Lumley, PhD, Environment Canada, Environment Technology Centre, 335 River Road, Ottawa, Ontario K1A0H3, Canada; and David Carter, PhD, University of Nebraska Lincoln, 202 Plant Industry Building, Lincoln, NE 68583-0816</i>	267
Improved Estimation of Postmortem Interval With Multiple Protein Markers and Improved Analytical Methods	<i>Behnoush Memari, MS*, Kenneth G. Furton, PhD, and Alberto Sabucedo, PhD, Florida International University, Department of Chemistry and Biochemistry, 11200 SW 8th Street University Park CP-345, Miami, FL 33199</i>	268
Drowning of a Child With a Cardiac Fibroma of the Interventricular Septum	<i>Darshan R. Phatak, MD*, and Luis A Sanchez, MD, Harris County Medical Examiner Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	268
Estimating Time of Death From Livor Mortis Patterns: A Case Presentation	<i>William Massello III, MD*, Office of the Chief Medical Examiner, 6600 Northside HS Road, Roanoke, VA 24019</i>	269
Dispersion of Hesitation Marks and Defense Wounds: A New Criterion of Differentiation of Sharp Force Suicide and Homicide	<i>Stéphanie Racette, BSc*, Célia Kremer, MSc, Anne Desjarlais, and Anny Sauvageau, MD, Laboratoire de Sciences Judiciaires et de Médecine Légale, 1701, Parthenais Street, 12th floor, Montreal, Quebec H2K 3S7, Canada</i>	269
Neck and Scleral Hemorrhage Due to Drowning	<i>Russell T. Alexander, MD*, and Jeffrey M. Jentzen, MD, Milwaukee County Medical Examiner's Office, 933 West Highland Avenue, Milwaukee, WI 53233</i>	270
Papillomacular Folds: Whiplash Maculopathy or Postmortem Artifact?	<i>Patrick E. Lantz, MD*, Wake Forest University Health Sciences, Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157</i>	270
To Dye or Magnify! A Proposal to Study the Efficacy of Toluidine Blue Dye vs. Colposcopy in the Postmortem Anogenital Examination	<i>Sharon R. Crowley, RN, MN*, 122 Emeline Avenue, Santa Cruz, CA 95060</i>	271
Virtopsy - Virtual Autopsy, Where We Go?	<i>Michael J. Thali, MD*, University Bern, Centre Forensic Imaging and Virtopsy, Buehlstrasse 20, Bern, Bern 3012, Switzerland</i>	272

Female Firearm-Related Suicides: A Reappraisal	<i>Kevin D. Whaley, MD*, Anna Noller, PhD, and William T. Gormley, MD, PhD, Central District, Office of the Chief Medical Examiner, Commonwealth of Virginia, 400 East Jackson Street, Richmond, VA 23219</i>	272
Agonal Sequences in Four Filmed Hangings: Analysis of Respiratory and Movement Responses to Asphyxia by Hanging	<i>Anny Sauvageau, MD*, and Stéphanie Racette, BSc, Laboratoire de Sciences Judiciaires et de Médecine Légale, 1701 Parthenais Street, 12th Floor, Montreal, Quebec H2K 3S7, Canada</i>	273
The Methods of Committing and Alcohol Intoxication of Suicides in the Southwestern Croatia From 1996 to 2005	<i>Alan Bosnar, MD, PhD*, Valter Stemberga, MD, Miran Coklo, MD, and Sanja Dobi Babic, BSc, Department of Forensic Medicine, Rijeka University School of Medicine, B. Branchetta 20, Rijeka, 51000, Croatia; and Emina Grgurevic, MD, Public Health Institute of Primorsko-Goranska County, Kresimirova 52a, Rijeka, 51000, Croatia</i>	273
Suicide by Self Immolation in Cook County, Illinois, USA	<i>Ponni Arunkumar, MD*, J. Scott Denton, MD, and Edmund R. Donoghue, MD, Cook County Medical Examiners Office, 2121 West Harrison Street, Chicago, IL 60612</i>	274
Seasonal Incidence of Suicides in Crete Island: A Five Year Study	<i>Marianna Kalyva, MD*, University of Crete, Department of Forensic Sciences, Medical School, Heraklion, 71110, Greece; Vasilios Stoukas, Telamonos 25, Anthoupoli, Peristeri, Athens 12135, Greece; and Anna Mavroforou, PhD, Elena F. Kranioti, MD, Panagiotis Mylonakis, MD, Antonios Papadomanolakis, MD, and Manolis Michalodimirkis, MD, JD, University of Crete, Medical School, Department of Forensic Sciences, Heraklion, 71110, Greece</i>	274
Suicidal Electrocution in Australia	<i>Peter Y. Chan, BSc*, and Johan A. Duflou, MBChB, MMed, Department of Forensic Medicine, PO Box 90, Glebe, NSW 2037, Australia</i>	275
Open Fractures in Pedestrians Mimicking Gunshot Wounds	<i>Melissa A. Brassell, MD*, Mary G. Ripple, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	275
Homicide in a Surgical Intensive Care Unit	<i>A. Thambirajah Balachandra, MBBS*, Johanna Abbott, and Carol Youngson, RN, Office of the Chief Medical Examiner, Manitoba Justice, 210-1 Wesley Avenue, Winnipeg, Manitoba R3C 4C6, Canada; John Burchill, Hate Crimes Unit Coordinator/Major Crimes Analyst, Winnipeg Police Service, PO Box 1680, 151 Princess Street, Winnipeg, Manitoba R3C 2Z7, Canada; and N.D.N. Asela Mendis, MBBS, and Sholeh Barooni, MD, Office of the Chief Medical Examiner, Manitoba Justice, 210-1 Wesley Avenue, Winnipeg, Manitoba R3C 4C6, Canada</i>	276
Subdural Hemorrhage, Subarachnoid Hemorrhage, and a Healing Tibia Fracture: Abuse or Complications of Leukemia?	<i>Veena D. Singh, MD, MPH*, University of New Mexico Health Sciences Center, Department of Pathology MSC08 4640, 1 University of New Mexico, Albuquerque, NM 87131; and Kurt B. Nolte, MD, and Ross Reichard, MD, Office of the Medical Investigator, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131</i>	277

An Exceptional Case of Death Due to Lesions of Water Nozzle	<i>Nunzio Di Nunno, MD, PhD*, Università degli Studi di Lecce, Via G. Dorso n. 9, Bari, 70125, Italy; Luigi Viola, MD, Università degli Studi di Bari, Sezione di Medicina Legale, DIMIMP, Policlinico di Bari, Piazza G Cesare 11, Bari, 70124, Italy; Fulvio Costantinides, MD, Università degli Studi di Trieste, San Pelagio n. 45, Duino-Aurisina, 34100, Italy; and Giandomenico Maria Battista, MD, and Cosimo Di Nunno, MD, Università degli Studi di Bari, Sezione di Medicina Legale, DIMIMP, Policlinico di Bari, Piazza G. Cesare 11, Bari, 70124, Italy</i>	277
Hanging Deaths in Ontario: Retrospective Analysis of 755 Cases	<i>Elena Tugaleva, MD*, and Michael J. Shkrum, MD, Department of Pathology, London Health Sciences Centre, 339 Windermere Road, London, Ontario N6A 5A5, Canada; Donald R. Gorassini, PhD, Department of Psychology, King's University College at The University of Western Ontario, 266 Epworth Avenue, London, Ontario N6A 2M3, Canada; and Barry A. McLellan, MD, Office of the Chief Coroner, 26 Grenville Street, Toronto, Ontario M7A 2G9, Canada</i>	277
Maternity and Paternity Testing of a Discarded Dead Neonate Involving a Young Girl and Her Father	<i>Jian Tie, MD, PhD*, Yuka Serizawa, BS, and Sesaku Uchigasaki, MD, PhD, Department of Legal Medicine, Nihon University School of Medicine, 30-1 Oyaguchi Kamimachi, Tokyo, 173-8610, Japan; Yoshihiro Mitsugi, Criminal Investigation Laboratory, Saitama Prefectural Police Headquarters, 3-10-1 Kizaki Urawa-ku, Saitama, Saitama 330-0042, Japan; and Shigemi Oshida, MD, PhD, Department of Legal Medicine, Nihon University School of Medicine, 30-1 Oyaguchi Kamimachi, Tokyo, 173-8610, Japan</i>	278
Undetected Polyglandular Autoimmune Syndrome Type II (Schmidt Syndrome) as a Cause of Sudden Death	<i>Michael S. Lantier*, Villanova University, 800 Lancaster Avenue, Villanova, PA 19085; and Fredric N. Hellman, MD, MBA, Office of the Medical Examiner, Delaware County, Route 352-Fair Acres, Lima, PA 19037</i>	278
Suicide by Ingestion of Carbamate Insecticide: Case Report and Regional Variations	<i>Lucas D. Duke, BS*, Drexel School of Medicine, 2125 Spring Garden Street, #3R, Philadelphia, PA 19130; Sepideh Samzadeh, BS, Drexel University School of Medicine, 135 South 20th Street, Apartment #1506, Philadelphia, PA 19103; and Fredric N. Hellman, MD, MBA, Office of the Medical Examiner, Delaware County, Route 352-Fair Acres, Lima, PA 19037</i>	279
Chemical Asphyxia and Bondage: Autoerotic Fatality Induced by Chloroform Inhalation	<i>Heather A. Cannon*, Mercyhurst College, 501 East 38th Street, Erie, PA 16546; and Fredric N. Hellman, MD, MBA, Office of the Medical Examiner, Delaware County, Route 352-Fair Acres, Lima, PA 19037</i>	279
Hemophagocytic Lymphohistiocytosis: A Case Report and Review of the Literature	<i>Julia M. Braza, MD*, and Meghan Delaney, DO, Beth Israel Deaconess Medical Center and Harvard Medical School, 330 Brookline Avenue, Boston, MA 02215</i>	280
Snake-Shot From a Handgun: An Unusual Gunshot Wound Suicide	<i>Karen B. Looman, DO*, and Wendy M. Gunther, MD, Tidewater Office of the Chief Medical Examiner, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510</i>	281

Non-Traumatic Homicide Following Assault: 16 Cases - A Review of Investigation, Pathology, Toxicology, and Judicial Outcome	<i>Patricia A. Aronica-Pollak, MD*, Jack M. Titus, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner State Of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	281
Death by Cue in the Parietal Pocket: An Unusual Injury Pattern Caused by the Use of a Blunt Object	<i>Valerie S. Green, MD*, Mary L. Anzalone, MD, Dwayne A. Wolf, MD, PhD, and Luis A. Sanchez, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	282
Pediatric Malignancies Presenting as Sudden Death: A Case Series	<i>Allison S. Nixdorf-Miller, MD*, Tracey S. Corey, MD, Barbara Weakley- Jones, MD, and William R. Ralston, MD, Office of the Chief Medical Examiner, 810 Barrett Avenue, Louisville, KY 40204</i>	282
An Experimental Comparison of Bone Wound Ballistics of Non-Lead and Lead Bullets	<i>Bryce O. Anderson, PhD*, and Tyler A. Kress, PhD, BEST Engineering, 2312 Craig Cove, Knoxville, TN 37919; Anne M. Kroman, MA, University of Tennessee, Department of Anthropology, Knoxville, TN 37996; David J. Porta, PhD, Bellarmine University, Department of Biology, 2001 Newburg Road, Louisville, KY 40205; and John C. Hungerford, PhD, University of Tennessee, 208 ESH, Knoxville, TN 37996</i>	283
Model Protocol for Forensic Medical Examination of Victims of Trafficking in Human Beings	<i>Djordje M. Alempijevic, MD, PhD*, Dragan S. Jecmenica, MD, PhD, Snezana Pavlekic, MD, PhD, Slobodan N. Savic, MD, PhD, and Branimir V. Aleksandric, MD, PhD, Institute of Forensic Medicine, Faculty of Medicine, University of Belgrade, 31a Deligradska Street, Belgrade, 11000, Serbia</i>	284
The Role of Postmortem Cardiac Enzymes in the Diagnosis of Acute Cardiac Deaths	<i>Nick I. Batalis, MD*, and Bradley J. Marcus, MD, Christine N. Papadea, PhD, and Kim A. Collins, MD, Medical University of South Carolina, 165 Ashley Avenue, Main Hospital, Suite 281, PO Box 250108, Charleston, SC 29425</i>	284
Histologic Evidence of Repetitive Blunt Force Abdominal Trauma in Three Pediatric Fatalities	<i>Daniel W. Dye, MD*, University of Arkansas for Medical Sciences Department of Pathology, 4301 West Markham, Slot #517, Little Rock, AR 72205; and Charles P. Kokes, MD, Arkansas State Crime Laboratory, 2 Natural Resources Drive, Little Rock, AR 72211</i>	285
Death by Suicide in Maryland: A Cross-Sectional Study, 2002 to 2005	<i>Jonrika M. Malone, MD*, Ana Rubio, MD, PhD, Corey Tayman, and David M. Fowler, MD, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	285
Can Mandibular Fractures Occur in Non-Oral Contact Shotgun Wounds of the Head?	<i>Edward L. Mazuchowski, MD, PhD*, Office of the Armed Forces Medical Examiner, 1413 Research Boulevard, Rockville, MD 20850; Mary G. Ripple, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Craig T. Mallak, JD, MD, Office of the Armed Forces Medical Examiner, 1413 Research Boulevard, Rockville, MD 20850; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	285
A Retrospective Review of Youth Suicide in New Mexico	<i>Veena D. Singh, MD, MPH*, University of New Mexico Health Sciences Center, Department of Pathology MSC08 4640, 1 University of New Mexico, Albuquerque, NM 87131; and Jeffrey S. Nine, MD, and Sarah Lathrop, DVM, PhD, Office of the Medical Investigator, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131</i>	286

A Homicide Due to a “Disguised Mail Bomb”	<i>Margherita Neri, MD*, Irene Riezzo, MD, and Emanuela Turillazzi, MD, PhD, Department of Forensic Pathology University of Foggia, Viale Pinto 1, Foggia, 71100, Italy</i>	287
Ocular Study in Pediatric Deaths Under Two Years of Age With Novel Findings in the Retina of Children Who Died of Sudden Infant Death Syndrome (1994 – 2004)	<i>Jorge L. Arredondo Marin, MD*, John R. Fernandes, MD, and Chitra Rao, MBBS, McMaster University, Department of Pathology and Molecular Medicine, Regional Forensic Pathology Unit, Hamilton Health Sciences Centre, 237 Barton Street East, Hamilton, Ontario L8L 2X2, Canada</i>	287
Exsanguination Associated With Vascular Access Sites in Hemodialysis Patients	<i>Donna M. Vincenti, MD*, and Patricia A. Aronica-Pollak, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Joshua M. Sharfstein, MD, City of Baltimore Health Department, 210 Guilford Avenue, Executive Suite, 3rd Floor, Baltimore, MD 21202; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	288
Potential Errors in Autopsy Reports of Custodial Deaths Temporally Associated With Electronic Control Devices: A Cardiovascular Perspective	<i>Mark W. Kroll, PhD*, University of Minnesota, Box 23, Crystal Bay, MN 55323; Dorin Panescu, PhD, St. Jude Medical Cardiac Rhythm Management Division, 705 East Evelyn Avenue, Sunnyvale, CA 94086; Jeffrey Ho, MD, Department of Emergency Medicine, Hennepin County Medical Center, 730 8th Street South, Minneapolis, MN 55415; Richard M. Luceri, MD, Holy Cross Hospital, 4725 North Federal Highway, Ft. Lauderdale, FL 33308; Igor R. Efimov, PhD, Washington University, 1 Brookings Drive, St. Louis, MO 63130; Hugh Calkins, MD, Johns Hopkins Hospital, 601 North Caroline Street, Baltimore, MD 21287; and Patrick J. Tchou, MD, Cleveland Clinic Foundation, 9500 Euclid Avenue, Cleveland, OH 44195</i>	288
Headache and Sudden Death in a Young Adult: An Unexpected Finding at Autopsy	<i>Adrienne Segovia, MD*, and Michelle A. Jorden, MD, Office of the Cook County Medical Examiner, 2121 West Harrison Street, Chicago, IL 60612</i>	289
Sudden Death in Duchenne Muscular Dystrophy With Noncompaction of the Ventricular Myocardium: A New Cardiomyopathy or a Compensatory Regression to Fetal Myocardiogenesis?	<i>Michael J. Caplan, MD*, and Kelly Rose, MD*, Medical University of South Carolina, Department of Pathology & Laboratory Medicine, Suite 309, 165 Ashley Avenue, Charleston, SC 29425</i>	290
Death By Giant Cells: Report of Two Cases of Sudden Cardiac Death Due to Giant Cell Inflammatory Processes	<i>Rebecca A. Hamilton, MD*, Office of the District 21 Medical Examiner, 70 Danley Drive, Fort Myers, FL 33907; Linda Sullivan, BS, Wuesthoff Reference Laboratory, 6800 Spyglass Court, Melbourne, FL 32940; and Barbara C. Wolf, MD, Office of the District 21 Medical Examiner, 70 Danley Drive, Fort Myers, FL 33907</i>	291
Sudden Death and Keratoderma Associated Cardiomyopathy: An “Affray” of the Heart	<i>Christopher M. Milroy, MD, LLB*, and Sacha Kolar, MBChB, Forensic Science Service, The Medico-Legal Center, Watery Street, Sheffield, South Yorkshire S3 7ES, United Kingdom; and Kim Survana, MBChB, Sheffield Teaching Hospitals, Northern General Hospital, Herries Road, Sheffield, South Yorkshire S5 7AU, United Kingdom</i>	291
Correlations for Expected Heart Weight	<i>William T. Gormley, MD, PhD*, Deborah Kay, MD, and Anna Noller, PhD*, Office of the Chief Medical Examiner, Commonwealth of Virginia, 400 East Jackson Street, Richmond, VA 23219</i>	292

Gagging, Strangulation By Single/ Double Ligature ...or Incaprettamento?	<i>João Pinheiro, MD, MSci*, and Duarte Nuno Vieira, PhD, Instituto Nacional de Medicina Legal, Largo Sé Nova, Coimbra, 3000 213, Portugal</i>	292
A Case Report of an Unexpected Accidental Electrocution	<i>Christopher K. Poulos, MD*, Indiana University Department of Pathology and Laboratory Medicine, 521 West McCarty Street, Indianapolis, IN 46225; Michele Catellier, MD, Forensic Pathology Associates of Indiana, 521 West McCarty Street, Indianapolis, IN 46225; Elena F. Bishop, MD, Indiana University Department of Pathology and Laboratory Medicine, Clarian Pathology Laboratory, 350 West 11th Street, Indianapolis, IN 46225; and Stephen S. Radentz, MD, Forensic Pathology Associates of Indiana, 521 West McCarty Street, Indianapolis, IN 46225</i>	292
Death From Truck Tire Servicing: A Report of Three Cases and Review of the Literature	<i>Patrick Cho, MD*, Aldo Fusaro, DO, and Richard C. Harruff, MD, PhD, King County Medical Examiner's Office, 325 Ninth Avenue, Seattle, WA 98104</i>	293
A Rare Injuring Tool in a Dyadic Death	<i>Sabina Di Donato, MD*, Giovanni Paolo Di Peri, MD, and Carmina Dambra, MD, Institute of Forensic Pathology, University of Foggia - Italy, Ospedali Riuniti, Viale L. Pinto n. 1 - 71100 Foggia - Italy, Foggia, 71100, Italy</i>	293
Independence Day Explosion on Lovers Key	<i>Brett E. Harding, MBA*, and Barbara C. Wolf, MD, Office of the District 21 Medical Examiner, 70 Danley Drive, Fort Myers, FL 33907</i>	294
Identifying the "Iceman"	<i>Sarah L. Bettinger, MSFS*, Devon R. Pierce, BS, and Suzanne M. Barritt, MS, Armed Forces DNA Identification Laboratory, 1413 Research Boulevard, Building 101, Rockville, MD 20850; Alexander F. Christensen, PhD, Joint POW/MIA Accounting Command, Central Identification Laboratory, 310 Winchester Avenue, Hickam AFB, HI 96853; and Louis N. Finelli, DO, Armed Forces DNA Identification Laboratory, 1413 Research Boulevard, Building 101, Rockville, MD 20850</i>	295
Caddisfly Cases Assist Homicide Case: Determining a Postmortem Submersion Interval (PMSI) Using Aquatic Insects	<i>John R. Wallace, PhD*, Millersville University, Department of Biology, Millersville, PA 17551; Richard W. Merritt, PhD, Ryan K. Kimbaraskas, MS, Mark E. Benbow, PhD, and Mollie McIntosh, PhD, Michigan State University, Department of Entomology, 243 Natural Science, East Lansing, MI 48824-1115; and Joyce deJong, MD, Sparrow Hospital, Forensic Pathology Department, Lansing, MI 48824</i>	295
A Standardized Field Protocol for Experimentally Investigating Variability in Entomology-Based Postmortem Intervals Over Multiple Sites and Years: A Proposal	<i>Kenneth G. Schoenly, PhD*, California State University, Stanislaus, Department of Biological Sciences, 801 West Monte Vista Avenue, Turlock, CA 95382; Jeffery K. Tomberlin, PhD, Texas A&M University, Texas Cooperative Extension, 1229 North U.S. Highway 281, Stephenville, TX 76401; John R. Wallace, PhD, Millersville University, Department of Biology, Millersville, PA 17551; M. Lee Goff, PhD, Chaminade University, 3140 Waialae Avenue, Honolulu, HI 96816; Jeffrey D. Wells, PhD, West Virginia University, Biological Sciences, Morgantown, WV 26506; and Richard W. Merritt, PhD, Michigan State University, Department of Entomology, 243 Natural Science Building, East Lansing, MI 48824</i>	296

Characteristics of Fatal All Terrain Vehicle (ATV) Accidents	<i>Michele Eichenmiller, MS, James A. Kaplan, MD*, David J. Clay, BA, Myron A. Gebhardt, MS, Brandon Lewis, BS, Nabila A. Haikal, MD, James C. Kraner, PhD, Office of the Chief Medical Examiner, 619 Virginia Street West, Charleston, WV 25302</i>	297
Using Ninhydrin to Detect Grave Soil	<i>David O. Carter, PhD*, Department of Entomology, University of Nebraska-Lincoln, 202 Plant Industry Building, Lincoln, NE 68583- 0816; David Yellowlees, PhD, School of Pharmacy and Molecular Sciences, James Cook University, Townsville, QLD 4811, Australia; and Mark Tibbett, PhD, Centre for Land Rehabilitation, School of Earth and Geographical Sciences, University of Western Australia, Crawley, WA 6009, Australia</i>	297
Insects and Time Since Death: What Do We Really Estimate?	<i>M. Lee Goff, PhD*, Division of Natural Sciences and Mathematics, Chaminade University of Honolulu, 3140 Waialae Avenue, Honolulu, HI 96816-1578</i>	298
Dying of the Cold in a Warm Climate - Hypothermia Deaths in Sydney, Australia	<i>Johan A. Duflou, MMed*, and Cathy Lim, MBBS, Department of Forensic Medicine, 42-50 Parramatta Road, Glebe, NSW 2037, Australia</i>	298
The Postmortem Picnic	<i>Kathryn Haden-Pinneri, MD*, Mary Lynn Anzalone, MD, and Luis A. Sanchez, MD, Office of the Medical Examiner of Harris County, Joseph A. Jachimczyk Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054</i>	299
Applying Statistical Principles to the Entomological Estimation of Postmortem Interval	<i>Bart J. Harvey, MD, PhD, MEd*, University of Toronto, 407-263 McCaul Street, Toronto, Ontario M5T 1W7, Canada; Sherah L. VanLaerhoven, PhD, University of Windsor, Room 23, Biology Building, 401 Sunset Avenue, Windsor, Ontario N9B 3P4, Canada; and Paul N. Corey, PhD, University of Toronto, Department of Public Health Sciences, 6th Floor, 155 College Street, Toronto, Ontario M5T 3M7, Canada</i>	299
The Validation of Gene Expression as a Means of Predicting the Age of the Blow Fly <i>Lucilia sericata</i>	<i>Aaron M. Tarone, BS*, Department of Zoology, Michigan State University, 203 Natural Sciences, East Lansing, MI 48824; and David R. Foran, PhD, Forensic Science Program, Michigan State University, 560 Baker Hall, East Lansing, MI 48824</i>	300
Have I Eaten Here Before? Considering Multigenerational Colonization of Remains by Blow Flies	<i>Timothy E. Huntington, MS*, and Leon G. Higley, PhD, University of Nebraska, Department of Entomology, 202 Plant Industry Building, Lincoln, NE 68583</i>	301
The Investigation of Animal Tissue as an Analogue for Human Tissue in Decomposition Studies in Soil	<i>Kathryn L. Stokes, BSc*, Centre for Forensic Science, University of Western Australia, 35 Stirling Highway, Nedlands, Perth, Western Australia 6009, Australia; Shari Forbes, PhD, University of Ontario Institute of Technology, Faculty of Science, University of Ontario Institute of Technology, 2000 Simcoe Street North, Oshawa, ON L1H 7K4, Canada; and Mark Tibbett, PhD, Centre for Land Rehabilitation, School of Earth and Geographical Sciences, Faculty of Natural and Agricultural Sciences, University of Western Australia, 35 Stirling Highway, Nedlands, Perth, Western Australia 6009, Australia</i>	301

Ndrangheta' Homicide (Executions)!	<i>Cristoforo Pomara, MD, Department of Forensic Pathology, University of Foggia, Ospedali Riuniti, via L. Pinto 1, Foggia, 71100, Italy; Floriana Monciotti, MD, Department of Forensic Pathology, University of Siena, Policlinico Le Scotte, Siena, 53100, Italy; and Marianna Di Padua, MD, and Carmela Fiore, MD, Department of Forensic Pathology, University of Foggia, Ospedali Riuniti, via L.Pinto 1, Foggia, 71100, Italy</i>	302
Pig-Mentation: Postmortem Iris Color Change in the Eyes of Sus Scrofa	<i>Elizabeth J. Abraham, MA, MSc*, University Health Network, MedWest, 750 Dundas Street West, 2nd Floor, Suite 279, Toronto, Ontario M6J 3S3, Canada; Margaret Cox, PhD, Inforce Foundation, Melbury House, 1-3 Oxford Road, Bournemouth, Dorset BH8 8ES, United Kingdom; and David Quincey, MSc, Bournemouth University, Institute of Health and Community Studies, Royal London House, 1st Floor, Christchurch Road, Bournemouth, Dorset BH1 3LH, United Kingdom</i>	302
Child and Adolescent Victims in Forensic Autopsy: A Five Year Retrospective Study	<i>Anny Sauvageau, MD*, and Stéphanie Racette, BSc, Laboratoire de Sciences Judiciaires ET de Médecine Légale, 1701, Parthenais Street, 12th Floor, Montreal, Quebec H2K 3S7, Canada</i>	303
Hemoglobin SC Disease Presenting as Sickle Crisis After Outpatient Surgery: A Case Report	<i>Wendy A. Lavezzi, MD*, and Mitra B. Kalekar, MD, Cook County Medical Examiner's Office, 2121 West Harrison Street, Chicago, IL 60612</i>	303
Hola Camp Massacre Kenya 1959	<i>Maurice G. Rogev, MB ChB, MD*, Zamenhof St.11/1, Tel-Aviv-Jafo, 64373, Israel</i>	304
Comparison of Wound Severity Between Center-Fire Rifle Projectiles and Shotgun Slugs	<i>Jennifer H. Park, DO*, Miami Dade County Medical Examiner Department, 1851 NW 10th Avenue, Miami, FL 33136-1133; and Richard C. Harruff, MD, PhD, King County Medical Examiner's Office, 325 Ninth Avenue, HMC, Box 359792, Seattle, WA 98104</i>	304
A Comparison of Penetration Distances for Five Ballistic Gelatins to a BB Gunshot Wound to a Live Human Forearm	<i>David J. Porta, PhD*, Drew H. Duerson, and Bill Tietjen, PhD, Bellarmine University, Department of Biology, 2001 Newburg Road, Louisville, KY 40205; and Tyler A. Kress, PhD, BEST Engineering, 2312 Craig Cove Road, Knoxville, TN 37919</i>	305
Suicidal and Homicidal Sharp Force Injury: A Five Year Retrospective Comparative Study of Hesitation Marks and Defense Wounds	<i>Stéphanie Racette, BSc*, Célia Kremer, MSc, and Anny Sauvageau, MD, Laboratoire de Sciences Judiciaires et de Médecine Légale, 1701, Parthenais Street, 12th floor, Montreal, Quebec H2K 3S7, Canada</i>	305
Estimation of Postmortem Interval Using Bioelectrical Impedance of the Human Body	<i>Beat Horisberger, MD*, and Patrice Mangin, MD, PhD, Institute of Legal Medicine, University of Lausanne, 21, Rue du Bugnon, Lausanne, CH-1005, Switzerland</i>	306
Postmortem Skeletal Survey Use in Pediatric Forensic Autopsies: A National Survey	<i>Antoinette L. Laskey, MD, MPH, Children's Health Services Research, Indiana University School of Medicine, The Regenstrief Institute for Health Care, 1001 West 10th Street, Bryce 2112, Indianapolis, IN 46202; and Michele J. Catellier, MD*, Forensic Pathology Associates of Indiana, LLC, 521 West McCarty Street, Indianapolis, IN 46225</i>	306

Near Miss Incidents in Police Custody Suites in London, UK: A One Year Prospective Study	<i>Jason Payne-James, MBBS*, Forensic Healthcare Services Ltd., 19 Speldhurst Road, London, E97EH, United Kingdom; Rebecca Teers, BA, Independent Police Complaints Commission, 90 High Holborn, London, WC1V 6BH, United Kingdom; Stefania Menin, MSc, Independent Police Complaints Commission, 90 High Holborn, London, WC1V 6BH, United Kingdom; and Margaret Stark, LLM, MBBS, Forensic Medicine Unit, St. George's Hospital, London, SW12, United Kingdom</i>	307
Probability and Pathological Findings in Suicidal Versus Homicidal Hanging Deaths: A Case Study in Forensic Epidemiology	<i>Michael D. Freeman, PhD*, Oregon Health and Science University School of Medicine, 205 Liberty Street, Northeast, Suite B, Salem, OR 97301</i>	308
Accuracy of Death Certification and Medical Examiner Notification in Nova Scotia	<i>Kelly A. Dakin Hache, MD, PhD, Anatomical Pathology, Dalhousie University, 5788 University Avenue, Halifax, Nova Scotia B3H 2Y9, Canada; Petra A. Rahaman*, Forensic Science-Biology, University of Toronto, 107 Linnsmore Crescent, Toronto, Ontario M4J 4K5, Canada; and Matthew J. Bowes, MD, Nova Scotia Medical Examiner Service, 5670 Spring Garden Road, Suite 701, Halifax, Nova Scotia B3J 1H7, Canada</i>	308
Comparative Analysis of Medical Examiner and Coroner Systems of Medicolegal Death Investigation: Is There a Bias Toward Manner of Death?	<i>Michael J. Caplan, MD*, and Bamidele Adeagbo, MD*, Medical University of South Carolina, Department of Pathology and Laboratory Medicine, Suite 309, 165 Ashley Avenue, Charleston, SC 29425</i>	309
Preliminary Findings of the Bureau of Justice Statistics 2005 Census of Medical Examiner and Coroner Offices	<i>Matthew J. Hickman, PhD, and Kristen A. Hughes, MA, U.S. Department of Justice, Bureau of Justice Statistics, 810 7th Street NW, Washington, DC 20531; and Jeri D. Ropero-Miller, PhD*, and Kevin J. Strom, PhD, RTI International, 3040 Cornwallis Road, Research Triangle Park, NC 27709</i>	310
Pituitary Macroadenoma Presenting as Hypothermia: A Case Report	<i>Michelle A. Jorden, MD*, Adrienne Segovia, MD, and Edmund R. Donoghue, MD, Cook County Medical Examiner's Office, 2121 West Harrison Street, Chicago, IL 60647</i>	310
Diatoms and Their Forensic Significance	<i>Ismail M. Sebetan, MD, PhD*, and Irelise C. Clendenin, MFS, National University, 11255 North Torrey Pines Road, La Jolla, CA 92037</i>	311
Evaluation of NT-proBNP as Marker of Heart Failure in Postmortem Examination	<i>Katarzyna Michaud, MD*, and Marc Augsburger, PhD, Institut Universitaire de Médecine Légale, Bugnon 21, Lausanne, 1005, Switzerland; Nicolas Donzé, Consilia, Grand Champsec86, Sion, 1950, Switzerland; and Marc Bollmann, MD, Béat Horisberger, MD, Bettina Schrag, MD, and Patrice Mangin, PhD, Institut Universitaire de Médecine Légale, Bugnon 21, Lausanne, 1005, Switzerland</i>	311
An Unusual Case of Sudden Death	<i>Luisa F. Florez, MD*, Baylor College of Medicine, One Baylor Plaza, Houston, TX 770303; Mary Anzalone, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054; and Carolina Gutierrez, MD, and Mario Cervantes, MD, Baylor College of Medicine, One Baylor Plaza, Houston, TX 77030; Kathy Haden-Pinneri, MD, Maximillian Buja, MD, and Luis A. Sanchez, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	312

Use of Beta-APP Stain in a Case of Fatal Dog Attack	<i>Paul L. Morrow, MD*, and Michael Rodriguez, MBBS, Department of Forensic Medicine, 42-50 Parramatta Road, Glebe, New South Wales 2037, Australia</i>	312
The Postmortem Diagnosis of Diabetic Coma	<i>Jørgen L. Thomsen, DMJ*, and Peter M. Leth, PhD, University of Southern Denmark, Winsløwparken 17, Odense, DK-5000, Denmark</i>	313
Forensic Diaphanoscopy Imaging: A New Tool in Clinical Forensic Medicine	<i>Beat Horisberger, MD*, University of Lausanne, Institute of Legal Medicine, 21 Rue du Bugnon, Lausanne, CH-1005, Switzerland; Sébastien Tanniger, School of Business and Engineering Vaud, HEIG-VD, 1 Route de Cheseaux, Yverdon-les-Bains, CH-1401, Switzerland; and Patrice Mangin, MD, PhD, University of Lausanne, Institute of Legal Medicine, 21 Rue du Bugnon, Lausanne, CH-1005, Switzerland</i>	313
“Drop Dead”: An Epidemic of Intravenous Fentanyl Deaths in Cook County, Illinois: 2005 to Present	<i>J. Scott Denton, MD*, Edmund R. Donoghue, MD, Mitra B. Kalekar, MD, and Nancy Wu Chen, PhD, Cook County Medical Examiner’s Office, 2121 West Harrison Street, Chicago, IL 60612-3705</i>	314
Bidding for Poison: The New Availability of Poisons and How to Use Them	<i>Rebecca A. Irvine, MD*, University of New Mexico, Office of the Medical Investigator, MSC 11 6030, University of New Mexico, Albuquerque, NM 87131-0001</i>	315
Cluster of Fentanyl-Tainted Heroin Deaths in a Three-Week Period in Maryland	<i>Mary G. Ripple, MS, MD*, Barry S. Levine, PhD, and Rebecca Jufer-Phipps, PhD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201; Erin Artigiani, Center for Drug Abuse Research, 4321 Hartwick Road, Suite 501, College Park, MD 20742; Suzanne Doyon, MD, Maryland Poison Center, 20 North Pine Street, Baltimore, MD 21201; and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	315
Suicidal Caffeine Overdose	<i>Wendy M. Gunther, MD*, Tidewater District Office of the Chief Medical Examiner, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510; Connie M. Luckie, PhD, Department of Forensic Sciences, Commonwealth of Virginia, 830 Southampton Avenue, Suite 400, Norfolk, VA 23510; and Karen B. Looman, DO, Tidewater District Office of the Chief Medical Examiner, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510</i>	316
Abuse of Prescription Narcotics: A Look Beyond Prescription Monitoring Programs	<i>Gretchen A. Grisbaum, JD*, Quick & Associates, Inc., 21449 Marion Lane, Suite 6, Mandeville, LA 70471; and Karen Ross, MD, Jefferson Parish Forensic Center, 2018 8th Street, Harvey, LA 70058</i>	316
Murder By Poison: Experiences of a Medical Examiner’s Office	<i>Christopher Swalwell, MD*, Office of the Medical Examiner, 5555 Overland Avenue, Suite 1411, San Diego, CA 92123</i>	317
Vaccine Death: A Rare Case of Anaphylactic Shock After Hexavalent Immunization	<i>Stefano D’Errico, MD*, Francesco Maria Morreale, MD, and Raffaella Bisceglia, MD, Institute of Legal Medicine, University of Foggia, Ospedali Riuniti, via L.Pinto 1, Foggia, 71100, Italy; and Rossi Giuseppina, MD, Institute of Legal Medicine, University of Siena, Policlinico Le Scotte, Siena, 53100, Italy</i>	317

Pattern of Injury in Child Fatalities Resulting from Child Abuse	<i>Ann H. Ross, PhD, North Carolina State University, Department of Sociology and Anthropology, CB 8107, Raleigh, NC 27695-8107; Suzanne M. Abel, PhD, Charleston County Coroner's Office, 4050 Bridgeview Drive, North Charleston, SC 29405; Deborah Radisch, MD, MPH, Office of the Chief Medical Examiner, CB 7580, Chapel Hill, NC 27599-7580; Beth Murnane, MD, Sunrise Pediatric Associates, 3909 Sunset Ridge Road, Suite 103, Raleigh, NC 27607; and Sheena Harris, BA, and Kelsie Ballance, North Carolina State University, Department of Sociology and Anthropology, CB 8107, Raleigh, NC 27695-8107</i>	318
Histopathology of Antemortem Infant Bone Fractures: Estimation of Time Since Insult	<i>Murray K. Marks, PhD*, University of Tennessee, Department of Anthropology, 250 South Stadium Hall, Knoxville, TN 37996-0720; and Darinka X. Mileusnic, MD, PhD, Regional Forensic Center, University of Tennessee Medical Center, 1924 Alcoa Highway, Knoxville, TN 37920</i>	319
The Likelihood of Inflicted Injury Is Better Evaluated by the Use of Inconsistent Histories With the Constellation of the Triad of Findings: Subdural Hemorrhage, Brain Swelling, and Retinal Hemorrhages	<i>M.G.F. Gilliland, MD*, Brody SOM at ECU, Department Pathology and Laboratory Medicine, Brody 7 S 10, Greenville, NC 27858</i>	319
Compressive Asphyxia Due to Prone Restraint Hold in a Child	<i>Robert F. Corliss, MD*, Andrew M. Baker, MD, and Kathryn K. Berg, MD, Hennepin County Medical Examiner's Office, 530 Chicago Avenue, Minneapolis, MN 55415</i>	320
Combined Types of Violence in Child Abuse: Report of Three Cases	<i>Wendy M. Gunther, MD*, Leah L. Bush, MD, Elizabeth L. Kinnison, MD, Department of Legal Medicine, Virginia Commonwealth University, Medical College of Virginia, Tidewater Office of the Chief Medical Examiner, Commonwealth of Virginia, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046; and Karen B. Looman, DO, Tidewater Office of the Chief Medical Examiner, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510</i>	320
Brainstem Axonal Injury and Retinal Hemorrhages as a Substrate for Sudden Death in Second Impact Syndrome: A Case Report	<i>Rudy J. Castellani, MD*, University of Maryland, Baltimore, 22 South Greene Street, NBW-81, Baltimore, MD 21201; and Joyce L. deJong, DO, Division of Forensic Pathology, Sparrow Health System, 1215 East Michigan Avenue, Lansing, MI 48912</i>	321
Sexual Abuse: Hymenal Findings in Girls With a History of Vaginal Penetration	<i>Annie Vesterby, MD, DMSc*, and Lene A. Hansen, MD, Institute of Forensic Medicine, University of Aarhus, Peter Sabroes Gade 15, Aarhus C, 8000, Denmark; and Svend Sabroe, MD, Institute of Public Health, Dept. of Epidemiology, University of Aarhus, Vennerlyst Boulevard 6, Aarhus C, 8000, Denmark</i>	322
A Chest Full of Blood: Hemothorax as a 26 Year Delayed Consequence of Repair of Transposition of the Great Vessels	<i>Karen B. Looman, DO*, and Wendy M. Gunther, MD, Tidewater Office of the Chief Medical Examiner, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510</i>	322
Suicidal Hanging of a Postpartum Woman Who Discontinued Anti-Depressant Medication During Pregnancy	<i>Gregory L. Hess, MD*, Jeffery M. Jentzen, MD, and Russell T. Alexander, MD, Milwaukee County Medical Examiner Office, 933 West Highland Avenue, Milwaukee, Wisconsin 53233</i>	323

A Simple Model for Teaching Postmortem Monocular Indirect Ophthalmoscopy	<i>Terrill L. Tops, MD*, and Patrick E. Lantz, MD, Wake Forest University Health Sciences, Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157</i>	323
A Case of Fatal Water Intoxication in a Toddler	<i>Nadia L. Krupp, MD, Indiana University School of Medicine, 702 Barnhill Drive, Indianapolis, IN 46202; Michele J. Catellier, MD*, Forensic Pathology Associates of Indiana, LLC, 521 West McCarty Street, Indianapolis, IN 46225; and Antoinette L. Laskey, MD, MPh, Indiana University School of Medicine, 702 Barnhill Drive, Indianapolis, IN 46202</i>	324

2006		
Otologic Injury as a Consequence of Blast Trauma; Evaluated by Postmortem Otoscopic and Computed Tomography Examination	<i>Carol J. Solomon, MS, MD*, Louis N. Finelli, DO, and John M. Getz, BS, Office of the Armed Forces Medical Examiner, 1413 Research Boulevard, Building 102, Rockville, MD 20850</i>	325
Natural Central Nervous System (CNS) Causes of Death: A Ten Year Retrospective Review (1994-2003)	<i>Gregory L. Hess, MD*, University of Arizona Health Sciences Center, 1501 North Campbell Avenue, PO Box 245108, Tucson, AZ 85724-5108; and David C. Winston, MD, PhD, Pima County Forensic Science Center, 2825 East District Street, Tucson, AZ 85714</i>	325
Frequency of Cases of Fatal Gunshot Wound Victims With Retained "Old" Projectiles From Previous Penetrating Gunshot Wounds	<i>Daniel W. Dye, MD*, University of Arkansas for Medical Sciences, 4301 W Markham, Slot 517, Little Rock, AR 72205; and Charles P. Kokes, MD, Arkansas State Crime Laboratory, #3 Natural Resources Drive, PO Box 8500, Little Rock, AR 72215</i>	325
Small Cell Carcinoma of the Lung Contributing to Pulmonary Barotrauma With Air Embolism in a Recreational Diver: A Case Report	<i>Carl W. Wigren, MD*, and J. Matthew Lacy, MD, King County Medical Examiner's Office, 325 Ninth Avenue, HMC Box 359792, Seattle, WA 98104</i>	326
Serum Levels of Pulmonary Surfactant Associated Proteins A and D (SP-A & SP-D) in Some Causes of Death	<i>M. Essam E. El-Sheikh, MD, PhD*, and Taisseur M. Mostafa, MD, PhD, Farwania, PO Box 1747, Kuwait, 1747, Kuwait</i>	326
Gliomatosis Cerebri as a Cause of Sudden Death in a Young Woman	<i>Timothy L. Williams, MD*, and William F. Hickey, MD, Dartmouth- Hitchcock Medical Center, Department of Pathology, One Medical Center Drive, Lebanon, NH 03756; and Thomas Andrew, MD, Office of the Chief Medical Examiner, 246 Pleasant Street, Concord, NH 03301</i>	327
Death in a Confined Space	<i>Nunzio Di Nunno, MD, PhD*, Universita' di Lecce, Via G. Dorso n. 9, Bari, 70125, Italy; Francesco Vimercati, MD, Universita' di Bari, Sezione di Medicina Legale, Piazza G. Cesare n. 11, Bari, 70125, Italy; Fulvio Costantinides, MD, Universita' di Trieste, P.zza Ospedale, Trieste, 34100, Italy; and Sandra Cornetta, MD, and Di Nunno Cosimo, MD, Universita' di Bari, Sezione di Medicina Legale, Piazza G. Cesare n. 11, Bari, 70125, Italy</i>	327
Primary Hyperoxaluria: A Case Report and Review of the Literature	<i>Julia M. Braza, MD and Karoly Balogh, MD, Beth Israel Deaconess Medical Center, Pathology Department, 330 Brookline Avenue, Boston, MA 02215</i>	328
Planned Complex Suicide: Report of Two Cases	<i>Cristian Palmiere, MD, Institut Universitaire de Médecine Légale, 9 Avenue de Champel, Genève, 1211, Switzerland; Francesco Ventura, MD, and Daniela Picchioni, MD, Dipartimento di Medicina Legale, Via de Toni 12, Genova, 16132, Italy; and Maria del Mar Lesta, MD, and Romano La Harpe, MD*, Institut Universitaire de Médecine Légale, 9 Avenue de Champel, Genève, 1211, Switzerland</i>	329
Effect of Toilet Detergent on Morphological Change of Spermatozoa	<i>Jian Tie, MD, PhD*, Yuka Serizawa, BS, and Shigemi Oshida, MD, PhD, Department of Legal Medicine, Nihon University School of Medicine, 30- 1 Oyaguchi Kamimachi, Itabashi-Ku, Tokyo 173-8610, Japan</i>	329
An Unusual Death of a Child at the Obstetrician's Office	<i>Albert Y. Chu, MD*, and Luis A. Sanchez, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	330

Methadone Treatment and Drug Overdose in Geneva, Switzerland, From 1994 to 2003	<i>Guillaume Perret, MD*, Institut Universitaire de Medecine Legale de Geneve, 9 av. de Champel, CMU, Geneva, 1211, Switzerland; Ann Ho, PhD, and Mary Jeanne Kreek, MD, Laboratory of the Biology of Addictive Diseases, Rockefeller University, 1320 York Avenue, New York, NY 10021; and Romano La Harpe, MD, Institut Universitaire de Medecine Legale de Geneve, CMU, 9 av. de Champel, Geneva, 1211, Switzerland</i>	330
Pathological Changes Associated With Aortic Valve Stenosis	<i>Lise A.M. Matzke, MSc*, and Courtney Young, BSc*, James C Hogg iCAPTURE Centre, Room 166, 1081 Burrard Street, Vancouver, BC V6Z 1Y6, Canada</i>	331
Fatal CO₂ Suicidal Poisoning	<i>Gilles Tournel, MD*, Fabrice Dedouit, MD, Anne Becart-Robert, DDS, PhD, Pierre Dutrieux, MD, Valéry Hedouin, MD, PhD, and Didier Gosset, MD, PhD, Institut de Médecine Légale, Faculté de Médecine, 1, place de Verdun, Lille, 59000, France</i>	331
Case Report – Sudden Death Due to Cystic Tumor of the Atrioventricular Node	<i>Carlos F. Chavez Arias, MD*, Kathryn Haden-Pinneri, MD, Maximiliam Buja, MD, and Luis A. Sanchez, MD, Harris County Medical Examiner's Office, Joseph J. Jachimcyzk Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054</i>	332
Sudden Death in a Healthy 37-Year-Old Man While Driving: Spontaneous Dissection of the Posterior Segment of the Right Coronary Artery	<i>Wendy M. Gunther, MD*, Department of Legal Medicine, Virginia Commonwealth University, Medical College of Virginia, 1101 E Marshall Street, Richmond, VA 23298-0568; and Jonrika M. Malone, MD, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046</i>	332
Fibrosis of the Cardiac Conduction System as a Possible Cause of Death in Chronic Cocaine Addicts	<i>Katarzyna Michaud, MD*, Thomas Krompecher, MD, Frank Sporkert, PhD, Franco Taroni, PhD, Béat Horisberger, MD, Marc Augsburger, PhD, and Patrice Mangin, MD, PhD, Institut Universitaire de Médecine Légale, Bugnon 21, Lausanne, 1005, Switzerland</i>	333
Fatal Venous Air Embolism in a Postmenopausal Female During Consensual Sexual Intercourse: A Case Report and Review of the Literature	<i>Erik D. Christensen, MD*, Office of the Greenville County Medical Examiner, 890 West Faris Road, Suite 110, Greenville, SC 29605</i>	333
Incidence of Laryngeal and Hyoid Fractures in Hangings and Strangulations Using Enhanced Examination Procedures	<i>Dana Austin, PhD, and Marc A. Krouse, MD, Tarrant County Medical Examiner, 200 Feliks Gwozd Place, Fort Worth, TX 76104-4919</i>	334
Agonal Sequences in a Filmed Suicidal Hanging: Analysis of Respiratory and Movement Responses to Asphyxia by Hanging	<i>Anny Sauvageau, MD, MSc*, Laboratoire de Sciences Judiciaires et de Médecine Légale, 1701 Parthenais Street, 12th Floor, Montreal, Quebec H2K 3S7, Canada; Stéphanie Racette, BSc, Laboratoire de Sciences Judiciaires et de Médecine Légale, 1701 Parthenais Street, 12th Floor, Montreal, Quebec H2K 3S7, Canada</i>	334
Visual Misidentifications of Human Remains: Lessons Learned	<i>Joyce L. deJong, DO*, Sparrow Hospital, 1215 East Michigan Avenue, Lansing, MI 48909-7980</i>	335

Identifying Corpses of Foreigners in the State of Advanced Decomposition: Sri Lanka After the Tsunami 2004	<i>Heike Klotzbach, MD, PhD*, Institute of Legal Medicine, Stiftsplatz 12, Bonn, 53111, Germany; Klaus Benedix, DMD, Dental Services German Air Forces, Dachauer Strasse 128, München, Bavaria 80637, Germany; Guido Beutler, Embassy of the Federal Republic of Germany, 6/50 Shantipath, Chanakyapuri, New Delhi, 110 021, India; and Thomas Lubnau, and Kerstin Schneider, Federal Criminal Police Office, Georg- Marshall-Strasse 20, Wiesbaden, 65173, Germany; Stephan Klein, Federal Criminal Police Office, Georg-Marshall-Strasse 20, Wiesbaden, 65173, Germany</i>	336
Mass Disaster Victim Identification: The Tsunami Disaster	<i>Sawai Kanluen, MD*, Chulalongkorn University, Department of Forensic Sciences, 254 Phayathai Road, Patumwan, Bangkok 10330, Thailand; and Tony Kanluen, MD, Henry Ford Hospital, Department of Emergency Medicine, 2799 W Grand Boulevard, Detroit, MI 48202</i>	336
Victim Trauma as an Identification Tool in Mass Disasters	<i>Maurice G. Rogev, MD, MBChB*, 11/1 Zamenhof Street, Tel-Aviv-Jaffa, 64373, Israel</i>	337
Differential Diagnosis: Antemortem vs. Postmortem Bone Trauma	<i>Nermin Sarajlic, MD, PhD*, International Commission on Missing Persons, Alipasina 45A, Sarajevo, 71000, Bosnia and Herzegovina; John Clark, MRCPPath, University of Glasgow, Joseph Black Building, Glasgow, Scotland G12 8QH, UK; and Eva-Elvira Klonowski, PhD, International Commission on Missing Persons, Alipasina 45A, Sarajevo, 71000, Bosnia and Herzegovina</i>	337
Personal Identification by Morphometric Analyses of Retinal Vascular Pattern	<i>Francesco Intronà, MD, PhD*, and Antonio De Donno, MD, Section of Legal Medicine (Di.M.I.M.P.), University of Bari, P.zza Giulio Cesare n.11, Bari, 70124, Italy; Carlo Sborgia, MD, and Francesco Boscia, MD, Section of Ophthalmology, University of Bari, P.zza Giulio Cesare n.11, Bari, 70124, Italy; Giuseppe Mastronardi, PhD, Electronic and Electrotechnic DPT, Via Orabona n.4, Bari, Bari, Italy; and Francesca Bellomo, MD, and Domenico Urso, MD, Section of Legal Medicine (Di.M.I.M.P.), University of Bari, P.zza Giulio Cesare n.11, Bari, 70124, Italy</i>	338
Laryngeal Nerve Iatrogenic Lesions	<i>Luigi Viola, MD*, Marina Albano, MD, Francesco Vimercati, MD, and Nunzio Di Nunno, MD, PhD, Università di Lecce, Via G. Dorso n. 9, Bari, 70125, Italy</i>	338
Electrocution by Arcing: A Non Fatal Case Study	<i>Biagio Solarino, MD*, Giancarlo Di Vella, MD, PhD, and Alessandra Arpaio, MD, Sezione di Medicina Legale - Di.M.I.M.P., Università degli Studi di Bari - Policlinico, Bari, 70125, Italy</i>	339
Abrasion or Gunshot Wound? The Primary Role of Forensic Pathologist	<i>Giancarlo Di Vella, MD, PhD*, and Biagio Solarino, MD, Sezione di Medicina Legale - Di.M.I.M.P., Università degli Studi di Bari - Policlinico, Bari, 70125, Italy</i>	339
Sudden Death in Toddlers Due To Influenza B Infection: A Report of Two Cases and a Review of the Literature	<i>Kristen Landi, MD*, and Andrea Coleman, MD, Office of the Chief Medical Examiner, 520 First Avenue, New York, NY 10016</i>	340

Neuropathology of Pre-Teen Homicides in the State of Maryland: 1994-2004	<i>Ana Rubio, MD, PhD*, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Miguel A. Riudavets, MD, Department of Pathology (Neuropathology), Johns Hopkins University School of Medicine, Baltimore, MD 21201; Ling Li, MD, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Christopher Cox, PhD, Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD 21201; David Reisz, BA, and David R. Fowler, MD, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; and Juan C. Troncoso, MD, Department of Pathology (Neuropathology), Johns Hopkins University School of Medicine, Baltimore, MD 21201</i>	341
Transplacental Intrauterine Herpes Simplex Virus Infection Resulting in Cutaneous Calcifications in an Infant	<i>Sam D. Simmons, MD, MBA*, Ashley O'Bannon, MD, and Subodh Lele, MD, University of Kentucky, Department of Pathology and Lab Medicine, 800 Rose Street, MS 117, Lexington, KY 40504</i>	341
Killer Hairdryer	<i>Francesco Introna, MD, PhD, Section of Legal Medicine (Di.M.I.M.P.), University of Bari, Policlinico - P.zza Giulio Cesare, 11, Bari, 70124, Italy; Simona Corrado, MD*, Section of Legal Medicine (Di.M.I.M.P.), Bari University, Policlinico - Piazza G. Cesare, 11, Bari, 70124, Italy; and Vittantonio Amoruso, Dipartimento di Elettrotecnica ed Elettronica, Politecnico di Bari, Via Orabona, 4, Bari, 70125, Italy</i>	342
Pyelonephritis—Sudden and Unexpected Death in Infancy	<i>Cristin M. Rolf, MD*, University of Kentucky, Office of the Associate Chief Medical Examiner, 100 Sower Boulevard, Suite 202, Frankfort, KY 40601-8272; and Bonnie Mitchell, MD, University of Kentucky, Department of Pathology and Laboratory Medicine, 800 Rose Street, UKMC MS 117, Lexington, KY 40536-0298</i>	343
Necrotizing Fasciitis: Manifestations, Microbiology and Connection With Black Tar Heroin	<i>Nancy M. Dunbar, BA*, Carl Wigren, MD, and Richard C. Harruff, MD, PhD, King County Medical Examiner's Office, HMC Box 359792, 325 Ninth Avenue, Seattle, WA 98104</i>	343
Was the Shawnee War Chief Blue Jacket a Caucasian?	<i>Carolyn Rowland, MS*, Forensic Bioinformatic Services, Inc., 2850 Presidential Drive, Suite 150, Fairborn, OH 45371; Dan E. Krane, PhD, Wright State University, Department of Biological Sciences, 2640 Colonel Glenn Highway, Dayton, OH 43435; Marc S. Taylor, MS, Technical Associates, Inc., 4125 Market Street, Suite 3, Ventura, CA 93003; and Robert Van Trees, BA, 589 Westwood Drive, Fairborn, OH 45324</i>	344
Using Multiplexed Microsatellite Markers of Cannabis sativa to Determine Genetic Diversity	<i>Maria Angelica Mendoza, MS*, Heather Erek, BS*, and José R. Almirall, PhD, 11200 SW 8th Street, CP194, Miami, FL 33199</i>	344
Co-Amplification of Cytochrome B and D-loop mtDNA Fragments for More Reliable Species Identifications	<i>Dongya Yang, PhD*, Department of Archaeology, Simon Fraser University, 8888 University Drive, Burnaby, BC V5A 1S6, Canada; and Speller Camilla, MA, Department of Archaeology, Simon Fraser University, 8888 University Drive, Burnaby, BC V5A 1S6, Canada</i>	345

Sternal Shard From Bystander Bullet: A Rare Mechanism of Homicide	<i>Wendy M. Gunther, MD*, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510</i>	345
False Positive Diagnosis of Subarachnoid Hemorrhage and Subdural Hemorrhage by Computerized Tomography	<i>Sangeeta Sandhu, MD*, St. Luke's-Roosevelt Hospital, 515 West 59 Street, #4K, New York, NY 10019; Stephen deRoux, MD, and Beverly Leffers, MD, Office of Chief Medical Examiner (Brooklyn), 520 First Avenue, New York, NY 10016-6402; and Thomas Gilson, MD, Office of Chief Medical Examiner (Manhattan), 520 First Avenue, New York, NY 10016-6402</i>	346
TASER-Related Fatalities: Case Report and Review of the Literature	<i>Amy T. Sheil, MD*, and Kim A. Collins, MD, Medical University of South Carolina, Department of Medical and Forensic Autopsy, 165 Ashley Avenue, Suite 309, Charleston, SC 29425</i>	346
A Demographic Analysis of Youth and Teen Suicide in Maryland (1994-2003)	<i>Melissa A. Brassell, MD*, Carol H. Allan, MD, Mary G. Ripple, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	347
Effectiveness of Death Investigation in Cases of Potential Elder Abuse	<i>Diane C. Peterson, MD*, and Richard E. Powers, MD, P220 West Pavilion, Department of Pathology, 619 19th Street South, Birmingham, AL 35233; James N. Robinson, BA, University of Alabama at Birmingham Medical School, VH P-100, 1530 3rd Avenue South, Birmingham, AL 35294; and Gregory G. Davis, MD, Jefferson County Coroner/Medical Examiner Office, 1515 Sixth Avenue South, Room 611, Birmingham, AL 35233-1601</i>	347
Use of CT as an Aid in the Recovery of Metallic Foreign Bodies at Autopsy	<i>Edward A. Reedy, PhD, MD*, John M. Getz, PhD, Lisa Pearse, MD, Craig T. Mallak, MD, JD, and James L. Caruso, MD, Armed Forces Medical Examiner System, 1413 Research Boulevard, Building 102, Rockville, MD 20850</i>	348
Antemortem and Postmortem Toxicological Findings in Motor Vehicle Accidents, Maryland (2003-2004): Does Impairment Equal Death?	<i>Sunil K. Prashar, MD*, State of Maryland, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Jami L. Grant, PhD, University of Baltimore, 1420 North Charles Street, Baltimore, MD 21201; Susan R. Hogan, MD, David R. Fowler, MD, and Mary G. Ripple, MD, State of Maryland, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; and Mary E. Kramer, RN, R. Adams Cowley Shock Trauma Center, 22 S Greene Street, Baltimore, MD 21201</i>	348
Descriptive Study on the Causes of Death of Residents of Boarding Homes	<i>Andrea L. Dickens, MD*, and Richard E. Powers, MD, P220 West Pavilion, Department of Pathology, 619 19th Street South, Birmingham, AL 35233; James N. Robinson, BA, University of Alabama at Birmingham Medical School, VH P-100, 1530 3rd Avenue South, Birmingham, AL 35294; and Gregory G. Davis, MD, Jefferson County Coroner/Medical Examiner Office, 1515 Sixth Avenue South, Room 611, Birmingham, AL 35233-1601</i>	349
The Death of an Italian Soldier in Iraq: Murder or Fatality?	<i>Margherita Neri, MD*, Marianna Di Padua, MD, Cristoforo Pomara, MD, and Emanuela Turillazzi, MD, PhD, Department of Forensic Pathology, University of Foggia, Viale Pinto 1, Foggia, 71100, Italy</i>	349

Prevention of Accidental Strangulation of Children in Their Sleeping Bags: Development of a New Sleeping Bag	<i>Kathrin Gerlach, MD*, Department of Legal Medicine, Pestalozzistrasse 22, Basel, 4056, Switzerland; Beat Horisberger, MD, Department of Legal Medicine, Rue du Bugnon 2, CH-1005 Lausanne, Switzerland, Walter Bar, MD, Department of Legal Medicine, Winterthurerstrasse 190, CH-8091 Zürich, Switzerland; and Volker Dittmann, MD, and Daniel Wyler, MD, Department of Legal Medicine, Pestalozzistrasse 22, CH- 4056 Basel, Switzerland</i>	350
VIRTOPSY (Virtual Autopsy) - Past, Present, and Future	<i>Michael J. Thali, MD*, University of Berne, Institut Forensic Science, Buehlstrasse 20, Bern, Switzerland; Peter Vock, MD, University of Berne, Radiology Department, Berne, 3005, Switzerland; and Richard Dirnhofer, MD, University of Berne, Institut of Forensic Medicine, Berne, Berne 3012, Switzerland</i>	350
Professional Quality in a Forensic Medical Setting: The Singapore Experience	<i>Paul P.S. Chui, MBBS, DMJ, MBA*, and Clarence T. Tan, MBBS, Health Sciences Authority, 11 Outram Road, Singapore, 169078, Singapore</i>	351
Insects of the Grave: A Cold Case History Involving Insects 27 Years After Death	<i>Richard W. Merritt, PhD*, Michigan State University, Department of Entomology, 243 National Science Building, East Lansing, MI 48824; Mark E. Benbow, PhD, Department of Biology, DePauw University, Greencastle, IN 46135; Ryan K. Kimbirauskas, MS, Michigan State University, Department of Entomology, East Lansing, MI 48824; Joyce L. deJong, DO, Sparrow Hospital, 1215 East Michigan Avenue, Lansing, MI 48909; and Richard Snider, PhD, Michigan State University, Department of Zoology, East Lansing, MI 48824</i>	351
Seasonal Effects on Blow Fly Species Composition and Behavior	<i>Jennifer Y. Rosati, BSc*, and Sherah L. VanLaerhoven, PhD, University of Windsor, Rm 119 Bio, 401 Sunset Avenue, Windsor, Ontario N9B 3P4, Canada</i>	352
Improving Postmortem Interval Estimates in Forensic Entomology: Blowfly Gene Expression and Development	<i>Aaron M. Tarone, BS*, Department of Zoology, 203 Natural Sciences Building, Michigan State University, East Lansing, MI 48824; and Kimberly C. Jennings, BS, and David R. Foran, PhD, School of Criminal Justice, 560 Baker Hall, Michigan State University, East Lansing, MI 48824</i>	352
The Developmental Studies of The Green Bottle Fly, <i>Phaenicia coeruleiviridis</i> (Diptera: Calliphoridae)	<i>Kc L. Deaver, MS*, 2704 72nd Avenue, SE, Mercer Island, WA 98040; and Jerry Cook, PhD, Sam Houston State University, Department of Biological Sciences, 300 Lee Drain, Box 2116, Huntsville, TX 77341</i>	352
Effects of Fluctuating Temperature and Larval Density on <i>Calliphora dubia</i> (Diptera: Calliphoridae) Implications for Postmortem Interval Estimation	<i>Ian Dadour, PhD*, and Sasha Voss, BSc, University of Western Australia, Centre for Forensic Science, 35 Stirling Highway, Nedlands, 6009, Australia</i>	353
The Composition and Succession of Soil Microbial Communities Following Cadaver (<i>Rattus rattus L.</i>) Burial	<i>David O. Carter, PhD*, Department of Plant Pathology, University of Nebraska-Lincoln, 406 Plant Sciences Hall, Lincoln, NE 68583-0722; David Yellowlees, PhD, School of Pharmacy and Molecular Sciences, James Cook University, Douglas, QLD 4811, Australia; and Mark Tibbett, PhD, School of Earth and Geographical Sciences, University of Western Australia, Crawley, WA 6009, Australia</i>	353

Nematode Community Dynamics Associated With Cadaver (<i>Sus scrofa L.</i>) Decomposition and Insect Activity on the Soil Surface	<i>David O. Carter, PhD*, Department of Plant Pathology, University of Nebraska-Lincoln, 406 Plant Sciences Hall, Lincoln, NE 68583-0722; Timothy E. Huntington, MSc, and Leon G. Higley, PhD, Department of Entomology, University of Nebraska-Lincoln, 202 Plant Industry, Lincoln, NE 68583-0816; and Thomas O. Powers, PhD, Department of Plant Pathology, University of Nebraska-Lincoln, 406 Plant Sciences Hall, Lincoln, NE 68583-0722</i>	354
Characterization of Adipocere Formation in Animal Species	<i>Shari L. Forbes, PhD*, University of Ontario Institute of Technology, Faculty of Science, 2000 Simcoe Street, N, Oshawa, Ontario L1H 7K4, Canada; and Barbara H. Stuart, PhD, and Boyd B. Dent, PhD, University of Technology, Sydney, Department of Environmental Sciences, PO Box 123, Broadway, NSW 2007, Australia</i>	354
Maggot Development During Morgue Storage and the Effects on Estimating the Postmortem Interval	<i>Timothy E. Huntington, MS*, Leon G. Higley, PhD, and Frederick P. Baxendale, PhD, University of Nebraska, Department of Entomology, 202 Plant Industry Building, Lincoln, NE 68583</i>	355
An Unusual Postmortem Change in a Child Homicide—Leaching	<i>Paul P.S. Chui, MBBS, DMJ, MBA*, Health Sciences Authority, 11 Outram Road, Singapore, 289160, Singapore</i>	355
Comparison Study of Various Protocols to Release Maximal Amounts of Amplifiable DNA From Decomposed Soft Tissue Exposed to Different Environmental Conditions	<i>Daniel E. Katz, MFS*, Delaware Office of the Chief Medical Examiner, 200 South Adams Street, Wilmington, DE 19801; Timothy McMahon, PhD, Armed Forces DNA Identification Laboratory, 1413 Research Boulevard, Building #101, 2nd Floor, Rockville, MD 20850; Arthur Young, BS, National Medical Services, 3701 Welsh Road, Willow Grove, PA 19090; Rebecca A. Kennedy, Cedar Crest College, 100 College Drive, Allentown, PA 18104; Michelle Malley, MSFS, Armed Forces DNA Identification Laboratory, 1413 Research Boulevard, Building #101, 2nd Floor, Rockville, MD 20850; and Rebecca E. Wallman, BS, MS, Delaware Office of the Chief Medical Examiner, 200 South Adams Street, Wilmington, DE 19801</i>	355
Eagles Syndrome: Case of an Elongated and Ossified Stylohyoid Ligament in an Elderly Female	<i>William C. Rodriguez III, PhD*, Office of the Armed Forces Medical Examiner, 1413 Research Boulevard, Building 102, Rockville, MD 20850; and Jack M. Titus, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201</i>	356
Where is the Head? A Case of Homicidal Decapitation	<i>Sabina Di Donato, MD*, Carmela Fiore, MD, and Emanuela Turillazzi, MD, PhD, Department of Forensic Pathology, University of Foggia, Viale Luigi Pinto, n.1, Foggia, 71100, Italy</i>	357
Simple Tissue Preservation Methods That Result in Reliable DNA Analyses	<i>Corinne L. Michaud, BS*, and David R. Foran, PhD, Forensic Science Program, School of Criminal Justice, 560 Baker Hall, Michigan State University, East Lansing, MI 48824</i>	357
Quantification and Amplification of mtDNA From Chemically Treated Hair	<i>Rayna L. Hebard, BS*, and Bruce R. McCord, PhD, Florida International University, International Forensic Research Institute, 11200 SW 8th Street, Miami, FL 33199; and DeEtta K. Mills, PhD, Florida International University, Forensic DNA Profiling Facility, 11200 SW 8th Street, Miami, FL 33199</i>	358

What is Forensic Informatics?	<i>Gilbert E. Corrigan, MD, PhD*, East Baton Rouge Coroner's Office, 4030 T.B. Herndon Road, Baton Rouge, LA 70808; and Sarah P. Corrigan, MS*, Reliagene Technologies, Inc., 5525 Moues Street, Suite 101, New Orleans, LA 70123</i>	358
Death in Custody: A Historical Analysis	<i>Jami R. Grant, PhD*, University of Baltimore, Forensic Studies, 1420 North Charles Street, Baltimore, MD 21201; Pamela E. Southall, MD*, and David R. Fowler, MD, Maryland State Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; and Shauna R. Scott, University of Baltimore, Forensic Studies, 1420 N Charles Street, Baltimore, MD 21201</i>	359
Simultaneous Diabetic Ketoacidosis and Neuroleptic Malignant Syndrome in a Patient on Olanzapine	<i>Erik D. Christensen*, Office of the Greenville County Medical Examiner, 890 West Faris Road, Suite 110, Greenville, SC 29605</i>	359
An Unusual Case of Child Head Injury by Coat Hanger	<i>Biagio Solarino, MD*, Sezione di Medicina Legale - Di.M.I.M.P. Universita degli Studi di Bari - Policlinico, Bari, 70125, Italy; Amy M. Burrows-Beckham, MD, Office of the Chief Medical Examiner, 810 Barret Avenue, Louisville, KY 40204; and Kathy Recktenwald, RN, Clinical Forensic Medicine, University of Louisville, 810 Barret Avenue, Louisville, KY 40204</i>	360
Adolescent Suicide Trends in the Third Largest County in the United States	<i>Andrea J. Harrison, BSN, RN*, Harris County Medical Examiners Office, 1885 Old Spanish Trail, Houston, TX 77054; Sharon M. Derrick, PhD, Harris County Public Health and Environmental Services, 2223 West Loop South, Houston, TX 77027; and Stacey A. Mitchell, MSN, RN, and Luis A. Sanchez, MD, Harris County Medical Examiners Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	360
Intraspecific Competition in the Blowfly <i>Chrysomya megacephala</i> (Diptera: Calliphoridae) Reared at Different Densities	<i>Sandra Pearson*, Criminal Justice Program, Chaminade University of Honolulu, 3140 Waialae Avenue, Honolulu, HI 96816-1578; and M. Lee Goff, PhD, Chaminade University of Honolulu, 3140 Waialae Avenue, Honolulu, HI 96816-1578</i>	361
Comparison of Early Decomposition Between Domestic Pig Carcasses Hanging and in Contact With the Ground on Oahu Island, Hawaii	<i>Reupena Sheck*, and M. Lee Goff, PhD, Chaminade University of Honolulu, 3140 Waialae Avenue, Honolulu, HI 96816-1578</i>	361
A Preliminary and Pilot Study About Mitochondrial DNA Deletion in Sudden Infant Death Syndrome: An Endemic Study in Taiwan	<i>Tsun-Ying Huang, MS*, Institute of Forensic Medicine, Ministry of Justice, 16, Lane 175, Tong-Hwa Street, Taipei, 106, Taiwan, Republic of China; Chia-Tung Shun, AP, National Taiwan University, College of Medicine, No. 1, Jen Ai Road Section 1, Taipei, 100, Taiwan, Republic of China; Jui-Ming Li, BS, Institute of Forensic Medicine, Ministry of Justice, 16, Lane 175, Tong-Hwa Street, Taipei, 106, Taiwan, Republic of China; and Shu-Huei Kao, PhD, Institute of Biomedical Technology, Taipei Medical University, 250, Wu-Xing Street, Taipei, 110, Taiwan, Republic of China</i>	361

Expression of Heat Shock Protein (hsp) 70 in Tissue of Different Human Organs After Burn Fatalities	<i>Heike Klotzbach, MD, PhD*, and Johanna Preuss, MD, Institute for Legal Medicine, Stiftsplatz 12, Bonn, 53111, Germany; Eberhard Lignitz, MD, PhD, Institute for Legal Medicine, Kuhstrasse 30, Greifswald, 17489, Germany; and Burkhard Madea, MD, PhD, Institute for Legal Medicine, Stiftsplatz 12, Bonn, 53111, Germany</i>	362
“Coca-Cola Man”: Sudden Death in a Jailed Mentally Retarded Man After an Altercation Involving Police	<i>Wendy M. Gunther, MD*, Department of Legal Medicine, Virginia Commonwealth University, Medical College of Virginia, 1101 East Marshall Street, Richmond, VA 23298-0568</i>	362
Estimating Time-of-Death by Body Temperature Analyses - A New Mathematical Strategy	<i>Anthony T. Paganini, PhD*, Michigan State University, A519 East Fee Hall, Division of Anatomy, Department of Radiology, East Lansing, MI 48824; and Thomas Adams, PhD, Michigan State University, Department of Physiology, 2240B Biophysical Sciences Building, East Lansing, MI 48824</i>	363
Photography of Abuse: Is There a Best Method?	<i>Lynette Landon-Chellemi*, PO Box 523, 59-076 Pupukea Road, Haleiwa, HI 96712; and Wilson T. Sullivan III, MPA, Chaminade University of Honolulu, Forensic Science Department, 3140 Waialae Avenue, Honolulu, HI 96816</i>	363
The Cave Man in the 21st Century: Chronicle of an Announced Tragedy: Preventive Measures and Repeating Risk	<i>Cristoforo Pomara, MD*, Stefano D'Errico, MD, Sabina Di Donato, MD, Marianna Di Padua, MD, Francesco M. Morreale, MD, Irene Riezzo, MD, and Margherita Neri, MD, Institute of Forensic Pathology, Foggia University, V.le Luigi Pinto 1, Foggia, 71100, Italy; and Giulio Zizzo, MD, Radiology Department Ospedali Riuniti, V.le Luigi Pinto 1, Foggia, 71100, Italy</i>	364
Hypothermia-Related Deaths in Cook County, Illinois From November 2000 to February 2005	<i>Wendy A. Lavezzi, MD*, Clare H. Cunliffe, MD, and Edmund R. Donoghue, MD, Cook County Medical Examiner's Office, 2121 West Harrison Street, Chicago, IL 60612</i>	364
Analysis of Gene Expression Patterns to Identify Tissue and Body Fluid Specific mRNA Species Using Real Time PCR Assays	<i>Rixun Fang, PhD, Christine Shulse, BS, Pius Brzoska, PhD, and Manohar R. Furtado, PhD*, Applied Biosystems, 850 Lincoln Center Dr., Foster City, CA 94404; and Chitra F. Manohar, PhD, Lawrence Livermore National Laboratory, 7000 East Ave, Livermore, CA 94550</i>	365
Caveat Emptor: A Series of Deaths Related to Subcutaneous Silicone Injections in Transgender Males	<i>Morna L. Gonsoulin, MD*, Ashraf Mozayani, PhD, Terry Danielson, PhD, and Luis A Sanchez, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054-2098</i>	366
Anogenital Anatomy: Colposcopy to Study the Appearance and Changes During the Postmortem Interval	<i>Sharon R. Crowley, MN, RN*, Forensic Clinical Nurse Specialist, 122 Emeline Avenue, Santa Cruz, CA 95060</i>	366
Unusual Suicide With Chain Saw: A Case Report	<i>Gilles Tournel, MD*, Fabrice Dedouit, MD, Anne Becart-Robert, DDS, PhD, Nicolas Pety, MD, Valéry Hedouin, MD, PhD, and Didier Gosset, MD, PhD, Institut de Médecine Légale, Faculté de Médecine, 1, place de Verdun, Lille, 59000, France</i>	367
Suicidal Hangings: A Growing Trend in Northern Virginia	<i>Erin E. Falconer, MFS*, Danielle L. McLeod, MFS, and Todd M. Luckasevic, DO, Northern Virginia Office of the Chief Medical Examiner, 9797 Braddock Road, Suite 100, Fairfax, VA 22032</i>	368

DNA Done Right: Manner of Death Determination, Based on Evidence Obtained From a Belt at a Complex Scene Involving a Decomposed Body	<i>Leah L. Bush, MD*, and Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510</i>	368
Guns That Fire Themselves: Report of Three Cases	<i>Elizabeth L. Kinnison, MD*, and Wendy M. Gunther, MD, Department of Legal Medicine, Virginia Commonwealth University, Medical College of Virginia, 1101 E Marshall Street, Richmond, VA 23298-0568</i>	369
Handgun to the Head: Suicide Trends in Northern Virginia	<i>Erin E. Falconer, MFS, Danielle L. McLeod, MFS, and Todd M. Luckasevic, DO*, Northern Virginia Office of the Chief Medical Examiner, 9797 Braddock Road, Suite 100, Fairfax, VA 22032</i>	369
Evaluation of Less-Lethal Impact Munitions	<i>Richard T. Wyant, MS*, Washington State Patrol, 2203 Airport Way South, Suite 250, Seattle, WA 98134; and Chris Myers, and Tom Burns, Seattle Police Department, 810 Virginia Street, Seattle, WA 98101</i>	370
A First Time for Everything: Homicide Involving the Brenneke® Super Sabot Shotgun Slug	<i>Amy Tharp, MD*, and Donald Jason, MD, JD, Department of Pathology, Wake Forest University Baptist Medical Center, Medical Center Boulevard, Winston-Salem, NC 27157</i>	370
Death by a Radio-Controlled Helicopter	<i>Ana E. Lopez, MD*, Harris County Medical Examiner, 1885 Old Spanish Trail, Houston, TX 77054; Luis A. Sanchez, MD, Harris County Medical Examiner, 1885 Old Spanish Trail, Houston, TX 77054</i>	370
A Fatality Due to Atomoxetine - The First Known Case	<i>Kathryn Haden-Pinneri, MD*, 21827 Hollow Field Lane, Katy, TX 77450</i>	371
Methadone Deaths are on the Increase in Maryland (1998-2004)	<i>Mary G. Ripple, MD*, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201; Cheryl Rinehart*, Margaret Hsu, Erin Artigiani, and Eric Wish, PhD, Center for Drug Abuse Research, 4321 Hartwick Road, Suite 501, College Park, MD 20740; and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	371
Methadone-Related Deaths: A Review of Medical Examiner Cases in a Large Metropolitan Area	<i>Lisa B. Shields, MD*, Donna M. Hunsaker, MD, and Tracey S. Corey, MD, Office of the Chief Medical Examiner, Urban Government Center, 810 Barret Avenue, Louisville, KY 40204; John C Hunsaker III, MD, JD, Office of the Associate Chief Medical Examiner, University of Kentucky Department of Pathology and Laboratory Medicine, 100 Sower Boulevard, Suite 202, Frankfort, KY 40601-8272; and Michael K Ward, MS, Kentucky Medical Examiner's Program, Office of Forensic Toxicology, 100 Sower Blvd Suite 202, Frankfort, KY 40601</i>	372
The Value of Expanded Postmortem Toxicology Testing Menu	<i>Luis E. Remus III, PhD, MD*, Ashraf Mozayani, PhD, Terry Danielson, PhD, and Luis A. Sanchez, MD, Harris County Medical Examiners Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	373
Arteriovenous Malformation and its Implications in Forensic Pathology: A Case Report	<i>Anny Sauvageau, MD, MSc*, Laboratoire de Sciences Judiciaires et de Médecine Légale, 1701 Parthenais Street, 12th Floor, Montreal, Quebec H2K 3S7, Canada</i>	373

Sudden Death in the Young in Australia	<i>Johan A. Duflou, MBChB, MMed *, Department of Forensic Medicine, PO Box 90, Glebe, NSW 2037, Australia; and Rajesh Puranik, MBBS, Clara K. Chow, MBBS, Michael J. Kilborn, DPhil and Mark A. McGuire, MBBS, PhD, Department of Cardiology, Royal Prince Alfred Hospital, Missenden Road, Camperdown, NSW 2050, Australia</i>	374
Suicide Among 10 to 20 Year Olds in Cook County, Illinois: A Retrospective Review	<i>Adrienne E. Segovia, MD, Clare H. Cunliffe, MD*, Mitra B. Kalekar, MD, and Michelle Jorden, MD, Office of the Medical Examiner, County of Cook, 2121 West Harrison Street, Chicago, IL 60612</i>	374
Immunohistochemical Examination of α-Lactalbumin in SIDS (Sudden Infant Death Syndrome)	<i>Annalisa Addante, MD, PhD*, Fiorenza Zotti, PhD, Andrea Marzullo, MD, Alessandro Dell'Erba, MD, PhD, and Massimo Collonna, MD, Section of Legal Medicine, University of Bari, Piazza Giulio Cesare, Bari, 70124, Italy</i>	375
Forensic Approach in a Case of Simultaneous Sudden Infant Death Syndrome	<i>Francesco M. Morreale, MD*, Irene Riezzo, MD, Stefano D'Errico, MD, and Raffaella Bisceglia, MD, Institute of Forensic Pathology Foggia University, V.le Luigi Pinto 1, Foggia, 71100, Italy</i>	376
Infant Position and the Assessment of Risk Factors for Asphyxia: A Review of 209 Sudden Unexpected Infant Deaths	<i>Melissa A. Pasquale-Styles, MD*, Wayne County Medical Examiner Office, 1300 East Warren Avenue, Detroit, MI 48207; Patricia L. Tackitt, RN, MS, Michigan Public Health Institute, 2438 Woodlake Circle, Suite 240, Okemos, MI 48864; and Carl J. Schmidt, MD, Wayne County Medical Examiner Office, 1300 East Warren Avenue, Detroit, MI 48207</i>	376
Hyperglycemic Hyperosmolar Nonketotic Syndrome in a Sixteen-Month Old Child With Rotaviral Diarrhea	<i>Mary E. Carr, MD*, and Andrew M. Baker, MD, Hennepin County Medical Examiner's Office, 530 Chicago Avenue, Minneapolis, MN 55415</i>	377
Starvation – Interpretation of Morphological Findings and Pitfalls	<i>Véronique Henn*, and Manfred Kleiber, PhD, Institute of Forensic Medicine Martin-Luther-University, Franzosenweg 1, Halle, 06112, Germany; and Eberhard Lignitz, PhD, Institute of Forensic Medicine Ernst-Moritz-Arndt-University, Kuhstr. 30, Greifswald, 17489, Germany</i>	377
Perimacular Circular Folds in the Eyes of Injured Children	<i>M.G.F. Gilliland, MD*, Brody SOM at East Carolina University, Department of Pathology & Laboratory Medicine, Brody 7 South 10, Greenville, NC 27834</i>	378
Postmortem Detection and Evaluation of Retinal Hemorrhages	<i>Patrick E. Lantz, MD*, and Constance A. Stanton, MD, Department of Pathology, Wake Forest University Health Sciences, Medical Center Boulevard, Winston-Salem, NC 27157-1072</i>	379
Examination of Sexually Abused Child: What is the Impact on Judgment?	<i>Nathalie S. Jousset, MD*, Department of Forensic Medicine, University Hospital, Angers, 49033, France; and Hubert C. Poirout, MD, Arnaud N. Gaudin, MD, Michel Penneau, MD, PhD, and Clotilde G. Rougé-Maillet, MD, Department of Forensic Medicine, 4 rue Larrey, Angers, 49033, France</i>	379

Sensitivity of Autopsy and Radiological Examination in Detecting Bone Fractures in an Animal Model: Implications for the Assessment of Fatal Child Physical Abuse	<i>Cristina Cattaneo, PhD, MD,* and Eloisa Marinelli, MD, Istituto di Medicina Legale, Università degli Studi, via Mangiagalli 37, Milano, 20133, Italy; Alessia Di Giancamillo, DVM, PhD, Dipartimento di Scienze e Tecnologie Veterinarie per la Sicurezza Alimentare, via Celoria 10, Milano, 20133, Italy; Mauro Di Giancamillo, DVM, and Olga Travetti, DVM, Dipartimento di Scienze Cliniche Veterinarie, via Celoria 10, Milano, 20133, Italy; and Laura Viganò, BSc, Pasquale Poppa, BSc, Davide Porta, BSc, Andrea Gentilomo, MD, PhD, and Marco Grandi, MD, Istituto di Medicina Legale, via Mangiagalli 37, Milano, 20133, Italy</i>	380
“Homicide by Heart Attack” - An Unusual Pediatric Death	<i>Dwayne A. Wolf, MD, PhD*, Harris County Medical Examiner Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	380

2005		
Deaths From Accidental Steam Inhalation During African Traditional Therapy	<i>Bhanwar Lal Bhootra, MD*, Department of Health, PO Box 1944, Polokwane, Limpopo 0700, South Africa</i>	382
Firearm Injuries in Angers: 1990 - 2000	<i>Arnaud Gaudin, MD*, and Nathalie Jousset, MD, Service de Médecine Légale, Centre Hospitalier Universitaire - 4 Rue Larrey, Angers, 49100 Cedex 01, France; Gilles Tournel, MD, Service de Médecine Légale, Institut Médico-Légal - Place Deverdun, Lille, 59000, France; and Michel Penneau, MD, and Clotilde Rougé-Maillart, MD, Service de Médecine Légale, Centre Hospitalier Universitaire - 4 rue Larrey, Angers, 49100 Cedex 01, France</i>	382
Evaluation of a Novel Tagging and Tissue Preservation System for Human Remains	<i>Martin Grassberger, MD, PhD*, and Christina Stein, PhD, Department for Forensic Medicine, Medical University of Vienna, Sensengasse 2, Vienna, A-1090, Austria; Stefan Hanslik, PhD, Identilab Forensic Services, Handelskai 94-96, Vienna, A-1200, Austria; and Manfred Hochmeister, MD, Department for Forensic Medicine, Medical University of Vienna, Sensengasse 2, Vienna, A-1090, Austria</i>	382
Lesch-Nyhan Syndrome and Child Abuse	<i>Andrea M. Berzlanovich, MD*, Institute of Forensic Medicine, University of Vienna, Sensengasse 2, Vienna, 1090, Austria; Martin Kraupp, MD, Department of Medical Chemistry, Medical University of Vienna, Währinger Straße 10, Vienna, A - 1090, Austria; Johannes A. Hainfellner, MD, and Herbert Budka, MD, Institute of Neurology, Medical University of Vienna, Währinger Gürtel 18-20, Vienna, A -1090, Austria; Wolfgang A. Keil, MD, Institute of Forensic Medicine, University of Munich, Frauenlobstraße 7a, Munich, D -80337, Germany; and Barbara Fazeny-Dörner, MD, Department of Medicine I, Medical University Vienna, Währinger Gürtel 18-20, Vienna, A -1090, Austria</i>	383
Determining a Postmortem Submersion Interval (PMSI) Based on Algal/Diatom Diversity on Decomposing Mammalian Carcasses in Brackish Ponds in Delaware	<i>John R. Wallace, PhD, Kathryn Zimmerman*, and Erin High, Department of Biology, Caputo Hall, Millersville University, Millersville, PA 17551</i>	384
Immunocompromised Female, Age 67, With an Angioinvasive Pulmonary Fungal Abscess	<i>Darshan R. Phatak, MD*, Beth Israel Deaconess Medical Center, Pathology Department, 330 Brookline Avenue, Boston, MA 02215</i>	384
Teen Fatality by Train: A Multidisciplinary Approach to Determination of Manner of Death	<i>Mary H. Dudley, MD*, Sedgwick County Regional Forensic Science Center, 1109 North Minneapolis, Wichita, KS 67214</i>	385
A Fatal Case Due to Abdominal Compartment Syndrome (ACS)	<i>Margherita Neri, MD*, Marianna Di Padua, MD, and Emanuela Turillazzi, MD, PhD, Department of Forensic Pathology, University of Foggia, Viale Pinto 1, Foggia, 71100, Italy</i>	385

Cane Corsos Attack: Two Fatal Cases	<i>Sabina Di Donato, MD*, and Emanuela Turillazzi, MD, PhD, Institute of Forensic Medicine, University of Foggia, Viale Luigi Pinto, 1, Foggia, 71100, Italy; Fernando Panarese, MD, Department of Experimental and Clinical Medicine, University of Magna Grecia, Policlinico Universitario Catanzaro, Via Tommaso Campanella 115, Catanzaro, 88100, Italy; Pietrantonio Ricci, MD, Department of Experimental and Clinical Medicine University of Magna Grecia, Policlinico Universitario Catanzaro, Via Tommaso Campanella 115, Catanzaro, 88100, Italy</i>	386
Fatal Dog Maulings Associated With Infant Swings	<i>Albert Y. Chu, MD, MHS*, Carol Allan, MD, Mary G. Ripple, MD, Tasha Z. Greenberg, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	387
Contribution of Burn Injury in a Blunt Trauma Case With Incineration	<i>John B. Davis, BS*, Eastern Virginia Medical School, 700 West Olney Road, Norfolk, VA 23507-1607; and Leah L. Bush, BS, and Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046</i>	387
A Field Study of the Foraging Behavior of Blowfly Maggots	<i>David L. Gibo, PhD*, and Deana Hathout, BSc, University of Toronto at Mississauga, 3359 Mississauga Road North, Mississauga, Ontario L5L 1C6, Canada; Brent Walker, BA, Conestoga College, Law and Security/Police Foundations, School of Health Sciences and Community Services, 299 Doon Valley Drive, Kitchener, Ontario N2G 4M4, Canada; and Brian Dixon, PhD, 1645 Howat Crescent, Mississauga, Ontario L5J 4G6, Canada</i>	388
Cavotricuspid Isthmus Rupture and Hemopericardium: A Delayed Complication of Cardiac Radiofrequency Catheter Ablation	<i>Ezra Ellis, MD*, and Patrick E. Lantz, MD, Department of Pathology, Wake Forest University Health Sciences, Medical Center Boulevard, Winston-Salem, NC 27157</i>	388
Sudden Death of a Fourteen-Year-Old Female With Hb S-C Disease	<i>Victor V. Frolov, MD*, Jeffrey M. Jentzen, MD, and John R. Teggatz, MD, Milwaukee County Medical Examiner Office, 933 West Highland Avenue, Milwaukee, WI 53233</i>	389
Interpreting Lesions to the Conduction System of the Heart in Case of Death Pursuant to Cocaine Ingestion	<i>Katarzyna Michaud, MD*, Thomas Krompecher, MD, Béat Horisberger, MD, Marc Augsburger, PhD, Frank Sporkert, PhD, and Patrice Mangin, MD, PhD, Institut Universitaire de Médecine Légale, Bugnon 21, Lausanne, 1005, Switzerland</i>	389
Defibrillator/Pacemaker Evaluation in the Los Angeles County Medical Examiner Office	<i>Lakshmanan Sathyavagiswaran, MD*, Daniel Rieders, MD, and Joseph Muto, Department of Coroner, Los Angeles County, 1104 North Mission Road, Los Angeles, CA 90033</i>	390
Traumatic Cardiovascular Complications of Catheter-Based Procedures: Relevance to Medicolegal Death Investigation	<i>Edward J. Tweedie, MD*, London Health Sciences Centre, 339 Windermere Road, London, Ontario N6A 5A5, Canada</i>	390

Increasing Heart Valve Donation by Utilization of a Cardiovascular Registry	<i>Susan J. Roe, MD*, Regina Medical Center, 1175 Nininger Road, Hastings, MN 55033; Shannon Mackey-Bojack, MD, and Rachel M. Meuleners, Jesse E. Edwards Cardiovascular Registry, 333 North Smith Avenue, Suite 4625, St. Paul, MN 55102; Lindsey C. Thomas, MD, Regina Medical Center, 1175 Nininger Road, Hastings, MN 55033; and Jack L. Titus, MD, PhD, Jesse E. Edwards Cardiovascular Registry, 333 North Smith Avenue, Suite 4625, St. Paul, MN 55102</i>	391
A Review of Pathologic Findings in Specimens Following Heart Valve Donation	<i>Shannon M. Mackey-Bojack, MD*, Jesse E. Edward's Registry of Cardiovascular Disease, John Nasseff Heart Hospital, 333 North Smith Avenue, Suite 4625, St. Paul, MN 55102; Susan J. Roe, MD, Rachel M. Meuleners, and Lindsey C. Thomas, MD, Regina Medical Center, 1175 Nininger Road, Hastings, MN 55033; and Jack L. Titus, MD, PhD, Jesse E. Edwards Registry of Cardiovascular Disease, John Nasseff Heart Hospital, 333 North Smith Avenue, Suite 4625, St. Paul, MN 55102</i>	391
Sudden Death in a Calipatria State Prison Inmate With a Single Coronary Artery	<i>Darryl J. Garber, MD*, Imperial County, California, Los Angeles County Coroner's Office/Department of Medical Examiner, 1104 North Mission Road, Los Angeles, CA 90033; and Henry Proo, Imperial County, California, 328 Applestill Road, El Centro, CA 92243</i>	392
An Accident Waiting to Happen: The Chicago Porch Collapse of 2003	<i>Aldo J. Fusaro, DO*, J. Scott Denton, MD, Adrienne E. Segovia, MD, Edmund R. Donoghue, MD, and Eupil Choi, MD, Cook County Medical Examiner's Office, 2121 West Harrison Street, Chicago, IL 60612; J. Lawrence Cogan, MD, LA County Medical Examiner's Office, 1104 North Mission Road, Los Angeles, CA 90033; Mitra B. Kalekar, MD, Cook County Medical Examiner's Office, 2121 West Harrison Street, Chicago, IL 60612</i>	393
Forensic Medicine in France	<i>Eric Baccino, MD*, Laurent Martille, MD, and Anne Dorandeu, MD, Service de Medecine Legale Chu de Montpellier, Hospital Lapeyronie 371 av du Doyen G. Giraud, Montpellier, 34295, France</i>	393
Near Miss Incidents: Feasibility Studies Assessing Forensic Physicians' Perceptions of Near Misses in Police Custody Suites in London, United Kingdom	<i>David Best, PhD, Institute of Psychiatry, King's College, De Crespigny Park, London, SE5 8AF, United Kingdom; Siobhan Havis, MSc, Police Complaints Authority, 10 Great George Street, London, SW1P 3AE, United Kingdom; and Jason Payne-James, LLM, MB, FRCS, DFM*, Forensic Healthcare Services, Ltd, 19 Speldhurst Road, Victoria Park, London, E9 7EH, United Kingdom</i>	394
Fatal Pulmonary Thromboembolism and Hereditary Thrombophilias	<i>James R. Gill, MD, and Susan F. Ely, MD*, OCME, 520 First Avenue, New York, NY 10016</i>	394
An Expert Witness Requests Re-evaluation of SOP in Autopsy Reporting, Supported With Case Examples	<i>Anita K.Y. Wonder, MA*, Wonder Institute, PO Box 1051, Carmichael, CA 95609-1051</i>	395

Sudden Death Following Brief Compression of the Neck	<i>John W. Eisele, MD*, Forensic Consultants Medical Group, 2291 March Lane, Suite 179E, Stockton, CA 95207; Gerald J. Berry, MD, Stanford Pathology Consultants, 300 Pasteur Drive, Room H-2110, Stanford, CA 94305; and Michael J. Ackerman, MD, PhD, and David J. Tester, BS, Long QT Syndrome Clinic and Sudden Death Genomics Laboratory, Mayo Clinic College of Medicine, 200 First Street, SW, Hilton 11, Rochester, MN 55905</i>	395
The Spontaneous Oesophagus Perforation: A Forensic Point of View	<i>Renaud Clement*, and Olivier Rodat, PhD, Department of Forensic Medicine, University of Nantes, 1 Rue Gaston Viel, Cedex, 44 093, France</i>	396
Human Wicks: The Almost Complete Destruction of Major Portions of the Human Body by Fire Fueled at Least Partly by the Body Fat of the Victim	<i>Phillip M. Burch, MD*, Office of the Medical Examiner, 1300 Clark Avenue, St. Louis, MO 63117</i>	396
DNA Extraction and Anthropological Aspects From 6th to 7th Century A.D. Bone Remains	<i>Nunzio Di Nunno, MD, PhD*, Sezione di Medicina Legale, Bari University, Piazza G. Cesare n. 11, Bari, 70125, Italy; Vito Scattarella, BSc, Sandro Sublimi Saponetti, BSc, and Patrizia Emanuel, BSc, Bari University, Piazza G. Cesare n. 11, Bari, 70125, Italy; and Stefania Lonero Baldassarra, BSc, and Cosimo Di Nunno MD, Sezione di Medicina Legale, Bari University, Piazza G. Cesare n. 11, Bari, 70125, Italy</i>	396
Risk Factor Analysis and Characteristics in Community Acquired MRSA	<i>Julia M. Braza, MD*, Karoly Balogh, MD,; and Anthony Martyniak, MD, Beth Israel Deaconess Medical Center at Harvard Medical School, 330 Brookline Avenue, Boston, MA 02215</i>	397
Commotio Cordis: Sudden Death Among Young People During Sporting and Recreational Activities	<i>Sunil K. Prashar, MD*, and Karoly Balogh, MD, Beth Israel Deaconess Medical Center, 330 Brookline Avenue, ES-112, Boston, MA 02115</i>	397
Guidelines and Medical Malpractice in Minor Head Injury Management	<i>Luigi Viola, MD*, Nunzio Di Nunno, MD, PhD, Roberto Quaranta, MD, Alessandro Dell'Erba, MD, PhD, and Francesco Vimercati, MD, Bari University, Piazza Giulio Cesare, 11, Bari, 70124, Italy</i>	398
Sudden Death Due to Bilateral Spontaneous Pneumothoraces in a Marijuana User	<i>Joseph A. Felo, DO*, Cuyahoga County Coroner's Office, 11001 Cedar Avenue, Cleveland, OH 44106</i>	398
Venous Bullet Embolism of a Large Caliber Bullet From the Right External Iliac Vein to the Heart: Case Report and Review of the Literature	<i>Mary G. Ripple, MD*, and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	399
Factors Affecting the Formation of Adipocere in Soils	<i>Shari L. Forbes, BSc, PhD*, Centre for Forensic Science, University of Western Australia, M420, 35 Stirling Highway, Crawley, WA 6009, Australia; Barbara Stuart, PhD, Department of Chemistry, Materials and Forensic Science, University of Technology, Sydney, PO Box 123, Broadway, Australia, 2007; Boyd Dent, PhD, Department of Environmental Sciences, University of Technology, Sydney, PO Box 123, Broadway, Australia, 2007; and Ian R. Dadour, BSc, PhD, Centre for Forensic Science, University of Western Australia, M420, 35 Stirling Highway, Crawley, WA 6009, Australia</i>	399

Seasonal Distribution and Abundance of Forensically Important Flies in Santa Clara County	<i>Adrienne Brundage, MS*, 1250 A Edgewood Road, Redwood, CA 94062</i>	400
Establishing a Protocol Between Clinical and Forensic Institutions to Treat and Investigate Violence Against Women Cases	<i>Miguel Lorente, MD, PhD*, and A. Carrasco, Institute of Legal Medicine of Granada (Spain), Av.Sur, 5, Granada, 18071, Spain; José A. Lorente, MD, PhD, University of Granada, Department of Forensic Medicine, Granada, 18012, Spain; Enrique Villanueva, MD, PhD, Department of Legal Medicine, University of Granada, Avda. Madrid, sn/, Granada, 18071, Spain</i>	400
Analytical Electron Microscopic Detection of Aluminum Received Intravenously	<i>Sarah M. Colvin, MD*, Carol Allan, MD, Laron Locke, MD, Mary G. Ripple, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201; and Victor Roggli, MD, Duke University Health Systems, Department of Pathology, Box 3712, DUMC, Durham, NC 27710</i>	401
Evaluation of Clinical Diagnostic Accuracy in Post-Coronary Artery Bypass Graft Surgery Mortality	<i>Marianne Hamel, MD, PhD*, Department of Pathology, Anatomy and Cell Biology, Thomas Jefferson University Hospital, 125 South 11th Street, Suite 204 Foerderer Pavilion, Philadelphia, PA 19107-4998; Johan A. Duflou, MMed, Department of Forensic Medicine, Central Sydney Laboratory Service, 42-50 Parramatta Road, Glebe, NSW 2037, Australia</i>	401
Adolescent Death: A 15-Year Retrospective Study	<i>Nick I. Batalis, MD*, and Kim A. Collins, MD, Medical University of South Carolina, 165 Ashley Avenue, Main Hospital, Room 281, Charleston, SC 29425</i>	402
Heightened Awareness of Bioterrorism: Three Cases of Unusual Skin Lesions	<i>John A. Stash, DO*, Zabiullah Ali, MD, Carol Allan, MD, Ana Rubio, MD, Mary G. Ripple, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	402
Amended Cause and Manner of Death Certification: A Six-Year Review of the New Mexico Experience	<i>Philip R. Croft, MD*, Sarah L. Lathrop, DVM, PhD, and Ross E. Zumwalt, MD, Office of the Medical Investigator, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131-0001</i>	403
The Relationship of Drug Abuse to Unexplained Sudden Death	<i>Amy C. Gruszecki, DO*, Jefferson County Coroner Medical Examiner Office, 1515 6th Avenue South, Suite 611, Birmingham, AL 35233; Gerald McGwin, Jr., PhD, Department of Epidemiology, School of Public Health, University of Alabama, Birmingham, AL 35233; C. Andrew Robinson, PhD, Department of Pathology, Forensic Division, University of Alabama, Birmingham, AL 35233; and Gregory G. Davis, MD, MSPH, Jefferson County Coroner Medical Examiner Office, 1515 6th Avenue South, Suite 611, Birmingham, AL 35233</i>	403
Natural Causes of Death Among a Federal Medical Center Prison Population	<i>Peter T. Lin, MD*, and Eric A. Pfeifer, MD, Mayo Clinic, 200 First Street, SW, Hilton 11, Rochester, MN 55905</i>	404
Distribution Pattern of Pulmonary Surfactant Protein A (SP-A) in Drowning and Opiate-Related Deaths	<i>Carlo P. Campobasso, MD, PhD*, Alessandro S. Dell'Erba, MD, PhD, Annalisa Addante, MD, PhD, Fiorenza Zotti, PhD, Sara Sblano, MD, and Massimo F. Colonna, MD, LLB, Section of Legal Medicine (Di.M.I.M.P.), University of Bari, Piazza Giulio Cesare, Policlinico di Bari, Bari, 70124, Italy</i>	405

Drowning vs. Trauma and Other Causes of Asphyxia in Deaths in Water	<i>Karen B. Looman, DO*, Pathology Residency Program, Eastern Virginia Medical School, 700 West Olney Road, Norfolk, VA 23507-1607; Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046; and E.L. Kinnison, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046</i>	405
Study of the Diagnostic Value of Iron in Freshwater Drowning	<i>Geoffroy Lorin de la Grandmaison, MD*, M. Lettereux, PharmD, K. Lasseguette, MD, J.C. Alvarez, PharmD, Philippe de Mazancourt, MD, PhD, and Michel Durigon, MD, PhD, Department of Forensic Pathology, Raymond Poincare Hospital, Garches, 92 380, France</i>	406
Elder Abuse and Neglect Death Review: Use of an Interagency Team	<i>Christopher Swalwell, MD*, Medical Examiner's Office, San Diego County, 5555 Overland Avenue, Building 14, San Diego, CA 92123</i>	406
Adolescent and Young Adult Suicide: A Ten-Year Retrospective Review of Kentucky Medical Examiner Cases	<i>Lisa B. Shields, MD*, and Donna M. Hunsaker, MD, Office of the Chief Medical Examiner, 810 Barret Avenue, Louisville, KY 40204; John C. Hunsaker III, JD, MD, Office of the Associate Chief Medical Examiner, Department of Pathology & Laboratory Medicine, 100 Sower Boulevard, Suite 202, Frankfort, KY 40601-8272; and Michael K. Ward, BS, Kentucky Forensic Toxicology Laboratory, Office of Forensic Toxicology, 100 Sower Blvd, Frankfort, KY 40601</i>	407
Which Field Method is Best? A Comparative Study of Four Entomological Methods for Sampling Forensically Important Arthropods on Human and Porcine Remains at the Anthropology Research Facility in Knoxville, Tennessee	<i>Kenneth G. Schoenly, PhD*, Department of Biological Sciences, California State University, Stanislaus, Turlock, CA 95382; Neal H. Haskell, PhD, Department of Biology, Saint Joseph's College, Rensselaer, IN 47978; and Robert D. Hall, PhD, JD, Department of Entomology, 1-87 Agriculture Building, University of Missouri, Columbia, MO 65211</i>	407
The Decomposition of a Pig Carcass in a Mesophytic Biotope, Oahu, Hawaii	<i>Anthony R. Russo, PhD*, Chaminade University of Honolulu, Forensic Science, 3140 Waialae Avenue, Honolulu, HI 96816</i>	408
A Comparison of Pig and Human Tissue in Studies of Decomposition: Can Flies Tell the Difference?	<i>Charlotte A. Wacker, MS*, University of California, Davis-Department of Cell Biology and Human Anatomy, One Shields Avenue, Tupper Hall Room 3301, Davis, CA 95616; Lawrence Stutler, MS, University of New Haven, School of Public Safety and Professional Studies, 300 Orange Avenue, West Haven, CT 06516; Brandi J. Schmitt, MS, University of California, Davis-Department of Cell Biology and Human Anatomy, One Shields Avenue, Tupper Hall Room 3301, Davis, CA 95616; and Rebecca A. Bullard, MS and Robert B. Kimsey, PhD, University of California, Davis, Department of Entomology, One Shields Avenue, Davis, CA 95616</i>	408

Inter-Observer Variability in Entomology-Based PMI Estimates: A Single Blind Study	<i>Rebecca A. Bullard, MS*, University of California, Davis, Department of Entomology, One Shields Avenue, Davis, CA 95616; Kenneth G. Schoenly, PhD, California State University, Stanislaus, Department of Biological Sciences, Turlock, CA 95382; and Robert Kimsey, PhD, University of California, Davis, Department of Entomology, One Shields Avenue, Davis, CA 95616</i>	409
Viral Testing of Adult Mosquitoes Collected in West Virginia for West Nile Virus Using NASBA Assay	<i>Justin M. Godby, BS*, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701</i>	409
An Instructional DVD on Collecting Entomological Evidence for Court	<i>Ryan K. Kimbirauskas, MS*, Richard W. Merritt, PhD, and Eric M Benbow, PhD, Michigan State University, 243 Natural Science Building, East Lansing, MI 48824; John R. Wallace, PhD, Millersville University, 1 South George Street, Millersville, PA 17551; and Jeff K. Tomberlin, PhD, Texas A & M University, 1229 North U.S. Highway 281, Stephenville, TX 76401</i>	409
How Cadaver Decomposition in Soil is Affected by Moisture: Part I: A Field Experiment to Investigate Seasonal Effects	<i>Mark Tibbett, PhD*, Centre for Land Rehabilitation, School of Earth and Geographical Sciences, University of Western Australia, Crawley, WA 6009, Australia; and David O. Carter, MSc, and David Yellowlees, PhD, School of Pharmacy and Molecular Sciences, James Cook University, Douglas, QLD 4811, Australia</i>	410
How Cadaver Decomposition in Soil is Affected by Moisture: Part II: A Controlled Laboratory Experiment	<i>David O. Carter, MSc*, School of Pharmacy and Molecular Sciences, James Cook University, Douglas, QLD 4811, Australia; Mark Tibbett, PhD, Centre for Land Rehabilitation, School of Earth and Geographical Sciences, University of Western Australia, Crawley, WA 6009, Australia; and David Yellowlees, PhD, School of Pharmacy and Molecular Sciences, James Cook University, Douglas, QLD 4811, Australia</i>	410
Clinically Stable Skull Fracture and Fatal Acute Pneumonia: An Unexpected Combination	<i>Christie L. Elliott, MD*, Forensic Pathology Consultants, PO Box 12815, Reno, NV 89510-2815</i>	411
The Dangers of Dumpster Diving: Deaths Associated With Garbage Collection in the Tidewater Region of Virginia	<i>Leah L. Bush, MD*, Office of the Chief Medical Examiner, Tidewater District, Commonwealth of Virginia, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046; and Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046</i>	411
The Differential Diagnosis Between Bioterrorism and Zoonosis and Spread to Humans: A Pathological Evaluation	<i>Maurice Rogev, MD*, Zamenhof 11, Tel Aviv 64373, Israel</i>	412
Suicides Among Youth in Geneva, Switzerland From 1993 to 2002	<i>Guillaume Perret*, Département de Psychiatrie, Clinique de Psychiatrie Adulte, HUG, Secteur Jonction, Bvd Saint-Georges 16-18, Geneva, 1205, Switzerland; Abлиз Абдурахеман, MD, Institut Universitaire de Médecine Légale de Genève, 9 Av de Champel, Geneva, 1211, Switzerland; Maja Perret-Catipovic, PhD, Département de Psychiatrie, Unité, Bd de la Cluse 51, Geneva, 1205, Switzerland; and Romano La Harpe, MD, Institut Universitaire de Médecine Légale de Genève, C.M.U, 9 av de Champel, Geneva, 1211, Switzerland</i>	412

Suffocation by Mistaken Use of a Biohazard Hood as a “Spit” Hood	<i>K. Alan Stormo, MD*, Jeffrey M. Jentzen, MD, Mary K. Mainland, MD, John R. Teggatz, MD, and Victor V. Frolov, MD, Milwaukee County Medical Examiner, 933 West Highland Avenue, Milwaukee, WI 53233</i>	413
Unsuspected Pheochromocytoma Discovered During Autopsy After Sudden and Unexpected Death in an Expectant Mother	<i>Sophie Gromb, PhD*, Nadia Khaldi, MD, Larbi Benali, MD, Mathurin Djodjo, MD, and Alain Miras, PhD, Department of Forensic Medicine - EA 3676 - IFR 99 of Public Health, CHU Pellegrin - Place Amélie Raba- Léon, Bordeaux, 33076, France</i>	413
Modeling Languages in Forensic Pathology	<i>Gilbert E. Corrigan, MD, PhD*, East Baton Rouge Coroner’s Office, 4030 T.B. Hearndon Avenue, Baton Rouge, LA 70807</i>	413
Polyarteritis Nodosa as a Rare Case of Sudden Death in Postmortem Diagnosis	<i>Wolfgang A. Keil, MD*, and Felicitas Dahlmann, MD, Institute of Forensic Medicine, Ludwig-Maximilians-University Munich, Frauenlobstraße 7a, Munich, D80337, Germany; and Andrea M. Berzlanovich, MD, Institute of Forensic Medicine, Medical University Vienna, Sensengasse 2, Vienna, A1090, Austria</i>	414
Autopsy Findings in Hypothermia: A Five Year Retrospective Study	<i>Patricia A. Aronica-Pollak, MD*, Jack M. Titus, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	414
Color Me Guilty: The Role of Paint Transfer in Weapon Linkage	<i>Diane Scala-Barnett, MD*, and Julie M. Saul, BA, Lucas County Coroner’s Office, 2595 Arlington Avenue, Toledo, OH 43614-2674</i>	415
The Role of Forensic Insects in Deposition of Pollen at a Death Scene	<i>Rebecca J. Kirby*, Anita L. Guedea, Phillip L. Watson, PhD, Roger E. Mitchell, PhD, and Scott M. Herron, PhD, Ferris State University, Department of Biology, Big Rapids, MI 49307</i>	415
Experimental Evaluation of Rigor Mortis - The Influence of the Central Nervous System on the Evolution of the Intensity of Rigor Mortis	<i>Thomas Krompecher, MD*, André Gilles, MD, Conxita Brandt- Casadevall, MD, Beat Horisberger, MD, and Patrice Mangin, MD, Institut Universitaire de Médecine Légale, Rue du Bugnon 21, Lausanne, 1005, Switzerland</i>	416
β-Phenylethylamine as a Biomarker in Mechanical Asphyxia-Related Fatalities	<i>Wen-Ling Lin, PhD*, and Kai-Ping Shaw, MD, PhD*, Institute of Forensic Medicine, Ministry of Justice, Republic of China, 161-1, Section 2, Keelung Road, Taipei, 106, Taiwan, Republic of China</i>	416
Forensic Pathologists and the NICHD Brain and Tissue Bank for Developmental Disorders	<i>Ling Li, MD*, David R. Fowler, MD, and Ana Rubio, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201; and Ronald Zielke, PhD, University of Maryland, Department of Pediatrics, Brain, and Tissue Bank for Developmental Disorders, 655 West Baltimore Street, Baltimore, MD 21201</i>	417
Causes of Death Among People in the Prison of Loos (Northern France), 1997-2003	<i>Gilles Tournel, MD*, Anne A. Bécart-Robert, DDS, PhD, Valéry C. Hédouin, MD, PhD, and Didier Gosset, MD, PhD, Institut de Médecine Légale, 1, Place de Verdun, Lille, 59 000, France</i>	417
Rathke’s Cleft Cyst: Alleged “Brain Tumor” in a Middle-Aged Cocaine Abuser	<i>Bridget B. Eutenier, BS*, and Karen B. Looman, Pathology Resident Program, Eastern Virginia Medical School, 700 West Olney Road, Norfolk, VA 23510-1046; Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046</i>	418

Microscopic Soft Tissue Decomposition and Time Since Death	<i>Murray K. Marks, PhD*, and Mariateresa A. Tersigni, MA, University of Tennessee, Department of Anthropology, 250 South Stadium Hall, Knoxville, TN 37996; and Darinka X. Mileusnic, MD, PhD, University of Tennessee Medical Center, Knox County Medical Examiner's Office, 1924 Alcoa Highway, Knoxville, TN 37920</i>	418
An Atypical Gunshot Wound With Absence of a Weapon? The Value of a Thorough Scene Investigation	<i>Clare H. Cunliffe, MD*, Office of the Medical Examiner, County of Cook, 2121 West Harrison Street, Chicago, IL 60612</i>	419
Suicide or Homicide - The Importance of Forensic Evidence: A Case Study	<i>Giancarlo Di Vella, MD, PhD*, Alessandra Arpaio, MD, Claudia Liuzzi, MD, and Francesco Vinci, MD, University of Bari, Di.M.I.M.P. - Sezione di Medicina Legale - Policlinico, Bari, 70125, Italy</i>	419
Determination of Range of Fire in Skeletal Remains	<i>Kathryn Haden, MD*, Office of the Chief Medical Examiner, Northern Virginia District, 9797 Braddock Road, Fairfax, VA 22032; Jill Urban, MD, and Karen Hendley, The Southwestern Institute for Forensic Sciences, 5230 Medical Center Drive, Dallas, TX 75235</i>	420
A Modern "Martyr's Crown": A Fatal Case of Multiple Self-Inflicted Nail Gun Shots	<i>Francesco Maria Morreale, MD*, Christoforo Pomara, MD, and Stefano D'Errico, MD, Institute of Legal Medicine, University of Foggia, Ospedali Riuniti, via L. Pinto 1, Foggia, I-71100, Italy; and Rocco Maglietta, MD, Hospital San Carlo, Potenza, I-85100, Italy</i>	421
.17 HMR – It's Not Your Father's .22	<i>J.C. Upshaw Downs, MD*, Coastal Regional Laboratory Georgia Bureau of Investigation, 925A Mohawk Street, Savannah, GA 31419; and Ron Van Fleet, BS, Donelle L. Pyle, MS, and Shannon Walden, Georgia Bureau of Investigation, 925A Mohawk Street, Savannah, GA 31419</i>	421
A Shot In the Dark? Investigating Accidental Gunshot Wounds	<i>J.C. Upshaw Downs, MD*, Donelle L. Pyle, MS, Ron Van Fleet, BS, and Shannon Walden, Coastal Regional Laboratory Georgia Bureau of Investigation, 925A Mohawk Street, Savannah, GA 31419</i>	421
Utilization of Automated Fingerprint Identification System (AFIS) to Aid in the Identification of Unknown Perpetrators to Close Unsolved Cases	<i>Kelly L. Hickey, MD*, Marcella F. Fierro, MD, and Timothy A. Powell, MPH, Office of the Chief Medical Examiner, 400 East Jackson Street, Richmond, VA 23219; and Robin Young, Division of Forensic Science, 700 North 5th Street, Richmond, VA 23219</i>	422
Dead Hits: Matching Decedents' DNA to Unsolved Crime Scenes	<i>Todd M. Luckasevic, DO*, Marcella F. Fierro, MD, and Timothy A. Powell, MPH, Office of the Chief Medical Examiner, 400 East Jackson Street, Richmond, VA 23219; and George C. Li, MS, Linda Johnston, BS, and Deanne F. Dabbs, MFS, Division of Forensic Science, 700 North 5th Street, Richmond, VA 23219</i>	422
To Dye or Not to Dye: A Tale of the Blues	<i>Sharon R. Crowley, RN, MN *, 122 Emeline Avenue, Santa Cruz, CA 95060; Brian L. Peterson, MD, Forensic Medical Group, 1860 Pennsylvania Avenue, Fairfield, CA 94533</i>	423
Postmortem Monocular Indirect Ophthalmoscopy	<i>Patrick E. Lantz, MD*, Department of Pathology, Wake Forest University Health Sciences, Medical Center Boulevard, Winston-Salem, NC 27157; and Gill G.W. Adams, BSc, MBChB, Moorfields Eye Hospital, 162 City Road, London, EC1V 2PD, United Kingdom</i>	424

Multislice Computed Tomography In Forensic Pathology	<i>Klaus Poulsen, MD*, and Jørn Simonsen, MD, Institute of Forensic Medicine, Frederik Vs Vej 11, Copenhagen, 2100, Denmark</i>	424
Murder in the Ancient Castle: A XIV Century Warrior Virtual Autopsy	<i>Cristoforo Pomara, MD*, Institute of Legal Medicine, University of Foggia, Viale Pinto 1, Foggia, 71100, Italy; Angelo Marrone, MD, Diagnostic Imaging Department, ASL Foggia 2, Cerignola (Fg), Via Trinitapoli, Foggia, 71042, Italy; Stefano Ricci, MD, PhD, Anthropological Laboratory, Department of Environmental Science, University of Siena, Via Mattioli n. 4, Siena, 53100, Italy; Irene Riezzo, MD, Institute of Legal Medicine, University of Foggia, Viale Luigi Pinto, 1, Foggia, 71100, Italy</i>	425
19th Century Autopsy Techniques: Failing to Meet 21st Century Forensic Science Needs	<i>O'Brian C. Smith, MD*, and Teresa A. Campbell, MD, 381 Cherry Hollow CV, Cordova, TN 38018; Elayne J. Pope, MA, Department of Anthropology, University of Arkansas, Fayetteville, AR 72701; Chantal Ferraro, PhD, C.W. Post Campus, Long Island University, Brookville, NY 11548; and Alexandr Senilnikov, MD PhD, Regional Forensic Center, 1060 Madison AV, Memphis, TN 38104</i>	425
Diesel Fumes Do Kill: A Case of Fatal Carbon Monoxide Poisoning Directly Attributed to Diesel Fuel Exhaust	<i>Sean M. Griffin, MS*, and Donna M. Hunsaker, MD, Office of the Chief Medical Examiner and the University of Louisville Department of Pathology and Laboratory Medicine, 810 Baxter Avenue, Louisville, KY 40204-1702; Kiran Charturvedi, MD, University of Kentucky Medical Center Department of Pathology and Laboratory Medicine, University of Kentucky, 800 Rose Street, Lexington, KY 40536; Michael K. Ward, BS, KY State Forensic Toxicology Laboratory, 100 Sower Boulevard, Frankfort, KY 40601; and Andrea R. Terrell, PhD, American Institute of Toxicology, 2265 Executive Drive, # A, Indianapolis, IN 46241</i>	426
Sublingual Tablet Thwarts Opioid Addiction	<i>William Vilensky, DO, RPh*, Forensic & Educational Consultants, 2113 Harbourside Drive, Longboat Key, FL 34228</i>	426
An Analysis of 35 Ethylene Glycol Fatalities in Cook County, Illinois From 1993 Through 2003	<i>J. Scott Denton, MD*, Valerie Arangelovich, MD, Michel Humilier, MD, and Edmund R. Donoghue, MD, Cook County Medical Examiner's Office, 2121 West Harrison Street, Chicago, IL 60612</i>	427
Patterns of Illicit Drug Use of Prisoners in Police Custody in London, United Kingdom	<i>Jason Payne-James, LLM, MB, FRCS, DFM*, Ian Wall, LLM, MRCGP, and Caroline Bailey, Forensic Healthcare Services, Ltd., 19 Speldhurst Road, Victoria Park, London, E9 7EH, United Kingdom</i>	428
Child Homicides in Hong Kong: A Retrospective Review of a Ten-Year Period From 1989-1998	<i>Philip S.L. Beh, MBBS, DMJ*, Department of Pathology, The University of Hong Kong, Room 126, University Pathology Building, Queen Mary Hospital, Hong Kong, Hong Kong SAR, China; and R.G. Broadhurst, Department of Sociology, The University of Hong Kong, Room 126, Hong Kong SAR, China</i>	428

Evolution of the Intentional Injury Infant Syndrome in Northern France	<i>Gilles Tournel, MD*, Institut de Médecine Légale, 1, Place de Verdun, Lille, 59 000, France; Marie Desurmont, MD, Institut de Médecine Légale, 10 Rue F Villon, Lille, 59 000, France; Valéry C. Hédouin, MD, PhD, Institut de Médecine Légale, 1, Place de Verdun, Lille, 59 000, France; Didier Gosset, MD, PhD, Institut de Médecine Légale, 10 Rue F Villon, Lille, 59000, France</i>	429
Breath Holding Spells Associated With Unexpected Sudden Childhood Death	<i>Kathryn K. Berg, MD*, Daniel W. Davis, MD, and Andrew M. Baker, MD, Hennepin County Medical Examiner's Office, 530 Chicago Avenue, Minneapolis, MN 55415</i>	429
An Interdisciplinary Approach for Diagnosis and Age Estimation of Infants' Fractures in the Course of the Autopsy	<i>Heike Klotzbach, MD, PhD*, Institute of Legal Medicine, Hamburg University, Butenfeld 34, Hamburg, 22529, Germany; Guenther Delling, PhD, Institute of Pathology, Department of Osteo-Pathology, Hamburg University, Lottesstrasse 2, Hamburg, 22529, Germany; Erich Richter, PhD, Institute of Radiology, Department of Pediatric Radiology, Martinistraße 52, Hamburg, 20246, Germany; and Klaus Pueschel, PhD, Institute of Legal Medicine, Hamburg University Butenfeld 34, Hamburg, 22529, Germany</i>	430
Are Retinal Hemorrhages Diagnostic of Shaken Baby Syndrome? What Really Killed Baby Cooper	<i>Christopher J. Plourd, JD*, 1168 Union Street, Suite 303, San Diego, CA 92101-3818</i>	430
Fatal Craniocerebral Trauma With Hemorrhagic Retinopathy in an Infant: Abuse or Accident?	<i>Amy M. Tharp, MD*, and Patrick E. Lantz, MD, Department of Pathology, Wake Forest University Health Sciences, Medical Center Boulevard, Winston-Salem, NC 27157</i>	431
The Evidence-Based Medicine Paradigm Shift and Forensic Pathology	<i>M.G.F. Gilliland, MD*, Brody School of Medicine at East Carolina, Department Pathology and Laboratory Medicine, Brody 7 S 10, Greenville, NC 27834</i>	431
Sequential SIDS or Double Homicide? Challenges of Delayed Investigation of Potential "Subtle" Child Homicides	<i>Stacy A. Drake, MSN, RN*, Teresa Royer, MSN, RN, Stephen K. Wilson, MD, Dwayne A. Wolf, MD, PhD, Ashraf Mozayani, PharmD, PhD, and Luis A. Sanchez, MD, Harris County Medical Examiner Office, 1885 Old Spanish Trail, Houston, TX 77054</i>	432
Case Presentation: Infant Death Due to Epidermolysis Bullosa	<i>Eugene L. Hart, MD*, Bonita Fung, MD, Ana Lopez, MD, and Luis A. Sanchez, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054-2098</i>	433
Child Abuse by Another Child: Can it Happen?	<i>Darinka Mileusnic-Polchan, MD, PhD*, University of Tennessee Medical Center, Knox County Medical Examiner's Office, 1924 Alcoa Highway, Knoxville, TN 37920; and Sharon O'Connor, Cook County Office of the Medical Examiner, 2121 West Harrison Street, Chicago, IL 60612</i>	433
Acute Pancreatitis in a 2½-Year-Old Child: A Fatal Therapeutic Complication of Polyethylene Glycol (PEG)-L-Asparaginase	<i>Cristin M. Rolf, MD*, and Heather Worne, BS, University of Kentucky, Department of Pathology and Laboratory Medicine/Office of the Associate Chief Medical Examiner, Kentucky Justice and Public Safety Cabinet, 100 Sower Boulevard, Suite 202, Frankfort, KY 40601-8272</i>	433

Increased Risk of Sudden Infant Death Syndrome (SIDS) Among Infants Harboring the Apolipoprotein E-4 Allele: Genetic and Pathologic Similarities to Alzheimer's Disease (AD)	<i>D. Larry Sparks, PhD*, Sun Health Research Institute, 10515 West Santa Fe Drive, Sun City, AZ 85351; Rob Friedland, MD, Bob Petersen, PhD, Ellen Grady, MS, and Sandra Richardson, PhD, Case Western Reserve University, 10900 Euclid Avenue, Cleveland, OH 44106; and Cristin M. Rolf, MD, and John C. Hunsaker III, MD, JD, Division of Medical Examiner Services, Kentucky Justice and Public Safety Cabinet, 100 Sower Boulevard, Suite 202, Frankfort, KY 40601-8272</i>	434
Ano-Genital Findings in Sexually Abused Children in Cases With a Conviction	<i>Lene Aagaard Nielsen, MD, and Soren J. Mikkelsen, MD, Children and Adolescent Psychiatric Hospital, University Hospital of Aarhus, 66 H. Selmersvej, Risskov, DK-8000, Denmark; and Annie Vesterby, MD, DMSci*, Department of Forensic Medicine, University of Aarhus, Children abd Adolescent Psychiatric Hospital of Aarhus, P. Sabroes Gade 15, Aarhus, DK-8000, Denmark</i>	435
The Contribution of Computerized Image Analysis to the Diagnosis of Munchausen Syndrome by Proxy	<i>Beat Horisberger, MD*, and Patrice Mangin, MD, PhD, Institute of Legal Medicine, University of Lausanne, Rue du Bugnon 21, Lausanne, 1005, Switzerland</i>	435

2004		
Penetrating Wound of Head by Slingshot: Medicolegal Aspects	<i>Bhanwar Lal Bhootra, MD*, Forensic Pathology Services, Limpopo Province, PO Box 1944, Polokwane, 0700, South Africa</i>	437
Suicide by Hanging in Children	<i>Ziadi Arbia* and Chadly Ali, MD, Department of Forensic Medicine, University Hospital Fattouma Bourguiba, Monastir, 5000, Tunisia</i>	437
The Effects of Liquid Bleach on Pig Decomposition in Southeastern Pennsylvania	<i>Lauren E. Way* and John R. Wallace, PhD, Department of Biology, Millersville University, PO Box 1002, Millersville, PA 17551</i>	437
The Use of Whole Body Donors in Forensic Research	<i>Charlotte A. Wacker, MS* and Brandi J. Schmitt, MS, University of California, One Shields Avenue, 3301 Tupper Hall, Davis, CA 95616</i>	438
Pediatric Homicides Related to Burn Injury	<i>William F. Zaloga, DO*, Wake Forest University Baptist Medical Center, Department of Pathology, Medical Center Drive, Winston-Salem, NC 27157; Kimberly A. Collins, MD, Medical University of South Carolina, 171 Ashley Avenue, Charleston, SC 29425</i>	438
Insect Succession Studies on Pig Carrion in Southwest Virginia and the Effects of Antemortem Ethanol Ingestion on Insect Succession and Development	<i>Kimberly L. Tabor, BA, MS*, Richard D. Fell, PhD, and Carlyle C. Brewster, PhD, Virginia Tech, 216 Price Hall, Blacksburg, VA 24061; Kevin Pelzer, DVM, Virginia Tech School of Veterinary Medicine, Blacksburg, VA 24061; George S. Behonick, PhD, Department of Criminal Justice Services, Division of Forensic Sciences, 6600 Northside High School Road, Roanoke, VA 24019</i>	438
The Detection of Saliva: Factors Affecting the Phadebas® Press and Tube Tests	<i>Melissa S Kell, BSc*, Wendy Lalonde, BSc, Roger Frappier, MSc, and Jonathan Newman, BSc, Centre of Forensic Sciences, 25 Grosvenor Street, Toronto, ON M7A 2G8, Canada</i>	439
Places to Commit Suicide	<i>Istvan F. Szentmariay, MD*, Institute of Forensic Medicine, Semmelweis University, Ulloii UT 93, Budapest, H-1091, Hungary</i>	440
Dramatic Rise in Methadone-Related Deaths in Oklahoma 1990-2002	<i>Ronald F. Distefano, DO*, Office of the Chief Medical Examiner, State of Oklahoma, 1115 West 17th Street, Tulsa, OK 74107</i>	440
Fatal Botox®-Induced Anaphylaxis? A Case Report	<i>Melissa Li, MD*, University of Florida College of Medicine, PO Box 100275, 1600 SW Archer Road, Gainesville, FL 32610-0275; Bruce A. Goldberger, PhD, University of Florida, PO Box 100275, Gainesville, FL 32610-0275; Carolyn Hopkins, MD, District 8 Medical Examiner's Office, 606 SW 3rd Avenue, Gainesville, FL 32601</i>	440
Significant Trends in Work-Related Deaths — United States	<i>Gordon K. Murphy, MD*, 814 Hathaway Road, Dayton, OH 45419-3555</i>	441
Over Diagnosis of Low Voltage Electrocution	<i>Ronald K. Wright, BS, MD, JD*, 2101 SW 29th Avenue, Fort Lauderdale, FL 33312</i>	441
Accidental Parachuting Death Due to Equipment Failure	<i>Martha J. Burt, MD and Matthew J. Bowes, MD*, Miami-Dade County Medical Examiner Department, Number One on Bob Hope Road, Miami, FL 33136</i>	442

The Richard Cory Phenomenon: Suicide and Socioeconomic Status in Kansas City, Missouri	<i>Thomas W. Young, MD*, Jackson County Medical Examiner, 660 East 24th Street, Kansas City, MO 64108; Suzanna Wooden, University of Missouri, Kansas City School of Medicine, 2411 Holmes, Kansas City, MO 64108; Jinwen Cai, MD and Gerald L. Hoff, PhD, Kansas City Missouri Health Department, 2400 Troost, Kansas City, MO 64108; Paul C. Dew, MD, MPH, University of Health Sciences, 1750 Independence Avenue, Kansas City, MO 64106</i>	443
Suicide: A Ten-Year Retrospective Review of Kentucky Medical Examiner Cases	<i>Lisa B. Shields, MD*, Donna M. Hunsaker, MD, and John M. Hunsaker III, MD, JD, Office of the Associate Chief Medical Examiner, 100 Sower Boulevard, Frankfort, KY 40601</i>	443
Homicidal Cerebral Artery Aneurysm Rupture	<i>Joseph A. Prahlow, MD*, c/o South Bend Medical Foundation and Indiana University School of Medicine, 530 North Lafayette Boulevard, South Bend, IN 46601</i>	444
Death by Defibrillator: A Unique Homicide by Electrocution	<i>Kendall V. Crowns, MD* and Adrienne Segovia, MD, Cook County Medical Examiners Office, 2121 W. Harrison Street, Chicago, IL 60612</i>	445
The Influence of Violence in the Media on Unusual Methods of Murder and Suicide	<i>Karin A. Margolius, MD, LLB* and Gerard A. Cadden, MD, PathCentre, Locked Bag 2009, Nedlands, Perth, WA 6009, Australia</i>	445
Use of the Impact Baton or So-Called “Rubber Bullet” as Less Lethal Force in Air vs. Water	<i>Darryl J. Garber, MD* and Irwin Golden, MD, County of Los Angeles Department of Coroner/Medical Examiner, 1104 N Mission Road, Los Angeles, CA 90033; Lakshmanan Sathyavagiswaran, MD, Chief Medical Examiner-Coroner, Los Angeles County, 1104 N Mission Road, Los Angeles, CA 90033</i>	446
Dissection, Preservation and Sexual Abuse of Bodies and Body Parts – An Exceptional Case of Necrophilia	<i>Martin Bauer, MD* and Thomas Tatschner, MD, University of Wuerzburg, Institute of Legal Medicine, Versbacher Str. 3, Wuerzburg 97078, Germany; Michael Roesler, MD, Institute of Forensic Psychology and Psychiatry, Saarland University, Kirrberger Straße, Homburg 66421, Germany; Dieter Patzelt, MD, Institute of Legal Medicine, University of Wuerzburg, Versbacher Str. 3, Wuerzburg 97078, Germany</i>	446
Too Many Causes of Death: What's the Manner?	<i>Wendy M. Gunther, MD*, Office of the Chief Medical Examiner and Department of Legal Medicine, Virginia Commonwealth University, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510</i>	447
Postmortem Analysis of Anastomotic Suture Line Disruption Following Carotid Endarterectomy	<i>Judy Melinek, MD, New York City Office of Chief Medical Examiner, 520 First Avenue, New York, NY 10016; Patrick Lento, MD*, Mount Sinai Hospital Medical Center, 1190 Fifth Avenue, New York, NY 10029; John Moalli, ScD*, Exponent Failure Analysis Associates, 149 Commonwealth Drive, Menlo Park, CA 94025</i>	447

Advanced Flow Cytometric DNA Degradation Analysis: Utility in Postmortem Interval Estimation	<i>Erica Williams, MD*, Hospital of the University of Pennsylvania, Department of Pathology and Laboratory Medicine, 6 Founder Building, 3400 Spruce Street, Philadelphia, PA 19104; Andrew Bantly, BS, Hospital of the University of Pennsylvania, Abramson Cancer Center Flow Cytometry and Cell Sorting Shared Resource, 3400 Spruce Street, Philadelphia, PA 19104; Jesse Chittams, MS, University of Pennsylvania School of Medicine, Department of Biostatistics and Epidemiology, 3400 Spruce Street, Philadelphia, PA 19104; Jonni Moore, PhD, Hospital of the University of Pennsylvania, Abramson Cancer Center Flow Cytometry and Cell Sorting Shared Resource, 3400 Spruce Street, Philadelphia, PA 19104</i>	448
The Impact of Dermatologic Consultation in Autopsy Examination: A Case of Pseudoxanthoma Elasticum	<i>Carrie L. Kovarik, MD*, UT Clay J. Cockerell, MD, Sheila D. Spotswood, MD, and Jeffrey J. Barnard, MD, University of Texas Southwestern Medical School - Forensic Science, 5323 Harry Hines Boulevard, Dallas, TX 75390</i>	448
Homicidal Injury or Resuscitation Artifact?	<i>Amy P. Hart, MD*, Venus J. Azar, MD, and Boyd G. Stephens, MD, Medical Examiner's Office, City and County of San Francisco, 850 Bryant Street, San Francisco, CA 94103</i>	449
Screening Items of Evidence for the Presence of Body Fluids/DNA in Forensic Biology Casework — A Hypothesis-Driven Approach	<i>Melissa Kell, BSc, Sobia Malik, MSc, Gerry Alderson, MSc*, and Andrew Greenfield, MSc, Centre of Forensic Sciences, 25 Grosvenor Street, Toronto, Ontario M7A 2G8, Canada</i>	449
Fatal Kawasaki Disease Associated With Cardiac Rhabdomyomas in an Infant	<i>Erik K. Mont, MD*, Miami-Dade County Medical Examiner Department, Number One on Bob Hope Road, Miami, FL 33136; Allen P. Burke, MD, Armed Forces Institute of Pathology, Department of Cardiovascular Pathology, 6825 16th Street, NW, Building 54, Room 2005, Washington, DC 20306</i>	450
Hmong Cultural Aversion to Forensic Autopsy: Bridging Communication and Cultural Barrier	<i>Thomas K. Resk, MD*, PO Box 3215, Chico, CA 95927-3215; Thomas A. Rudd, MD, PO Box 332, Highwood, IL 60040-0332</i>	451
Postmortem Diagnosis of Genetic Arrhythmia Syndromes	<i>Carolyn H. Revercomb, MD*, Northern District Office of the Chief Medical Examiner, Fairfax, Virginia, and Department of Legal Medicine, Virginia Commonwealth University School of Medicine, 9797 Braddock Road, Fairfax, VA 22032</i>	452
Is Hypertension a Risk Factor for Fatal Rupture of Intracranial Aneurysms?	<i>Ana Rubio, MD, PhD*, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Christopher Cox, PhD, Division of Epidemiology, Statistics and Prevention, National Institute of Child Health and Human Development; DHHS, 6100 Executive Boulevard, Room 7B05, Bethesda, MD 20892; David Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Juan Troncoso, MD, Neuropathology Unit; Department of Pathology, Johns Hopkins School of Medicine, 720 Rutland Avenue, Baltimore, MD 21205</i>	452

Fatal Acute Thrombosis of Anomalous Right Coronary Artery Arising From the Left Sinus of Valsalva	<i>Supriya Kuruvilla, MD*, Harris County Medical Examiner Office and University of Texas Health Science Center, J.A. Jachimczyk Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054; Antonio Neto, MD, University of Texas Health Science Center, 6431 Fannin, MSB 2.120, Houston, TX 77030; Dwayne A. Wolf, MD, PhD, Harris County Medical Examiner Office, J.A. Jachimczyk Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054</i>	453
Undiagnosed Cardiac Sarcoidosis and Sudden Death: Report of 14 Cases	<i>Carol H. Allan, MD*, Ling Li, MD, Susan Hogan, MD, and Mary G. Ripple, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201; Allan Burke, MD, Department of Defense, Armed Forces Institute of Pathology, 14th & Alaska Avenue Northwest, Washington, DC 20306; David Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	453
Accidental Insulin Overdose	<i>Nick I. Batalis, MD*, Medical University of South Carolina, 1032 Yorktown Drive, Charleston, SC 29412; Joseph A. Prahlow, BS, MD, South Bend Medical Foundation, 530 North Lafayette Boulevard, South Bend, IN 46601</i>	454
Unexplained Sudden Death and the Likelihood of Drug Abuse	<i>Amy C. Gruszecki, MSFS, DO* and Gregory G. Davis, MD, MSPH, Jefferson County Coroner/Medical Examiner Office, 1515 Sixth Avenue South, Room 611, Birmingham, AL 35233-1601</i>	454
Acute Bacterial Meningitis With Predominance of Immature Granulocytes	<i>Reade A. Quinton, MD*, University of Texas Southwestern Medical Center, Department of Pathology, 5323 Harry Hines Boulevard, Dallas, TX 75390-9073; Loren Clarke, MD and Javad Towfighi, MD, Penn State Milton S. Hershey Medical Center, Department of Anatomic Pathology - H179, 500 University Drive, PO Box 850, Hershey, PA 17033-0850; Jeffrey J. Bernard, MD, Southwestern Institute of Forensic Sciences, 5230 Medical Center Drive, Dallas, TX 75390; Rene L. Galindo, MD, PhD and Philip J. Boyer, MD, PhD, University of Texas Southwestern Medical Center, Department of Neuropathology, 5323 Harry Hines Boulevard, Dallas, TX 75390</i>	455
Coronary Artery Anomalies and Sudden Death: Two Case Reports in Young People	<i>Margherita Neri, MD*, Department of Forensic Pathology, University of Foggia, Viale Pinto 1, Foggia 71100, Italy; M. Di Pudua, MD, Institute of Forensic Medicine, University of Foggia, Ospedali Riuniti Via Luigi Pinto n. 1, Foggia 71100, Italy</i>	456
Neurofibromatosis Type 1 Associated With Hydrocephalus and Acute Cardiac Failure: A Fatal Case	<i>Sabina Di Donato, MD*, Arcangela Marucci, MD, and Francesco M. Morreale, MD, Department of Forensic Pathology University of Foggia, Viale Pinto n.1, Foggia, Puglia 71100, Italy</i>	457

A Cluster of Child Deaths: A Medical Examiner System Participates in an Epidemiologic Investigation in Virginia	<i>Mary Jo Martin, MD*, Office of the Chief Medical Examiner, 400 East Jackson Street, Richmond, VA 23219; Wendy M. Gunther, MD*, Office of the Chief Medical Examiner, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510; Lisa A. Weymouth, PhD*, Virginia Division of Consolidated Laboratory Services, 600 North 5th Street, Richmond, VA 23219; Elizabeth L. Kinnison, MD, Office of the Chief Medical Examiner, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510; Deborah Kay, MD, Office of the Chief Medical Examiner, 400 East Jackson Street, Richmond, VA 23219; William T. Gormley, MD and Marcella F. Fierro, MD, Office of the Chief Medical Examiner, 400 East Jackson Street, Richmond, VA 23219</i>	458
Police Custody Deaths in the State of Maryland: Passing the Torch	<i>Pamela E. Southall, MD*, Ling Li, MD, and David Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201</i>	458
Characterization of Recent Cocaine and Methadone-Related Death Trends in Caddo Parish, Louisiana, With Comparison to National Trends	<i>Elizabeth J. Miller, MD*, Caddo Parish Coroner's Office, 1704 Market Street, Shreveport, LA 71101; Sharon Brooks, Jacksonville State University, Jacksonville, AL 36265; Patricia Dooley-Netherland, and George M. McCormick III, MD, PHD, Caddo Parish Coroner's Office, 1704 Market Street, Shreveport, LA 71101</i>	459
Positional Asphyxia and Alcoholism: Review of Three Cases	<i>Elizabeth L. Kinnison, MD* and Wendy M. Gunther, MD, Office of the Chief Medical Examiner, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510</i>	460
Causes of Death in Chronic Alcoholics: A Comprehensive Retrospective Analysis of Medical Examiner Cases	<i>Martha J. Burt, MD*, Matthew J. Bowes, MD, and Mark J. Shuman, MA, MD, Miami-Dade County Medical Examiner Department, Number One on Bob Hope Road, Miami, FL 33136</i>	460
FluiDDB.com: A Model Database for Unidentified Bodies	<i>Michael C. Britt, BS* and Marta U. Coburn, MD, District Twenty Medical Examiner, 3838 Domestic Avenue, Naples, FL 34104</i>	461
Compressional Asphyxia Due to a Crowd Stampede: The E2 Nightclub Disaster	<i>Adrienne Segovia, MD, Mitra B. Kalekar, MD*, Aldo J. Fusaro, DO, Scott Denton, MD, Edmund R. Donoghue, MD, Kendall V. Crowns, MD, Eupil Choi, MD, J. Lawrence Cogan, MD, Ronald Knoblock, MD, Cyndi D. Gardner, MD, and Barry D. Lifschultz, MD, Cook County Medical Examiners Office, 2121 West Harrison Street, Chicago, IL 60612</i>	461
Perspectives on the Variety of Mass Identification Projects	<i>Charles H. Brenner, PhD*, Consultant in Forensic Mathematics, 6568 Sobrante Road, Oakland, CA 94611-1123</i>	462
Investigation, Identification, and Repatriation of Contaminated Fatalities	<i>Craig T. Mallak, MD JD*, Office of the Armed Forces Medical Examiner, Armed Forces Institute of Pathology, 1413 Research Boulevard, Rockville, MD 20850; Elspeth C. Ritchie, MD*, USUHS, Department of Psychiatry, Room B3068, 4301 Jones Bridge Road, Bethesda, MD 20814</i>	463
When is SIDS Over-Laying?	<i>W.P. Ryan, MBBS*, PO Box 267, Nowra, NSW 2541, Australia</i>	463
Unexpected Death From Ureterocele in an Infant	<i>Joyce L. de Jong, DO*, Sparrow Hospital, Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909</i>	463

An Unusual Motorized Vehicle Fatality	<i>Russell T. Alexander, MD*, John Turner, MD, and Louis Dibernardo, MD, Duke University Medical Center, Department of Pathology, DUMC Box 3712, Durham, NC 27710</i>	464
Three Unusual Cases of Sudden Unexpected Death in Pregnancy Occurring in One Week in the State of Maryland	<i>Tasha L. Zemrus, MD* and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201-1020</i>	464
Compressed Gas Cylinder Related Injuries: Case Report of a Fatality Associated With a Recreational Paintball Gun, Review of the Literature and Safety Recommendations	<i>Nabila A. Haikal, MD*, and Richard C. Harruff, MD, PhD, King County Medical Examiner's Office, 325 9th Avenue, HMC Box 359792, Seattle, WA 98104</i>	465
Cerebral Air Embolism: An Uncommon Complication of a Common Procedure	<i>Bret M. Wehrli, MD*, London Health Sciences Centre, 339 Windermere Road, Department of Pathology, Room A3-147, London, Ontario N6A 5A5, Canada; Sidney Siu, MD, 827 Richmond Street, London, Ontario N6A 3H7, Canada; Edward Tweedie, MD and Michael J. Shkrum, MD, London Health Sciences Centre, 339 Windermere Road, London, Ontario N6A 5A5, Canada</i>	466
Legal Outcome of Sexual Assault Cases, The County of Aarhus, Denmark	<i>Marianne C. Rohde, MD*, Jytte Banner, MD, PhD, and Annie Vesterby, MD, MDSc, Department of Forensic Medicine, University of Aarhus, Peter Sabroes Gade 15, Aarhus 8000 C, Denmark</i>	466
Boating People Pathology	<i>Francesco Introna, MD*, Alberto Tortorella, MD, Roberto Vaglio, MD, and Antonio De Donno, MD, Sezione di Medicina Legale-DIMIMP, P.zza Giulio Cesare, 11, Bari, 70100, Italy</i>	467
Do Centenarians Die Healthy? – An Autopsy Study	<i>Andrea M. Berzlanovich, MD*, Department of Forensic Medicine, University of Vienna, Sensengasse 2, Vienna, Austria A – 1090 Austria; Thomas Waldhoer, PhD, Department of Epidemiology, Institute of Cancer Research, University of Vienna, Borschkegasse 8a, Vienna, Austria A - 1090, Austria; Ernst Sim, MD, Meidling Traumatology Center, Kundratstraße 37, Vienna, Austria A - 1120, Austria; Peter Fasching, MD, Geriatric Center Baumgarten, Baumgartner Höhe 1, Vienna, Austria A - 1140, Austria</i>	467
Degenerative Changes of the Conduction Tissue in Drug Addicts	<i>Michaud Katarzyna, MD*, Béat Horisberger, MD, and Patrice Mangin, PhD, Institut Universitaire de Médecine Légale, Rue du Bugnon 21, Lausanne, Vaud 1005, Switzerland</i>	467
Systemic Amyloidosis in an Intravenous Drug Abuser	<i>Jennifer J. Prutsman-Pfeiffer, MA*, Strong Memorial Hospital, Neuropathology and Postmortem Medicine, Box 626, 601 Elmowwd Avenue, Rochester, NY 14642</i>	468
Photographic Imaging of Handgun Gas Clouds Compared to Gunshot Residue Swabs	<i>D'Michelle P. DuPre, BA, MD*, Miami-Dade County Medical Examiner's Office, Number One Bob Hope Road, Miami, FL 33136- 1133; Joe Castorenga, Bexar County Forensic Science Center, 7337 Louis Pasteur Drive, San Antonio, TX</i>	469
Who was Driving: A Case Report	<i>Ersi Abaci-Kalfoglou, PhD*, Hulya Yukseloglu, PhD, Tanyý Baskan, PhD, and Sevil Atasoy, PhD, Istanbul University, Institute of Forensic Sciences, Cerrahpasa, Istanbul 34303, Turkey</i>	469

The Contribution of Researching DNA Breaks to the Evaluation of Postmortem Delay	<i>Anne Dorandeu, MD*, Eric Baccino, MD, and Maguy Ursule, MD, Lapeyronie University Hospital, 371 Avenue du Doyen Gaston Giraud, Montpellier, Herault 34295, France</i>	469
From VIRTopsy to VIRTObOT: Photogrammetry Based Optical Surface Scanning and Radiological Virtual Autopsy	<i>Michael J. Thali, MD* and Marcel Braun, University of Berne, Buehlstrasse 20, Berne 3012, Switzerland; Buck Ursula, Emin Aghayev, MD, and Christian Jackowski, MD, University of Berne, Buehlstrasse 20, Berne 3012; Martin Sonnenschein, MD, University of Berne, Inselspital, Berne 3012, Switzerland; Peter Vock, MD and Richard Dirnhof, MD, University of Berne, Buehlstrasse 20, Bern 3012, Switzerland</i>	470
Comparative Study of DNA Yield and STR Profile Quality Obtained From Various Tissue Types of a Decomposed Body	<i>Shelly A. Steadman, MS*, Sedgwick County Regional Forensic Science Center, 1109 North Minneapolis, Wichita, KS 67214; Jaime L. Oeberst, MD, Sedgwick County Regional Forensic Science Center, 1109 North Minneapolis, Wichita, KS 67214; Daniel J. Fahnestock, MS, Sedgwick County Regional Forensic Science Center, 1109 North Minneapolis, Wichita, KS 67214</i>	470
Experimental Evaluation of Rigor Mortis Nysten's Law: Does it Apply to Rats?	<i>Thomas Krompecher, MD*, Andre Gilles, MD, Conxita Brandt-Casadevall, MD, and Patrice Mangin, MD, Institut Universitaire de Médecine Légale, Rue du Bugnon 21, Lausanne, Vaud 1005, Switzerland</i>	471
Microbial Processes in Soils Associated With Skeletal Muscle Tissue and Cadaver Decomposition at Different Temperatures	<i>David O. Carter, MSc*, James Cook University, School of Pharmacy & Molecular Sciences, Douglas, Queensland 4814, Australia; Mark Tibbett, PhD, University of Western Australia, Soil Science and Plant Nutrition, School of Earth and Geographical Sciences, Crawley, Western Australia 6907, Australia; David Yellowlees, PhD, James Cook University, School of Pharmacy and Molecular Sciences, Douglas, Queensland 4811, Australia</i>	472
Does Carcass Enrichment Alter Community Structure of Predaceous and Parasitic Arthropods? A Second Test of the Arthropod Saturation Hypothesis at the Anthropology Research Facility in Knoxville, Tennessee	<i>Kenneth G. Schoenly, PhD*, Department of Biological Sciences, California State University, Stanislaus, Turlock, CA 95382; Adam Shahid, MS, University of Missouri, Department of Entomology, 320 Connaway Hall, Columbia, MO 65211; Neal H. Haskell, PhD, Department of Biology, Saint Joseph's College, Rensselaer, IN 47978; Robert D. Hall, PhD, JD, University of Missouri, Department of Entomology, 1-87 Agriculture Building, Columbia, MO 65211</i>	473
Trends in Forensic Entomology in the United States and Abroad	<i>Jeffery K. Tomberlin, PhD, Department of Entomology, Texas A&M University, 1229 North U.S. Highway 281, Stephenville, TX 76401; Jason Byrd, PhD*, Office of the Medical Examiner, 1360 Indian Lake Road, Daytona Beach, FL 32164; John Wallace, PhD*, Department of Biology, Millersville University, Fredrick Street, Science and Technology Building, Millersville, PA 17551</i>	473
Temperature-Dependent Development of the Blow Fly Calliphora Vicina (Diptera: Calliphoridae) and the Effects on the Estimation of the Postmortem Interval	<i>Timothy E. Huntington, BS; Leon G. Higley, PhD, and Frederick P. Baxendale, PhD, University of Nebraska, Department of Entomology, 202 Plant Industry, Lincoln, NE 68583</i>	474

Evidence for Neglect of Children and Elderly Persons by Use of Forensic Entomology	<i>Mark Benecke, PhD, MSc*, International Forensic Research & Consulting, Postfach 250411 Cologne, NRW 50520, Germany</i>	474
DNA-Based Identification of Forensically Significant Blowflies of Australia and Southern Africa	<i>Michelle L. Harvey, BSc, BA* and Ian R. Dadour, PhD, Centre for Forensic Science, University of Western Australia, Stirling Highway, Nedlands, Perth, Western Australia 6009, Australia; Martin H. Villet, PhD, Department of Zoology and Entomology, Rhodes University, Grahamstown 6140, South Africa; Mervyn W. Mansell, PhD, Plant Protection Research Institute, Private Bag X134, Pretoria, Gauteng 0001, South Africa</i>	475
Fatal Pediatric Head Impact Biomechanics: Homicide vs. Accident	<i>John B. Lenox, MD, PhD, PE*, Design Excellence, Inc, 435 Isom Road, Suite 224, San Antonio, TX 78216-5144</i>	475
The Enigma of SIDS: Variations in Diagnosis and Recommendations	<i>Peter Vasilenko, PhD*, Michigan State University, College of Human Medicine, Department of Obstetrics, Gynecology, and Reproductive Biology, 227 West Fee Hall, East Lansing, MI 48824; Joyce de Jong, DO and Brian Hunter, MD, E.W. Sparrow Hospital, Department of Pathology, 1215 East Michigan Avenue, Lansing, MI 48912</i>	476
Investigations and Eye Findings in Crush and Other Accidental Traumas in Lethally Injured Infants and Children	<i>M.G.F. Gilliland, MD*, Brody School of Medicine at East Carolina University, Department of Pathology, Forensic Division, Greenville, NC 27858-4354</i>	477
Meningitis Mimicking Inflicted Abusive Head Trauma	<i>Christie L. Elliott, MD* and Ellen G.I. Clark, MD, Forensic Pathology Consultants, 475 Kirman Avenue, Reno, NV 89502</i>	478
Fatal Hyponatremia, Cerebral Edema and Seizures Associated With Bilateral Peripheral Retinal Hemorrhages in a 20-Month-Old Child Following Hypotonic Fluid Administration for Dehydration: Case Report with Critical Appraisal of the Current Literature	<i>Patrick E. Lantz, MD*, Department of Pathology, Wake Forest University School of Medicine, Medical Center Boulevard, Winston- Salem, NC 27157-1072</i>	478
Delayed Jejunal Rupture in a Three-Year-Old Child After Minor Blunt Impact	<i>Leah L.E. Bush, MD, Office of the Chief Medical Examiner, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046; Wendy M. Gunther, MD*, Office of the Chief Medical Examiner and Department of Legal Medicine, Virginia Commonwealth University, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510; Gregory Raczniak, MPhil, Eastern Virginia Medical School, 714 Woodis Avenue, Norfolk, VA 23510</i>	479
Virulence Factors in Neisserial Meningococcemia	<i>Wendy M. Gunther, MD, Office of the Chief Medical Examiner and Department of Legal Medicine, Virginia Commonwealth University, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046; Gregory Raczniak, MPhil*, Eastern Virginia Medical School, 714 Woodis Avenue, Norfolk, VA 23510; Elizabeth L. Kinnison, MD, Office of the Chief Medical Examiner, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510</i>	479
SARS, Monkeypox, West Nile, Dengue, and Plague: Pitfalls of Globalization	<i>Saul B. Wilen, MD*, International Horizons Unlimited/Litigation Strategies Group, PO Box 40578, San Antonio, TX 78229</i>	480

Pure Group A Beta Streptococcal Peritonitis in a Child With Inflammatory Bowel Disease	<i>Sally S. Aiken, MD*, Spokane County Medical Examiner, 5901 North Lidgerwood, Suite 24B, Spokane, WA 99208</i>	480
Acute Dissection of the Left Subclavian Artery in a Patient With Ehlers-Danlos Syndrome	<i>Cristin M. Rolf, MD*, University of Kentucky/Office of the Associate Chief Medical Examiner, Commonwealth of Kentucky, 100 Sower Boulevard, Suite 202, Frankfort, KY 40601-8272</i>	481
A Case of Sudden Death in a 3-Year-Old Infant With Prader Willi Syndrome	<i>Cristoforo Pomara, MD*, Department of Forensic Pathology, University of Foggia, Viale Pinto n°1, Foggia 71100, Italy; Stefano D'Errico, MD and Irene Riezzo, MD, Institute of Legal Medicine, University of Foggia, Ospedali Riuniti, via L.Pinto 1, Foggia 71100, Italy</i>	481
Pediatric Asthma Mortality in the Cook County Medical Examiner's Office, 1 to 14 Years: 1998 - 2002	<i>Eupil Choi, MD* and Edmund R. Donoghue, MD, Cook County Medical Examiner's Office, 2121 West Harrison Street, Chicago, IL 60612</i>	482
Fatal Accidental Intravascular Injection of Air in Infants	<i>Angela R. Wetherton, MD* and Tracey S. Corey, MD, Office of the Chief Medical Examiner, 810 Barret Avenue, Louisville, KY 40204</i>	483
Lucid Interval Revisited: Delayed Onset of Unconsciousness in an Impacted Child	<i>Darinka Mileusnic, MD, PhD*, Knox County Medical Examiner's Office, University of Tennessee Medical Center, Department of Pathology, Knoxville, TN 37922; Edmund R. Donoghue, MD, Cook County Office of the Medical Examiner, Chief Medical Examiner, 2121 West Harrison Street, Chicago, IL 60612</i>	483

2003		
Investigation of Infant Fatalities in Maryland (1990-1999)	<i>Ling Li, MD*, and David R. Fowler, MD, Office of The Chief Medical Examiner, State of Maryland, Baltimore, MD; Liang Liu, MD, Tongji, Medical University, Wuhan, China; and Mary G. Ripple, MD, Zoe Lambros, RN, JD, Havre de Grace, MD, and John E. Smialek, MD, Office of The Chief Medical Examiner, State of Maryland, Baltimore, MD</i>	484
Sudden Infant Death Syndrome in North Carolina From 1999-2000: The Prevalence of Risk Factors and Its Relation to 2000 Census Data on a County by County Basis	<i>Russell Alexander, MD*, Duke University Medical Center, Department of Pathology, Box 3712, Durham, NC; Krista Ragan, BS, Castleton State College, Castleton, VT; Deborah Radisch, MD, MPH, Office of the Chief Medical Examiner, Campus Box 7580, Chapel Hill, NC; and Robin Vollmer, MD, Veterans Affairs Medical Center, Department of Pathology, 508 Fulton Street, Durham, NC</i>	484
Epidemiological Study of SIDS in an Apulian Population	<i>Nunzio Di Nunno, MD*, and Luigi Vimercati, MD, Sezione di Medicina Legale, Dipartimento di Medicina Interna e Medicina Pubblica, Università degli Studi di Bari, Policlinico, Piazza G. Cesare n. 11, Bari, Italy; Barbara Boninfante BSc, Dipartimento di Scienze Statistiche, Facoltà di Economia e Commercio, Università degli Studi di Bari, Italy; and Francesco Vimercati, MD, Sezione di Medicina Legale, Dipartimento di Medicina Interna e Medicina Pubblica, Università degli Studi di Bari, Policlinico, Piazza G. Cesare n.11 Bari, Italy</i>	485
A Five Year Retrospective Study of Unnatural Deaths in Children 12 Years and Younger in Singapore From 1997-2001	<i>Paul Peng Sun Chui, MBBS, DMJ, MRCPPath, MBA*, Centre for Forensic Medicine, Health Sciences Authority, 11 Outram Road, Singapore</i>	486
Bone Scintigraphy and Battered Children: Limit and Indication About a Case Report	<i>Laurent Martrille*, Anne Dorandell, MD, Lauren Boismenu, Oliver Cougnenc, and Eric Baccino, MD, Service de Médecine Légale, CHU Lapeyronie, 191 av, Montpellier, France</i>	486
Fatal Capnocytophaga Infection Associated With Splenectomy	<i>Mary H. Dudley, MD*, Lawrence A. Czarnecki, DO, and Mark A. Wells, BS, Sedgwick County Regional Forensic Science Center, 1109 North Minneapolis, Wichita, KS</i>	486
Look Until You See: An Unexpected Delayed Death Following a Motor Vehicle Accident	<i>Julie Wilson Lemmon, MD*, Tripler Army Medical Center, Tripler Army Medical Center, Tripler AMC, HI; Cynthia D. Gardner, MD, Department of Forensic Pathology, University of Tennessee Health Science Center, 1060 Madison Avenue, Memphis, TN</i>	487
Basketball-Related Sudden Deaths in Young Adults: A Medical Examiner Study	<i>Dennis J. Chute, MD*, Division of Neuropathology, UCLA Medical Center, 650 Charles Young Drive, South, Room 18-126, Los Angeles, CA; and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD</i>	488
The Significance of Tattoos in Forensic Autopsy	<i>Oguz Polat, MD, Bulent Sam, MD, and Esra Saka, MD, The State Institute of Forensic Medicine, Ministry of Turkey, Istanbul, Turkey; and Nevzat Alkan, MD, Istanbul University, Istanbul Medical Faculty, Department of Forensic Medicine, Istanbul, Turkey</i>	488

Epilepsy—A Major But Disregarded Health Problem	<i>Annie Vesterby, MD, DMSc*, Department of Forensic Medicine, Peter Sabroes Gade 15, Aarhus, Denmark; Soren Dalager-Petersen, MD, Department of Forensic Medicine, Aarhus University Hospital, Aarhus, Denmark; Simona Tigaran, MD, PhD, Department of Neurology, Aarhus University Hospital, Aarhus, Denmark; and Ulrik Baandrup, MD, Department of Pathology, Aarhus University Hospital, Aarhus, Denmark</i>	488
Death at Dinner: Foreign Body Asphyxiation – An Unknown Cause of Death in the Elderly?	<i>Andrea M. Berzlanovich, MD*, Institute of Forensic Medicine, University of Vienna, Sensengasse 2, A - 1090 Vienna, Austria; Thomas Waldhoer, Institute of Cancer Research, Department of Epidemiology, University of Vienna, Borschkegasse 8a, A - 1090 Vienna, Austria; Ernst Sim, MD, Meidling Traumatology Center, Kundratstraße 37, A - 1120 Vienna, Austria; Peter Fasching, Geriatric Center Baumgarten, Huetteldorferstraße 188, A - 1140 Vienna, Austria; and Manfred A. Muham, Department of Cardiothoracic Anesthesia and Intensive Care Medicine, University of Vienna, Waehringerstraße 18 - 20, A - 1090 Vienna, Austria</i>	489
Death During EMS Transportation	<i>Istvan F. Szentmariay, MD, DMJ*, and Gyorgy Dunay, MD, Institute of Forensic Medicine, Semmelweis University, Budapest, Hungary, Ullio Street 93, Budapest, Hungary</i>	489
Sudden Asphyxial Death Due to Regurgitation of a Pedunculated Esophageal Lipoma: A Case Report and Review of the Literature	<i>Tasha Zemrus, MD*, Assistant Medical Examiner, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD; Adrienne Segovia, MD, Deputy Medical Examiner, Office of the Cook County Medical Examiner, 2121 West Harrison Street, Chicago, IL</i>	490
First Report of Fatal Outcome by Accidental Intrathecal Injection of Vindesine	<i>Gilles Tournel, MD*, Anne Becart-Robert, DDS, Philippe Courtin, MD, Valéry Hedouin, MD, and Didier Gosset, MD, PhD, Forensic Department, Institut de Médecine Légale de Lille, Lille, France</i>	490
The Importance of an Interdisciplinary Review Process in the World Trade Center Mass Disaster Investigation	<i>Jason M. Wiersema, MA*, and Eric J. Bartelink, MA, Department of Anthropology, Texas A&M University, Department of Anthropology, College Station, TX; Zoran Budimlija, MD, PhD, Mechthild Prinz, PhD, Robert Shaler, PhD, and Amy Zelson Mundorff, MA, Office of Chief Medical Examiner, New York City, 520 First Avenue, New York, NY; and Gaille MacKinnon, MS, Department of Conservation Sciences, University of Bournemouth, Bournemouth, England, United Kingdom</i>	491
Media Relations and the Identification of the September 11 Pentagon Terrorist Attack Victims: The Perspective of the Office of the Armed Forces Medical Examiner	<i>Christopher C. Kelly, MMgmt*, Armed Forces Institute of Pathology, 6825 16th Street, NW, Building 54, Room 1106, Washington, DC</i>	491

Victim Identification Following the Crash of United Airlines Flight 93	<i>Paul S. Sledzik, MS*, Region III DMORT, National Museum of Health and Medicine, Armed Forces Institute of Pathology, 6825 16th Street, NW, Washington, DC; Wallace Miller, BA, Somerset County Coroner's Office, 555 Tayman Avenue, Somerset, PA; Dennis C. Dirkmaat, PhD, Mercyhurst Archaeological Institute, Mercyhurst College, 501 East 38th Street, Erie, PA; Joyce L. de Jong, DO, Sparrow Hospital Pathology, 1215 East Michigan Avenue, Lansing, MI; Patricia J. Kauffman, MD, GlaxoSmithKline, 2187 Harts Lane, Whitemarsh, PA; David A. Boyer, MFS, Department of Defense DNA Registry, 1413 Research Boulevard, Armed Forces Institute of Pathology, Rockville, MD; Fedric N. Hellman, MD, Delaware County Coroner's Office, Fair Acres, Lima, PA</i>	492
Domestic Homicide or International Terrorism? A St. Louis Murder Crosses the Line	<i>Phillip M. Burch, MD*, Saint Louis University, 1300 Clark Avenue, St. Louis, MO</i>	493
Smallpox and the Medical Examiner/Coroner System	<i>Donald R. Jason, MD, JD*, Wake Forest University School of Medicine, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC</i>	493
Autopsy Procedure and Findings in a Case of Inhalational Anthrax	<i>Mary G. Ripple, MD*, Jack M. Titus, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD</i>	494
Discrepancy Between the Legal and Medical Definitions of Homicide	<i>Jeffrey M. Jentzen, MD*, Milwaukee County Medical Examiner's Office, 933 West Highland Avenue, Milwaukee, WI; Ayako Kobayahi, University of Wisconsin at Milwaukee, 1-3-4 Nozawa, Setagaya-ku, Tokyo, Japan; Eileen Weller, RN, MHA, Milwaukee County Medical Examiner's Office, 933 West Highland Avenue, Milwaukee, WI; and Mallory O'Brien, PhD, Harvard School of Public Health, 2501 East Menlo Boulevard, Shorewood, WI</i>	494
Rape/Sadistic-Homicide vs. Accidental Death During Voluntary Violent Sexual Activity: Three Case Reports Illustrating Difficulties in Assessing the Circumstances of the Deaths	<i>Dominique Lecomte, MD*, and Paul Fornes, PhD, Forensic Institute of Paris, Medical School Cochin Port-Royal, Paris, France</i>	495
Postmortem Genital Examinations and Evidentiary Protocol With Colposcopy	<i>Sharon R. Crowley, RN, MN*, Forensic Clinical Nurse Specialist, 122 Emeline Avenue, Santa Cruz, CA</i>	495
Validation of the Anthropology Research Facility in Knoxville, TN, as a Research and Training Site For Forensic Entomology	<i>Adam Shahid, MS, University of Missouri, Columbia, Department of Entomology, 1-87 Agriculture Building, Columbia, MO; Kenneth G. Schoenly, PhD*, California State University, Stanislaus, Department of Biological Sciences, Turlock, CA; Neal H. Haskell, PhD, Forensic Entomology Consultant, 425 Kannal Avenue, Rensselaer, IN; and Robert D. Hall, PhD, JD, University of Missouri, Columbia, Department of Entomology, 1-87 Agriculture Building, Columbia, MO</i>	496
Extracting Human DNA From the Crops of Maggots That Have Been Collected During Different Stages of Development and Preserved Using Different Methods	<i>Jason G. Linville, BS*, Department of Biology, University of Alabama at Birmingham, 2909 Highland Avenue, S Apartment 207, Birmingham, AL; Jeffrey D. Wells, PhD, Department of Justice Sciences, University of Alabama at Birmingham, 901 15th Street South, Birmingham, AL</i>	497

Bioterrorism Response and Training: Building Upon Mass Disaster and Multiple Fatality Preparedness at the Office of the Chief Medical Examiner, Boston, MA	<i>Richard J. Evans, MD*, Office of the Chief Medical Examiner, 720 Albany Street, Boston, MA; Ann Marie Mires, PhD, Office of the Chief Medical Examiner, 7416 Falmouth Street, Boston, MA; and Alexander Chirchov, MD, PhD, Faryl Sandler, MD, and William M. Zane, MD, Office of the Chief Medical Examiner, 720 Albany Street, Boston, MA</i>	497
Computerization of the Autopsy Report "How to Build Your Own Desktop"	<i>Coleen Crawford, MFA*, and William M. Zane, MD, OCME Commonwealth of Massachusetts, 720 Albany Street, Boston, MA</i>	498
Using STR Analysis to Detect Human DNA From Exploded Pipe Bomb Devices	<i>Kelly J. Esslinger, MS*, 1805 Arbor Lane, #304, Crest Hill, IL; Jay A. Siegel, PhD, School of Criminal Justice, Michigan State University, 560 Baker Hall, East Lansing, MI; and Heather Spillane, BS, and Shawn Stallworth, Michigan State Police Crime Laboratory - Northville, 42145 West Seven Mile Road, Northville, MI</i>	498
An Atypical STR Genotype, Including a Three-Banded Allelic Pattern, From a Biopsy Tissue Sample	<i>Sobia Malik, MSc*, Centre of Forensic Sciences, 25 Grosvenor Street, 4th Floor, Toronto, Ontario, Canada</i>	499
DNA Databank Hits: Identification of the Perpetrator?	<i>Sarah Johnston, MSc*, Roger Frappier, MSc, and Jonathan Newman, BSc, Centre of Forensic Sciences, 25 Grosvenor Street, 4th Floor, Toronto, Ontario, Canada</i>	499
Everything Old is New Again: A Program to Examine "Cold" Sexual Assault Cases	<i>Linda Parker, MSc, Jack Laird, MSc, Elida Kafarowski, MSc, Brian Peck, MSc*, Suzanne Lima, MSc, and Jonathan Newman, BSc, Centre of Forensic Sciences, 25 Grosvenor Street, 4th floor, Toronto, Ontario, Canada</i>	500
Bone Extraction Procedure for Nuclear DNA Analysis Used in World Trade Center Human Identification Project	<i>Zoran M. Budimilja*, MD, PhD, Bianca Nazzaruolo, MA, Sheila M. Estacio, BS, Mechthild K. Prinz, PhD, and Robert C. Shaler, PhD, Office of Chief Medical Examiner, Department of Forensic Biology, 520 First Avenue, New York, NY</i>	501
Digestion Time of Human Mitochondrial DNA in Blowfly Larvae, <i>Calliphora vicina</i>	<i>Paula M. Do*, California State University, Bakersfield 2001 Stockdale Highway, Bakersfield, CA</i>	501
Postmortem Interval (PMI) Determined by Analyzing Temperature Variations of Maggot Masses	<i>Sonja L. Peters, BS*, 5333 Southwest 75th Street, Apt. S-105, Gainesville, FL; Jerry F. Butler, PhD, Department of Entomology & Nematology, University of Florida, P.O. Box 110620, Gainesville, FL; Jerome A. Hogsette, PhD, USDA-ARS, CMAVE, P.O. Box 14565, Gainesville, FL; Anthony B. Falsetti, PhD, Anthropology Department, C.A. Pound Human Identification Laboratory, P.O. Box 117305, Gainesville, FL; and Roxanne Rutledge, PhD, Florida Medical Entomology Laboratory, 200 9th Street, SE, Vero Beach, FL</i>	502
A Summer Carrion Study in the North of Italy	<i>Mirella Gherardi, MD*, Gabriella Costantini, and Marina Caligara, Institute of Legal Medicine - University of Milan, Via Mangiagalli, 37, Milan, Italy; Giancarlo Belluzzi, Veterinary Service, ASL, via Ghinaglia, 6, Cremona, Italy; and Massimo Boldini, Experimental Zooprophylactic Institute, Cremona, Italy</i>	502

Of Leaves and Men: Botanical Evidence Leads Investigators to a Missing Girl's Body	<i>Rebecca A. Bullard, MS*, Department of Entomology, University of California, Davis, Department of Entomology, University of California at Davis, Davis, CA; and Kristina A. Schierenbeck, PhD, Department of Biological Sciences, California State University, Chico, Department of Biological Sciences, California State University at Chico, Chico, CA</i>	503
A Study of Three Suicidal Hangings in Jail Using Telephone Cords	<i>Reade A. Quinton, MD*, University of Texas Southwestern Medical Center Department of Pathology, 5323 Harry Hines Boulevard, Dallas, TX; David Dolinak, MD, Dallas County Medical Examiner, 5230 Medical Center Drive, Dallas, TX</i>	504
Diabetic Ketoacidosis—A Silent Death	<i>Zabiullah Ali, MD*, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD; Mary G. Ripple, MD, 68 Bluebird Road, Port Deposit, MD; and Barry S. Levine, PhD, and David R. Fowler, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD</i>	504
Investigation of Time Interval For Recovery of Semen and Spermatozoa From Female Internal Genitalia	<i>Tracey S. Corey, Office of the Chief Medical Examiner, Department of Pathology and Laboratory Medicine, University of Louisville School of Medicine; Angela R. Weiherton, MD*, Department of Pathology and Laboratory Medicine, University of Louisville School of Medicine; Pamela J. Froncek, RN, Office of the Chief Medical Examiner; and Dawn Katz, BS, Kentucky State Police Forensic Science Laboratory, Louisville KY</i>	505
The Role of Hyponatremia in Fresh Water Drowning and Water Intoxication: Making the Distinction at Autopsy	<i>Kenneth S. Snell, MD* Medical Examiner, Mecklenburg County Medical Examiner's Office, Charlotte, NC; Keith C. Kocis, MD, MS, Associate Professor of Pediatrics, Department of Pediatrics, University of North Carolina at Chapel Hill, Chapel Hill, NC; and Deborah L. Radisch, MD, MPH, Associate State Medical Examiner, Office of the Chief Medical Examiner, Chapel Hill, NC</i>	505
An Unusual Cause of Sudden Death in Infancy: Hypertrophic Cardiomegaly	<i>Marie E. Cannon, MD*, Office of the Chief Medical Examiner, 720 Albany Street, Boston, MA; Eva Patalas, MD, Massachusetts General Hospital, 55 Fruit Street, Boston, MA; and Alexander Chirkov, MD, PhD, Office of the Chief Medical Examiner, 720 Albany Street, Boston, MA</i>	506
Use of Expert Consultation in the Evaluation of Tissue Donors With a Postmortem Diagnosis of "Hepatitis" to Determine Eligibility For Transplantation	<i>Stephen L. Sgan, MD*, and Shobha Sharma, MD, Department of Pathology and Laboratory Medicine, Emory University School of Medicine, 1364 Clifton Road, NE, Atlanta, GA; and Judith Woll, MD, and Lance D. Trainor, MD, Community Blood Center / Community Tissue Services, 349 South Main Street, Dayton, OH</i>	507
Determining the Cause of Death and Contributing Factors in Fatal Recreational SCUBA Diving Accidents	<i>James L. Caruso, MD*, Office of the Armed Forces Medical Examiner, The Armed Forces Institute of Pathology, Washington, DC</i>	508
Sphenoid Sinus Petechiae: Incidence and Significance	<i>Kathryn H. Haden, MD*, and David Dolinak, MD, Southwestern Institute of Forensic Sciences and the University of Texas Southwestern Medical Center, Dallas, TX</i>	508

Homicide in the Elderly— Paris and Its Suburbs, 1996-2001	<i>M. Berrouche, MD, Paul Fornes, MD, PhD*, and Dominique Lecomte, MD, Forensic Institute of Paris, Medical School Cochin Port Royal, Paris, France</i>	509
Abuse and Neglect: A 10-Year Review of Mortality in Elders	<i>Lisa B.E. Shields, MD *, and Donna M. Hunsaker, MD, Office of the Chief Medical Examiner, University of Louisville School of Medicine, Louisville, KY; and John C. Hunsaker III, MD, JD, Office of the Associate Chief Medical Examiner, University of Kentucky College of Medicine, Frankfort and Lexington, KY</i>	509
Elderly Neglect/Abuse	<i>Kanthi von Guenthner, MD*, Chief Medical Examiner, Department of the Medical Examiner, City and County of Honolulu, 835 Iwilei Road, Honolulu, HI</i>	510
Morphological Considerations of the Hyoid Bone	<i>Joanne L. Devlin, PhD*, Department of Anthropology, University of Tennessee, 250 South Stadium Hall, University of Tennessee, Knoxville, TN</i>	510
Relevance of the Autopsy as a Medical Tool: A Large Database of Physician Attitudes	<i>Jody E. Hooper, MD*, U.S. Navy, General Medical Officer, Branch Medical Clinic, Naval Air Station, North Island, Coronado, CA</i>	510
Analysis of Five Thousand Forensic Medical Expert Opinions	<i>Istvan F. Szentmariay, MD, DMJ, Marta Hubay, MD, and Gyorgy Dunay, MD*, Institute of Forensic Medicine, Semmelweis University, Budapest, Hungary, Ullo Street 93, Budapest, Budapest, Hungary</i>	511
The Happy Land Homicides: 87 Deaths Due to Smoke Inhalation	<i>Lara B. Goldfeder, BS, MD*, James R. Gill, MD, and Marina Stajic, PhD, Office of the Chief Medical Examiner, 520 First Avenue, New York, NY</i>	512
Documenting Patterns of Injury in Fire Victims	<i>O' Brian C. Smith, MD*, Regional Forensic Center of the University of Tennessee, 1060 Madison Avenue, Memphis, TN; and Elayne J. Pope, MA, University of Arkansas, 330 Old Main, Fayetteville, AR</i>	512
Suicide Attempt Using a Self-Made Rifle	<i>Jean-Sebastien Raul, MD*, Antoine Tracqui, MD, PhD, and Bertrand Ludes, MD, PhD, Institut de Medecine Legale, 11 rue Humann, Strasbourg, France</i>	513
Suicidal Jumping	<i>Istvan Szentmariay, MD, DMJ*, and Gyorgy Dunay, MD, Institute of Forensic Medicine, Semmelweis University, Budapest, Hungary, Ullo Street 93, Budapest, Budapest, Hungary</i>	513
Suicide in Eastern Crete	<i>Katerina Kanaki, MD*, Researcher, Department of Forensic Sciences, University of Crete, Heraklion, Greece; Ersi Abaci Kalfoglu, PhD, Professor, Institute of Forensic Sciences, University of Istanbul, Istanbul, Turkey; and Manolis Michalodimitrakis, MD, Professor, Department of Forensic Sciences, University of Crete, Heraklion, Greece</i>	513
Postmortem Findings in 22 Victims Due to Two Grain Silo Explosions in France	<i>Sophie Gromb, MD, JD, PhD*, and Koffi Bott, Service of Forensic Sciences, University of Bordeaux, Bordeaux, France; and Alain Miras, MD, University of Lyon, IML Avenue Rockefeller, Lyon, France</i>	514
Injuries of an Armored Vehicle Occupant During Armed Robbery: A Case Report	<i>Giancarlo Di Vella, MD, PhD*, Rosa Falamingo, MD, PhD, Maura Belviso, MD, PhD, and Francesco Vinci, MD, Section of Legal Medicine - University of Bari - Italy, Policlinico, piazza G. Cesare, 70124 – Bari, Italy</i>	514
Roll-Over Automobile Accident Survived By the Author as a Passenger	<i>Gordon K. Murphy, MD*, 814 Hathaway Road, Dayton, OH</i>	515

Intracranial Internal Carotid Laceration at the Site of an Atherosclerotic Plaque: A Case Report	<i>Kristin Gilmore, MD*, Department of Pathology, Kings County Hospital, Brooklyn, NY; David Kindleberger, MD, SUNNY Health Science Center College of Medicine, Brooklyn, NY; and Charles A. Catanese, MD, Office of the Chief Medical Examiner, Brooklyn, NY</i>	515
An Unusual Case of Crossbow Homicide	<i>Sabina Di Donato, MD, Marianna Di Padua, MD, Floriana Monciotti, MD, Francesco Maria Morreale, MD, Margherita Neri, MD, and Cristoforo Pomara, MD*, Department of Forensic Pathology, University of Foggia, Viale Pinto 1, Foggia, Italy</i>	515
Body Found in the Waterway of Lille—Accident, Suicide, or Homicide?	<i>Gilles Tournel, MD*, Sandrine Gaulon, Anne Becart-Robert, DDS, Valéry Hedouin, MD, and Didier Gosset, MD, PhD, Forensic Department, Institut de Médecine Légale de Lille, Lille, France</i>	516
Pink Teeth in a Series of Bodies Recovered From a Single Shipwreck	<i>Carlo Pietro Campobasso, MD, PhD*, Giancarlo Di Vella, MD, PhD, and Antonio De Donno, MD, Section of Legal Medicine, University of Bari, Piazza Giulio Cesare, Bari, Italy; Giorgia Girone, DDS, and Gianfranco Favia, MD, School of Dentistry, University of Bari, Piazza Giulio Cesare, Bari, Italy; and Francesco Intronà, MD, Section of Legal Medicine, University of Bari, Piazza Giulio Cesare, Bari, Italy</i>	517
Calcified Primary and Metastatic Pancreatic Carcinoma Discovered in Skeletonized Remains	<i>Joseph P. O'Hara, MD*, and Debra Komar, PhD, University of New Mexico Health Sciences Center, Office of the Medical Investigator, Albuquerque, NM</i>	517
Undefeated by Surgery: The Utility of Post-Surgical Foot and Ankle Radiographs for Identification: Focus on the Ankle	<i>Dorothy E. Dean, MD*, Franklin County Coroner's Office, Columbus, OH; Nancy E. Tatarek, PhD, Ohio University, Athens, OH; Jeremy Rich, DPM, Brigham and Women's Hospital, Boston, MA; Robert H. Powers, PhD, Hamilton County Coroner's Office, Cincinnati, OH; B.G. Brogdon, MD, University of South Alabama Medical Center, Mobile, AL; and Bradley J. Lewis, MD, Franklin County Coroner's Office, Columbus, OH</i>	518
To Rave or Not to Rave: A Report of Three Fatal GHB Poisonings	<i>John R. Fernandes, MDCM*, Regional Forensic Unit, 237 Barton Street East, Hamilton, Ontario, Canada; Marcella F. Fierro, MD, Office of Chief Medical Examiner, 400 East Jackson Street, Richmond, VA; and James Cairns, DRCOG, Office of Chief Coroner, 26 Brenville Street, Toronto, Ontario, Canada</i>	518
Methadone-Related Deaths in Palm Beach County	<i>Barbara C. Wolf, MD*, Palm Beach County Medical Examiner's Office, 6065 Ellis Lane, Loxahatchee, FL; Wendy A. Lavezzi, MD, Albany Medical College, 47 New Scotland Avenue, Albany, NY; and Lisa M. Flanagan, MD, Palm Beach County Medical Examiner's Office, 3126 Gun Club Road, West Palm Beach, FL</i>	519
Comparison of the Distribution of Fentanyl in Deaths Related to Use and Abuse of the Duragesic® Patch and Intravenous Administration of Patch Contents	<i>Jaime L. Oeberst, MD*, and Timothy P. Rohrig, PhD, Sedgwick County Regional Forensic Science Center, 1109 North Minneapolis, Wichita, KS</i>	519

Sufentanil Toxicity in Healthcare Professionals	<i>Douglas Posey, MD*, Joye M. Carter, MD, and Jessie Adame, MD, Harris County Medical Examiner Office, 1885 Old Spanish Trail, Houston, TX; and Ashraf Mozayani, PharmD, PhD, Autopsy and Pathology Services, Inc., P.O. Box 920903, Houston, TX</i>	520
Acute Fatal Propafenone Toxicity: Drug Concentration, Distribution, and Clinical Features in Two Suicides	<i>Dwayne A. Wolf, MD, PhD*, and Ashraf Mozayani, PharmD, PhD, Harris County Medical Examiner's Office, Joseph A. Jachimczyk Forensic Center, 1885 Old Spanish Trail, Houston, TX; and Christopher LaVergne, MD, North Houston Heart Center, 800 Peakwood, Suite 8A, Houston, TX</i>	521
Flecainide: A Suicidal Pharmacist's Choice	<i>Dwayne A. Wolf, MD, PhD*, and Ashraf Mozayani, PharmD, PhD, Harris County Medical Examiner Office, Joseph A. Jachimczyk Forensic Center, 1885 Old Spanish Trail, Houston, TX</i>	521
The Use of Lidocaine to Commit Homicide: A Case Report and Review of the Literature	<i>Brian C. Hunter, MD*, 1215 East Michigan Avenue, Lansing, MI; John H. Trestrail III, BS, RPh, Regional Poison Center, Grand Rapids, MI; and Stephen D. Cohle, MD, Spectrum Health East Campus, Pathology Department, Grand Rapids, MI</i>	522
The Normal Heart Weight: Diagnostic Criteria for Cardiomyopathies	<i>Paul Fornes, PhD*, and Dominique Lecomte, MD, Forensic Institute of Paris, Medical School Cochin Port Royal, Paris, France</i>	523
Isolated Noncompaction of the Left Ventricle: A Rare Cause of Sudden Death	<i>Kendell V. Crowns, MD*, and Adrienne Segovia, MD, Cook County Medical Examiner's Office, 2121 West Harrison Street, Chicago, IL</i>	523
Normal Fat in the Right Ventricle vs. Arrhythmogenic Right Ventricular Cardiomyopathy/Dysplasia	<i>Paul Fornes, PhD*, and Dominique Lecomte, MD, Forensic Institute of Paris, Medical School Cochin Port Royal, Paris, France</i>	523
Trauma-Related Hemorrhage vs. Spontaneous Rupture of Vascular Malformation: Three Case Reports Illustrating Medico-Legal Aspects	<i>Dominique Lecomte, MD*, and Paul Fornes, PhD, Forensic Institute of Paris, Medical School Cochin Port Royal, Paris, France</i>	524
Esophageal and Pharyngeal Injury Associated With the Esophageal-Tracheal Combitube®	<i>Robert Stoppacher, MD, MS, BS*, Milwaukee County Medical Examiner's Office 933 West Highland Avenue, Milwaukee, WI</i>	524
Determination of Time Since Death—Cardiac Troponin I	<i>Alberto J. Sabucedo*, PhD, and Kenneth G. Furton, PhD, Department of Chemistry and International Forensic Research Institute, Florida International University, University Park, Miami, FL</i>	524
Quantitative Measurement of Ribonucleic Acid Degradation as a Possible Indicator of Postmortem Interval	<i>Ira Gramlich, Dieter Patzelt, MD, and Martin Bauer, MD*, Institute of legal Medicine, University of Wuerzburg, Versbacher Str. 3, Wuerzburg, Germany</i>	525
Experimental Evaluation of Rigor Mortis: The Influence of the Breaking (Mechanical Solution) on the Development of Rigor Mortis	<i>Thomas Krompecher, MD*, André Gilles, MD, Conxita Brandt-Casadevall, MD, and Patrice Mangin, MD, Institut universitaire de Médecine légale, Rue du Bugnon 21, 1005 Lausanne, Switzerland</i>	526

Evaluation of a Putative Snuff Film	<i>William R. Oliver, MD*, Armed Forces Institute of Pathology, 1413 Research Boulevard, Rockville, MD; Peter G. Lawson, Naval Criminal Investigative Service, 620 John Paul Jones Circle, Portsmouth, VA; William C. Rodriguez III, PhD, Armed Forces Institute of Pathology, 1413 Research Boulevard, Rockville, MD; and Douglas Knittel, MD, Naval Medical Center, 630 John Paul Jones Circle, Portsmouth, VA</i>	526
Analysis of Electric Injury Patterns in Human Skin by Magnetic Resonance Microscopy	<i>Michael Thali, MD*, Office of the Armed Forces Medical Examiner, Rockville, MD, and Institute of Forensic Medicine, University of Berne, Berne, Switzerland; William R. Oliver, MD, and William C. Rodriguez III, PhD, Armed Forces Institute of Pathology, Rockville MD; Richard Dirnhofer, MD, Institute of Forensic Medicine, University of Berne, Berne, Switzerland; and Kimberlee Potter, PhD, Armed Forces Institute of Pathology, Rockville, MD</i>	527
Coins as Intermediate Targets: Reconstructive Analysis With Body Models	<i>Michael Thali, MD*, Office of the Armed Forces Medical Examiner, Armed Forces Institute of Pathology, Rockville, MD, and Institute of Forensic Medicine, University of Berne, Berne, Switzerland; Beat P. Kneubuehl, PhD, Institute of Forensic Medicine, University of Berne, Berne, Switzerland; William C. Rodriguez III, PhD, Office of the Armed Forces Medical Examiner, Armed Forces Institute of Pathology, Rockville, MD; James Smirniotopoulos, MD, Uniformed Services University of the Health Sciences, Bethesda, MD; A. Charles Richardson, DDS, National Naval Medical Center, Department of Radiology, Bethesda, MD; David R. Fowler, MD, Offices of the Medical Examiner of the State Maryland, Baltimore, MD; Michael L. Godwin, BS, and Aaron Jurrus, Office of the Armed Forces Medical Examiner, Armed Forces Institute of Pathology, Rockville, MD; Doug Fletcher, PhD, National Naval Medical Center, Department of Radiology, Bethesda, MD; and Craig T. Mallak, MD, Office of the Armed Forces Medical Examiner, Armed Forces Institute of Pathology, Rockville, MD</i>	527
Two Gunshots to the Head: Suicide or Homicide? A Biomechanical Study	<i>Jean-Sebastien Raul, MD*, Institut de Medecine Legale, 11 rue Humann, Strasbourg, France; C. Deck, and F. Meyer, Institut de Mécanique des fluides - ULP-CNRS 7507, Strasbourg, France; Annie Geraut, and Antoine Tracqui, MD, PhD, Institut de Medecine Legale, 11 rue Humann, Strasbourg, France; R. Willinger, Institut de Mecanique des Fluides, ULP-CNRS 7507, Strasbourg, France; and Bertrand Ludes, MD, PhD, Institut de Medecine Legale, 11 rue Humann, Strasbourg, France</i>	528
Application of Biomechanics to the Interpretation of Pathology Data	<i>Robert O. Andres, PhD*, Ergonomic Engineering, Inc., 20 Gulf Road, Pelham, MA; and Joseph H. Davis, MD*, 8905 Southwest 115 Terrace, Miami, FL</i>	529
Evaluation of Iron and Macrophages in Meninges of Infants Dying Suddenly and Unexpectedly	<i>Ellen G.I. Clark, MD, 475 Kirman, Reno, NV; Kathy P. Raven, MD*, King County Medical Examiner's Office, 325 Ninth Avenue, Box 359792, Seattle, WA; Daniel Anderson-Wooley, 475 Kirman, Reno, NV; and Richard C. Harruff, MD, PhD, 325 Ninth Avenue, Seattle, WA</i>	529

Extent and Distribution of Retinal Hemorrhages in Abusive and Non-Abusive Head Injury	<i>M.G.F. Gilliland, MD*, Brody School of Medicine East Carolina University Department of Pathology and Laboratory Medicine, Brody 7510, Greenville, NC</i>	529
Perimacular Retinal Folds and the Shaken Baby Syndrome: Critical Appraisal Testing of the Current Medical Literature	<i>Patrick E. Lantz, MD*, Wake Forest University Health Sciences, Medical Center Boulevard, Winston-Salem, NC</i>	530
Neuropathology of Abusive Head Injury	<i>Mary E.S. Case, MD*, Saint Louis University Health Sciences Center, 6039 Helen Avenue, St. Louis, MO</i>	531
Pediatric Injury Evaluation: A Clinical Forensic Pathology Program in Georgia	<i>Lora A. Darrisaw, MD*, Julie P. Gardiner, BA, Geoffrey P. Smith, MD, and Kris L. Sperry, MD, Georgia Bureau of Investigation, 3121 Panthersville Road, Decatur, GA</i>	531
Physical Findings in Confessed Homicidal Suffocation of Children: A Case Series	<i>Tracey S. Corey, MD, and Deirdre Schluckebier, MD*, Office of the Chief Medical Examiner and University of Louisville School of Medicine, OCME, 810 Barret Avenue, Louisville, KY</i>	532
Escalated Homicide: Cultural Changes Produce a New Type of Child Death	<i>Chantal Ferraro, PhD*, Long Island University at Brookville, Brookville, NY; and O'Brian C. Smith, MD, University of Tennessee at Memphis, 1060 Madison Avenue, Memphis, TN</i>	532
Magnetic Resonance Microscopy as an Adjunct in The Evaluation of Infant Rib Fractures	<i>Andrew M. Baker, MD*, Office of The Hennepin County Medical Examiner, 530 Chicago Avenue, Minneapolis, MN; and Kimberlee Potter, PhD and William R. Oliver, MD, Armed Forces Institute of Pathology, 14th and Alaska Avenue, Northwest, Washington, DC</i>	533
Mother/Infant Co-Sleeping/Bed-Sharing and Sudden Infant Death Syndrome	<i>James J. McKenna, PhD*, University of Notre Dame, 613 Flanner, South Bend, IN; and Joseph A. Prahlow, MD*, South Bend Medical Foundation & Indiana University School of Medicine, 530 North Lafayette, South Bend, IN</i>	534
Death Certification in Sudden Infant Death Syndrome and Related Infant Deaths	<i>Joseph A. Prahlow, MD*, South Bend Medical Foundation & Indiana University School of Medicine, 530 North Lafayette, South Bend, IN; and Randy L. Hanzlick, MD, Fulton County Medical Examiners Office, 430 Pryor Street, SW, Atlanta, GA</i>	534
Pediatric Mortality in the Cook County Medical Examiner's Office, 1 to 4 Years: 2000-2001	<i>Eupil Choi, MD*, and Edmund R. Donoghue, MD, Office of the Medical Examiner, Cook County, 2121 West Harrison Street, Chicago, IL</i>	535
Suicide in Children: A 12-Year Retrospective Study	<i>Jeffrey M. Jentzen, MD*, and Eileen Weller, RN, MHA, Milwaukee County Medical Examiner's Office, 933 West Highland Avenue, Milwaukee, WI; and Adam Ruck, University of Wisconsin-Milwaukee, 2465 Oakland Ave, Milwaukee, WI</i>	535

2002		
Overview of Suicide Cases in Geneva, Switzerland During a Twenty-five Year Period (1971-1995)	<i>Romano La Harpe, MD*, Institut Universitaire de Médecine Légale, Av. de Champel 9 (CMU), Genève 4, Switzerland</i>	536
An Unusual Presentation of a Rare Entity: Essanguination by Ruptured Left Subclavian Aneurysm	<i>Reade A. Quinton, MD*, UT Southwestern Medical Center, Department of Pathology, 5323 Harry Hines Boulevard, Dallas, TX; and Joni L McClain, MD, Southwestern Institute of Forensic Sciences, 5230 Medical Center Drive, Dallas, TX</i>	536
An Unusual Cause of Sudden Death in Infancy: Histiocytoid Cardiomyopathy, Report of an Autopsy Case	<i>Frank Evangelista, MD*, Office of the Chief Medical Examiner, 720 Albany Street, Boston, MA; Melissa P. Upton, MD, Beth Israel Deaconess Medical Center-Department of Pathology, 330 Brookline Avenue, Boston, MA; Richard J. Evans, MD, Eva Patalas, MD, and Alexander M. Chirkov, MD, PhD, Office of the Chief Medical Examiner, 720 Albany Street, Boston, MA</i>	537
The Changing Faces of the Medico-Legal Autopsies at the Office of the Chief Medical Examiner of the State of Maryland— A Decade of Experience	<i>Aurelian Nicolaescu, MD*, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD; Joseph A. Kufura, MA, National Study Center for Trauma and EMS, 701 West Pratt Street, Baltimore, MD; Jack M. Titus, MD, and David R. Fowler, MB, ChB, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD</i>	537
Malaria Deaths in the United States: Case Report and Review of Deaths, 1979-1998	<i>Robert Stoppacher, MD*, Milwaukee County Medical Examiner's Office, 5258 North, Bay Ridge Avenue, White Fish Bay, WI; and Stephen P. Adams, MD, Vermont Office of the Chief Medical Examiner, 111 Colchester Avenue, Burlington, VT</i>	538
North Carolina's Death Investigation Database	<i>D'Michelle P. DuPre, MD*, Duke University Medical Center, PO Box 3712, Durham, NC; and Kenneth S. Snell, MD, and Thomas B. Clark III, MD, Office of the Chief Medical Examiner, Chapel Hill, NC</i>	538
"Homicide by Heart Attack" Revisited	<i>Staci D. Turner, MD*, Jeffrey J. Barnard, MD, and Sheila D. Spotswood, MD, Southwestern Institute of Forensic Sciences, 5230 Medical Center Drive., Dallas, TX; and Joseph A. Prahlow, MD, South Bend Medical Foundation and Indiana University School of Medicine, University of Notre Dame, South Bend, IN</i>	539
The Significance of Pulmonary Interstitial Emphysema in Fetal and Infant Autopsies	<i>Wendy A. Lavezzi, MD*, Department of Pathology and Laboratory Medicine, 56 South Westcott Road, Schenectady, NY; and Barbara C. Wolf, MD, Forensic Medicine, PC, Albany, NY</i>	540
Motor Vehicle Collision-Related Death Due to Delayed-Onset Subarachnoid Hemorrhage Associated With Anticoagulant Therapy	<i>Ana E. Lopez, MD*, Jeffrey J. Barnard, MD, and Charles L. White III, MD, Southwestern Institute of Forensic Sciences, 5230 Medical Center Drive, Dallas, TX; Jaime L. Oeberst, MD, Sedgwick County Regional Forensic Science Center, Wichita, KS; and Joseph A. Prahlow, MD, South Bend Medical Education, University of Notre Dame, South Bend, IN</i>	540

A Comprehensive Analysis of Forensic Science Training in Forensic Pathology Fellowship Programs	<i>J. Keith Pinckard, MD, PhD*, Division of Laboratory Medicine, Washington University School of Medicine, Box 8118, 660 South Euclid Avenue, Saint Louis, MO; Donna M. Hunsaker, MD, Office of the Chief Medical Examiner, 810 Barrett Avenue, Louisville, KY; and Victor W. Weedin, MD, JD, Carnegie Mellon University, 4400 Fifth Avenue Mellon Institute, Room 292, Pittsburgh, PA</i>	541
Postmortem Microbiology: Friend or Foe?	<i>Kathryn H. Haden, MD*, Lisette L. Lester, MD, JD, Sandra K. Elkins, MD, and Mark Cole, University of Tennessee Medical Center, 1924 Alloa Highway, Box U-108, Knoxville, TN</i>	542
Sufentanil Toxicity in Healthcare Professionals	<i>Jessie Adame, MD, Autopsy and Pathology Services, PO Box 920903, Houston, TX; Douglas H. Posey, MD*, Joye Carter, MD, and Ashraf Mozayani, PharmD, PhD, Harris County Medical Examiner Office, 1885 Old Spanish Trail, Houston, TX</i>	542
Oxycodone (OxyContin) Related Deaths in Maryland 1998-2000	<i>Ellen C. Riemer, MD, JD*, Barry S. Levine, PhD, Jack M. Titus, MD, and David R. Fowler, MB, ChB, Office of the Chief Medical Examiner of the State of Maryland, 111 Penn Street, Baltimore, MD</i>	543
Deaths Related to Conduction System Pathology	<i>Katarzyna Michaud, MD*, Nathalie Romain, MD, and Patrice Mangin, MD, PhD, Institut Universitaire de Médecine Légale, Rue du Bugnon 21, Lausanne, Switzerland</i>	543
Commotio Cordis Intermedius: Digital Interposition Between Projectile and Thorax	<i>William Q. Sturmer, MD*, Office of the Medical Examiner, Arkansas State Crime Laboratory, PO Box 8500, Little Rock, AR</i>	544
Genetics of Sudden Cardiac Death: Prothrombotic Mutations of Blood Platelet Glycoprotein Receptors are Common Among Men Who Die of Prehospital Myocardial Infarction at Early Middle Age	<i>Pekka J. Karhunen, MD, PhD*, University of Tampere, POB 602, Tampere, Finland; J. Mikkelsson, Schools of Medicine and Public Health, University and University Hospital of Tampere, Tampere, Finland; M. Perola, Department Human Molecular Genetic, National Public Health, Institute Tampere, Helsinki; P. Laippala, Schools of Medicine and Public Health University and University Hospital of Tampere Department Clinic Pathology and Forensic Medicine, Tampere, Finland; and A. Penttila, Department Forensic Medicine, University of Helsinki, Tampere, Helsinki</i>	544
Under Reporting of Fatal Child Abuse by State Vital Statistics ICD-9 Codes	<i>Mary H. Dudley, MD*, and Shari L. Beck, BA, Chief Medical Investigator, Sedgwick County Regional Forensic Science Center, Wichita, KS; Larry Czarnecki, DO, Office of the Medical Investigator, and University of New Mexico School of Medicine, Albuquerque, NM</i>	545
Venous Air Embolism— A Difficult Postmortem Diagnosis	<i>Mitra B. Kalekar, MD*, Kendall Crowns, MD, and Edmund R. Donoghue, MD, Chief Medical Examiner, Cook County Medical Examiner's Office, 2121 West Harrison Street, Chicago, IL</i>	545

Viropsy—New Horizons in Forensic Radiology: Documentation and Analysis of Gunshot Victims With Postmortem Multi-Slice Computer Tomography and Magnetic Resonance	<i>Michael J. Thali, MD*, Office of the Armed Forces Medical Examiner, AFIP - Annex, 1413 Research Boulevard, Building 102, Rockville, MD; K. Yen, Wolf Schweizer, and E. Scheurer, Institute of Forensic Medicine, University of Berne, Buchlstrasse 20, Berne, Switzerland; P. Vock, Institute of Diagnostic Radiology, University of Berne, Berne, Switzerland; C. Ozdoba, and G. Schroth, Department of Neuroradiology, University of Berne, Berne, Switzerland; M. Sonnenschein, Institute of Diagnostic Radiology, University of Berne, Berne, Switzerland; Ch. Boesch, Department. Clinical Research, Magnetic Resonance Spectroscopy, University of Berne, Berne, Switzerland; M. Ith, Department of Neuroradiology, University of Berne, Berne, Switzerland; K. Brugger, Department. Clinical Research, Magnetic Resonance Spectroscopy, University of Berne, Berne, Switzerland; E. Spielvogel, Institute of Diagnostic Radiology, University of Berne, Berne, Switzerland; U. Koenigsdorfer, and R. Dorn, Institute of Forensic Medicine, University of Berne, Buchlstrasse 20, Berne, Switzerland; and R. Dirnhofer, Institute of Diagnostic Radiology, University of Berne, Berne, Switzerland</i>	546
Evaluation of 122 Forensic Autopsies of Unprotected Victims Killed in Traffic Accidents	<i>Georges Krompecher, MD, Thomas Krompecher, MD, PhD*, and Patrice Mangin, MD, PhD, Institut Universitaire de Médecine Légale, Rue du Bugnon 21, Lausanne, Switzerland</i>	546
Undefeated by Surgery: The Utility of Post-Surgical Foot and Ankle Radiographs as a Basis for Identification	<i>Jeremy Rich, DPM*, Harvard Medical School, Beth Israel Deaconess Medical Center, 330 Brookline Avenue, Boston, MA; Nancy E. Tatarek, PhD, Ohio University, 293 Lindley Hall, Athens, OH; Robert H. Powers, PhD, Hamilton County Coroner's Office, 3159 Eden Avenue, Cincinnati, OH; Bradley J. Lewis, MD, and Dorothy E. Dean, MD, Franklin County Coroner's Office, 520 King Avenue, Columbus, OH</i>	547
Paraphyly in <i>Lucilia Cuprina</i> (Diptera: Calliphoridae) Mitochondrial DNA: Implication for Forensic Entomology and Evidence for an Ancient Hybridization Event	<i>Jamie R. Stevens, PhD, University Exeter, Biological Science, Prince of Wales Road, Exeter, United Kingdom; Richard Wall, PhD, University Bristol, Biological Sciences, Woodland Road, Bristol, United Kingdom; and Jeffrey D. Wells, PhD*, University of Alabama Birmingham, Justice Science, 901 15th Street South, Birmingham, AL</i>	548
Investigation of Italy's Deadliest Building Collapsed: Forensic Aspects of a Mass Disaster	<i>Carlo Pietro Campobasso, MD, PhD*, Rosa Falamingo, MD, and Francesco Vinci, MD, Section of Legal Medicine (DIMIMP), University of Bari, Policlinico, Plaza Giulio Cesare, Bari, Italy</i>	548
Differential Decomposition I: Partial Ground Contact	<i>Kathryn H. Haden, MD, Department of Anthropology; and Murray K. Marks, PhD*, Department of Pathology, The University of Tennessee Medical Center, 250 South Stadium Hall, Knoxville, TN</i>	549
Are Autopsies Necessary in Centenarians?	<i>Andrea M. Berzlanovich, MD*, Ernst Sim, MD, Peter Fasching, MD, and Manfred A. Muhm, MD, Department of Forensic Medicine, University of Vienna, Sensengasse 2, Vienna, Austria</i>	549

In-Hospital Deaths for Forensic Autopsy	<i>Istvan F. Szentmariay, MD*, and Gyorgy Dunay, MD, Institute of Forensic Medicine, Semmelweis University, Ulloii Ut 93, Budapest, Hungary</i>	550
Characteristics of Different Types of Fatal Head Trauma and the Factors That Influence Survival Time and Activity Prior to Death	<i>Erin H. Kimmerle, MA*, University of Tennessee, 121 West Jackson Avenue North, Knoxville, TN; Matthias Okoye, MD, JD, Pathology Medical Services, PC Lincoln General Hospital, 2300 South 16th Street, Lincoln, NE; and Sue Gabriel, RN, BSN, Nebraska Wesleyan University, Lincoln, NE</i>	550
Seizure Associated Fatalities: An Analysis of Cases in Milwaukee County	<i>Michael A. Stier, MD*, University of Wisconsin-Madison, Department of Pathology, 1300 University Avenue, Madison, WI; and John R. Teggatz, MD, Milwaukee County Medical Examiner's Office, 933 West Highland Avenue, Milwaukee, WI</i>	550
Homicide by Second Impact Syndrome... or Unfortunate Coincidence?	<i>Dwayne A. Wolfe, MD, PhD*, Office of Medical Examiner of Harris County, Joseph A. Jachimczyk Forensic Center, 1885 Old Spanish Trail, Houston, TX</i>	551
A New Technique to Estimate a Postmortem Submersion Interval (PMSI) Using Algal Growth Rates	<i>James Haefner, and John B. Wallace, PhD*, Department of Biology, Millersville University, Millersville, PA; and Richard W. Merritt, PhD, Department of Entomology, Michigan State University, East Lansing, MI</i>	551
Assisting the Living	<i>Butch M. Huston, MD*, and Janis C. Amatuzio, MD, Midwest Forensic Pathology, 3960 Coon Rapids Boulevard, Suite LL21, Coon Rapids, MN</i>	552
Some Empirical Data on the Past and Future of the Autopsy	<i>Jody E. Hooper, MD*, United States Navy, General Medical Officer, 5240 Fiore Terrace, San Diego, CA</i>	552
The Postmortem Diagnosis of Skull and Brain Injuries by Imaging Methods (MRI, Multi-Slice CT)	<i>Kathrin Yen, MD*, Wolf Schweitzer, MD, Eva Scheurer, MD, and Michael J. Thali, MD, Institute of Forensic Medicine, University of Berne, Buehlstrasse 20, 3012 Berne, Switzerland; Christoph Ozdoba, MD, Gerhard Schroth, MD, and Martin Sonnenschein, MD, Departement of Neuroradiology, University of Berne, Freiburgstrasse, 3010 Berne, Switzerland; Chris Boesch, MD, PhD, Michael Ith, PhD, and Karin Brugger, MR-Spectroscopy Center, University of Berne, 3010 Berne, Freiburgstrasse, Switzerland; Elke Spielvogel, Department of Neuroradiology, University of Berne, 3010 Berne, Freiburgstrasse, Switzerland; and Richard Dirnhofser, MD, Institute of Forensic Medicine, University of Berne, Buehlstrasse 20, 3012 Berne, Switzerland</i>	553
Use of Magnetic Resonance Microscopy for Evaluation of Retinal Hemorrhage	<i>William R. Oliver, MD*, and Kimberlee Potter, PhD, Armed Forces Institute of Pathology, Washington, DC; J.C. Upshaw Downs, MD, Director, Alabama Department of Forensic Sciences and Chief Medical Examiner, PO Box 3510, Auburn, AL; and David R. Fowler, MB, ChB, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street., Baltimore, MD</i>	553
Phenylpropanolamine and Acute Intracerebral Hemorrhage	<i>Yvonne I. Milewski, MD*, Office of Chief Medical Examiner, 520 First Avenue, New York, NY</i>	554

The Use of Lidocaine to Commit Homicide	<i>Brian C. Hunter, BA, MD*, Department of Pathology, Sparrow Health System, 1215 East Michigan Avenue, Lansing, MI; John Trestrail III, BS, RPh, Regional Poison Center, Grand Rapids, MI; and Stephen D. Cohle, MD, Spectrum Health East Campus, Pathology Department, Grand Rapids, MI</i>	554
Where Do People Die Suddenly and Unexpectedly?	<i>Istvan F. Szentmariay, MD*, Gyorgy Dunay, MD, and Marta Hubay, MD, Institute of Forensic Medicine, Semmelweis University, Ullói Ut 93, Budapest, Hungary</i>	555
The “Holy Crown United” Southern Italian Mafia Organization Homicides	<i>Francesco Intronà, MD*, Francesco Faggiano, MD, Alberto Tortorella, MD, and Antonio De Donno, MD, University of Bari, Italy, Istituto di Medicina Legale, Policlinico, Bari, Italy</i>	555
Homicide Attempt With a Japanese Samurai Sword	<i>Jean-Sebastien Raul, MD*, Laurent Berthelon, MD, Annie Geraut, MD, Antoine Tracqui, MD, PhD, and Bertrand Ludes, MD, PhD, Institut de Médecine Légale, 11 Rue Humann, Strasbourg Cedex, France</i>	556
Sharp Force Injury Fatalities in New York City	<i>James R. Gill, MD*, and Charles Catanese, MD, New York City of Chief Medical Examiner and Department of Forensic Medicine, 520 First Avenue, New York, NY</i>	556
No Homicide on Christmas Eve !? — Case Report of an Unusual Stab Wound of the Brain	<i>Martin Bauer, MD*, and Dieter Patzelt, MD, Institute of Legal Medicine, University of Wuerzburg, Versbacher Str. 3, Wuerzburg, Germany</i>	557
Accidental Hanging Death of a 10-Year-Old Boy From a Lanyard Key Chain	<i>J. Scott Denton, MD, Cook County Medical Examiner’s Office, 2121 West Harrison Street, Chicago, IL</i>	557
Sudden Death in Baseball: A Case Report and Review of Literature	<i>Abraham T. Philip, MD*, Alexander M. Chirkov, MD, and Richard J. Evans, MD, Office of the Chief Medical Examiner, 720 Albany Street, Boston, MA</i>	558
Post Collision Vehicular Fires—Determination of Probability of Occupant Survival Post Impact	<i>Joseph L. Burton, MD* and Paul R. Lewis, Jr., MS, BME, Burton & Associates, 13784 Highway 9, Alpharetta, GA</i>	558
Decapitation by Motorized Shoulder Harness: A Case Report	<i>Thomas W. Young, MD*, C. Chase Blanchard, MD, and Ronald E. Brasfield, Office of the Jackson County Medical Examiner, 660 East 24th Street, Kansas City, MO</i>	559
The Memorials at the Lockerbie and Ermenonville Forest Air Disaster Sites	<i>Gordon K. Murphy, MD*, 814 Hathaway Road, Dayton, OH</i>	559
Experiences Following the Crash of Singapore Airlines SQ006 Boeing 747-400 in Taipei	<i>Kai-Ping Shaw, PhD*, John M. Fong, ME, John Wang, ME, Ching Hu, ME, Ming-Houng Chen, ME, Chiang-Shin Liu, ME, Tse-Hua Lo, ME, and Chia-Tung Shung, Ministry of Justice Investigation Bureau; and Chang-En Pu, MS, Institute of Forensic Medicine, Ministry of Justice, Taipei, Taiwan</i>	560
Mortality Estimate for the 1994 Northridge Earthquake	<i>Christopher A. Rogers, MD*, and Lakshmanan Sathyavagiswaran, MD, Department of Coroner, 1104 North Mission Road, Los Angeles, CA</i>	560
Death in the Desert: Multiple Fatalities as a Consequence of Environmental Exposure	<i>Bruce O. Parks, MD*, Eric D. Peters, MD, Cynthia M. Porterfield, DO, Diane Karluk, MD, Walter H. Birkby, PhD, and Bruce E. Anderson, PhD, Office of the Medical Examiner, Forensic Science Center, 2825 East District Street, Tucson, AZ</i>	561

The Role of the Forensic Anthropologist in Determining the Manner of Death in Suicidal Shotgun Wound to the Back of the Head	<i>Brian C. Hunter, MD*, Department of Pathology Sparrow Health System, 1215 Michigan Avenue, Lansing, MI; Norman J. Sauer, PhD, and Todd W. Fenton, PhD, Department of Anthropology, Michigan State University, East Lansing, MI; Joyce L. de Jong, DO, Department of Pathology, Forensic Pathology Division, Sparrow Health System, 1215 Michigan Avenue, Lansing, MI; and Michael G. Koot, BA, Department of Anthropology, Michigan State University, East Lansing, MI</i>	561
Sudden Death Due to Myocardial Infarct Associated With Systemic Lupus Erythematosus: Two Case Reports and a Review of the Literature	<i>Joyce L. de Jong, DO*, and Brian C. Hunter, MD, Sparrow Health System - Forensic Division, 1215 East Michigan Avenue, Lansing, MI</i>	562
Unexpected Multicystic Encephalopathy After Accidental Intoxicaction by a Corrosive Agent: Case Report	<i>Giancarlo Di Vella, MD, PhD*, Maura Belviso, MD, Sazione di Medicina Legale, DIMIMP, University of Bari, Italy; Gabriella Serio, MD, PhD, Giuseppe Parisi, MD, Roberto De Blasi, MD, Unità Operativa di Neuroradiologia, University of Bari Italy, Policlinico, piazza G. Cesare, Bari, Italy</i>	562
Notochord Regression Failure Initially Suspected as an Abusive Fracture in an Infant	<i>Patricia A. Aronica-Pollak, MD*, 2708 Neonlight Drive, York, PA, Vincent H. Stefan, PhD, Department of Anthropology, Lehman College, CUNY, Bronx, NY, Jerri McLemore, MD, Office of the Medical Investigator, University of New Mexico School of Medicine, Albuquerque, NM, and Madelyn Stazzone, MD, Radiology Department, University of New Mexico School of Medicine, Albuquerque, NM</i>	563
The Clinical and Pathological Features of Fatal Concussion	<i>Stephany Fiore, MD*, and Vernon Armbrustmacher, MD, Office of Chief Medical Examiner, 520 First Avenue, New York, NY</i>	564
Doctors as Detectives" (1987 - 2001): Fifteen Years of Introducing Forensic Medical Science to High School Students in Northwest Ohio and Southeast Michigan	<i>Frank P. Saul, PhD*, Regional Commander, USPHS DMORT 5, OH; Julie Mather Saul, BA, Director, Forensic Anthropology Laboratory, James R. Patrick, MD, Lucas County Coroner, Diane Scala-Barnett, MD, Deputy Lucas County Coroner, Robert B. Forney, Jr., PhD, Director of Toxicology, and Robert A. Burns, DDS, MS, Consultant, Forensic Odontology, Lucas County Coroner's Office and Medical College of Ohio, 2529 Arlington Avenue, Toledo, OH; Jerome DeBruin, PhD, Professor of Education, University of Toledo, 2801 West Bancroft, Toledo, OH</i>	565
Exsanguination From a Dialysis Catheter: Trace Evidence Examination in Determining Manner of Death	<i>Michael A. Trimpe, BS, Robert R. Pfalzgraf, MD, and Carl L. Parrott, Jr., MD*, Hamilton County Coroner's Office, 3159 Eden Avenue, Cincinnati, OH</i>	565
Sudden Death Due to Idiopathic Giant Cell Myocarditis: Case Report and Literature Review	<i>Maryanne Gaffney-Kraft, DO*, Hong Yin, MD, and Patrick E. Lantz, MD, Department of Pathology, Wake Forest University Baptist Medical Center, Medical Center Boulevard, Winston-Salem, NC</i>	566

Immunopathological Study of Methamphetamine (MAP)-Induced Fatalities	<i>Fang-Chun Chung, MS*; Chang-En Pu, MS, Section Chief; Way-Lin Lin, Associate Researcher, Institute of Forensic Medicine, 40-11, Lane 103 Hsing-An Street, Taipei, Taiwan (Roc); Way-Hwa Lee, Professor; John M. Fong; and, Kai-Ping Shaw, Chairman, Department Forensic Pathology, Institute of Forensic Medicine, 40-11, Lane 103 Hsing-An Street, Taipei, Taiwan (ROC)</i>	566
Experiences of Human Bodies Identified by DNA Typing in Singapore Airlines SQ006 Crash in Taipei	<i>Chang-En Pu, MS*, Ministry Justice Investigation Bureau, PO Box 3562, Taipei, Taiwan; Chi-Hsiang Chao, Division Chief, Ministry Justice Investigation Bureau, Taipei, Taiwan; Fang-Chin Wu, Wen-Hsiung Ho, Kuo-Chun Wu, Ling-Min Meng, Researcher, Ministry Justice Investigation Bureau, Taipei, Taiwan; and Kai-Ping Shaw, Director of Forensic Pathology, Institute of Forensic Medicine, Ministry of Justice, Taipei, Taiwan</i>	567
A Case Report of Sudden Death in a Patient With Kartagener Syndrome	<i>Cristin M. Rolf, MD*, University of Kentucky Department of Pathology & Laboratory Medicine, Central Laboratory Facility, 100 Sower Boulevard, Suite 202, Frankfort, KY</i>	567
Micro-Computed Tomography: An Advantageous Tool for the Analysis of Patterned Tool Marks in Bones	<i>Michael J. Thali, MD*, Office of the Armed Forces Medical Examiner, Armed Forces Institute of Pathology - Annex, 1413 Research Boulevard, Building 102, Rockville, MD; Ulrike Taubenreuther, Institute of Medical Physics, University of Erlangen, Germany; Marcel Braun, Institute of Forensic Medicine, University of Berne, Berne, Switzerland; Nicolette Scholz, Institute of Medical Physics, University of Erlangen, Germany; Walter Brueschweiler, Institute of Forensic Medicine, University of Berne, Berne, Switzerland; Willi Kalender, Institute of Medical Physics, University of Erlangen, Germany; Richard Dirnhofer, MD, Institute of Forensic Medicine, University of Berne, Berne, Switzerland</i>	568
Immunohistochemical Study for Determining the Time of Injury to Rats Following Stab Wounds and Blunt Trauma to the Brain	<i>Mona M.A. Hassan, MD* and Ragaa T. Darwish, MD, Department of Forensic Medicine & Toxicology, Alexandria, Egypt; and Samar M. El-Sheikh, PhD, Department of Pathology, Faculty of Medicine, University of Alexandria, 33, Safeya Zaghloul St. #52, Alexandria, Egypt</i>	568
Postmortem Interval Decomposition Chemistry of Human Remains: A New Methodology for Determining the Postmortem Interval	<i>Arpad A. Vass, PhD*, Stacy-Ann Barshick, PhD, Gary Segal, PhD, John Canton, PhD, James T. Skeen, Jennifer C. Love, PhD, and Jennifer A. Synstelien, BA, Oak Ridge National Laboratory, PO Box 2008, Oak Ridge, TN</i>	569
Effect of Ant Activity on Decompositional Rates and Estimation of Postmortem Interval: A Case Study	<i>William C. Rodriguez, III, PhD*, Office of the Armed Forces Medical Examiner, Armed Forces Institute of Pathology, 1413 Research Boulevard. Biulding 102, Rockville, MD</i>	569
Forensic Entomology: Decomposition in Cars	<i>Ian Dadour, PhD*, Centre for Forensic Science, University of Western Australia, Nedlands, Australia, Western Australia</i>	570

Deceased, Dismembered, and Disarranged: Central Nervous System Consequences of an Unusual Body Disposal Strategy	<i>John M. Andrews, MD*, Jeffrey P. Gutstadt, MD, Hideo H. Itabashi, MD, Steven J. Dowell, BS, Mark S. Schuchardt, Department of Coroner, County of Los Angeles, 1104 North Mission Road, Los Angeles, CA; and Elizabeth A. Miller, PhD, Department of Anthropology, California State University, Los Angeles, CA</i>	570
Detection of Chemical Signals by the Parasitic Wasp <i>Microplitis Croceipes</i>	<i>Jeffery K. Tomberlin, PhD*, W. Joe Lewis, PhD, Marco D'Alessandro, BS, and Moukaram Tertuliano, PhD, Department of Biological and Agricultural Engineering, PO Box 748, Tifton, GA</i>	571
Suicidal Air Rifle Wound of the Head	<i>Jennie V. Duval MD*, Dallas County Medical Examiner's Office Southwestern Institute of Forensic Science, Susan B. Allen BS, Dustin S. Engel BA, Criminal Investigation Laboratory Firearms Section, and Jeffrey J. Barnard MD, Dallas County Medical Examiner's Office, 5230 Medical Center Drive, Dallas, TX</i>	572
Pediatric Injuries: Can CPR Related Injuries Mimic Inflicted Injuries?	<i>Chitra Rao, MBBS*, Forensic Pathologist, Regional Forensic Pathology Unit, General Site -HHS, 237 Barton Street East, Hamilton, Ontario, L8L 2X2, Canada</i>	572
When "Non-Terminal" Is Fatal—Medical Examiner Cases of Fibromyalgia Fatalities	<i>Carolyn Bertrand, PhD, Forensic Psychology Research Fellow, County of San Diego, Mark J. Shuman, MD, MS*, Deputy Medical Examiner, County of San Diego, and Brian D. Blackbourne, MD, Chief Medical Examiner County of San Diego, San Diego, CA</i>	572
Rapid Death From Phlegmonous Gastritis Associated With Lymphoma	<i>Lakshmanan Sathyavagiswaran, MD*, Chief Medical Examiner, Coroner, Los Angeles County, 1104 North Mission Road, Los Angeles, CA</i>	573
Victim-Offender Relationship in Florida Medical Examiner District 8	<i>Shuala S. Martin, MA*, C.A. Pound Human Identification Laboratory, University of Florida, 124 Fisherman Road, Satsuma, FL</i>	573
Medical Malpractice: A Case History Study by the Forensic Medicine Section From Bari	<i>Nunzio Di Nunno, MD*, Alessandro Dell' Erba, MD, Francesco Vinci, MD, Stanislao Mangiatordi, MD, Luigi Viola, MD, and Francesco Vimercati, MD, Sesione di Medicina Legale, Dipartimento di Medicina Interna e Medicina Pubblica, Bari University, Policlinico, Piazza G. Cesere n. 11, Bari, Italy</i>	574
Nuclear and Mitochondrial DNA Analyses Following X- and Gamma-irradiation	<i>J.C. Upshaw Downs, MD*, Alabama Department of Forensic Sciences, PO Box 3510, Auburn, AL, S. Elaine Scott, MS, Alabama Department of Forensic Sciences, 2451 Fillingim Street, Mobile, AL, William Jones, Armed Forces Institute of Pathology, 2451 Fillingim Street, Mobile, AL, Robert Neyland, PhD, Maria Jacobsen, and Paul Mardikian, Warren Lasch Conservation Center, Former Charleston Naval Base 1250 Supply Street, Building 255, North Charleston, SC; Sudhir K. Sinha, PhD, ReliaGene, 5525 Mounes Street, New Orleans, LA; and Douglas W. Owsley, PhD, National Museum of Natural History, Smithsonian Institution, Department of Anthropology, Washington, DC</i>	574
Recovery and Processing of Co-Mingled Remains Following Extended Submersion Period Facilitated by Computer Animation	<i>J.C. Upshaw Downs, MD*, Alabama Department of Forensic Sciences, PO Box 3510, Auburn, AL; and William R. Oliver, MD, Armed Forces Institute of Pathology, Washington, DC</i>	575

Comparison of Drug Concentration in Blowflies (Diptera: Calliphoridae) and Human Tissues	<i>Mirella Gherardi, MD*, Marina Caligara, PharmD, and Luca Sironi, PharmD, PhD, Institute of Legal Medicine - University of Milan, Via L. Mangiagalli, 37, Milan, Italy</i>	575
Removing External Contamination of Maggots With a Bleach Solution Without Inhibiting Genetic Analysis of Maggot Crop Contents	<i>Jason G. Linville, BS*, Department of Biology, and Jeffrey D. Wells, PhD*, Department of Justice Sciences, University of Alabama at Birmingham, Birmingham, AL</i>	576
The Child Abuse Works of Ambroise Tardieu...Had We Only Taken French	<i>C. Ferraro, PhD, University of Long Island, Brookville, NY; and O'Brian C. Smith, MD*, Steven A. Symes, PhD, Cynthia D. Gardner, MD, and T.A. Campbell, MD, University of Tennessee, Memphis, 1060 Madison Avenue Memphis, TN</i>	576
Coming of Age in Memphis... How Our Children Die	<i>C. Ferraro, PhD*, Long Island University, Brookville, NY; O'Brian C. Smith, MD, Steven A. Symes, PhD, Cynthia D. Gardner, MD, and T.A. Campbell, MD, University of Tennessee, Memphis, 1060 Madison Avenue Memphis, TN</i>	577
Bruises in Infancy: How Many Are Too Many?	<i>Betty S. Spivack, MD*, University of Louisville, Kentucky Justice Cabinet, Office of the Chief Medical Examiner 810 Barret Avenue, Louisville, KY</i>	578
Child Abuse Autopsy Technique... What Works for Us	<i>O'Brian C. Smith, MD*, Steven A. Symes, PhD, Cynthia D. Gardner, MD, Susan B. Patton, MNSc, and T. A. Campbell, MD, University of Tennessee, Memphis, 1060 Madison Avenue, Memphis, TN; and C. Ferraro, PhD, Long Island University, Brookeville, NY</i>	578

PATHOLOGY/BIOLOGY

G1 Fatality Involving Complications of Bupivacaine Toxicity and Hypersensitivity Reaction: A Case Report

Mary H. Dudley, MD, Jackson County Medical Examiner's Office, 660 East 24th Street, Kansas City, MO 64108; Steven W. Fleming, MS, Children Mercy Hospital, Toxicology Laboratory, 2401 Gillham Road, Kansas City, MO 64108; Uttam Garg, PhD, Children's Mercy Hospital, Department of Pathology, 2401 Gillham Road, Kansas City, MO 64108; and Jason M. Edwards, PhD, University of Missouri Kansas City School of Medicine, 2411 Holmes Street, Kansas City, MO 64108*

After attending this presentation, attendees will understand the complications from use of bupivacaine local anesthesia when administered in the head and neck region, including CNS, cardiac sequelae, and death.

This presentation will impact the forensic science community in understanding the possible adverse effects of local nerve block anesthesia when administered in the head and neck region, the actions, pharmacokinetics, contraindications, and toxicity of bupivacaine are detailed. In addition a hypersensitivity reaction may result from bupivacaine as measured by postmortem tryptase. The importance of a complete forensic autopsy and forensic toxicological analysis to accurately certify the cause and manner of death is emphasized.

This case represents unusual findings of elevated bupivacaine and tryptase concentrations following local anesthetic, bupivacaine, administered as a scalene nerve block for elective rotator cuff repair surgery. The patient exhibited almost immediate seizure activity, bradycardia, and cardiac arrest following bupivacaine injection. Resuscitative efforts including cardiopulmonary bypass restored a cardiac rhythm. However, the clinical medical status of the decedent progressively declined and he died seven hours following administration of the local anesthetic. An autopsy was performed and various biological specimens were collected for toxicological analysis. Autopsy revealed several abnormalities of the heart including cardiomegaly, myocardial bridging, and lipomatous hypertrophy of the intra-atrial septum. The cardiac findings may have contributed to bradycardia and arrhythmia. Autopsy findings associated with hypersensitivity reactions such as urticaria or laryngeal edema were not observed at autopsy. The absence of these findings alone does not rule out a suspected case involving a hypersensitivity reaction.

Postmortem toxicology results revealed an elevated cardiac bupivacaine and tryptase concentration. An elevated concentration of bupivacaine in the blood taken seven hours post-injection is indicative of an intravascular injection. When taking into account that the patient was alive for seven hours post-injection of bupivacaine and the half-life of bupivacaine is about two hours, it was estimated that the subclavian blood concentration of bupivacaine was most likely much higher at the time of seizure activity than at the time of sample collection. However, the postmortem cardiac blood analyzed had a similar bupivacaine concentration at the time of seizure activity due to intraventricular blood stasis resulting from cardiopulmonary bypass for approximately five hours.

Patients receiving local scalene nerve block anesthesia that is in close proximity to the carotid artery may be at greater risk of CNS and cardiac toxicity due to a greater risk of inadvertent intravascular injection or an injection into a highly vascular tissue area. This would result in rapid absorption of the local anesthetic into the systemic circulation causing cardiac and CNS sequelae. Therefore, this type of

injection may increase the risk of adverse effects including seizures, bradycardia, and cardiac arrest as seen in this case.

Postmortem toxicology also included analysis of tryptase. This analysis revealed an elevated cardiac total tryptase concentration and a normal subclavian total tryptase concentration. The discrepancy between the cardiac and subclavian tryptase concentrations may also be due to intraventricular blood stasis resulting from cardiopulmonary bypass; whereas subclavian blood was actively circulating throughout intervention. Furthermore, tryptase peaks within 15 to 120 minutes post exposure to the allergen and follows first-order kinetics with a half life of 1.5 to 2.5 hours; therefore, approximately 3 half-lives had elapsed between symptomatic onset and blood collection. Thus, obtained subclavian serum tryptase concentrations are expected to be much lower than values at symptomatic onset if in fact an anaphylactic reaction occurred. The moderately elevated cardiac tryptase concentration in conjunction with the cardiac arrest and rapid onset of seizure activity post injection of bupivacaine indicates the possibility of an anaphylactic reaction. However, it is possible that the moderate increase in cardiac tryptase is due to lysis of mast cells in the tissue of the chest. At autopsy the chest had massive hemorrhages due to prolonged cardiopulmonary resuscitation.

In summary this unintentional death of a 37-year-old male during elective shoulder surgery was determined to be due to complications of bupivacaine. The moderately elevated cardiac tryptase concentration raises the possibility of anaphylaxis that may have contributed to the cause of death.

Forensic Pathology, Bupivacaine Toxicity, Postmortem Tryptase

G2 Undiagnosed, Untreated Natural Disease Mistaken for Lethal Child Neglect: Liability of the Family in Determining Child's Death

Lucia Tattoli, PhD, Sabrina Leonardi, MD, and Biagio Solarino, PhD, Section of Legal Medicine - University of Bari, Pizza Giulio Cesare 11, Bari, 70124, ITALY*

After attending this presentation, attendees will understand that in cases in which there is a potential component of neglect or abuse, careful scene investigation, review of medical records, complete autopsy with skeletal survey, toxicology, chemical and metabolic testing should be requested.

This presentation will impact the forensic science community by emphasizing the fact that even if lethal neglect is a rare cause of death in industrialized countries, natural disease being mistaken for child abuse is rare too. As a matter of fact there are many potential organic diseases which may mimic neglect or abuse and an appropriate histological examination of all organs should be undertaken to assist in ruling out organic disease.

A case is presented of a 4-month-old infant who was found unresponsive at home and transported at a local hospital, where he expired in the Emergency Department. Physicians noted child's cachectic state; the mother stated he had fever, vomiting, and diarrhea for seven days but she was afraid to seek medical care because was fearful of legal action against her. Further investigations revealed a completely inappropriate and inadequate diet of meat, homogenized milk, and oatmeal from his birth. The infant was never breastfed.

Crime scene investigation showed the extremely poor living conditions of the apartment where the 22-year-old mother lived with her parents and her sons. The family was occasionally followed by social care workers. The infant had never been followed by a pediatrician.

The child weighed 4,000 g and was 62 cm long. His clothing and bedding were urine-soaked and vomit-covered. Whole body radiographic examination showed no fractures. At autopsy, there were clear signs of malnutrition and dehydration, like skin tenting and wrinkled loose skin, sunken fontanelles and ocular globes, depressed cranial sutures, focal alopecia, prominent ribs and bony planes, and dry serosal and mucous membranes. Partial lack of subcutaneous and deep fat deposits with a severe atrophy of skeletal muscles was found. Brownish material was found in gastrointestinal tract. There was a severe atrophy of skeletal muscles, heart, liver, spleen, and kidneys; the small intestinal wall appeared swollen, with reddish discolored mucosa.

Further histological examination showed a T-cell lymphoblastic massive infiltrate of the liver, kidneys, and other organs with multiple foci of bronchopneumonia in lungs, and sporadic evidence of aspiration. Immunocytochemical studies confirmed the diagnosis of acute lymphoblastic leukemia of childhood. Toxicological examination revealed no substances in blood or urine. The cause of death was attributed to an Acute Lymphoblastic Leukemia (ALL) – related cachexia, worsened by malnutrition and dehydration.

The ALL is rare under one year and the youngest infants (ages 0 to 6 months) have the worst outcome. At diagnosis of childhood ALL, anorexia-cachexia syndrome may occur, presenting with anorexia, weight loss, wasting of muscle and adipose tissue, hyperlipidemia, and other metabolic abnormalities.

In the case presented here, an early recognition with appropriate treatment of ALL would probably have given the child a chance of survival. In fact, despite the progressive improvements in outcomes achieved for the children treated on chemotherapy, the outcome is positive in less than 25% of cases.

Cases of suspected child abuse which ultimately are determined to result from natural diseases are extremely rare. Moreover, although it is important to suspect child abuse when the history and examination are consistent with the diagnosis, it is equally important to think of other potential diagnoses, considering legal medico-legal aspects related the liability of the parents in determining child's death.

Lethal Neglect, Acute Lymphoblastic Leukemia, Malnutrition

G3 Sudden Unexpected Cardiac Deaths: An Autopsy Based Study From Mangalore, South India

Tanuj Kanchan, MD*, Kasturba Medical College, Department of Forensic Medicine, Light House Hill Road, Mangalore, 575 001, INDIA

After attending this presentation, attendees will be able to identify with the pattern and trend of sudden cardiac deaths in a coastal region of South India.

This presentation will impact the forensic science community by developing an understanding of the burden of sudden cardiac deaths in the coastal region. This presentation defines the problem status of sudden cardiac deaths in the region and emphasizes the importance of forensic pathologists in diagnosing the same at autopsy.

Forensic pathologists deal not only with unnatural deaths, but also with a wide range of natural deaths, especially, if the death occurs suddenly in apparently healthy individuals. Cardiovascular diseases are reportedly the most important cause of sudden natural deaths. Sudden cardiac death is defined as death due to cardiac causes, heralded by abrupt loss of consciousness within one hour of the onset of acute symptoms, in an individual who may have known preexisting heart disease but in whom the time and mode of death are unexpected. This

autopsy based retrospective research was conducted to determine the causes and the epidemiological aspects of sudden cardiac deaths in Mangalore, a coastal township in South India. The study was conducted at the Department of Forensic Medicine, Kasturba Medical College, Mangalore. All the cases recorded in the departmental file as sudden deaths from January 2005 to December 2007 were included in the study and autopsy case files of the same were studied in detail. The data was analyzed using statistical software.

During the study period a total of 1864 autopsies were conducted, of which 207 cases were classified as sudden unexplained deaths. Sudden cardiac deaths constituted of 39.6% of the total sudden deaths during the study period (n=82). Males were predominantly affected (91.5%). Age of victims varied from 19 to 80 years, mean age of the victims being 49.96 years. Majority of deaths were reported in the 5th and 6th decade of life. Mean BMI was 20.8 kg/m². The monthly distribution revealed that most of the sudden cardiac deaths were reported in May followed by February. Weight of heart varied from 210 to 560 grams (Mean=335.4 grams). Coronary artery diseases remained the most common cause of sudden cardiac deaths followed by cardiac hypertrophy, cardiomyopathy, myocarditis, and valvular diseases. More than 50% occlusion of the coronary arteries was evident in approximately half of the cases. Left anterior descending artery was the most commonly affected. Atherosclerotic changes were observed in the great vessels in most of the cases.

Cardiac causes are responsible for most of the sudden deaths in this region and coronary artery diseases are responsible for most of the cardiac deaths. Atherosclerotic changes were observed in the great vessels in most of the cases in our study. Atherosclerosis is responsible for significant cardiovascular morbidity and mortality worldwide. Medicolegal autopsies are an important source of epidemiological data that should effectively be used in planning the preventive strategies. Modifying the stressful life style and screening those at high risk are the measures to be emphasized to prevent such deaths.

Sudden Death, Cardiac Death, Coronary Artery Disease

G4 Periventricular Leukomalacia in a 2-Month-Old Infant Who Was Born With Cocaine Addiction: A Case Report

Baiyang Xu, MD*, 1520 Penn Avenue, Pittsburgh, PA 15222; Todd M. Luckasevic, DO, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222; and Abdulrezak M. Shakir, MD, and Karl Williams, MD, Allegheny County Medical Examiner Office, 542 Fourth Avenue, Pittsburgh, PA 15219

After attending this presentation, attendees will be aware of the neuropathologic sequela in a 2-month-old infant born with addiction to cocaine. The prenatal history and the scenario surrounding the infant's death will be presented. Common outcomes of the effects of cocaine on the fetus and newborn are reviewed.

This presentation will impact the forensic science community by demonstrating that cystic periventricular leukomalacia is one of the irreversible neurological complications that directly or indirectly may occur in cocaine-exposed fetuses and the dilemma in considering the cause and manner of death of the similar cases will be discussed.

Case presentation: The decedent was a 2-month-old African American female who was born precipitously in an ambulance at 30 weeks gestational age to a 29-year-old mother who had a history of cocaine and marijuana abuse and used crack cocaine the day she gave birth. She had no prenatal care for this pregnancy. She had given birth to three live children, including the decedent, and all three were born addicted to cocaine. She also gave birth to one stillborn (female). This decedent's birth weight was 1,034 grams and length was 19 inches. She was diagnosed with cocaine addiction and respiratory failure, was on

mechanical ventilation for the first two days of her life, and stayed in hospital for 20 days before being discharged home. The discharge diagnosis includes bilateral periventricular leukomalacia. The infant was adopted by her biological mother's sister. The decedent's condition was stable and she was fed with formula. At 20:04 on the day of the incidence, when lying supine on the couch in the living room with her adoptive mother, the decedent suddenly exhaled and stopped breathing. The adoptive mother started to gently rub the decedent's chest and the decedent still did not get breath. 911 was called and the decedent was transported to a hospital by ambulance with an admission diagnosis of cardiac arrest. CT scans/X-rays revealed a large right pneumothorax and pneumoperitoneum. An emergency chest tube placement and exploratory laparotomy were performed in the operating room. The decedent was taken to the intensive care unit and her condition deteriorated. Pronouncement was made at 13:40 the next day after the incident.

Autopsy findings included a poorly developed 2-month-old black female with less than 5th percentile of body weight and length. No traumatic injuries were identified. The lungs exhibited atelectasis. The brain exhibited bilateral cystic periventricular leukomalacia and severe hypoxic/ischemic encephalopathy. Accessory tests were non-contributory.

Discussion: Effects of cocaine on the developing central nerve system of a fetus may cause different pathologic changes, such as germinal matrix hemorrhage or cystic changes, intraventricular hemorrhage, and periventricular leukomalacia. However, those changes are difficult to interpret as the sole consequence of the effects of cocaine because risk factors in cocaine abusing pregnant women tend to cluster together and interact, such as multiple drug use, poor maternal nutrition, lack of prenatal care, infectious disease, placental insufficiency, impaired fetal oxygenation, fetal intrauterine growth retardation, and premature birth. All the above CNS pathological changes can also be present in the premature newborn without intrauterine cocaine exposure. In addition, the premature infants with or without intrauterine cocaine-exposed tends similarly to be poorly grown, easily susceptible to infection and vulnerable for sudden infant death. *Cause of Death:* Although a definitive cause and effect relationship between these conditions and cocaine use is difficult to reach, the fact of intrauterine exposure of cocaine could not be ignored in this case. The cause of death was the complication of premature born with addiction to cocaine associated with cerebral cystic periventricular leukomalacia and severe hypoxic/ischemic encephalopathy. *Manner of Death:* Detailed history of the mother's cocaine abuse and the circumstances surrounding the decedent's addiction to cocaine at the time of birth were unclear, even though thorough investigation was performed and the death occurred two months after birth. In addition, constitutional issues may preclude criminal prosecution in many of these kinds of cases. The manner of death was classified as "Undetermined."

Cocaine, Fetus, Periventricular Leukomalacia

G5 A Man Without a Head: Postmortem Decapitation by German Shepherd Dogs

Claas T. Buschmann, MD, Institute of Legal Medicine and Forensic Sciences, Turmstrasse 21, Building L, Berlin, 10559, GERMANY; Biagio Solarino, PhD, Università degli Studi di Bari, Sezione di Medicina Legale, Pizza Giulio Cesare, 11, Bari, 70125, ITALY; and Michael Tsokos, MD, Institute of Legal Medicine & Forensic Sciences, Turmstr 21, Haus L, Berlin, 10559, GERMANY*

After attending this presentation, attendees will understand that in cases of postmortem animal depredation of human corpses or remains, physicians and crime scene investigators not experienced in the field of forensic medicine are often unable to attribute the questioned injuries to their true origin.

This presentation will impact the forensic science community by emphasizing that postmortem injury by domestic animals is only rarely documented in the literature therefore lacking knowledge regarding morphologic features and the criteria for the differentiation of such postmortem soft tissue destruction may cause considerable complications in clarifying the cause of death. This is particularly true when postmortem animal depredation is caused by a domestic dog's activity.

A case of a 55-year-old man will be presented who was found putrefied in the bedroom of his apartment; head and neck of the body were missing. The rest of the body, in particular the hands, was intact. Also his well-feed two German shepherd dogs (8 and 1½ years old) were in the flat. The flat was locked with the windows closed. He had been seen for the last time one week before the incident. The public health service had been called one year earlier because the man and his two dogs had not left the dwelling for eight weeks. Policemen were called to the scene as the dogs had been barking for four days. In the hallway and the living room they remarked several remnants of small supposed human bone parts and crowned teeth in puddles of feces and vomitus. The flat was in messy condition with garbage, emptied alcohol bottles, and moldy food in every room. Lots of accessible dog food was also found. The dogs are brought to pet asylum, and an autopsy of the incomplete body is ordered. Autopsy showed a fatal gastrointestinal bleeding by rupture of esophageal varicose veins (while head and neck were still missing). Furthermore, signs of chronic alcoholism could be determined. Toxicological examinations led to no specific findings. At postmortem, animal depredation signs, canine-like bite traces and tissue defects were found surrounding the collar region. The right pleural cavity was opened by animal depredation; parts of the right pulmonary lobe were missing as well as the cervical vertebral bodies 1-6. The clavicles, the scapulae and 7th cervical vertebral body showed extensive gnawing traces. After autopsy, the apartment was searched again for head and neck of the man by forensic scientists and police; still the missing parts could not be found. From forensic point of view, it must be presumed that the dogs ate head and neck of the corpse completely.

Postmortem Injuries, German Shepherd Dogs, Animal Depredation

G6 Responses of Mast Cells in the Dura to Traumatic Brain Injury in an Animal Model

Kazuhiko Kibayashi, MD, Tokyo Women's Medical University, Department of Legal Medicine, School of Medicine, 8-1 Kawada-cho, Shinjuku-ku, Tokyo, 162-8666, JAPAN; and Ryo Shimada, PhD, and Rui Furutani, PhD, Tokyo Women's Medical University, 8-1 Kawada-cho, Shinjuku-ku, Tokyo, 162-8666, JAPAN*

After this presentation, attendees will understand the responses of mast cells in the *dura* to traumatic brain injury (TBI), the histamine-mediated brain damage after TBI, and the significance of histological examinations of the *dura* in cases of head trauma.

This presentation will impact the forensic science community by providing evidence for changes in the dural mast cells after TBI and the role of dural mast cells in the development of brain injuries. This presentation will also emphasize the need for histological examinations of the *dura* in autopsies of head trauma cases.

Mast cells secrete stored histamine in response to extrinsic stimuli. Histamine plays a role in the formation of brain edema and induces histamine receptor expression in the brain. Histamine receptors exert a protective effect against histamine neurotoxicity. Because the *dura* contains mast cells, it is hypothesized that blunt force to the head activates dural mast cells, leading to the release of their histamine and exacerbation of brain injury. Therefore, the time-dependent changes in dural mast cells and histamine receptor expression in the brain after TBI in a rat controlled cortical impact model was investigated.

* Presenting Author

Male adult rats (7-10-weeks-old) weighing 200–310 g were used in this study. Under general anesthesia, a craniotomy of 6.0 mm in diameter was performed over the left parietal bone taking care not to penetrate the dura. A blunt force impact was applied to the craniotomy site using a pneumatic impact device and generated a cortical contusion on the left cerebral hemisphere. In sham-operated rats, the same surgical procedures were performed, but no impact was applied. Rats were perfused transcardially with phosphate-buffered saline under general anesthesia at 1, 4, 7, or 14 days after the surgery. Toluidine blue staining for mast cells and immunohistochemistry for histamine receptor H3 were performed on paraffin sections of the dura and cerebrum. Real-time PCR analysis of histamine receptor H3 mRNA expression was performed on total RNA extracts from the cerebrum.

The number of toluidine blue-stained dural mast cells at the site of impact was significantly decreased at one and four days after the trauma. The immunoreactivity and mRNA expression of histamine receptor H3 at the cortical contusion of the cerebrum were significantly increased at one and four days after the trauma. A previous report showed that activated mast cells release histamine-containing vesicles and appear unstained with toluidine blue. Therefore, the present results indicate that blunt force to the head causes dural mast cell degranulation and induces histamine receptor H3 expression in the cerebrum. The findings further indicate that a decreased number of toluidine blue-stained mast cells in the dura provide evidence of head trauma, suggesting that histological examinations of the dura may help to diagnose blunt force impacts to the head.

Forensic Neuropathology, Head Injury, Dura

G7 Plastic Bag Asphyxia: Suicide and Literature

Cristina Cordeiro, MSc*, Instituto Nacional De Medicina Legal, Largo Da Se Nova, Coimbra, 3000-213, PORTUGAL; and Duarte N.P. Vieira, PhD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL

The goal of this presentation is to show: (1) the importance of a careful autopsy in cases of asphyxia; (2) the importance of the death scene traces; and, (3) the influence of the literature in some cases of suicide.

This presentation will impact the forensic science community by showing how the literature and media could influence and help someone to commit a suicide.

Asphyxial deaths using plastic bags are not common. Most frequently classified as suicide or accident (usually involving children, volatile inhalants, and autoerotic situations), they also can have a homicide origin. The death may be caused by mechanisms such obstruction of the external air passages, usually called smothering, and/or oxygen deprivation, included in the general group of mechanical asphyxia by suffocation.

The cases of suicide using plastic bags have increased with the publication, in March 1991, of the book *Final Exit: The Practicalities of Self-Deliverance and Assisted Suicide for the Dying* written by Derek Humphry. The book describes this method of suicide, in combination with drugs, as a painless way for those suffering from a terminal illness to end their lives. In New York City asphyxia deaths using plastic bags increased by more than 300% immediately following the publication of the book. However, these deaths have only been responsible for less than 5% of all suicides in the year after the book was released. In many other countries, like Portugal, this method of suicide is however rarely used.

The death scene investigation may be crucial to determine a suicidal aetiology. As a matter of fact, if the plastic bag has been removed, and as in such cases the external evidence of injury could be minimal, the death may be initially understood as a natural death.

A case of suicide using plastic bag is presented, in which the victim, a retired translator, left nearby the book *Final Exit* open to the chapter

Suicide Using Plastic Bag. Some pills were also found, as well as letters expressing his suicide intentions and last will.

The need, in such situations, of a high index of suspicion for the diagnosis of this entity is emphasized. When numerous petechiae are present, particularly in the conjunctivae, an attempt to identify their origin should be made to exclude other manner of the death, such strangulation. So, a full and careful autopsy, including toxicological analysis, combined with the investigation of the evidence at the death scene is mandatory in these cases.

Plastic Bag, Asphyxia, Suicide

G8 The Bone Collector: When Reality Overcomes Fantasy

Luigi Cipolloni, MD, Manuela Rosini, MSc, Silvia Zoppis, MD*, Department of Legal Medicine University of Rome "Sapienza", Viale Regina Elena 336 00161, Rome, ITALY; Fabio Verginelli, PhD, Department of Oncology and Experimental Medicine, G. d'Annunzio University, Via dei Vestini 31, 66100, Chieti, ITALY; Michaela Lucci, PhD, Alfredo Coppa, Department of Environmental Biology, University of Rome "Sapienza", P.le A. Moro 5, 00185, Rome, ITALY; Filippo Terrasi, Circe, Innova and Department of Environmental Sciences, 2nd University of Naples, Via Vivaldi 43, 81100, Caserta, ITALY; and Carla Vecchiotti, Department of Legal Medicine University of Rome "Sapienza", Viale Regina Elena 336, 00161, Rome, ITALY

After attending this presentation, attendees will understand the importance of the application of a multidisciplinary approach in challenging cases of identification of human remains.

This presentation will impact the forensic science community by demonstrating that a case that may apparently seem simple may instead reveal great methodological and interpretative challenges, making it imperative to use a multidisciplinary approach with methods that require specific professional expertise in various specialties (e.g., pathology, genetics, anthropology, physics, chemistry).

All who work in the forensic field know that the more crucial the biological samples to be analyzed are (charred remains in an advanced state of decomposition, fragments of tissues, bones, etc.), the more complex personal identification is. In these challenging cases it is extremely important to apply a multidisciplinary approach for identification.

A case that came under their observation in July 2007 in Rome will be presented. A skeleton was discovered by firefighters after extinguishing a fire in a grassy field. The skeleton was almost complete and its right side was charred because of the flames. Beside the skeleton, a bag containing a bunch of keys and an identity card was found, fortunately not destroyed by the fire. These items belonged to an elderly man who disappeared in that area four years before.

Genetic tests were performed on a left femoral bone sample in order to confirm the presumed identity of the skeleton and instead provided a genetic profile that was not compatible with the sons of the missing man. Thus, other samples were taken from different bones and examined resulting in five different genetic profiles, corresponding to three women and two men, and none of them was compatible with the sons of the missing man.

Therefore the prosecutor asked for an anthropological expertise, who confirmed morphologically that the skeleton was composed by bones belonging to different individuals and could also give a range for the approximate age of these individuals at the time of death.

Thus, the prosecutor asked for the time-of-death estimation of these individuals and, at this request, specific investigations on the bone remains were carried out based on the measure of the isotopic ratio of ¹⁴C in lipids and collagen by Accelerator Mass Spectrometry (AMS), which can provide a dating for the remains in exam.

So far, five DNA profiles have been identified but not all the bones available have been genetically examined yet, so it is possible that the genetic profiles, and therefore the number of individuals involved in the case, may be more.

Identification, Multidisciplinary, Approach

G9 Cancer Patient mtDNA Forensic Identification: A Case Report

Fabio Verginelli, PhD, Department of Oncology and Experimental Medicine, G. d'Annunzio University, Via dei Vestini 31, 66100, Chieti, ITALY; Manuela Rosini, MSc, Department of Legal Medicine, Viale Regina Elena 336, 00161, Rome, ITALY; Silvia Zoppis, MD, Department of Legal Medicine University of Rome "Sapienza", Viale Regina Elena 336 00161, Rome, ITALY; and Carla Vecchiotti, Department of Legal Medicine, Viale Regina Elena 336, 00161, Rome, ITALY*

After attending this presentation, attendees will understand how to manage a forensic identification case in a cancer patient, when only neoplastic tissue is available for the genetic analyses.

This presentation will impact the forensic science community by demonstrating that, because of the frequency of mutations in mtDNA is higher than in nuclear DNA in a variety of human cancers (as suggested from several studies), the mtDNA profiling should not be applied as the unique analysis in cases of forensic identification of cancer patients when only neoplastic tissue is available. Moreover, direct automated sequencing lacks adequate resolution to detect mtDNA heteroplasmy when, as in cancer cells, the somatic mutation tend to homoplasmcy.

Mitochondrial genome mutations are described in many kinds of human malignancies, including lung cancer. These mutations can be base substitutions, insertion, or deletions, and the 1.1 kb d-loop region has been recently identified as a mutational "hot spot" in the mitochondrial DNA (mtDNA) of neoplastic tissue. Cancer cells harbor homoplasmic rather than heteroplasmic mutations; therefore, somatic mutant mtDNA appears as a single copy among a majority of wild-type mtDNA molecules and becomes dominant in the cancer cell probably due to the growth/survival advantages that such mutation confers to the cell.

A case of forensic identification will be presented in which a widow claimed medical malpractice by the physicians that had taken care of her husband, who was affected by a malignant lung disease. The wife thought that he had been wrongly diagnosed with cancer and, therefore, he had undergone massive and inappropriate therapies that finally led him to death.

In this case, the prosecutor ordered the seizure of the neoplastic histological samples attributed to the deceased and the comparison of the genetic profile obtained from these samples with those of the relatives, in order to establish the presence or absence of genetic compatibility among the neoplastic tissue and the relatives of the deceased.

To this end, autosomal markers were analyzed and compared with those of the two daughters of the deceased, while Y-chromosome markers and mtDNA were analyzed and compared with those of his brother.

While both autosomal and Y-chromosome markers confirmed the correspondence of the histological samples to the deceased, in the case of mtDNA a difference at nucleotide 16093 of HVRI region has been highlighted: in fact the brother had a C while the lung tissue examined showed a transition from C to T. In order to ascertain the full genetic compatibility it was therefore necessary to study the nature of this nucleotide difference by cloning of PCR products.

Sequencing of PCR cloning products thus allowed highlighting a heteroplasmic site (tending to homoplasmcy) at nt.16093 in tumor cells with respectively 75% of mutated mtDNA and only 25% of germ-line mtDNA compatible with the brother reference sequence.

mtDNA Profiling, Heteroplasmy, Neoplastic Tissue

G10 Method of Concealment of Corpses in Mafia Related Homicides: Melting in Strong Acids

Massimo Grillo, MD, Filippo M. Cascino, MD*, Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via del Vespro 129, Palermo, 90127, ITALY; and Valentina Murgo, MD, Palermo University, Via Del Vespro, n. 127, Palermo, 90100, ITALY; Livio Milone, Via Del Vespro, n. 127, Palermo, 90100, ITALY*

After attending this presentation, attendees will learn about some awful methods of concealing corpses used by Mafia criminal organizations.

This presentation will impact the forensic science community by showing experimental data to help attendees better understand how strong acids and bases could melt a body; in particular, it will be shown using sulfuric acid activated with water, both soft tissues and bones could colligate in few days, in contrast with pure sulfuric acid.

The criminal organization called "Cosa Nostra" has implemented brutal approach to commit murders over the past years, with dramatic symbolic implications, in order to prolong the agony of the victims, extract useful information, and no only to cause death as quickly and bloody as possible, but also to facilitate the concealment and the disappearance of the corpse itself. In the mafia, ritual murder must be view beyond the event itself, even the meaning of such gestures, take value as a warning to strike terror. Regarding the concealment of the corpses, nothing was known until the "pentiti" (those Mafiosi who turned informant) began to tell the dramatic episodes of which they witnessed or participated in from time to time, shedding light on a particular aspect of the phenomenology in Mafia's homicides known as "lupara bianca" (literally "white shotgun"): the disappearance of a subject who was known to be dead, but without knowledge of where his corpse was.

To hide the bodies of the victims tortured and killed, criminals used various methods, like burial in land, immersion in seawater with weights tied to the victims to get them to the bottom, disposal of corpses in natural caves or wells, or burning of bodies in ovens or cars. But the most chilling and ingenious method was destruction by "melting" by using strong acids or bases. In particular, some pentiti spoke about a "death's chamber," property of the criminal clan of Brancaccio and his boss, Filippo Marchese, called "u milinciana" (the eggplant, because of his skin's color), where the police found some tanks full of acid, torture instruments, and human remains.

This report's goal, therefore, is to verify experimentally the use of strong acids (sulfuric acid) for the dissolution of biological tissues animals, and also observing the macroscopic changes that the soft tissues and bones undergo over the time, in order to verify the claims of the Mafia's "pentiti" in their statements. In particular, two different tests were conducted: in the first, dipping a pork knuckle weighing 160 grams in a glass bowl containing pure sulfuric acid of known concentration, highly caustic, water-soluble, and able to carbonize organic matter. In this case, after only 30 minutes, the piece of pork appeared to be "cooked," with brownish color, in two days the muscle structures were loose, while after only six days, the bone began to be eroded, although it remained essentially integrated. The second test was made by dipping the knuckle of pork into a bath of 700 cc of sulfuric acid activated with water. In this case, the muscle-cartilaginous component disappeared after only 12 hours and after two days the bone appeared dissolved in the liquid component.

These experimental test made have thus demonstrated that it appears unlikely that an entire body can be dissolved in few minutes (as reported by some "pentiti") using the normal commercially available sulfuric acid, but in any case it's likely that, in several days, a corpse could be colligated and made unrecognizable.

Mafia's Homicide, Concealment, Melting

G11 When Ribs Penetrate the Heart in Blunt Chest Wall Trauma

Tanuj Kanchan, MD, Kasturba Medical College, Department of Forensic Medicine, Light House Hill Road, Mangalore, 575 001, INDIA*

After attending this presentation, attendees will be able to identify with the possible mechanism of penetrating trauma caused directly to the heart by the fractured ends of the ribs in run over traffic mishaps.

This presentation will impact the forensic science community by illustrating a type of injury that is well known but rare. The injury is reported for the first time in a run over traffic accident. Cardiac lacerations caused directly as a result of rib fractures although a rare phenomenon in blunt force trauma to the chest, its possibility should be explored so that prompt and early treatment saves the patient from a fatal outcome.

Cardiac damage in non-penetrating chest trauma is uncommon. Direct penetrating injuries to the heart are commonly observed in stab and gunshot wounds. The fractured ends of the ribs are very rarely reported to cause penetrating injuries to the heart. One such rare case where the sharp ends of fractured ribs has caused extensive damage to the heart in a run over vehicular accident is reported. The reported rare case illustrates the possible mechanism of direct cardiac injuries from broken sharp jagged fractured ends of ribs in blunt force trauma to the chest in run over traffic mishaps.

A 45-year-old male fell from a moving bus while trying to get off. By the time brakes were applied, the moving bus had run over the left side of his chest, neck, and head. The victim died instantly and the body was subjected to medicolegal autopsy. On external examination, the head and face of the victim was deformed. Underlying comminuted skull fractures were palpable. No external injuries were evident on the chest region. Avulsed lacerations were present on the lower limbs. Internal examination revealed multiple fractures of the cranial vault and base of the skull with diffuse subdural and subarachnoid hemorrhage, intraventricular bleeding, and extensive brain damage. Fractures of the 2nd to 6th ribs in anterior axillary line on the left side, and fracture of 1st and 2nd ribs in mid-clavicular line on the right side with corresponding chest wall muscle contusions were present. Pleura contained 300 and 400 ml of frank blood in the right and left sides respectively. Pericardium was torn and extensive damage to the left ventricle was evident. The heart weighed 280 grams. Transmural lacerations of the left ventricle were present, corresponding to the pointed fractured ends of the ribs on the left side. Peritoneal cavity contained 200 ml of blood. Multiple lacerations over the right liver lobe were present. All visceral organs were pale on cut section. Lungs escaped any major trauma in the reported case.

The rib cage acts as a protection for the thoracic organs and support for the vertebral column. Penetrating injuries to the heart in blunt chest trauma thus remain uncommon. Even when the ribs are fractured recoil of the intercostal muscles keeps the architecture of the rib cage intact preventing subsequent injuries to the thoracic organs. Fractured ribs at times may act as a weapon of offense causing damage to the underlying organs directly. In the present case of a run-over traffic mishap, no external injuries or deformity were apparent on the chest wall. On internal examination, intercostal muscle contusions were present but apparently the rib cage had retained its shape due to recoil of the intercostal muscles. It was only on further dissection that the major insult to the pericardium and the heart was observed. It is illustrated how the sharp jagged ends of the fractured ribs move medially on external pressure to cause penetrating injuries to the heart. It is proposed that as a consequence of the transient phenomenon of deformation of chest cavity under pressure in run over traffic mishaps, the projecting fractured ends of the ribs penetrate the underlying thoracic organs causing fatal injuries.

Ribs, Heart, Run Over Traffic Mishap

* Presenting Author

G12 Examination of Sexually Abused Children: Presentation of the First Danish Center for the Investigation and Care of Abused Children

Annie Vesterby, MD, DMSc, Institute of Forensic Medicine, University of Aarhus, Brendstrupgårdsvæj 100, 8200 Aarhus N, DK-8000, DENMARK*

After attending this presentation, attendees will understand how the first Danish Child Protection Center was organized, and the importance of the participation of the forensic department and the forensic pathologist.

This presentation will impact the forensic science community by showing the importance of the involvement of the forensic pathologist in the investigation of child sexual abuse.

The prevalence of sexual abuse of children in the Nordic countries is unknown, but has been estimated to be around 5%. Very few cases of sexual abuse are reported to the police. The police may request a medical examination to document or verify the child's testimony.

Until now, the child and the child's family have had to go to the police station to give a videotaped interview to the police, go to a medical or a forensic doctor with examination rooms located elsewhere, followed by pediatric evaluation and treatment and psychosocial follow-up at yet another place.

In November 2007, the first Danish centre for the protection of abused children was established at Aarhus University Hospital, Skejby.

The Center, which receives all kinds of child abuse cases, is located in a building neighboring the Department of Forensic Medicine, Aarhus, and headed by a steering group with representatives from the Pediatric Department, the police, and the Department of Forensic Medicine; the Center is managed by a pediatric consultant.

Videotaped interviews by the police are performed at the centre as well as the forensic medical examination, pediatric and psychosocial evaluation and follow-up.

Experience and perspectives from the first Danish child protection centre for the forensic community will be presented.

Sexual Abuse, Child Protection Center, Forensic Pathology

G13 An Innovative Proteomic Approach for the Identification of Novel Plasma Biomarkers in Patients With Brugada Syndrome

Domenica Scumaci, PhD, Magna Graecia University of Catanzaro, Laboratory of Proteomics and Mass Spectrometry, Department of Experimental and Clinical Medicine, Salvatore Venuta University Campus, viale "S. Ve, Catanzaro, 88100, ITALY; Simona Grasso, Antonio Curcio, PhD, and Marco Gaspari, PhD, Magna Graecia University of Catanzaro, Salvatore Venuta University Campus, Viale Europa, Catanzaro, AL 88100, ITALY; Silvia Priori, PhD, Molecular Cardiology Laboratory, IRCCS, Via Ferrata 8, Pavia, AL 27100, ITALY; Ciro Di Nunzio, Institute of Legal Medicine, School of Medicine, Magna Graecia University, Viale Europa Germaneto, Catanzaro, 88100, ITALY; Antonio Oliva, PhD, and Francesco Ausania, MD, Institute of Forensic Medicine, Catholic University, School of Medicine, Largo Francesco Vito 1, Rome, 88100, ITALY; Ciro Indolfi, PhD, Magna Graecia University, Viale S Venuta, Catanzaro, AL 88100, ITALY; Pietrantonio Ricci, PhD, Università degli Studi Magna Graecia Catanzaro, Viale Europa - Località Germaneto, Catanzaro, 88100, ITALY; and Giovanni Cuda, PhD, Magna Graecia University of Catanzaro, Viale S. Venuta, Catanzaro, AL 88100, ITALY*

After attending this presentation, attendees will understand how plasma potentially carries important information whose knowledge

could help to improve early disease detection and prognosis in Brugada syndrome.

This presentation will impact the forensic science community by providing potential new tools for the correct diagnosis of “at risk” individuals with Brugada syndrome carrying specific gene mutations. The molecular signature obtained by the study of plasma proteome will complement genomic information therefore increasing the chance of disease detection in these individuals who are exposed to a dramatic risk of sudden cardiac death.

Brugada syndrome (BS) is a polygenic inherited cardiac disease characterized by life threatening arrhythmias and high incidence of sudden death. In the family enrolled in the present study, the disorder is caused by Q1118X-mutation in the SCN5A gene, encoding the cardiac sodium channel. 2D-PAGE was used to investigate specific changes in the plasma proteome of BS affected patients and family members sharing the same gene mutation, compared to healthy controls, with the goal to identify potentially specific disease biomarkers.

In order to reduce plasma sample complexity, the combinatorial hexapeptide ligand libraries were used.¹ The use of the beads prior 2D-PAGE enabled detection of many new protein spots and increased resolution and intensity of low abundance proteins.

Approximately 900 protein spots were detected in each gel. Proteins, whose expression was significantly different among the two groups, were excised, trypsin-digested and analyzed by LC-MS/MS.

Data showed that the levels of several proteins were significantly altered in BS patients compared with controls. In particular, Apolipoprotein E, Prothrombin, Vitronectin, Complement-factor H, Vitamin-D-binding protein, Voltage-dependent anion-selective channel protein 3, and Clusterin were considerably increased in plasma sample of BS patients, whereas Alpha-1-antitrypsin, Fibrinogen, and Angiotensinogen were considerably decreased; moreover, post-translational modification of Antithrombin-III was detected in all affected individuals.

In the light of these results, it is hypothesized that these proteins might be considered as potential markers for the identification of disease status in BS. Further analysis is being conducted in our laboratory in order to validate these findings in a larger number of cases and to elucidate the pathogenetic role of these proteins in this specific cardiac disease.

Brugada Syndrome, Plasma Biomarkers, Proteomics

G14 A Case of Lethal Peripartum Eosinophilic Myocarditis

Maria Carolina Romanelli, MD, Eloisa Maselli, MD, Biagio Solarino, PhD, Section of Legal Medicine - University of Bari, Piazza Giulio Cesare, 11, Bari, 70124, ITALY; and Giancarlo Di Vella, PhD, Sezione di Medicina Legale, DIMIMP, University of Bari, Policlinico, Piazza G. Cesare, Bari, 70121, ITALY*

The goal of this presentation is to report an uncommon case of lethal peripartum cardiomyopathy in a young woman. A complete forensic approach was performed through autopsy, histological, and microbiological examinations and final results showed that the cause of death was due to an Eosinophilic Myocarditis (EM).

This presentation will impact the forensic science community showing that eosinophilic myocarditis is a rare, potentially fatal disease if left untreated.

Eosinophilic myocarditis is a histological diagnosis characterized by a mixed inflammatory cell infiltrate containing a variable amount of

eosinophils within the myocardium. This phenomenon may be associated with a variety of disease such as idiopathic hypereosinophilic syndrome (IHES), hypersensitivity myocarditis, giant cell myocarditis, toxic myocarditis, Churg-Strauss syndrome, or parasitic infection.

Clinical presentation includes a wide spectrum of nonspecific signs and symptoms: chest pain, fever, shortness of breath, chills, cough, but they are not always present at the same time and sometimes unusual symptoms, such as epigastric pain, can be the only indication of a pathological state. They can be also associated with peripheral eosinophilia and transient or persistent left ventricular dysfunction.

EM is considered, together with coronary heart dissection, one of the clinical presentations of peripartum cardiomyopathy that usually occurs one month before to six months following delivery. EM etiology and pathogenesis are unknown: eosinophils may be present and activated because of the systemic hormonal perturbation occurring during the period of uterine involution.

A major problem is that EM is rarely recognized clinically and is often first discovered only at postmortem examination.

A correct diagnostic approach in these patients should include an echocardiogram study (with evidence of low ejection fraction and decreased left ventricular systolic function) and an endomyocardial biopsy (confirming eosinophils as a major inflammatory cell component).

If successfully diagnosed, EM can be treated with beta-blockers and ACE inhibitors to support heart failure and corticosteroids to reduce the inflammatory process that is involving the myocardium. Prognosis is strictly linked to ventricular function recovery because those patients with severe myocarditis-induced heart failure have less survival chances if normal cardiac function is not restored.

Few EM cases are reported in literature and most of them are based only on autopsy diagnosis.

A case is reported of a 29-year-old woman who was admitted to critical care unit in respiratory and cardiac failure, three weeks after giving birth. Patient clinical history was non-existent for allergy or autoimmune diseases. The third day after birth, she complained of thoracic pain but echocardiogram was negative. During hospitalization physicians treated her with antacids and gastric inhibitors and then she was discharged with prescription of proton pump inhibitors with the suggestion of gastroenterology visit. The following three weeks were characterized by growing anterior and back thoracic pain associated with general discomfort, but neither specific symptoms nor peripheral eosinophils increase were present; only inflammatory indexes (velocity of erythrocyte sedimentation, VES, and creatine kinase, CK) were slightly increased. With progressive and worsening clinical symptoms, she was finally sent to emergency room in critical condition: dyspnea, confusion, fever, and tachycardia. Echocardiogram showed severe left ventricular systolic dysfunction and 25% of ejection fraction; chest radiograph and TC displayed pleural effusion with general edema. The young woman died after seven hours of cardio-respiratory failure and no medical approach was effective. External examination of the body was completely negative. Autopsy revealed bilateral pleural effusions, increased lung weights, and hepatomegaly. Heart was normal in size and shape, but myocardium and papillary muscles showed malacic areas. Histological examination pointed out massive eosinophilic infiltrates, more evident in cardiac samples. The cause of death was indeed attributed to peripartum eosinophilic myocarditis.

The role of “peripartum” in the etiopathogenesis of such cardiomyopathy as well as possible medical liability in lacking diagnosis and treatment of myocarditis will be discussed.

Eosinophilic Myocarditis, Peripartum, Heart Failure

G15 The Bodies of Two Missing Children in an Enclosed Underground Environment

Francesco Introna, PhD, Antonio De Donno, PhD, Valeria Santoro, PhD, Section of Legal Medicine - DiMIMP, P.zza Giulio Cesare n.11, Bari, 70124, ITALY; Simona Corrado, MD, Sezione di Medicina Legale, Bari, 70100, ITALY; Vito Romano, MD, Medicina Legale Miulli, Acquaviva delle Fonti, Acquaviva delle Fonti - Bari, 70100, ITALY; Francesco Porcelli, PhD, Section of Entomology and Zoology (Di.B.C.A.), University of Bari (Italy), Via G Amendola, Bari, 70126, ITALY; and Carlo P. Campobasso, PhD*, University of Molise, Via De Sanctis, Snc, Campobasso, 86100, ITALY

The goal of this presentation is to illustrate a little-known but noteworthy case concerning the wrongful conviction of a Southern Italy father whose two missing children were found dead in enclosed environment after approximately 1.5 years since their disappearance.

This presentation will impact the forensic science community by warning and improving search operation, methods of investigation, and indictment process, based on the autopsy findings and physical evidence collected on the scene and from the bodies.

Two young kids, 13- and 11-years-old respectively, originally from a small town in Southern Italy, were missing on June 5, 2006 (06:30 p.m.). Soon after their disappearance, a “missing child” search began. Broadcasters promptly aired a description of the missing children pushing the entire community to assist in the search and safe recovery of the child. But every effort was in vain for more than one year. During the search, the investigators collected enough evidence against the father who was arrested 17 months after the disappearance. He was indicted for kidnapping, homicide, and concealment of the two bodies. He never confessed the crimes and he claimed to be innocent.

Three months after the conviction, a fireman found the two corpses in a subterranean dry cistern next to a more than 20-meter-high well water. The bodies were well preserved, almost mummified with only few body-parts skeletonized. Based on dental records they were identified as those of the two children missing 1.5 years before. Signs of a very low insect activity were present, reasonably consistent with a rapid skin dehydration. The autopsy showed no signs of defense injuries or ligature consistent with strangulation or captivation except for fractures of the axial skeleton at a number of points consistent with a fall from a low-medium height. The body of the elder brother (CP) presented major injuries with signs of recent hemorrhages and gut content analysis consistent with the last meal which provided enough evidence to ascertain a very short survival time. The younger brother (TP) showed minor injuries, signs of old hemorrhage, gastric and intestine emptying time consistent with a longer survival time of approximately 3-4 days, spent alone in the dark and cold cistern. No evidence of body removal or corpse displacement following death was observed. A long postmortem interval (PMI) of approximately 20 months was estimated mainly from the pattern of insect succession. Based on such physical evidence, on March 4, 2008, four months after conviction and 40 days after the recovery of the two bodies, the father was released from prison and exonerated from previous indictment of homicide.

Missing Children, Wrongful Conviction, Postmortem Interval

G16 Diagnosis Of Drowning: The Contribution Of Microbiological Investigations

Pistolesi Luca, MD*, Institute of Legal Medicine, Via Del Giochetto Snc, Perugia, ID 06100, ITALY

After attending this presentation, attendees will gain knowledge of the effectiveness of marine bacteria and/or bacterial indicators of water fecal pollution as a new marker of drowning.

This presentation will impact the forensic science community by introducing an alternative test that could be useful in drowning diagnosis.

To investigate the effectiveness of marine bacteria and/or bacterial indicators of water fecal pollution as a new marker of drowning, an experimental protocol was performed to identify bacteria on samples of drowned victims recovered from umor vitreo (UV) and blood of different anatomic sites such as: right ventricular blood (RV), left ventricular blood (LV) and peripheral blood (P). The study, performed in 2008 and 2009, was performed on ten victims: six drowned victims (two cases in sea water, three in rivers or lake; one in rainwater collection tank) (study group), and four subjects who died from causes other than drowning (three cases of heart attack and one case of death by vehicle collision) (control group). From all groups at least 0.5 ml of each sample were obtained and the tests were calibrated by considering the water fecal pollution rates. Selective culture media were used to detect bacterial growth. Each samples of control or study groups (RV, LV, P and UV) or water samples (all 100 ml) were incubated in Tryptic soy broth (TSB) for 48 h at 37°C and 5% CO₂. After incubation, evaluation of bacterial growth was assessed by plating 100 ml of each sample onto: Todd Hewitt and Marine agars, selective for marine bacteria, m-FC agar, selective for fecal coliforms (FC) and KF Streptococcus agar, selective for fecal streptococci (FS). The plates were incubated for 24 h at 44°C and for 48 h at 37°C and 5% CO₂ to determine FC and FS growth, respectively. The presence of FC was indicated by the development of blue colonies, whereas the presence of FS was indicated by the development of red colonies. The absence of blue and red colonies indicated a negative result, i.e., no blood fecal pollution. The presence of marine bacteria was evaluated through the observation of their growth on selective culture media. Results showed that in the samples of drowned victims in sea water there is growth of marine bacteria, as evidenced by the presence of colonies on TH4% and MA culture media for LV and P blood samples, for the case 1, and for P and UV samples for the case 2. Moreover, the case 2 showed growth of FS and FC bacterial colonies. Regarding drowned victims in rivers or lake water, the analysis of case 4 showed the presence of marine bacteria from RV blood sample; on the other hand the case 5 resulted positive to marine bacteria and fecal streptococci. Surprisingly, case 3 was negative for marine bacteria and fecal streptococci. All anatomic sites of case 6, drowned victim in rainwater collection tank, resulted positive to all the bacterial species considered. Bacteriological analysis of RV, LV, P and UV samples of the control group evidenced a total absence of bacteria. This result showed the reliability of the microbiological test. All the water samples obtained from locations where corpses were found showed a bacterial presence according to samples obtained from the related victims. Applied method is sensitive since a very few bacteria aspirated at follow drowning can be evidenced. Positive results obtained for various anatomic sites (RV, LV, P, and UV) can be an internal control of the sampling procedure to avoid the possibility of bacterial contamination during blood and umor vitreo sampling. Notably, umor vitreo as a new sample for the microbiological test of drowning diagnosis was used.

Drowning Diagnosis, Microbiological Test, Umor Vitreo

G17 Butane Inhalation and Sudden Death: A Case Report

Maria Celeste Landolfa, MD*, Michela Cicconi, MD, Massimo Gallo, MD, and Andrea Gianelli Castiglione, MD, Department of Legal and Forensic Medicine, Via de Toni 12, Genova, I-16132, ITALY; and Francesco Ventura, MD, Department of Forensic Pathology, University of Genova, Via de' Toni, 12, Genova, 16132, ITALY

After attending this presentation, attendees will have learned about a case of sudden death due to butane inhalation in a young inmate.

This presentation will impact the forensic science community by stressing the importance of combining autopsy data and the detection of volatile substances in blood and tissues in all cases of unclear death of young people.

This presentation will inform attendees of something they do not do correctly—the misdiagnosed problem of sudden death due to abuse of volatile substances, especially in adolescents and people living in remote communities. In the current practice, forensic pathologists don't often consider that volatile substances are very easily accessible, and lethal if abused. They should learn how to detect halogenated hydrocarbons, and when it is correct to analyze the concentrations of these volatile substances in blood and tissues. This kind of investigation should be performed in order to avoid mistakes, especially in cases of sudden death of young people with aspecific pathological findings or unremarkable histological examinations.

The deliberate inhalation of volatile substances has been reported from most parts of the world, mainly among adolescents, individuals living in remote communities, and those whose job gives easy access to these substances, with a higher incidence in Countries with large rural populations. Although it is less widespread than twenty years ago, inhalant use still remains a problem today ranging from 10% to 15% among U.S. teenagers and young people (M.R. Marsolek et al., 2010).

Solvents from contact adhesives, typewriter correction, dry cleaning fluids, cigarette lighter refills, petrol (gasoline), halogenated solvents, and aerosol propellants are commonly abused in this way, but cigarette lighter refills and butane-containing cans for portable cooking stoves are the most frequently abused ones. Although aliphatic hydrocarbons are considered safe as aerosol propellants, the acute inhalation of these substances, particularly n-butane, may potentially cause severe damage in healthy hearts (M. Ago et al., 2002).

Volatile substance abuse gives rise to dose-related effects similar to those of hypnotics. Small doses can rapidly lead to euphoria and other behavior disturbances similar to those caused by ethanol (alcohol), and may also induce delusions and hallucinations. Higher doses may produce life-threatening effects such as seizures, coma, and sudden death (R.J. Flanagan et al., 1994). The mechanism of sudden death directly related to volatile abuse includes cardiac arrhythmia, hypoxia, and respiratory depression.

Butane is a gaseous aliphatic hydrocarbon, also called n-butane, with the “n” designating it as normal butane. Its other isomer is isobutene, but the name butane is used collectively to denote both n-butane and isobutane (R.L. Myers, 2007). N-butane and isobutane have an anesthetic or narcotic effect on the central nervous system, and induce fatal arrhythmia at 0.5–15% concentrations in the air (H. Sugie et al., 2004). It has been reported that many n-butane or isobutane abusers experienced fatal ventricular fibrillation immediately after a sudden fright or intense muscular exercise such as running and sexual activity (C. Jackowski et al., 2005. H. Sugie et al, 2004). A few cases of suicide by propane-butane inhalation have been reported too (A. Gross et al., 2002).

A case of sudden death of a 22-year-old male inmate is described. He had a history of drug addiction, depression, and multiple self-inflicted superficial incised wounds. His cellmates reported that the body was found in the bathroom of the cell. The bathroom smelled of gas. The body was lying on the bidet, with his back leaning against the wall; a butane-containing can and a portable cooking stove were found on the floor adjacent to the body. A complete medicolegal autopsy was performed. The external examination showed marked livor mortis, nosebleed, and some parallel linear scars on the forearms; no signs of recent injuries or trauma were observed. The internal examination revealed marked lung congestion; the other organs showed no pathological findings, but evidence of congestion. Histological examinations were unremarkable. Blood samples were collected and analyzed for halogenated hydrocarbons and drugs, using gas chromatography. A concentration of about 0.5 µg/ml for n-butane, with traces of isobutane and butene was measured; drug screening revealed

therapeutic concentrations of benzodiazepines and 0.5 g/L of ethanol in blood samples. The cause of death was ascribed to n-butane poisoning inducing fatal cardiac arrhythmia.

In conclusion, abuse of volatile substances is a serious problem because it is not illegal and agents are easily available and cheap. Thus, the risk of sudden death due to abuse of volatile substances in an environment with no witnesses should be taken into consideration in all cases of unclear death of young people. It is recommended that medicolegal death investigators become familiar with the principles of detection of volatile substances in blood and tissues, especially in those cases with unspecific macroscopic and histological findings.

Volatile Substance Abuse, Butane, Sudden Death

G18 Case Report of a Fatal Intoxication by Nucynta®

Dori M. Franco, DO, OAFME, 1413 Research Boulevard, Building 102, Rockville, MD 20904; Zabiullah Ali, MD, Barry S. Levine, PhD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Robert A. Middleberg, PhD, Annette Ervin, BS, Francis X. Diamond, BS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will learn about a case, in which, Nucynta®, a newly released analgesic, a Schedule II controlled substance, comparable to tramadol, was fatally ingested.

This presentation will impact the forensic science community by raising the awareness of the toxicity of novel drugs, which is essential for medical examiners and forensic toxicologists.

Tapentadol (Nucynta®) is a centrally acting opioid analgesic prescribed for the treatment of moderate to severe acute pain. Its efficacy is believed to be due to mu-opioid receptor agonist activity and inhibition of norepinephrine reuptake resulting in increased norepinephrine concentrations. Metabolism of tapentadol is via glucuronidation to inactive metabolites. There are no cases in the literature relating to the toxicity of this agent or reports of fatalities. This report documents a case in which tapentadol was identified as the cause of death. The decedent was a 40-year-old obese male who was found at home by his girlfriend. He had been prescribed Nucynta® (tapentadol) for shoulder pain, Lexapro (citalopram), and amitriptyline. There appeared to be more tablets missing than expected. At autopsy, there were early decomposition changes and hepatomegaly with fatty change.

Routine volatile, therapeutic drug, and abused drug testing was performed on the heart blood in this case. This included: (1) methanol, ethanol, acetone, and isopropanol analysis by head space gas chromatography (GC); (2) acid/neutral drug screen by GC-nitrogen-phosphorus detection (NPD); (3) alkaline drug screen by GC-NPD; (4) acetaminophen and salicylate by color test; and, (5) morphine and benzodiazepines by enzyme-linked immunosorbent assay (ELISA). The blood ethanol concentration was 0.01 g/dL; the vitreous humor ethanol concentration was negative. The alkaline drug screen was positive for diphenhydramine (0.6 mg/L), amitriptyline (1.1 mg/L), nortriptyline (<0.1 mg/L), and citalopram (0.3 mg/L). All were confirmed by full scan electron ionization gas chromatography/mass spectrometry and quantified by GC-NPD.

Given the case history, the heart blood was sent to a reference laboratory for tapentadol analysis. Tapentadol was quantified by liquid chromatography – mass spectrometry/mass spectrometry (LC-MS/MS) using D5-tapentadol as internal standard. Extraction of tapentadol from blood involved addition of carbonate buffer followed by methyl-tert-butylether (MBTE). After taking the MTBE layer to dryness, methanol was added and then transferred to an autosampler vial for injection. The limit of detection (LOD) and limit of quantitation (LOQ) of the assay were 0.06 ng/mL and 0.5 ng/mL, respectively.

The therapeutic range for tapentadol is 5-300 ng/mL. The tapentadol concentration found in the heart blood submitted in this case was 6600 ng/mL; more than 20 times the upper limit of the therapeutic range. Possible mechanisms of death include respiratory depression, CNS depression, and serotonin syndrome.

Based on the scene investigation and autopsy findings in this case, the medical examiner determined that the cause of death was narcotic (Nucynta®) intoxication and the manner-of-death was undetermined.

Tapentadol, Nucynta®, Overdose

G19 Nasal Mucociliary Motility: New Forensic Tool for Estimating Time Since Death

Biagio Solarino, PhD, Università degli Studi di Bari, Sezione di Medicina Legale, Piazza Giulio Cesare, 11, Bari, 70125, ITALY; Carolina Romanelli, MD, Lucia Tattoli, MD, and Giancarlo Di Vella, PhD, Section of Legal Medicine - University of Bari, Piazza G. Cesare 11, Bari, 70124, ITALY; and Luisa Fiorella, MD, and Matteo Gelardi, MD, Department of Otolaryngology II - University of Bari, Piazza G. Cesare 11, Bari, 70124, ITALY*

After attending this presentation, attendees will understand the potential contributions of postmortem investigation of nasal mucociliary motility in time of death estimation.

This presentation will impact the forensic science community by emphasizing the potential role of nasal scraping that could become a routine procedure in estimating time-since-death.

Postmortem interval (PMI) estimation is one of the most difficult issues in forensic medicine. Time-of-death is usually appreciated by recognizing early postmortem changes to the body prior to the onset of gross decomposition phenomena: algor mortis, rigor mortis, and livor mortis.

The study of these physical processes is strictly connected to the operator's subjectivity hence it can be source of confusion in estimating PMI. Moreover these body changes can be altered by several internal and external factors: body temperature at death time, subcutaneous fat, muscular mass, clothes, environmental temperature, humidity, and ventilation.

There have been many proposed innovative methods in attempts to avoid this trouble defining PMI objectively as possible. The goal of these new techniques is to find a link between PMI and objectively detectable values such as infrared tympanic thermography, skin fluorescence, electrolyte concentration in cerebro-spinal fluid, pericardial fluid or vitreous humor. All these samples, on the other hand, present practical difficulties in performing and require invasive methods and long time waiting.

Some studies have been published about nasal scraping role in clinical practice (ciliary dyskinesia, NARES, allergic rhinosinusitis), but no studies have never been performed in cadavers for PMI estimation.

A study concerning the examination of ciliary motility as residual life phenomenon, realizing a study on time of death evaluation using a new, rapidly available requiring substrate: nasal mucosa is presented.

Nasal mucosa is composed by numerous cell types (goblet cells, basal cells, ciliated and non-ciliated cells) and can be easily obtained by nasal scraping, a technique commonly used in otolaryngology; it consists of a curette crept on nasal mucosa and cells picked up in this way are then observed.

From June 2009 to June 2010, nasal scraping in 70 cadavers was performed. Age ranged from 24 to 95 years and the cause of death was most frequently due from ischemic cardiopathy, septic shock, and car accident. The only exclusion criteria of this study was nose bleeding.

A specimen of ciliated epithelium was obtained by scraping from the middle third of the inferior turbinate with a spoon-shaped nasal probe (Rhinoprobe). An *in vitro* evaluation of ciliary movement was performed. Ciliary beat frequency (CBF) was analyzed by phase-

contrast microscopy. Three different samples at different postmortem intervals were carried out: between 4 and 6 h (T1), between 10 and 12 h (T2) and after 24 h (T3). Then CBF (beat number/second) was classified in: present (3-4/sec), hypo-valid (1-2/sec) and absent.

Results demonstrated that, except for those cases which showed fungal or bacterial infections, at T1 motility was present in the majority of cases; at T2 motility was still present, but it was hypo-valid in a higher percentage. Ciliary activity was absent at T3. It is believed that all these findings can be explained with progressive metabolic reserves lowering: the more time passes after death, the more ciliated cells loose energetic substrates for ciliary motility.

In conclusion, mucociliary motility seems to be linked to PMI and thus nasal scraping can be considered as a new, easy, cheap, and efficient objective tool in detecting PMI; further studies are required.

Nasal Scraping, Mucociliary Motility, Time Since Death

G20 Fatal Spontaneous Non-Traumatic Subdural Hematoma and Terson Syndrome

Christina J. Tatum, MD, 522 Cliff Place, Homewood, AL 35209; and Constance A. Stanton, MD, and Patrick E. Lantz, MD, Wake Forest University Health Sciences, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072*

After attending this presentation, attendees will learn that a ruptured cerebral aneurysm can cause a compressive acute subdural hematoma without concomitant subarachnoid hemorrhage.

This presentation will impact the forensic science community by expanding the attendees knowledge base by increasing awareness of causes of non-traumatic subdural hematomas and retinal hemorrhages.

This presentation will inform attendees of something that they do not know. While most acute subdural hemorrhages are the result of trauma, forensic pathologists must be aware that a ruptured cerebral saccular aneurysm can cause a spontaneous non-traumatic subdural hemorrhage along with associated retinal hemorrhages (Terson syndrome).

Cerebral saccular aneurysms frequently rupture into the subarachnoid space, accounting for 70-80% of non-traumatic subarachnoid hemorrhages (SAH); however, aneurismal rupture also may result in concomitant intraparenchymal, intraventricular, or subdural hemorrhage. Most acute subdural hematomas (SDH) in adults are due to traumatic head injuries, although less common causes include coagulopathies, non-traumatic intracranial hemorrhage, intracranial hypotension, or post-surgical complications. A ruptured cerebral berry (saccular) aneurysm causing only an acute SDH is rare, representing < 0.5 - 2% of all ruptured aneurysms in several large case series. In 1881, Litten first described intra-retinal hemorrhage associated with SAH. However, Terson's description in 1900 of vitreous hemorrhage following SAH is now associated with this syndrome. Although originally defined by the presence of vitreous hemorrhage in association with SAH, Terson syndrome now encompasses any intraocular hemorrhage associated with intracranial hemorrhage and elevated intracranial pressures.

A case of 46-year-old woman who died suddenly and unexpectedly at her residence is presented. Found on the bathroom floor, she had no obvious injuries. According to investigations by the medical examiner and law enforcement, she had a vague past medical history significant for hypertension but did not consume alcoholic beverages or use illicit drugs. Subsequent toxicological analysis did not reveal any licit or illicit drugs.

At autopsy, she appeared well nourished and had a body weight, length, and body mass index of 49.1 kg, 160 cm, and 19.1, respectively. Postmortem monocular indirect ophthalmoscopy revealed bilateral retinal hemorrhages. The right and left fundi exhibited 25-35 and 15-20 flamed-shaped and dot retinal hemorrhages over the posterior poles, respectively.

A 1.5 cm subscalpular contusion was left of the vertex over the parietal area. No subgaleal extravasated blood or skull fractures were present. Diffuse liquid and clotted subdural blood covered the cerebral convexities ($R > L$) and weighed 67 gm. The calvarial dura had adherent non-organizing blood over the right and left frontoparietal regions. The leptomeninges were thin and translucent without any extravasated blood. Compression of the midbrain involved the inferomedial temporal lobes and $2 \times 1.5 \times 0.3$ cm dusky area of hemorrhage was in the inferomedial right temporal lobe (medial to the groove caused by transtentorial herniation). The arteries of the circle of Willis were in the usual anatomic configuration and patent. A $0.5 \times 0.2 \times 0.2$ cm ruptured saccular aneurysm projected from the callosal side of the bifurcation of the left pericallosal and callosal marginal arteries. The brainstem contained Duret hemorrhages in the pons and midbrain.

Ophthalmological examination revealed bilateral diffuse optic nerve sheath hemorrhages and extravasated blood within the perineural fat. The right and left fundi had 75-100 and 25-35 flame-shaped and dot retinal hemorrhages, respectively. These involved all four quadrants and extended past the equator but did not abut the ora serrata. The fundal hemorrhages were in all retinal layers and scant blood was in the vitreous of both globes.

A non-traumatic SDH can occur due to the rupture of cerebral saccular aneurysm. Most of these aneurysms are located on the internal carotid artery followed by the middle cerebral artery and anterior communicating artery, but only rarely arise from the distal anterior cerebral artery. Four mechanisms have been proposed by which blood from a ruptured cerebral aneurysm causes a SDH:

1. Successive small hemorrhages allow adhesions to develop and the final rupture dissects between the subarachnoid and subdural layers
2. The arachnoid membrane is breached by the rapidly accumulating blood from the rupturing aneurysm
3. A massive hemorrhage ruptures the cortex and breaches the arachnoid membrane
4. A carotid artery aneurysm located between the arachnoid layer and dura mater ruptures causing a SDH

Subarachnoid hemorrhage almost invariably develops following the rupture of a cerebral aneurysm and only extremely rarely does a SDH occur without an associated SAH. While most acute subdural hemorrhages are the result of trauma, forensic pathologists must be aware that a ruptured cerebral saccular aneurysm can cause a spontaneous non-traumatic SDH along with associated retinal hemorrhages (Terson syndrome).

Acute Non-Traumatic Subdural Hematoma, Cerebral Aneurysm, Retinal Hemorrhages

G21 A Fatal Complication of Vacuum-Assisted Vaginal Delivery

Lezah P. McCarthy, MD, Wake Forest University Baptist Medical Center, Medical Center Boulevard, Winston Salem, NC 27157; and Constance A. Stanton, MD, and Patrick E. Lantz, MD, Wake Forest University Health Sciences, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072*

After attending this presentation, attendees will learn of a fatal complication following vacuum-assisted vaginal delivery.

The presentation will impact the forensic science community by expanding the familiarity with a fatal complication of vacuum-assisted vaginal delivery, neonatal mortality, and conditions associated with retinal hemorrhages.

This presentation will inform attendees of something they do not know—that fatal neonatal subgaleal hemorrhage can result from birth assisted vacuum extraction and have associated extensive retinal hemorrhages.

An Edinburgh professor of obstetrics, James Young Simpson, first introduced a successful obstetric vacuum extractor in 1849. Technical difficulties limited its effectiveness and vacuum extraction (VE) fell from clinical interest until 1956 when the stainless steel cup vacuum device was introduced. While common in Europe, VE did not gain continued popularity in the United States until the 1980s. Early studies showed no significant traumatic complications attributed to VE when limited to 15 minutes and/or two “pop-offs” of the vacuum cap. The “pop-off” presumably served as a safety valve that would protect the neonate from excessive tractional forces. The development of the soft cup VE device with its implied safety caused VE to gain increasing popularity. Currently forceps and VE are used as delivery instruments, but over the past decade VE has replaced forceps as the main delivery instrument in assisted vaginal deliveries. However, controversy continues concerning which instrument is the best to use in specific clinical situations. VE remains popular because of its relative ease of use, lower maternal morbidity, and supposed safety. Nevertheless, severe neonatal complications can occur. The reported incidence of fetal death or severe fetal injury from VE ranges from 0.1-3 cases per 1,000 assisted deliveries. Three cases are presented of neonates who died from complications following vacuum-assisted vaginal delivery.

Case 1: Delivered by vacuum-assisted vaginal delivery, a 2.8 kg, 37-weeks-gestational age neonate had Apgar scores of 7 and 8 at 1 and 5 minutes, respectively. His initial hemoglobin (Hgb) was 17.4 gm/dL, but 5 hours later when he began grunting and developed hypothermia his Hgb was 6.8 gm/dL. He was transferred to a medical center with admitting diagnoses of subgaleal hemorrhage, anemia, hypotension, disseminated intravascular coagulopathy, and respiratory failure. After three weeks in the intensive care unit, the family withdrew care due to his increasingly poor prognosis. At autopsy, he had severe anasarca and hypoxic-ischemic/re-perfusion injury to his heart, liver, spleen, kidneys, and brain. An organizing subgaleal hematoma measured 15 cm and weighed 77 gm. No retinal hemorrhages (RHs) were identified by postmortem monocular indirect ophthalmoscopy (PMIO) and he had no documented clinical fundal examination.

Case 2: Born by vacuum-assisted vaginal delivery due to an arrested second stage of labor and shoulder dystocia, a 4.36 kg term neonate had Apgar scores of 0 at 1, 5, and 10 minutes and 2 at 15 minutes. She experienced immediate respiratory distress, hemodynamic instability, and presumed sepsis. Her initial Hgb was 14.9 gm/dL that later decreased to 10.7 gm/dL. An electroencephalogram demonstrated severe encephalopathy and her condition continued to decline until she died a day later. At autopsy, she had large subgaleal and subscalpular hematomas that were 20 cm in greatest dimension and weighed 54 gm. No skull fractures were present but she had bilateral subdural hematomas as well as subarachnoid hemorrhage. A clinical fundal examination was not done, but PMIO detected extensive bilateral multi-layered RHs.

Case 3: Delivered by cesarean section after a failed vacuum-assisted delivery, a 3.8 kg term neonate had Apgar scores of 3, 5, and 7 at 1, 6, and 10 minutes, respectively. He had respiratory distress, hemodynamic instability, and developed disseminated coagulopathy. The parents withdrew care the following day. At autopsy, extensive subgaleal and subscalpular extravasated blood was present measuring 35 cm in greatest dimension and weighing 140 gm. No skull fractures, epidural, or subdural hemorrhage was identified. PMIO revealed extensive RHs in the right globe and 1 RH in the left fundus; however, no clinical fundal examination was documented in the medical record.

The most common extracranial injuries associated with VE are superficial scalp abrasions, lacerations, and hemorrhage that can occur in 10% of neonates. Two major types of scalp injury are the common, but clinically unimportant, cephalohematomas and the relatively rare, but potentially life threatening, subgaleal (SG) hemorrhage where extravasated blood dissects between the periosteum of the skull and the galea aponeurotica. The mortality rate of SG hemorrhage following VE is estimated at 20%. Vacuum-assisted vaginal delivery is a relatively common procedure and most often benign. However, forensic

pathologists must be aware that a fatal SG hemorrhage can result from VE and have associated extensive RHs.

Vacuum-Assisted Vaginal Delivery, Subgaleal Hemorrhage, Retinal Hemorrhages

G22 The Relationship of Back Surgery to Overdose at Autopsy

Emily F. Gorman, MD, University of Alabama at Birmingham, Department of Pathology, P220 West Pavilion, Birmingham, AL 35233-7331; Robert M. Brissie, MD, Medical Examiner Office, 1515 6th Avenue, South, Birmingham, AL 35233; and Gregory G. Davis, MD, Jefferson County Medical Examiner's Office, 1515 6th Avenue, South, Room 220, Birmingham, AL 35233-1601*

The goal of this presentation is to define the relationship between the presence of a scar in the midline of the back, indicating a history of laminectomy, with drug intoxication sufficient to cause death.

This presentation will impact the forensic science community by discussing how presence of a laminectomy scar is a powerful marker for a drug related death. In a practice where toxicology is not routinely performed on all cases, the presence of a laminectomy scar should lead to toxicological analysis for that case.

Rationale: Individuals who have died suddenly and unexpectedly in which examination reveals a scar in the midline of the back of the sort left by a lumbar or cervical laminectomy are regularly received. Because the cause of death in such individuals is frequently intoxication with some drug, it is hypothesized that death due to a drug overdose is more common in individuals with evidence of a previous laminectomy than in individuals with no prior laminectomy. Therefore, we tested the null hypothesis. There is no difference in the frequency of death from a drug overdose in a study group with a linear scar in the midline of the back when compared to the frequency of drug overdose in cases evaluated at the medical examiner office in which no scar is found on the midline of the back.

Methods: A retrospective case-control study of deaths in 2008 investigated by the Jefferson County Coroner/Medical Examiner Office, Alabama was conducted. The study group consisted of decedents 18 years of age or older who had a linear scar in the midline of the back; as determined by review of the autopsy protocol (body diagram or written report). The control group was chosen from all the decedents examined at the Jefferson County Coroner/Medical Examiner Office, Alabama in 2008. Controls were matched to the study cases by age, race, and sex. Race and sex were matched exactly. Age was matched to the same year in 21 cases, to within one year in five cases, and to within two years in three cases. When more than one control was available the control used was determined randomly the throw of a die. The charts of both the study group (back scar) and of the control group (no scar) were reviewed for the cause of death and evidence of intoxication. All toxicology results were noted in the decedents, including the presence of cocaine, any other drugs or medications, and ethanol. Bodies charred by fire (six cases) or recovered as skeletal remains (two cases) were excluded from the study. This project was approved by the medical Institutional Review Board of the University of Alabama at Birmingham.

Results: For all decedents 18 years of age or older in 2008, the likelihood of death being due to a drug overdose was 12.8%. The study group of decedents with a linear back scar consisted of 27 decedents, nine of whom died as a result of acute intoxication with some substance of abuse. In the matched control group one decedent died of acute intoxication with a substance of abuse. Decedents with a back scar were thirteen times (odds ratio 13.0; 95% confidence interval 1.9-85; p= 0.011) more likely to die of a drug overdose than the controls. In other words, a body with a laminectomy scar is 13 times more likely to die as a result of an overdose than is another body without a laminectomy scar. Given the small p-value, chance is an unlikely explanation for these

results. The confidence interval is large because of the few cases in the study; a larger study will narrow the confidence interval.

Conclusion: This study shows that, when found at postmortem examination, the presence of a linear scar in the midline of the back of the sort following laminectomy is a powerful marker for a drug related death. In a practice where toxicology is not routinely performed on all cases, the presence of a laminectomy scar should lead to toxicological analysis for that case.

Back Scar, Drug Overdose, Intoxication

G23 The Use of Raman Spectroscopic Imaging in Cases of Ethylene Glycol Toxicity

Victor W. Weedn, MD, Maryland State Office of the Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Mary G. Ripple, MD, 68 Bluebird Road, Port Deposit, MD 21904; Sara Nedley, MS, ChemImage, 7301 Penn Avenue, Pittsburgh, PA 15208; and David R. Fowler, MD, and Kristin A. Johnson, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will have reviewed ethylene glycol toxicity, the pathophysiology and histology of ethylene glycol poisoning, and be introduced to the concept of Raman imaging and how it can be used to identify calcium oxalate crystals in tissues.

This presentation will impact the forensic science community by introducing a new method to identify crystalline deposits in the kidneys when ethylene glycol is suspected.

The American Association of Poison Control Centers reported 6,077 exposures to ethylene glycol in the United States, resulting in 40 deaths in 2002. The State of Maryland had 15 cases of ethylene glycol intoxication from 1996-2009. Ethylene glycol is a colorless, odorless liquid which is the principal component of antifreeze. The toxic dose varies but more than 0.1 ml/kg body weight is the reported toxic dose requiring medical treatment. The primary symptoms are CNS depression followed by a cardiopulmonary stage with eventual renal failure. The lethal dose is approximately 100 ml in an adult. It is metabolized to oxalic acid which binds the calcium in the body forming calcium oxalate crystals that eventually lead to the renal failure. In addition, it does not show up on toxicologic analysis in a routine volatile screen.

Forensic pathologists may be presented with a death without an obvious cause, but crystals may be seen in the kidneys that suggest ethylene glycol poisoning with initial negative toxicology. Four cases involving probable ethylene glycol ingestion and the use of Raman imaging to identify calcium oxalate crystals are presented. The cases presented include three cases of known ethylene glycol toxicity and one case of suspected ethylene glycol toxicity with negative ethylene glycol and glycolic acid blood analyses and crystals in the kidneys.

The case that prompted the use of Raman imaging was that of a 52-year-old black male found deceased with vomitus on a pillow next to him in his father's vacant home. The decedent had no known psychiatric or past medical history. At autopsy an anomalous right coronary artery and dull green stomach contents were found. Microscopic examination of the kidneys revealed multiple polarizable crystals consistent with calcium oxalate. This prompted additional police investigation revealing the subject was estranged from his family. No additional medical or social history was gained. Toxicologic analysis of blood for ethylene glycol and oxalic acid was negative. Raman imaging showed that the crystals were indeed calcium oxalate. The cause of death was anomalous right coronary artery complicated by oxalosis and the manner classified as Undetermined. Three other cases of known ethylene glycol toxicity underwent Raman imaging. In all cases, toxicologic analysis of the blood was positive for ethylene glycol, autopsy showed crystals in the kidneys, and the cause of death was ethylene glycol intoxication and manner was undetermined.

Raman molecular imaging is a method used to identify molecular structures. It is a physical phenomenon involving the interaction of light with molecules. This method is based on inelastic (Raman) scattering of monochromatic light from a source such as a visible laser, a near infrared laser, or near ultraviolet laser. The laser interacts with phonons in the system, resulting in the energy of the laser photons being shifted up or down. The shift in energy is then related as data concerning the phonons in the system being studied. The unstained aluminum slide is illuminated with a laser beam, light from this spot is collected with a lens, and then sent through a monochromator. Wavelengths similar to the laser are filtered out, and the rest of the light is collected into a detector. A given solid material has characteristic phonon modes that can help to identify it.

Raman molecular imaging was able to characterize the unknown crystals as calcium oxalate in all four cases of suspected ethylene glycol toxicity. The confirmation of the calcium oxalate crystals in the kidneys in the case with negative blood ethylene glycol and oxalic acid was helpful. In this case, the inability of investigation to establish clear social and medical history or the source of the oxalosis left the possibility of primary or secondary hyperoxaluria or an exogenous ingestion. Therefore, the manner was best certified as Undetermined.

This case series demonstrates the utility of Raman imaging to confirm the presence of calcium oxalate crystals in the kidneys. The correlation of these crystals to ethylene glycol intoxication requires complete toxicologic analysis and thorough investigation. Raman imaging could have many broad applications in the forensic pathology community and to the forensic community in general in the identification of unknown substances in tissues of all types.

Raman Imaging, Ethylene Glycol, Calcium Oxalate

G24 Death From Severe Anorectal Injury of a Jet Ski Passenger

Dennis Rhee, MD*, and Lynn A. Salzberger, MD, Southwest Institute of Forensic Sciences, 5230 Southwestern Medical Avenue, Dallas, TX 75235

After attending the presentation, attendees will understand the basic principles of jet ski propulsion and the potential for hydrostatic injury to the perineum.

This presentation will impact the forensic science community by bringing awareness to an unusual mechanism of injury in jet ski accidents. Such knowledge would prevent initial confusion and unnecessary use of resources to investigate other causes. In addition, it would serve to promote better safety practices in the use of jet skis.

This presentation will highlight the unusual case of a young woman who sustained lethal anorectal trauma after falling from the back of a jet ski.

It is recognized that both the popularity of personal watercraft and injuries related to their use have been increasing. Non-lethal lacerations, contusions, sprains, and fractures make up the majority of these injuries. Rare, but more serious injuries include closed head injury and intra-abdominal injury involving high velocity and rapid deceleration. The latter types of injury are typically those which result in fatality involving personal watercraft.

In the case presented, the autopsy showed a midline laceration posterior to the vaginal introitus which passed through the anus. The laceration extended to involve the deep soft tissues and the distal rectum was seen to be transected and free in the pelvic cavity. The full extent of her injury became apparent when the laceration was seen to extend within the retroperitoneal space to a level above the kidneys.

Given the extensive injury, initial suspicion surrounded possible impalement by a solid object. Witnesses at the scene as well the operator of the jet ski reported that the decedent fell straight back into unobstructed water. A subsequent review of the accident site revealed no

fixed obstructions. The decedent was initially conscious in the water, but became unresponsive shortly after being pulled to shore. Bloody drainage was seen from her perineum, and her wound was extensively packed. Despite this, resuscitation was unsuccessful.

A review of her medical history revealed a recent c-section. Her obstetrician reported that her c-section had been uncomplicated. Autopsy supported this as her gynecologic organs were intact. No other injuries were identified. The combination of history, literature, and autopsy findings indicated that the cause of death in this case was due to severe anorectal trauma from the water thrust of a jet ski.

Risk factors for injury in this case included the fact that the decedent was a passenger and fell straight backward. When a passenger falls from a jet ski, the throttle does not shut off automatically as it would for a driver who fell. Further, the decedent was wearing a bathing suit at the time of the accident. A wetsuit may have provided more protection.

While occasional case reports of similar, non-fatal injuries from jet ski accidents have been documented in the surgical literature, such a case has never been reported in the forensic literature to our knowledge. In the surgical cases reported, patients who sustained vaginal and/or rectal lacerations underwent successful repair with recovery of normal function.

Anorectal, Trauma, Jet Ski

G25 Sudden Unexpected Infant Death: Peripheral Retinal Hemorrhages Associated With Accidental Positional Asphyxiation (Wedging)

Stephen Lenfest, MD*, Wake Forest University Baptist Medical Center Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157; Candace H. Schoppe, MD, Wake Forest University School of Medicine, Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157; Constance A. Stanton, MD, Department of Pathology, Wake Forest University Health Sciences, Medical Center Boulevard, Winston-Salem, NC 27157; Donald R. Jason, JD, Wake Forest University School of Medicine, Medical Center Boulevard, Winston-Salem, NC 27157-1072; and Patrick E. Lantz, MD, Wake Forest University Health Sciences, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072

After attending this presentation, attendees will learn that peripheral retinal hemorrhages extending to the ora serrata are not specific for abusive head trauma (shaken baby syndrome) and can be associated with accidental positional asphyxia (wedging).

This presentation will impact the forensic science community by emphasizing the importance of routine retinal examinations (postmortem monocular indirect ophthalmoscopy) in infants dying suddenly and unexpectedly.

This presentation will inform attendees of something they do not know—multiple retinal hemorrhages, involving the peripheral retina and extending to the ora serrata in infants, are not specific for abusive head trauma (shaken baby syndrome).

Current data (1999 -2007) from the Centers for Disease Control lists accidental suffocation as the leading cause of unintentional death in infants. Of those deaths 65.7% were due to accidental asphyxiation in bed (all mechanisms). Accidental positional asphyxia from wedging often occurs when an infant becomes entrapped between the mattress and wall, headboard, or bed frame of an adult bed. Despite the number of unintentional wedging deaths in infants, to find published reports of retinal hemorrhages (RHs) associated with accidental positional asphyxia (wedging) were not found. A number of authors have asserted that multiple retinal hemorrhages (RHs) involving the peripheral retina and extending to the ora serrata occur only in abusive head trauma (AHT) or rarely with severe head injuries from motor vehicular

collisions or crush head injuries. This reports two infants who died suddenly and unexpectedly from wedging who had multiple RHs including peripheral RHs extending to the ora serrata.

Case 1: A father had been sleeping in an adult bed with his previously healthy 4-month-old infant son while the mother slept in another room with one of the infant's two older siblings. During the night the father heard the 3-year-old sibling wake up; he got up to check on her, but fell asleep her room. At 8:00 a.m., the mother found the infant unresponsive, wedged head down between the mattress and headboard of the bed. Paramedics pronounced him dead at the scene. At autopsy, he had parallel lines on his forehead corresponding to the mattress edging and ticking. Postmortem monocular indirect ophthalmoscopy (PMIO) revealed multiple RHs in the right fundus mainly over the equatorial region and two RHs in the left fundus at the mid-periphery. Microscopically, the right-sided RHs extended to the ora serrata and primarily involved the nerve fiber layer with focal involvement of the inner and outer nuclear layers. The left eye had one tiny retinal hemorrhage in the inner nuclear layer. No optic nerve sheath hemorrhages were identified grossly or microscopically. The *dura mater* had remote subdural membranes over the right and left frontal and left parietal regions. The brain had no ischemic or traumatic lesions. His postmortem radiographic skeletal survey revealed no acute or healing fractures.

Case 2: A previously healthy 6-month-old infant was sleeping in bed with her mother and was last seen alive at 2:00 a.m. Her mother found her wedged between the mattress and wall, face down on a stuffed animal, at about 6:00 a.m. She immediately drove her to the local emergency department where resuscitative efforts were unsuccessful. The infant was born at term by cesarean section without complication. At autopsy no scalp or subgaleal hemorrhages, skull fractures, cerebral edema, or epidural, subdural or subarachnoid hemorrhages were present. PMIO revealed bilateral RHs. Ocular examination disclosed 30-50 flame-shaped and dot hemorrhages circumferentially located from the mid equator to the ora serrata on the right side. The left eye displayed two posterior RHs measuring approximately $\frac{1}{4}$ disc diameter in size, located inferior and nasal to the fovea at the 3:00 position and 1 disc diameter from the optic nerve head at the 5:00 position, respectively. In addition, from the mid equator to the ora serrata were 40-60 pinpoint to flame-shaped or dot hemorrhages extending to, and focally abutting, the ora serrata in all 4 quadrants. No optic nerve sheath hemorrhages were observed grossly or microscopically. Intradural extravasated blood involved the falx cerebri and the right calvarial dura. The brain had age-appropriate development with no ischemic or traumatic lesions. Her postmortem radiographic skeletal survey revealed no acute or healing fractures.

These two cases with reliable histories of positional asphyxia demonstrate the importance of routine postmortem ocular examination of infants to better appreciate the spectrum of RHs seen in this age group. Multiple retinal hemorrhages in an infant, involving the peripheral retina and extending to the ora serrata, are not specific for AHT.

Sudden Unexpected Infant Death, Retinal Hemorrhages, Accidental Positional Asphyxia (Wedging)

G26 Antiepileptic Drug Intoxication: Report of One Case and a Forensic Pathologist's Approach

Ana R. Pereira, MD, Ladeira das Alpenduradas nº13A, Coimbra, 3030-167, PORTUGAL; Paula C. Oliveira, MD*, Konara Gunathilake, MD, Bruno M. Santos, MSc, Paula Proenca, PharmD, and Miguel Franco, MSc, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; Maria C. Mendonça, PhD, Instituto Nacional de Medicina Legal, Largo Sé Nova, Coimbra, 3000, PORTUGAL; and Duarte N.P. Vieira, PhD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL*

After attending this presentation, attendees, will learn a better forensic approach in investigating fatal cases where there is suspicion of antiepileptic drug misuse.

This presentation will impact the forensic science community by showing a fatal case of intoxication with valproic acid. In addition, further discussion is made in order to clarify and systematize forensic approaches (crime scene investigation and autopsy procedure) in cases involving suspicion of antiepileptic drug misusage, fatal consequences of antiepileptic drug, particularly valproic acid, including its direct toxic effects, adverse reactions and interactions with other drugs, possible mechanisms, causes and manners of death in these type of cases, and promotion of prevention measures with physicians to avoid fatal cases in patients taking antiepileptic drugs.

Valproic acid is formally an antiepileptic drug but currently it has wider clinical uses, including treatment of some psychiatric disorders, such as bipolar and affective disorders. Since prescription of valproic acid has been growing, it is becoming an increasingly common agent to be used in intentional overdoses. Although considered a relatively safe drug, it is known to cause hepatotoxicity and pancreatitis, amongst other adverse reactions. In patients co-ingesting other medications, specifically, those acting as CNS depressants, side effects and toxicity can become more dangerous and even fatal for the patient.

This study presents a 45-year-old blind female, who was found dead by her husband inside their house. The forensic pathologist called to the scene, found five empty blisters-packs of valproic acid. Previous pathologic history included epilepsy, bipolar disorder, and chronic alcohol abuse with prior suicide threats. At autopsy, external and internal examination didn't reveal significant traumatic lesions. The organs showed generalized congestion, the liver was significantly enlarged, the pancreas showed no macroscopic abnormalities and a whitish substance was present in the stomach.

Histological ancillary investigation confirmed congestion in the lungs and kidneys, and also, mild hepatic steatosis. Toxicological results revealed high concentrations of valproic acid (556.0 μ g/mL); therapeutic concentrations of other psychiatric drugs (tiapride, mirtazapine, nordiazepam, and oxazepam) and blood ethyl alcohol concentration of 1.34 g/L.

After excluding death due to natural or traumatic causes, a direct toxic effect by valproic acid was considered. Taking into account the autopsy, histopathology and toxicological findings, along with the circumstantial evidence, the cause of death was attributed to suicide by intoxication with valproic acid in association with other CNS depressants.

In conclusion, this case illustrates that is crucial for forensic pathologists to: (1) participate or have detailed information from the crime scene, prior to autopsy; (2) know the deceased' complete medical history and prescribed medication; (3) do a careful postmortem examination to exclude natural and traumatic causes of death; (4) study target organs of valproic acid action by macroscopic and microscopic approach; and, (5) do toxicological studies and exclude other causes of death.

When prescribing multiple CNS depressant drugs to patients with alcohol abuse and suicidal ideation, physicians should always be

particularly aware of the risk of valproic acid toxicity, interactions with other drugs and possible adverse reactions, besides the potential accidental or intentional intoxication.

Forensic Pathology, Antiepileptic Drug Intoxication, Valproic Acid

G27 Are Peripapillary Intrascleral Hemorrhages Pathognomonic for Abusive Head Trauma?

Candace H. Schoppe, MD, Wake Forest University Baptist Medical Center, Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157; Constance A. Stanton, MD, Department of Pathology, Wake Forest University Health Sciences, Medical Center Boulevard, Winston Salem, NC 27157; and Patrick E. Lantz, MD, Wake Forest University of Health Science, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072*

After attending this presentation, attendees will learn that peripapillary intrascleral hemorrhages are not diagnostically specific for abusive head trauma (shaken baby syndrome).

The presentation will impact the forensic science community by stressing the necessity for consistent postmortem ocular examinations of infants and young children to identify all conditions associated with certain ocular findings such as peripapillary intrascleral hemorrhages.

This presentation will inform attendees of something they do not know—that peripapillary intrascleral hemorrhages are not diagnostically specific for abusive head trauma (shaken baby syndrome) and exemplify the need for unbiased consistent ocular examinations, both clinically and at autopsy.

The American Academy of Pediatrics' Committee on Child Abuse and Neglect, Section on Ophthalmology, has acknowledged that searching for retinal hemorrhages (RHs) only in infants suspected of abuse creates a selection bias. However, they have also stated that postmortem eye removal might not be indicated "in children who have clearly died from witnessed severe accidental head trauma or otherwise readily diagnosed systemic medical conditions." Although infrequently described in the child abuse literature, peripapillary intrascleral hemorrhages have been considered "probably pathognomonic" for abusive head trauma (shaken baby syndrome) due to severe repetitive acceleration-deceleration forces with or without blunt head trauma.

Case 1: A 2-day-old male neonate had significant blunt force head trauma including bilateral subgaleal hemorrhages, right subscalpular hemorrhage, bilateral parietal skull fractures, diastatic separation of the sutures, subdural and subarachnoid hemorrhages, cerebral edema, and hypoxic ischemic brain injury. Indirect ophthalmoscopy revealed 30-50 flame-shaped and dot RHs involving all four quadrants of the left globe, extending anteriorly from the posterior pole past the equator to the ora serrata. Peripapillary intrascleral hemorrhages were in the left eye in addition to bilateral optic nerve sheath hemorrhages and bilateral periorbital soft tissue hemorrhage. The right globe had an artifactual papillomacular fold but no RHs. Neither eye exhibited papilledema. Hemothoraces and bilateral rib fractures were present. He had been delivered by cesarean section at 36-weeks estimated gestational age.

Case 2: A 3-day-old female neonate had severe blunt force head trauma. She had a small contusion on the right side of her forehead plus faint abrasions and ecchymoses overlying the right mastoid process. She had bilateral subgaleal hemorrhages, bilateral parietal skull fractures, and a diastatic fracture of the left lambdoid suture. Subdural and subarachnoid hemorrhages, cerebral cortical contusions, cerebral edema and diffuse hypoxic-ischemic brain injury were identified. Indirect ophthalmoscopy revealed multiple bilateral RHs. Subsequent examination of the orbital structures demonstrated bilateral preretinal, intraretinal, and subretinal hemorrhages, optic nerve sheath hemorrhages, peripapillary intrascleral hemorrhages and perineural extravasated blood. The right fundus had 15-20 flame-shaped RHs radiating from the optic nerve head for a distance of two to four disc

diameters. The largest of these measured approximately three disc diameters and was nearly confluent between the fovea and the superior temporal vascular arcade. No hemorrhages were evident past the equator on the right. On the left, the fundus had 10-15 flame-shaped RHs in all four quadrants, located mainly posteriorly, measuring approximately $\frac{1}{4}$ disc diameter in size. Two faint RHs at the 7:00 and 8:00 positions were flame-shaped and located 3-4 disc diameters from the ora serrata. Papilledema was not evident on either side. She had been delivered by cesarean section at 38-weeks estimated gestation age.

Both neonates had been delivered by emergency cesarean section following the involvement of their respective mothers in motor vehicle collisions. Both had Apgar scores of 0 at 1, 5, and 10 minutes and required prolonged resuscitation lasting 20 minutes and 14 minutes, respectively, before a heart rate was established. In the first case, the mother, a passenger in the vehicle, was ejected in a single vehicle rollover accident. She suffered only minor injuries. In the second case, the mother was the restrained driver of a van that crossed over the midline and hit an oncoming car. Extraction was prolonged and the mother suffered multiple pelvic fractures but no other serious injuries. In both cases the babies' heads were engaged in the pelvis at the time of the accidents. No uterine or placental injuries were found in either case and the mothers were not in labor at the time of the accidents. Neither neonate had a documented clinical fundal examination while hospitalized in the intensive care unit.

In-utero skull fractures with severe brain injury are uncommon but well documented. It is believed, RHs with peripapillary intrascleral hemorrhages have not been previously reported in neonates sustaining *in-utero* skull fractures and traumatic brain injuries. These cases demonstrate that peripapillary intrascleral hemorrhages are not diagnostically specific for abusive head trauma and exemplify the need for consistent, unbiased ocular examinations, both clinically and at autopsy.

Peripapillary Intrascleral Hemorrhages, Accident, Intrauterine Traumatic Brain Injury

G28 The Correlation of Serum Stress Hormone Levels With Cause and Circumstance of Death

Robert C. Shaler, PhD, 30 Spring Street, Flemington, NJ 08822; Dominic Flaim, PMFS, Pennsylvania State University, 107 Whitmore Lab, State College, PA 16802; and Thomas Andrew, MD, Office of the State Chief Medical Examiner, 246 Pleasant Street, Concord, NH 03301*

The goal of this presentation is to alert forensic professionals that biological markers have the potential to provide significant information concerning the psychological state and stress levels of someone just before death.

This presentation will impact the forensic science community by providing medical examiners and the courts a mechanism to understand the degree of stress someone was going through immediately prior to death.

Interleukin 6 (IL-6) is a major regulator of immune function, and has been shown to increase due to both physical and psychological stress. Knowledge of whether or not an individual was under psychological stress prior to death may be important in many cases. In this study, levels of IL-6 and its soluble receptor (sIL6-r) with an assumed level of psychological stress prior to death was correlated. Postmortem serum samples were obtained from the New Hampshire Medical Examiner's Office and analyzed using ELISA to determine concentration of both sIL6-r and IL-6. The raw data for the soluble receptor could be placed into four groups. However, these groupings were inconsistent with stress levels based on a study of the case histories of the decedents. The data for IL-6 however correlated well with the level of psychological and emotional stress an individual was under prior to death. This study shows that measurement of postmortem serum IL-

6 can be a potentially useful technique for determination of psychological and emotional stress prior to death.

Stress Hormones, Interleukin 6, Circumstance of Death

G29 Stippling Mimics — Differentiating Pseudostippling From Stippling: A Report of Four Cases

Jeffery G. Gofson, MD, and Wendy M. Gunther, MD*, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046*

After attending this presentation, attendees will be able to recognize factors from scene investigation, history, autopsy, and histology which may help in reliably differentiating stippling from stippling mimics, and understand the role of history and investigation as well as direct observation in differentiating stippling from stippling mimics.

This presentation will impact the forensic science community by assisting forensic pathologists in recognizing patterned injuries which may mimic stippling, and in utilizing history and scene investigation integrated with observation to draw valid conclusions about the origin of apparent stippling.

A valid outcome results from valid input. A forensic pathologist who relies only on observation, whether gross or microscopic, may draw invalid conclusions from what appear to be readily classifiable patterns of injury. Integrating history and scene findings into the decision-making process may allow the pathologist to come to reliable and valid conclusions about the source of a patterned injury that appears to be stippling.

A 20-year-old man died in a parking lot from a gunshot wound to the face, less than three weeks after sustaining nonfatal gunshot wound injury. Initial observation of the fatal gunshot wound, which entered the cranium through the tip of the nose, suggested a band or outline of stippling above the eyebrow, consistent with wearing a pair of glasses or sunglasses at the time he was shot. Multiple witnesses reported that the decedent was shot by an assailant from a car across the parking lot, far outside any possible stippling range. Scene re-investigation showed that the marks of pseudostippling matched the gravel in the parking lot. There were no glasses.

A 25-year-old male front-seat passenger in a vehicle, along with the driver was fatally shot by police during a chaotic incident that resulted from a confrontation following a police chase. The driver's body showed typical distant gunshot wounds, but the passenger, who was shot twice, had one distant gunshot wound, and one gunshot wound of the face surrounded by a dense 3" x 3" oval of apparent stippling. History and scene investigation suggested glass fragmentation injury from a bullet which passed through the passenger's window prior to striking him. A similar finding was noted in a homicide a year later when the driver of another vehicle was found dead in the front seat.

A 22-year-old woman was shot by her ex-boyfriend in a homicide-suicide event. The shooting was partially witnessed. The boyfriend shot the victim from a balcony of an outside staircase on which he stood two stories above her. He died immediately afterwards in the same location from a characteristic gunshot wound to the right temple. The decedent appeared to have stippling to the left axilla, and wounds suggestive of blunt to sharp force trauma across the neck, torso, and thigh. Extensive scene investigation was performed and co-ordinated with the autopsy findings to explain the apparent discrepancy between the locations of the shooter and the victim, and the victim's wounds.

These case reports are utilized, along with examples of true stippling for comparison, to demonstrate the dangers of invalid conclusions about patterned injuries when only observation is relied upon.

Stippling, Pseudostippling, Glass Fragmentation Patterns

G30 DNA Extraction From Paraffin Blocks: Organ Selection and Pre-Embedding Fixation Times – Practical Implications for Forensic Pathologists

Alex John, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish trail, Houston, TX 77054; Dwayne A. Wolf, PhD, Harris County Medical Examiner's Office, JAJ Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054; Jennifer Petrasch, MS, Shahida Flores, BS, Dustin Foley, MS, Lisa Gefrides, MS, and Roger Kahn, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX*

After attending this presentation, attendees will gain an understanding of which organs or tissues are optimal for paraffin archival for the purposes of subsequent DNA extraction; attendees will recognize the importance of the length of formalin fixation prior to paraffin embedding.

This presentation will impact the forensic science community by helping attendees to be able to direct histologic sampling to one or two tissue types (in decomposed and non-decomposed bodies) for the purposes of DNA sampling. Attendees will understand the critical time parameter for pre-embedding formalin fixation.

Synopsis: In recent years re-examination of old death investigation cases in the form of prosecutorial post-conviction review, defense review (prompted by the Innocence Project and others), law enforcement cold case initiatives (often with federal grant support), and ancestry inquiries is increasingly frequent. These reviews are aided and sometimes initiated by the existence of advanced DNA technology that may not have existed until after conclusion of the original investigation. Therefore the ability to obtain usable DNA evidence from items stored for extended periods is increasingly important. While standard forensic practices vary with regard to storage times for various pathology specimens (formalin fixed wet tissues in particular), forensic centers and hospital pathology services often retain paraffin embedded tissue blocks indefinitely; current National Association of Medical Examiners (NAME) accreditation guidelines require a retention time of at least 10 years. Consequently, paraffin blocks are an available resource for stored DNA evidence. However, forensic pathology practice varies regarding number of organs sampled for paraffin preservation, and even whether or not sections are taken in all types of cases; NAME accreditation guidelines allow discretion as to types of cases in which slides are produced but do recommend a one-year retention of paraffin embedded tissues when slides are not produced. To address the question of which tissue would be optimal for DNA recovery using modern methods, these experiments were designed to determine whether decomposition changes that answer, and whether the length of pre-embedding fixation is a critical variable.

Tissue obtained at autopsy was divided into three groups based on formalin fixation times of 1, 5, and 12 days prior to dehydration and paraffin embedding. Sections of each organ were deparaffinized with heat and DNA was purified from the residual tissue via organic extraction. Subsequent purification was accomplished by one of several different methods. Extracted DNA was quantified then amplified using a PCR amplification kit and separated by 3130x1 capillary electrophoresis. The electropherograms were analyzed for DNA profiles.

Tissues compared were heart muscle, skeletal muscle (psoas), liver, spleen, and brain. Cases included both non-decomposed and decomposed bodies. Preliminary results for quantitative DNA recovery indicate that spleen is superior to liver, heart or skeletal muscle. A striking loss of recoverable DNA is observed between pre-embedding fixation times of 5 to 12 days. The loss of DNA with increasing fixation times is maximum in spleen and skeletal muscle followed by liver and heart, but the differences between organs are small. Studies are ongoing, but preliminary data suggest that although quantitative DNA recovery is

greatest from spleen, the degree of degradation may also be greatest with spleen. Studies comparing brain to the other tissue types and the effects of decomposition are ongoing.

Impact: This project was undertaken to better define which tissue types are the best for extraction of DNA from paraffin blocks using modern DNA technology. With this knowledge forensic pathologists will be able to selectively sample organs in order to efficiently preserve DNA evidence while minimizing the expense of embedding multiple tissues and organs from all cases.

DNA Extraction, Paraffin, Formalin Fixation Time

G31 The Potential Value of Bone Marrow Analysis for Forensic Purposes: Evaluation of Needle Aspiration and Biopsy Taken From the Sternum

Biagio Solarino, PhD, Lucia Tattoli, PhD, Eloisa Maselli, MD, and Maria C. Romanelli, MD, Section of Legal Medicine, University of Bari, Piazza Giulio Cesare, 11, Bari, 70122, ITALY; Michael Tsokos, PhD, Institute of Legal Medicine and Forensic Sciences, University of Berlin, Turmstr. 21, Building L, 10559, Berlin, 10559, GERMANY; Alessandro Dell Erba, PhD, Section of Legal Medicine, University of Bari, Piazza Giulio Cesare, 11, Bari, 70122, ITALY; and Mario Delia, PhD, Hematology Section, University of Bari, Piazza Giulio Cesare, 11, Bari, 70122, ITALY*

After attending this presentation, attendees will understand the potential contributions of postmortem investigations of bone marrow (BM) taken from sternum in order to validate the diagnosis of some type of death.

This presentation will impact the forensic science community by emphasizing the potential contributions of postmortem BM evaluation that should become a routine procedure, especially if the forensic pathologist can not detect real cause of death during autopsy.

The importance of studying the bone marrow in clinical practice is well known and techniques such as marrow needle biopsies, smears from aspirate, and imprint preparations, allow the diagnosis of several blood disorders. On the other hand, many studies have explored the involvement of bone marrow also in systemic illnesses, including metastatic involvement with tumors, granulomatous diseases, AIDS, in staging of carcinomas, and for the follow-up evaluation of patients undergoing chemotherapy or transplantation. Other studies have strongly suggested that inflammatory cells originating from the BM contribute to sustain pathophysiological processes, e.g., allergy, sepsis, healing wounds. For example, in allergies, progenitor cells migrate to the site of allergic inflammation via blood, where they differentiate into tissue-dwelling and classic effector cells, such as mast cells and eosinophils. These modifications are probably secondary to the production of various cytokines which either block or stimulate the proliferation of hematopoietic stem cells (growth factors) and their differentiation.

A number of studies has been published in recent years about the use of BM specimens taken from iliac crest and rib as alternative tissue in forensic toxicology, concerning the detection of postmortem alcohol and drug content. Nevertheless, there is a lack of studies regarding an alternative role of the sternum aspiration and needle biopsy which can help to understand pathophysiological changes in response to stress, infection, or other external stimuli.

A study based on BM samples (needle aspiration and biopsy) taken from the sternum which were obtained from 70 autopsy cases performed in the Section of Legal Medicine, Bari University, from subjects died due to several causes (cardiovascular diseases, craniocerebral trauma, sepsis, etc) will be presented. The histopathological results will be discussed in

the light to underline the potential value of BM analysis for forensic purposes.

Assuming that by using sternum evaluation, the limit of poor samples possibly obtained by iliac aspiration, especially in postmortem work-up, might be avoided. Moreover, cytomorphological evaluation on sternum smears might offer more elements than those obtained by just histopathological examination, because of the less frequent postmortem alterations frequently described in bone marrow biopsy. In fact, BM is surrounded by solid cortical bone, which results in mechanical stability, this makes it more secure than other organs, e.g., against postmortem changes. Finally, sampling from sternum can easily be performed in larger amounts, easily accessible in routine autopsies, without changing the structure of the corpse in a relevant way.

The goal of this preliminary study is to demonstrate the presence of bone marrow postmortem activated cells in various causes of death as well as to analyze, for the first time in the literature, the sternum as the most important site for studying cells of such lymphoid organ in cadavers.

Bone Marrow, Postmortem, Immunology

G32 2009 H1N1 Fatalities: The New Mexico Experience

Erin G. Brooks, MD, Office of the Medical Investigator, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131; Clare H. Cunliffe, MD, Office of Medical Investigator, 700 Camino de Salud Northeast, Albuquerque, NM 87106; Catherine Avery, Chad Smelser, MD, and Deborah Thompson, MD, New Mexico Department of Health, 1190 South Saint Francis Drive, Santa Fe, NM 87502; and Kurt B. Nolte, MD, Office of Medical Investigator, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131-0001*

After attending this presentation, attendees will be able to describe the clinical and epidemiologic features associated with H1N1 fatalities, recognize the spectrum of histologic features that can be seen in H1N1 fatalities gain a familiarity with laboratory diagnostic options in cases of suspected H1N1, and recognize the importance of the autopsy in tracking the epidemiology of infectious disease.

This presentation will impact the forensic science community by raising awareness of which subgroups have greater H1N1 influenza mortality risk, and therefore may benefit from early antiviral treatment. It will also illustrate that H1N1 fatalities with a relatively rapid disease course may have far subtler respiratory histologic findings than those of previously published studies.

Hypothesis: New Mexico is an ethnically and racially diverse state with a large Native American population, among others. It is hypothesized that this population heterogeneity may predict a similar diversity of clinical and pathologic findings in 2009 New Mexico H1N1 fatalities.

Methods: A retrospective review of hospital, laboratory, field investigative, and autopsy reports of all H1N1 positive influenza fatalities reported to the New Mexico Department of Health in 2009 was performed. In those cases in which autopsies were performed, all available microscopic slide sections were independently reviewed by a study pathologist. All respiratory sections were additionally reviewed by a study pathologist with pulmonary pathology expertise.

Results: There were 52 H1N1 deaths reported to the New Mexico Department of Health in 2009: of these, 14 were autopsied. In two autopsied cases, H1N1 infection was determined to not be the cause of death. These cases were excluded from further study. In 3 out of 12 autopsied cases, the diagnosis of H1N1 influenza was made via antemortem studies, while in 9 out of 12 cases it was made at autopsy via reverse-transcriptase PCR on nasopharyngeal specimens +/- viral

nasopharyngeal/lung cultures. The most common respiratory histologic findings were alveolar edema (75%), interstitial inflammation (100%), bronchitis/bronchiolitis (83.3%), tracheitis (87.5%), and bronchopneumonia (66.7%). Of the total autopsied and non-autopsied fatalities, race/ethnicity was 42% Hispanic, 36% Caucasian, and 22% Native American. Ages ranged from 2 months – 89 years, with peaks in the 40 (18%) and 50 (26%) year decades.

Conclusions: This study highlights the importance of the autopsy in tracking the epidemiology of infectious disease: in 9/12 (75%) cases, H1N1 influenza was not known to be the cause of death until after autopsy. Most other studies of H1N1 pulmonary histopathology report diffuse alveolar damage (DAD) in the majority of autopsied fatalities (74%-100%). In this series, only 2 out of 12 (16.7%) cases manifested DAD. Also, the majority had a relatively rapid disease course: time from onset of symptoms to death in autopsied cases ranged from 1-12 d (avg 3.5 d) vs. the other largest published series' range of 2-44 d (median 7 d). These findings may indicate that New Mexico H1N1 influenza fatalities generally did not survive long enough to develop the more classic pulmonary manifestations. Native Americans comprised 2 out of 12 (16.7%) of autopsied fatalities and 9 out of 38 (23.7%) of non-autopsied fatalities. As the overall New Mexico population is only 9.6% Native American, Native Americans are disproportionately represented among the 2009 NM H1N1 fatalities.

H1N1, Influenza, Autopsy

G33 The Potential Use of Aquatic Invertebrate for Postmortem Submersion Interval (PMSI) Determination

Simona Corrado, MD, Sezione di Medicina Legale, Bari, 70100, ITALY; Lucio Rositani, PhD, Laboratory of Marine Biology, Molo Pizzoli, Bari, 70100, ITALY; Maurizio Scarpa, MD, Piazza G. Cesare 11 Università di Bari, Bari, 70100, ITALY; and Francesco Introna, PhD, Section of legal Medicine - DiMIMP, Piazza Giulio Cesare n.11, Bari, 70124, ITALY*

After attending this presentation, attendees will understand that in cases in which a human body is found in aquatic environments, careful aquatic scenes investigation, review of medical records, complete autopsy with skeletal survey, marine biology, and taphonomy testing are required.

This presentation will impact the forensic science community by emphasizing the fact that although estimating postmortem interval in terrestrial environments are standardized and widely accepted in courts of law, estimating immersion interval in aquatic environments are largely unexplored. The Postmortem Submersion Interval (PMSI) in aqueous environments refers to the time period from when the body enters the water to the point of discovery, noting that the body may be totally submerged for all or part of the time period. Understanding the growth phases of aquatic plants and animals that attach themselves to submerged remains is particularly valuable information and can be used to estimate a minimum PMSI.

A case of an adult human body discovered on an Ionian coast (South Italy) in February 2009, whose soft parts were converted into adipocere with partial skeletonization and disarticulation and showed the presence of barnacle stratification on bone surfaces is presented.

Barnacles specimens collected from bone surface consisted of a body divided into two regions: (1) the peduncle (stalk); and, (2) the capitulum. The peduncle is fleshy, large, and long, and it attaches to the substrate using the first antennae. The body is compressed laterally, covered by two folds of mantle, where five thin calcareous plates are attached. The carina is a dorsal unpaired plate, which forms a central keel. Paired scuta are large, and are located at the anterior region of the body. Paired terga are short and are located at the posterior-most region

of the body. Six pairs of thoracic, biramous cirri bordered with chaetae are visible through an aperture present in the mantle cavity. In the mantle cavity, there is a short head, a thorax with six thoracic, biramous limbs, a mouth, and a long, setose penis. The length of pedunculated barnacles ranged between 0.7 and 2 cm.

These barnacles belong to the family of Lepadidae, genus *Lepas*, species *Lepas anatifera*, order pedunculate barnacles.

The *Lepas anatifera* live in tropical and subtropical waters, and after attachment to the substrate is increased by an average of 1mm/die in seabed with temperatures between 15°C and 30°C. The growth of the barnacle is blocked at temperatures below 15°C or above 30°C.

Therefore stratification found on the surface of long bones of the lower limbs of *Lepas anatifera*, require at least 20-30 days at water temperatures between 15 °C to 30° C for achieving the maximum size observed in this case (2 cm).

The average temperature estimated in the Ionian Sea in February 2009 was 10.7°C, so it can be assumed that seawater temperature along the Ionian coast drops below 15 degrees for November-March. Hence, in November 2008 the corpse was already skeletonized and already converted into adipocere since the colonization of barnacles was already present on skeletonized limbs. This data suggested the amount of time the body was in standing water was at least six months/one year prior to attachment barnacles (October 2008) and, as a consequence, the range of immersion was identified in a period between October and November 2007 and March/April 2008.

The use of aquatic invertebrate in this case suggests a new avenue of basic research that forensic investigators can apply to cases involving submersed and/or floating human remains. In fact, the study of biology of aquatic invertebrates along with a timeframe of decomposition in the aquatic environments, can provide important clues on the length of soak time, however influenced by a high number of variables can potentially influence this process (e.g., temperature, water depth, currents, tides, season, dissolved oxygen, debris, substrate type, salinity, acidity, interactions between chemical and physical processes, and micro and macrofauna activity).

Adipocere, Marine Biology, Barnacle

G34 Epidemic Outbreak of Meningococcal Meningitis in a Nursery: Two Fatal Cases of Waterhouse-Friderichsen Syndrome

Alessandro Bonsignore, MD, Francesca Fossati, MD, Federica Portunato, MD, Francesco Ventura, PhD, and Francesco De Stefano, MD, Department of Legal and Forensic Medicine, University of Genova, Via de Toni 12, Genova, 16132, ITALY*

The goal of this presentation is to focus on two fatal cases of undiagnosed meningitis occurring simultaneously in two children from the same nursery. A forensic approach by means of autopsy, microscopic examination, and microbiological studies led to the conclusion that the cause of death in both infants was septic shock due to meningococcal meningitis in association with hemorrhagic adrenalitis.

This presentation will impact the forensic science community by demonstrating how important a thorough forensic investigation is to reach the correct postmortem diagnosis, as well as, by showing how rapidly children can develop a fatal meningococcal infection as well as explaining the importance of an early clinical diagnosis in order to avoid unexpected death and epidemic outbreaks.

Waterhouse-Friderichsen syndrome (WFS), first described in the early 1900s in England and Denmark, is the most severe form of meningococcal septicemia. The infection leads to massive hemorrhage in one or usually both adrenal glands. It is most commonly caused by *Neisseria meningitidis* (NM) but many other species of bacteria and also viruses are associated with WFS.

The onset of a meningococcal infection is non-specific with symptoms of fever, rigor, vomiting, and headache. Soon a rash appears; first macular, then rapidly becoming petechial and purpuric. In most cases the resulting hypotension rapidly leads to septic shock. In WFS, meningitis generally does not occur but if present, many clinical signs can be found such as hypoglycemia with hyponatraemia and hyperkalemia, thrombocytopenia and typical markers of diffuse intravascular coagulation.

Only microbiological studies can lead to the final diagnosis through culturing of blood or cerebrospinal fluid (CSF).

Fulminate meningococcemia is a medical emergency and needs to be treated with adequate antibiotics as fast as possible, also in order to prevent an epidemic outbreak. The administration of corticosteroids can sometimes reverse the adrenal shock.

Case 1: A 21-month-old child, previously in good health, developed high fever (40°C) on a Sunday morning. Paracetamol was administered twice during the day but both times with a low response. Few hours after the onset of the fever, the child began to vomit. In the evening the parents noticed a red\black “purpura” on the abdomen and the back. However, at the time, the child seemed to feel better, ate with a good appetite, and was afterward sleeping normally. Early the next morning the father found him lifeless in his bed.

Case 2: A healthy 19-month-old child, later discovered to be taken care of in the same nursery as the previous child, had a very similar clinical history. On the same Sunday afternoon, he developed high fever (39°C) and was treated with paracetamol but with a weak response. The next morning, after a normal night's sleep, he suddenly started to vomit and became cyanotic. The parents immediately called an ambulance but the baby died on the way to the hospital.

Complete postmortem autopsy of both children were performed 24 hours after death. Gross examinations revealed that they were age-accordingly developed. They were covered with purple petechial spots all over the body but no other remarkable external findings were observed.

Autopsies showed cerebral oedema and venous congestion, diffuse whitish and milky subpial exudation, adrenal glands with massive hemorrhagic infiltration of the parenchyma, and polyvisceral stasis. No other significant abnormalities were found.

The macroscopic appearance led to the suspicion of meningeal infection and hence, CSF, buccal, pharyngeal, and nasal swabs, as well as blood samples were taken for microbiological studies. These showed NM DNA positive for NM serotype B. Furthermore, all samples were culture positive after 72 hours of incubation. No other pathogenic agents were present.

The microscopic histological study, performed by using formalin-fixed paraffin embedded tissue sectioned at 4 µm and stained with haematoxylin-eosin, revealed subpial and cortical oedema, mild inflammatory infiltration along penetrating, deep brain vessels. The adrenal glands showed massive hemorrhagic infiltration, the lungs focal oedema, and there was polyvisceral stasis.

In conclusion, two infants died one shortly after the other 72 hours after they had last been in the same nursery and 24 hours after the onset of their symptoms. In both cases, a multidisciplinary approach revealed the cause of death to be septic shock due to acute meningococcal infection with hemorrhagic adrenalitis (Waterhouse-Friderichsen Syndrome).

Waterhouse-Friderichsen Syndrome, Epidemic Outbreak, Forensic Diagnosis

G35 Postmortem Animal Injuries: A Forensic Pathologist's Perspective

Ana R. Pereira, MD*, Ladeira das Alpenduradas nº13A, Coimbra, 3030-167, PORTUGAL; Bruno M. Santos, MSc, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; Carmen Barbu, MD, Instituto de Medicina Legal de Sf. Gheorghe, Romania, Bucharest, ROMANIA; Pedro A. Rezende, MSc, Jardim Carrilho Videira, Porto, PORTUGAL; Paula C. Oliveira, MD*, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; Jorge C. Santos, PhD, South Branch National Institute of Legal Medicine, R. Manuel Bento de Sousa, nº 3, 1150-219 Lisboa, Lisboa, PORTUGAL; and Duarte N.P. Vieira, PhD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL

After attending this presentation, attendees, will become aware of how traumatic injuries, especially those arising after suspicion of assault, could be instead, inflicted by local fauna where the body was found.

This presentation will impact the forensic science community by showing several cases involving postmortem traumatic lesions produced by different animals, which can lead to misdiagnosis, since they may resemble, inflicted and non-inflicted antemortem lesions. Therefore, postmortem animal injuries must always be taken in consideration by forensic pathologists, with the objective of avoiding mistakes in the initial investigation and further autopsy conclusions.

Postmortem animal predation on human death bodies is an important taphonomic phenomenon in forensic pathology, since animals, depending on their size and environment (land, water, or air), can produce a great variety of lesions. These type of animal injuries can be produced during early and/or late postmortem period creating some forensic implications and difficulties, including: (1) mimicking antemortem lesions, particularly when they are produced shortly after death; (2) modifying antemortem injuries, with loss of identifying features, which may lead to interpretation problems; and, (3) mistaken for signs of assault due to differential diagnostic problems.

This study presents several cases of postmortem injuries produced by animals from different environments, including ants, cats, dogs, sea and river fauna with the corpses being found indoors (home) or outdoors (forest, sea marine and river). The postmortem animal lesions didn't show any vital signs and the majority were located in unprotected body extremities, like face, upper and lower limbs. In these cases, autopsy findings allowed to identify both natural and violent causes of death, including two cases of asphyxia by drowning.

In conclusion, cases like those presented, illustrate that forensic pathologists need to have specific and especially attention when postmortem animal injuries may be present. Apart from the crime scene investigation and the autopsy procedure, it is essential that the pathologist: (1) have knowledge of local fauna, in particular from his own geographic area in order to better understand characteristic injury patterns produced by different animals; (2) always make a careful and detailed examination of the traumatic lesions, including morphological features and topographical distribution, so an accurate trauma etiology diagnosis can be done; and, (3) make a correct differential diagnosis which may clarify between antemortem and postmortem lesions.

Forensic Pathology, Postmortem Injuries, Animal Predation

G36 Neck Findings in Hanging and Strangulation Cases That Underwent Autopsy in Adana, Turkey

Ahmet Hilal, MD*, Necmi Cekin, MD, Mete K. Gulmen, PhD, and Kemal C. Yildirim, MD, Cukurova University School of Medicine, Department of Forensic Medicine, Balcali, Adana, 01330, TURKEY

The goal of this presentation is to demonstrate the neck findings in hanging and strangulation cases.

This presentation will impact the forensic science community by presenting macro-morphological findings in hanging and strangulation cases during the autopsy performance.

Deaths due to the mechanical forces applied to the neck area are frequently encountered in forensic medicine practices. Among these, hanging accounts for the majority of the forensic cases. It is seen in the majority of the studies performed in various regions of the world that hanging is the leading method of suicide. Strangulation cases are also seen though not common. The origin of the event is sometimes suspicious in the case where the crime scene has been altered, or in the case that the corpses had been pulled down or had fallen down because the string had broken.

In these cases, different problems may be in question and the direction of the inquest may change. Regarding the frequently encountered death cases due to the mechanical forces applied to the neck area caused by the above mentioned reasons, assessment and interpretation of the neck findings have important place for the forensic medicine. The consistency of these findings with the inquest and the information about the crime scene, as well as the method used and the presence, type, and characteristic of the traumatic findings in the neck area gain special importance. Fracture in the bone and cartilage tissues of this area and hemorrhage into the soft tissues are of great importance for the diagnosis as well as for the etiology to be exposed. These lesions are considered the indicators of a mechanical force applied to this area. Therefore, forensic medicine specialists carefully examine the neck during autopsies, remove the hyoid bone and thyroid cartilage, and completely evaluate. This present study was conducted in Adana province that is located in South Turkey, has a population of 2.5 million with high rate of unemployed subjects, and is exposed to high rate of internal migration because of extensive land available for agriculture. The records of the autopsies performed at the Group Presidency of Adana Institute of Forensic Medicine (IFM) between the years 2008 and 2009 were retrospectively reviewed. One-hundred and seventy cases (6.2%) that were assessed to have died due to a mechanical force (hanging or strangulation) were included in the study among 2,726 cases. Of the cases, 159 died of hanging and 11 died of strangulation. It was determined that 104 of the cases (61.2%) were male and 66 were female, hanging accounted for 93.5% and strangulation accounted for 6.5%, all of the hangings were suicidal, whereas the strangulations were murder. The age of the cases ranged between 4 and 86 years; the majority of the cases (n=37, 21.7%) were between 21 and 30 years of age, whereas 32 cases were between 11 and 20 years of age. It was determined that two girls between the ages 0 and 10 years died of strangulation. It was observed that 121 of the hanging cases were typical (the node was behind the neck), whereas 38 were atypical. Thyroid cartilage fracture was determined in 43 cases (25.3%) from hanging and strangulation, whereas hyoid bone fracture was determined in 25 cases (14.7%) and both thyroid cartilage fracture and hyoid bone fracture were determined in 11 cases (6.5%). Fracture or dislocation in cervical vertebra was observed in seven cases. A total of 86 cases (50.6%) had thyroid cartilage, hyoid bone, and cervical vertebra findings. It was determined that, 90 of the cases (52.9%) had hemorrhage into the soft tissues either with or without fracture and that 60 cases (35.3%) had no finding other than skin lesions. Both thyroid cartilage and hyoid bone fractures were observed in 2 cases (18.2%) died of strangulation, whereas only hyoid bone fracture was

observed in one case and hemorrhage into soft tissues was observed in five cases. It was determined that the neck findings were higher in hanging cases as compared to the strangulation cases. Toxicological analyses revealed that ethanol was present in 18 cases with a range 34mg/dl to 334mg/dl. This present study was performed to put forward the prevalence of neck findings in the hanging and strangulation cases that are frequently come across by the forensic medicine specialists, as well as to discuss the results with the information in the literature.

Hanging, Hyoid Fracture, Thyroid Fracture

G37 Evaluation of Cardiac Conduction System Pathologies in Sudden Deaths in Adana Region

Mete K. Gulmen, PhD*, Cukurova University School of Medicine, Department of Forensic Medicine, Adana, 01330, TURKEY; Ramazan Karanfil, MD, Kahramanmaraş Sutcu Imam University, School of Medicine, Department of Forensic Medicine, Kahramanmaraş, 46100, TURKEY; and Ahmet Hilal, MD, and Necmi Cekin, MD, Cukurova University School of Medicine, Department of Forensic Medicine, Balcali, Adana, 01330, TURKEY

The goal of this presentation is to encourage the forensic pathologists in evaluating the cardiac conduction tissues in sudden death cases.

This presentation will impact the forensic science community by presenting the microscopical findings of the cardiac conduction tissues in sudden cardiac death cases.

A forensic pathologist is frequently asked to find the cause of death in cases of sudden unexpected deaths in adults. Approximately 50% of all medico-legal deaths are due to natural causes. Approximately 1-5% of all those cases remain as negative autopsies. Sudden cardiac death is usually defined as death from cardiac causes without apparent antecedent symptoms or within the first hour after onset of symptoms. Studies of morbidity and mortality related to cardiac disease estimate that there are between 300,000 and 400,000 sudden cardiac deaths annually in the United States. On the other hand, Turkey does not have a serial study of cardiac diseases as autopsy findings. Therefore, this preliminary study was planned. Examination of the cardiac conduction system is often looked upon as a last resort in the evaluation of a victim of sudden death. It is reasonable to conclude, then, that unfamiliarity with conduction system anatomy and pathology and lack of experience with the examination techniques are the true reasons for this reluctance, which is not surprising because many anatomic pathology and forensic medicine residents complete their training without learning about the cardiac conduction system. This lack of training is symptomatic of the ongoing decline of the autopsy as a teaching tool. Careful case selection for conduction system analysis, coupled with a sensible approach to dissection and histological sampling, will result in an increased yield of diagnostically specific, potentially lethal lesions with only a minimal increase in the expenditure of time or money.

Twenty-seven SUD and four known cause of death forensic cases had been chosen for this study. The autopsies held in the Morgue of the Adana Branch of the Turkish Forensic Medicine Council. The cardiac tissue and coronary artery samples were dissected as described by the CAP and the Cardiac Conduction System examined as already has been described by Cohle et al and Gulino Sam. Harris' H+E, Masson's Trichrome, Verhoeff's elastic Van Gieson and also for amiloidosis, Lieb's Crystal Violet stains had been used histochemicaly.

The 31 autopsy cases differed in age from age of 17 to 78 years with an average 41.7. Fifteen cases had serious atherosclerotic changes in the coronaries. In 13 cases there were infarctions. In this study cardiac conduction tissue pathologies in the 11 was revealed.

Serious fibrotic and remarkable adipose tissue changes in the SA and AV nodes were found. Many of the similar studies show parallel results with this study. The difference in between these serials can be explained by the difference of the countries, socio-cultural specifics, life conditions, environment, nutrition, and genetic variations. Hypoxic changes of the myocardial tissue may also cause conduction system pathologies. Myocardial infarctions were present in four of the SA nodes and two of the AV nodes of all cases. This is an important finding to understand and reveal the conduction system effects of the early and late myocardial infarctions. Amyloidosis was not found case in this serial. Any significant pathologic changes in any of the control cases was not noticed. In some of the SUD cases, the pathology is not morphological yet functional. Yet, still in some cardiac rhythm disturbances cases, some may find cardiac conduction tissue pathology histologically. The relationships between cardiac conduction tissue morphological pathologies and cardiac rhythm disturbances will only be demonstrated clearly by clinico-pathologic evaluations with in large serial studies.

Further study is needed of the cardiac conduction tissue on larger SUD serials, and to understand the pathologies and mechanisms of deaths in especially young SUD cases at our region and country. The findings in this model study are very important in demonstrating the young SUD cases and its relation with the conduction tissue pathologies. Therefore, examination of the cardiac conduction system can be a very useful adjunct to the examination of the heart in cases of sudden cardiac death especially in our region. Careful case selection, proper technique, and mindfulness of nonspecific findings or normal variants increase the likelihood of identifying abnormalities that may serve as the morphologic substrate for sudden cardiac death.

Sudden Cardiac Death, Conduction Tissue, Histochemistry

G38 A Peculiar Fatal Lightning Strike Inside a Cottage

Federica Portunato, MD, Manuela Botto, MD, and Alessandro Bonsignore, MD, University of Genova, Department of Legal and Forensic Medicine, Via de' Toni 12, Genova, I-16132, ITALY; and Francesco Ventura, MD, University of Genova, Department of Forensic Pathology, Via de' Toni, 12, Genova, 16132, ITALY*

After attending this presentation, attendees will learn about a case of instantaneous death due to a peculiar form of lightning storm.

This presentation will impact the forensic science community by stressing the importance of crime scene investigation in order to assess real causes and means of death.

Lightning strike is a fascinating and unpredictable natural phenomenon with potentially devastating effects and represents one of the most common causes of deaths from environmental phenomena. The incidence of fatalities had been estimated in the United States to be around 150-300 cases/year (Duclos PJ et al, 1990), representing a third of all lightning strikes (Sheela SR et al, 2000).

Benjamin Franklin first demonstrated 200 years ago that lightning consists of a gigantic electrical discharge. The physical processes that take place in and around a thundercloud occur at the micro-particle level and at a much larger scale that involves the entire Earth as an electrical circuit. Lightning happens when the difference in voltage between a cloud and the ground or another object exceeds 2 million V/m. Afterwards, an arc occurs and there is the release of a great amount of electrical energy that can cause severe damage to organs, also resulting in high mortality (Copper MA et al, 2001).

The most vulnerable subjects for lightning strike are individuals who work in open fields such as farmers or swimmers; additionally, it is more rare for lightning to strike inside a building as in the case hereby presented.

The risk of being struck by lightning is also a function of population density and it comprises terrain features that may protect or not occupants of an area (Ritenour AE et al, 2008).

According to literature review, data appears to be significantly affected by underreporting when comparing Meteorological Offices to medical and death-certificate databases (Cherington M et al, 1999).

Five most common mechanism of injury were described: direct strike, ground current, flash discharge, contact strike, and blunt trauma.

A 53-year-old man started to renovate his own cottage after lunch. In the evening, receiving no answer from him, the family called the police. When they arrived, with the forensic pathologist, the scene investigation revealed the man lifeless lying on his right side between two metal sawhorses. The body was covered by burnt pieces of his working clothes. The man presented diffuse second, third, and fourth degree burns in several areas of the body but especially in the abdominal region, in the root of the thighs, and on his genitals.

There was complete carbonization of beard and hairs all over the body and the scalp. The surrounding environment showed no signs of burning. His working tools were scattered around and there was a generator that had been set up to perform the work. However, the firefighter technical assistant found no damage to the generator or electrical malfunction.

The Meteorological Office reported that in the same area, few hours before, there had been a thunderstorm. Moreover, another person had been simultaneously injured by a lightning strike while crossing a bridge in the same village.

The cottage presented a rudimentary system of walls containment with steel beams pointing from outside to the center of the premises through the roof. The beams might have played a decisive role in the conduction of an electrical atmospheric discharge. This was further facilitated in the room by the presence of metal working tools directed toward the ceiling.

All investigation data suggested that a lightning had entered into the cottage thorough the beams creating an arc in the point where the victim was working.

Necropsy and histological findings confirmed the suspicion of lightning strike.

In conclusion, a detailed analysis of crime scene investigation, environmental, and autopsy data led to the correct determination of the real nature of the suspicious death which could be related to other different causes which may also be not accidental.

Lightning Strike, Fatal Injury, Crime Scene Investigation

G39 Enterobacter Cloacae Peritonitis Secondary to Hemorrhagic Cystitis in a Long-Term Substance Abuser

Elena Bulakhtina, MD, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222; Zhuo Wang, MD, Conemaugh Valley Memorial Hospital, 1020 Franklin Street, Johnstown, PA 15905; Todd M. Luckasevic, DO, Baiyang Xu, MD, and Abdulrezak M. Shakir, MD, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222; and Karl E. Williams, MD, MPH, Allegheny County Medical Examiner's Office, 542 Fourth Avenue, Pittsburgh, PA 15219*

The goal of this presentation is to illustrate an unusual case of peritonitis caused by hemorrhagic cystitis.

This presentation will impact the forensic science community by illustrating the need for microbiological cultures and routine histology in cases of peritonitis where an obvious source or rupture site is not identified.

Introduction: The major causes of peritonitis are appendicitis, perforations associated with diverticulitis, peptic ulcers, gangrenous

gallbladder, gangrenous obstruction of the small bowel, incarcerated hernia, and volvulus. Peritonitis secondary to cystitis is a rare, life threatening condition due to the unique anatomic characteristics of the urinary tract. Predisposing factors include anatomic anomalies of the urinary tract, vascular impairment, previous surgery, irradiation and high virulence pathogens. Making a diagnosis of peritonitis due to cystitis is difficult and the prognosis is usually poor.

Materials and Methods: This case involves a 47-year-old African-American female with a long standing history of alcohol, heroin, and cocaine abuse, who was found dead in her secure apartment. According to witnesses, she experienced flu-like symptoms for the past few days. The examination of the scene revealed a cluttered and unkempt dwelling with numerous empty and full malt liquor cans. Dark colored stains were noted on the bed and the floor, and a bucket with vomitus was discovered near the deceased.

Results: Postmortem examination revealed a poorly nourished African-American female, weighing 102 pounds and measuring 65.5 inches (BMI – 16.5). Signs of prior drug abuse, i.e., multiple remote circular scars (“skin popping” sites), were noted on the upper and lower extremities. At autopsy, the abdominal cavity contained 500 cc of serous fluid. Fibrinous exudate was observed on the dusky red small and large intestines. The urinary bladder contained 20 cc of dark-brown blood and exhibited a markedly thickened, hemorrhagic mucosal surface. No gross perforation was identified.

Microscopic examination revealed severe full thickness acute and chronic inflammation, focal hemorrhage, and necrosis of the urinary bladder. Both kidneys displayed acute tubulointerstitial nephritis.

Peritoneal fluid and urine cultures grew *Enterobacter Cloacae*. Postmortem toxicology was positive for Ethanol (0.011% in the blood; 0.020% in the vitreous fluid).

No other pathologic abnormalities or trauma were identified during the autopsy.

Conclusion: Secondary peritonitis follows contamination of the peritoneum by organisms released from the infected organs or perforated viscera. Peritonitis due to acute cystitis is a rare occurrence with only a handful of reports published in the medical literature. Most of the cases involved gangrenous inflammation of the urinary bladder with or without perforation.

In this case, integrity of the bladder wall was preserved. The significant amount of blood in the bladder cavity and severe acute transmural inflammation with hemorrhage and focal necrosis supported the diagnoses of hemorrhagic cystitis.

Hemorrhagic cystitis results from damage of the transitional epithelium and blood vessels by infection (bacteria, viruses) and non-infection etiologies (drugs, toxins, radiation). In this case, *Enterobacter Cloacae* colonies were isolated from urine and peritoneal fluid. It is worth noting, that in adults *Enterobacter* affects individuals with underlying physical or structural anomalies, metabolic disorders or immunodeficiency causing complicated urinary tract infections. *Enterobacter* comprises 1.9% to 9.6% of all UTI pathogens.

The past history of the deceased played an important role in the evolution of what started as an innocent urinary tract infection (UTI) to a fatal condition. A number of studies have shown that drugs of abuse, including cocaine, opiates, and alcohol, alter not only neuropsychological and pathophysiological responses of individuals but also immune functions. This decedent's extensive history of polysubstance abuse and malnutrition (BMI of 16.5; normal 18-24) apparently caused severe debilitation of the immune system with rapidly progressive infection and the resultant grim outcome.

Peritonitis, Hemorrhagic Cystitis, Cocaine User

G40 Two Suicidal Deaths From Head Injuries Caused by Unusual Sharp Force Instruments and Review of the Literature

Patricia A. Aronica-Pollak, MD, and Mary G. Ripple, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Juan C. Troncoso, MD, Department of Pathology, Johns Hopkins University School of Medicine, 600 North Wolfe Street, Baltimore, MD 21287; Kyle C. Shaw, MBBS, District 5 Medical Examiner's Office, 809 Pine Street, Leesburg, FL 34748; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will become familiar with unusual penetrating sharp force wounds of the head, the external wounds and wound types produced, and internal wound trauma created.

This presentation will impact the forensic science community by reporting the first suicidal death by a meat thermometer to the head and by reviewing the literature of other sharp force penetrating suicidal wounds that have resulted in death.

Deaths due to sharp force penetrating wounds of the head are uncommon due to the thickness of the cranium and the difficulty of penetration to the brain. Even with brain penetration, individuals may survive with or without neurological deficits. These types of injuries are most often self-inflicted but homicide must be considered especially if the injury implementing instrument is no longer present in the wound.

Two unusual suicidal deaths due to penetrating head injuries will be presented. One case is that of a 44-year-old man who had previously served time in prison for second degree murder. He was at his residence when law enforcement officers arrived in order to arrest him on new molestation charges. They received no response after knocking at the door. Another resident arrived and entered the residence. The police remained outside of the dwelling. She found the man, unresponsive but still breathing, lying on the bed with a meat thermometer impaled into the right temple area of his head. Survival time was 26 hours but non-survivability was determined within the first few hours of the hospital stay following the CT scans. The thermometer was left in place until autopsy. Postmortem radiograph revealed the thermometer traversed the majority of the right side of the skull and brain. Autopsy revealed a 1/8" round puncture/stab wound on the right temple following removal of the thermometer. The right temporal lobe and basal forebrain were lacerated with massive hemorrhage of the basal forebrain with extension into the ventricular system. A laceration of a dural blood vessel, basilar subarachnoid hemorrhage, focal epidural hemorrhage, and cerebral edema at the entrance defect were also noted. Postmortem toxicology for ethanol and drugs was negative.

The second case was that of a 47-year-old man with a history of schizophrenia. He had been to many doctors in the past trying to “get the wires out of his head.” After a request was made by his parents for a welfare check, police found him in his secure residence in his bathtub filled halfway with water mixed with blood. The shower curtain was pulled from the wall and located partially beneath the decedent. On the sink was a plugged in electrical drill with an attached 1-1/2" hole saw drill bit with skin and hair in the teeth. On the top of the head was a roughly circular scalp defect and underlying 1-1/2" circular skull injury with central 1/4" drill hole. Blood spatter on the walls indicated the decedent likely stood in front of the mirror at the sink while inserting the drill into his head and prior to collapsing into the tub. Drug paraphernalia was present at the scene and postmortem toxicology was positive for morphine.

In addition to these cases, a review of the literature will evaluate other unusual cases of penetrating injury of the head with special focus on the regions of the brain and skull injured and the survivability of the injuries.

Heat Thermometer, Electric Drill, Suicide

G41 Iatrogenic Laceration of a Pulmonary Angiomatoid Lesion: Fatal Complication or Medical Error?

Paolo Fais, MD, and Giovanni Cecchetto, MD, Via Faloppio 50, Padova, 35121, ITALY; Guido Viel, MD, University of Padua, Via Faloppio 50, PADOVA, 35121, ITALY; Rossella Snenghi, MD, and Rafael Boscolo-Berto, MD, Via faloppio 50, Padova, 35121, ITALY; Andrea Zuin, MD, Via Giustiniani 2, Padova, ITALY; and Massimo Montisci, PhD, Via Faloppio 50, Padova, 35121, ITALY*

After attending this presentation, attendees will understand the iatrogenic lesion.

This presentation will impact the forensic science community by stressing the importance of performing histological examination in any iatrogenic deaths to recognize underlying diseases and their eventual causal role in determining the fatality.

Percutaneous tube thoracostomy is a standard therapy for a number of pulmonary disorders. Even if it remains the most widely performed procedure to manage blunt or penetrating chest traumatism, and it is generally considered a simple procedure, this life-saving maneuver can be frequently associated with several complications, such as lung or heart perforations, arterial or venous injuries, neurological dysfunctions, injuries to the oesophagus, phrenic nerve and abdominal organs, bronchocutaneous fistula, and perforations of the mediastinal pleura with subsequent contralateral pneumothorax.

A case of a 76-year-old man, admitted to a peripheral hospital after a car accident, presenting bilateral flail chest, and subcutaneous emphysema is presented. Bilateral chest tubes were placed between the anterior and the mid-axillary lines. On the 3rd and 9th day of hospitalization the patient underwent surgical stabilization of bilateral flail chest with Kirshner wires and metal plates. The postoperative recovery was characterized by multiple recurrences of pneumothorax and subcutaneous emphysema with oxygen desaturation. For these reasons several bilateral drains were inserted with the trocar technique, the last one on the 25th day of hospitalization. A control CT scan showed that the tip of the chest tube, inserted between the anterior and the mid-axillary line, was located in the parenchyma of the left lung. Immediately after the withdrawal of the drainage tube the patient became unstable with low blood pressure and tachycardia, and was intubated with a double-lumen tracheal device. A fibrobronchoscopy performed through the tracheal tube revealed profuse hemorrhagic secretions. Because of the severe clinical conditions, the patient was transferred to our hospital where, despite multiple blood transfusions, he arrived pulseless and died after 60 minutes of cardiopulmonary resuscitation.

At autopsy the victim was found to be affected by an extensive hemotorax resulting from the laceration of a dilated vessel on the anterior surface of the inferior lobe of the left lung. Histology revealed that the vessel consisted of an "angiomatoid lesion," the distal component of a plexiform complex, the hallmark of plexogenic pulmonary arteriopathy, an idiopathic disease that may accompany primary pulmonary hypertension.

The risk of lung perforation during tube thoracostomy depends on several factors related to the patient (pulmonary contusion, pleural adhesion, adult respiratory distress syndrome, age above 60, mechanical ventilation) or to the method used for the insertion of the chest tube. Particularly, lung perforations have been reported more frequently with the trocar technique, where the insertion is determined by a metal rod projecting slightly from the tip of the tube, rather than the blunt dissection technique, where the penetration of the tube through the chest wall is prepared with a Kelley clamp.

In the reported case, even if the trocar insertion procedure was performed correctly, the penetration of the metal rod into the lung parenchyma produced a tear of a sub-pleural angiomatoid lesion. Initially the catheter blocked the blood flow through the iatrogenic

injury, but its removal generated a profuse and extensive bleeding into the pleural space.

The treatment of choice in such cases is an emergency resuscitative thoracotomy, defined as a thoracotomy performed immediately in the emergency room/department or in the operating room, because it enables a fast identification and suture of the vascular injury. However, when huge and dilated vessels are lacerated with subsequent extensive pleural hemorrhage (as in the reported case), the outcome is very poor. Thus, the most important thing is to prevent similar emergency conditions by choosing the blunt dissection technique instead of the more dangerous trocar insertion method, particularly in patients affected by adult respiratory distress syndrome or pulmonary hypertension that show an increased incidence of peripheral venous ectasias.

It is believed that the case could be of interest for the forensic community not only for the singularity of the reported lesion, but also for underlining once again the importance of performing histological examination in any iatrogenic deaths to recognize underlying diseases and their eventual causal role in determining the fatality.

Forensic Pathology, Angiomatoid Lesion, Iatrogenic Death

G42 Pedestrian Fatalities in Maryland: How Many, Who, When, Where, Why, How, and Ways to Prevent Them

Ana Rubio, PhD, Carol H. Allan, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will have a clear picture of the characteristics of pedestrian fatalities in Maryland. The presentation includes social, geographic, medical, and traffic related data from the previous five years.

This presentation will impact the forensic science community by discussing how understanding the nature and causes of a problem in its totality (in this case pedestrian deaths in an entire state), is the first step in correcting it. This presentation will suggest implementations for reducing the rate of fatal pedestrian accidents in the State.

How Many: In the last five years, a total of 400 pedestrian fatalities were studied at the State of Maryland Office of the Chief Medical Examiner (OCME). The majority of the cases had a complete postmortem examination (97.5 %), with toxicologic analysis (for the presence of volatiles in 99% and drugs screening performed in 92%).

Who: The majority of the victims were male (69.5%), aged 1 to 89 years (mean and standard deviation: 43.9 and 19.9 respectively). 179 individuals (44.8%) were African-American, 168 (42%) Caucasian, 36 (9%) Hispanic, 10 (2.5) Asian, and 7 (1.7%) belonged to other racial/ethnic groups. More than half of the victims (54.3%) were transported to the hospital before they were pronounced dead (data is skewed due to a few cases with long survival; median survival of 59 minutes, mean of 34.6 days), and 181 individuals (45.2%) were pronounced at the scene (15.6 minutes after the accident on average; median of 7 minutes). Another individual died at home three and a half days following the accident, and another at a nursing home, three months after the accident.

How: Most (more than 90%) events were witnessed and had a single vehicle involved. The impacting vehicle was recorded in 339 cases (85%), 181 (53.4%) were passenger cars, 62 (18.3%) SUVs, 28 (8.3%) pick-up trucks, 25 (7.4%) vans, 22 (6.5%) other trucks, 9 (2.6%) buses, 8 (2.4%) trains, 3 (0.8%) motorcycles and 1 (0.2%) was a bicycle. The manner of death in the majority of the death certificates were listed as accident (98.3%); there were 2 homicides, 3 suicides, and 2 deaths were undetermined. The cause of death was listed as: multiple injuries in 349 cases (87.3%), head or head and neck injuries only in 27 cases (6.8%), and complications of multiple injuries in 14 cases (4 %), with a variety of other causes listed in the remaining 10 cases. Ethanol in blood

was positive in 146 cases (36.7%) with a mean concentration of 0.16% (+/- 0.09; range: 0.01 to 0.39%). Toxicologic screening for drugs was positive in 107 cases; 28 individuals (7%) had narcotics in blood (12 morphine, 8 methadone, 5 tramadol, and 3 oxycodone), 21 (5.1%) cocaine or cocaine metabolites, and 6 (1.5%) had PCP.

When: In the five years studied, there was no clear change in the incidence rate. The highest incidence was found in December (12% of all cases), and November (11.75%), and the lowest in January (5.7%) and July (6.5%). Saturday (19.7%) and Friday (17%) had rates up to 1.8 times higher than Thursday (9.3%) or Tuesday. The majority of the accidents occurred at night (70.3%), 6.2% happened at dusk, 4.5% at dawn, and 19% during the day light.

Where: Graphical representation of the location of incidents throughout the State is provided. Location was also classified according to road type and presence or absence of traffic signals at intersections.

Why: Attempts to determine possible causes for the accident were made. Detailed examination of the incident description, police report, and in some cases complete accident reconstruction specified which was the party at fault (whether the pedestrian or the driver of the motor vehicle), weather conditions, light, etc.

Conclusion: Nearly 100 pedestrians die each year in Maryland. Possible ways to prevent or decrease the rate are provided based on the data collected in the prior five years.

Pedestrian Fatalities, Who, Prevention

G43 Sudden Cardiac Death in an Athlete: A Case Report

Damien Mauillon, MD*, Service de Médecine Légale, Centre Hospitalier Universitaire, 4 rue Larrey, Angers Cedex 9, 49933, FRANCE; Nathalie Jousset, MD, Centre Hospitalier Universitaire, 4 rue Larrey, Angers Cedex 9, 49933, FRANCE; Paul Fornes, PhD, Hospital Robert Debre, Avenue du General Koeing, Reims, 51100, FRANCE; and Clotilde Rouge-Maillart, PhD, Centre Hospitalier Universitaire, Service de Médecine Légale, 4 rue Larrey, Angers Cedex 9, 49933, FRANCE

After attending this presentation, attendees will learn of a case showing unusual cardiac cause of sudden death in an athlete, including arrhythmogenic right ventricular cardiomyopathy (ARVC), and coronary artery disease (CAD) after chronic cocaine use.

This presentation will impact the forensic science community by revealing various histological cardiac lesions observed after a sudden death in a retired doping athlete.

Cardiovascular diseases represent the most frequent causes of sudden death in athletes, including hypertrophic cardiomyopathy, anomalous coronary artery anatomy, arrhythmogenic right ventricular cardiomyopathy, and aortic aneurysm. Disorder of cardiac rhythm and stenosis of the coronary arteries are physiopathological mechanisms that can explain cardiac arrest.

This case involved a 36-year-old man who was a two-time world champion while he was cocaine-dependant. He participated in triathlons after his career as a recreational sport without taking cocaine. He had neither medical history nor cardiovascular risk factor except tobacco. He died suddenly during sleep. A complete postmortem examination was performed. The descendant was 172 cm tall and weighed 77 kg (BMI 26). The autopsy showed several cardiac lesions:

- A cardiomegaly (520g) with a symmetric left ventricular hypertrophy usually expected in elite athlete; there was no dilatation and no architectural disorganization.
- An epicardial coronary stenosis of the left anterior descending artery and the first diagonal branch (80-90%) with recent thrombosis on the surface of an atheromatous plaque; there is no acute myocardial infarction.
- Several areas of fibrosis in left ventricular, resulting from an ancient ischemia.

- Limited right ventricular hypertrophy with replacement of the myocardium by fibrofatty tissue in restricted expanse, which is a feature of ARVC.

Those findings allow the conclusion that rhythm disorder caused death. The association of ARVC and CAD in athlete is really unusual.

Arrhythmogenic right ventricular cardiomyopathy is a myocardial disease characterized by fibrofatty replacement and ventricular arrhythmias. ARVC is a hereditary disease with autosomal dominant transmission in at least 50% of cases. It occurs specifically in athletes and affects predominantly men. The prevalence in the general population varies between 1 in 1,000 to 1 in 5,000. Diagnosis rests on criteria including signs such as severe segmental dilatation of the right ventricle and fibrofatty replacement of myocardium on endomyocardial biopsy for example. This disease leads to sudden death by ventricular arrhythmias.

Atherosclerotic disease is primarily responsible for sudden death in athletes older than 35 years. Traditional markers of CAD are widely known, like hypertension, obesity, smoking, diabetes, and lipid abnormalities. Cardiac effects of cocaine chronic abuse also exist. It is associated with CAD by multiple pathogenic mechanisms: elevation in blood pressure, acceleration of atherosclerosis, increase of thrombosis risk by activating platelets, and vasoconstriction.

To conclude, this case report brings to light unusual arrhythmogenic factor leading to sudden death in athlete.

Sudden Death, Athlete, Arrhythmogenic Right Ventricular Cardiomyopathy

G44 Myocarditis With Giant Cells in an Infant: A Case Report and Review of the Literature

Tera A. Jones, MD*, Douglas County Coroner's Office, 4000 Justice Way, Castle Rock, CO 80109

After attending this presentation, attendees will be able to recognize the various entities associated with myocarditis with giant cells, most notably idiopathic giant cell myocarditis, and its clinico-pathologic features.

This presentation will impact the forensic science community by highlighting a case of an uncommon disease entity which is commonly fatal, and generally affects young, healthy adults, but can also affect the pediatric population.

The subject was a 26-day-old, Asian female infant born at 31 weeks gestation with no complications at birth. While under the care of her parents, she vomited once and then was reported to be feeding poorly. She was taken to her pediatrician's office where she was "sick appearing." In the clinician's office she became unresponsive, was subsequently admitted to the nearest hospital, and died within four hours. Family history included a "head cold" in an older sibling and her mother was believed to suffer from an autoimmune-type disease which was undiagnosed.

At autopsy, the subject's growth parameters were between the 10th to 90th percentiles when corrected for prematurity, her skin was free of rashes, and her abdomen was distended. Within the abdominal cavity, there was 60 cc of ascites. The lungs were congested and heavy with a combined weight of 53 grams. The heart weighed 16 grams; it was normally formed, and had a probe patent ductus arteriosus. Externally, the epicardium of the heart was mottled pale tan to erythematous. Cut sections of the myocardium were equally mottled. The other major organs were appropriate weights and unremarkable for an infant of her age. No lymphadenopathy was identified. Blood cultures obtained from the hospital and at autopsy were negative. Toxicology and vitreous electrolytes were unremarkable.

Histological sections of the heart revealed patchy myocyte necrosis with mononuclear cells, a prominent collection of eosinophils, and scattered multinucleate giant cells. No granulomas were identified. The

intramyocardial vessels and epicardial fat were free of inflammation. Histological sections of the other organs were free of granulomatous inflammation, viral cytopathic effect, or vasculitis.

Myocarditis with giant cells is seen in association with many recognized entities including tuberculosis, fungal infections, rheumatic myocarditis, measles, syphilis, foreign body reaction, Wegener's granulomatosis, hypersensitivity reaction, and sarcoidosis. Idiopathic giant cell myocarditis is as the name implies a myocarditis with giant cells, but of unknown etiology. It is a rare, but commonly fatal form of myocarditis which has been recognized since the beginning of the 20th century. This disease generally affects previously healthy, young adults (mean age 42 years); however, approximately 16 cases have been reported in the pediatric population. The youngest to date was 6-weeks-of-age; however, the majority of reported pediatric patients are teenagers. Symptoms generally are due to congestive heart failure, although numerous other symptoms have been reported including sudden death and palpitations. Diagnosis has classically been made at autopsy, although, the disease is being diagnosed by endomyocardial biopsy and following cardiac transplant. Gross identification of the disease ranges from "normal" to serpiginous areas of myocardial necrosis. Histology demonstrates myocyte necrosis, with lymphoplasmacytic inflammation with eosinophils and multinucleate giant cells. While the disease generally affects previously healthy people, approximately 20% of patients have immunologic disorders including inflammatory bowel disease, optic myocytis, thyroid disorders, systemic lupus erythematosus, Takayasu's arteritis, myasthenia gravis as well as others. The most successful treatment consists of cardiac transplantation with immunosuppression. Giant cell myocarditis has, however, been known to recur post-cardiac transplant at a rate of 20-25%. Without treatment, the average survival time from diagnosis to either death or cardiac transplantation is 5.5 months.

Based on the history including no known exposure to any drugs, maternal history of an autoimmune disease, and following review of the histology and other studies, the cause of death of this infant is due to idiopathic giant cell myocarditis. Based on the literature review, this is the youngest reported patient with the disease.

Myocarditis, Heart Failure, Sudden Death in Infants

G45 Massive Systemic Fat Embolism Detected by Postmortem Imaging and Biopsy

Patricia M. Flach, MD; Steffen G. Ross, MD; Garyfalia Ampanozi, MD; Stephan A. Boliger, MD; Gary M. Hatch, MD; Michael Thali, MD; and Tanja Germerott, MD, Institute of Forensic Medicine, University of Bern-Virtopsy, Buehlstrasse 20, Bern 3012 SWITZERLAND

After attending this presentation the participants will learn about systemic fat embolism and the characteristic image features of systemic fat embolism on pre-autopsy computed tomography compared to autopsy and histopathological findings.

This presentation will impact the forensic science community by raising awareness of the feasibility to detect systemic fat embolism on postmortem computed tomography prior to autopsy. Finding on computed tomography were significant and serve as quality improvement to forensic procedures.

Purpose: The purpose of our case study is to describe the findings of lethal systemic fat embolism (FE) on postmortem unenhanced computed tomography (PMCT), PMCT-Angiography (PMCTA), and image-guided lung biopsy, with correlation to conventional autopsy and histopathology.

Materials and methods: An 89-year-old woman with traumatic femoral neck fracture died due to cardiac arrest during implantation of a cemented total hip prosthesis. The patient was under long-term anticoagulation for atrial arrhythmia. In the course of the hip trauma, anticoagulation had to be stopped and antidote (vitamine K) was

administered. No disorder of lipid metabolism or transport or renal failure was known. The body underwent whole-body PMCT (Somatom Emotion 6, Siemens, Erlangen, Germany) with subsequent cannulation via an unilateral inguinal incision and contrast application by a modified heart-lung machine. PMCTA was then performed with an arterial and venous injection. The body was moved from the supine to prone position to improve filling of nondependant vessels. After PMCT and PMCTA, image-guided biopsy of the lung was obtained. The harvested specimens were stained to detect fat embolism.

Results: Unenhanced PMCT revealed a distinct fat level on top of sedimented layers of corporcular blood particles and serum in the systemic arterial system and the pulmonary trunk. This finding was measured (Hounsfield Unit) and compared to possible small position-dependent air embolism and evaluated as negative. PMCTA showed no clotting suggesting pulmonary thrombembolism. The triple layered intravascular finding was reproducible after PMCTA and after turning of the corpse. Autopsy showed no evidence of patency of the foramen ovale that would account for paradoxical embolism. In addition, there were no autopsy findings other than fatal fat embolism that were relevant to the cause of death. There were no petechial rash or kidney changes visible. There was no evidence for cholesterol embolism, e.g. triggered by anticoagulation. Both image-guided biopsy and histopathological specimens confirmed the findings of PMCT/PMCTA demonstrating severe FE (Grade IV).

Conclusion: PMCT/PMCTA established the cause of death as systemic fatal FE. It is believed that this is the first description of these unusual systemic imaging findings in the postmortem setting. Autopsy and histopathological specimens validated imaging and biopsy findings.

Fat Embolism, Postmortem Computed Tomography, CT

G46 Radiocarbon and Stable Isotope Results of Fingernails of Breastfed Mother-Infant Pairs to Investigate Deviation of Year-of-Birth Determinations Due to Diet

Kaelyn M. Ormsby, BS, and Guaciara M. Santos, PhD, KCC-AMS Preparation Laboratory, University of California, Irvine, B321 Croul Hall, Irvine, CA 92697; and Benjamin T. Fuller, PhD, Max Planck Institute for Evolutionary Anthropology, Department of Human Evolution, Deutscher Platz 6, Leipzig, D-04103, GERMANY*

The goal of this presentation is to find a possible explanation to justify outliers in ¹⁴C results from a recent pilot experiment measuring human tissues to determine the year-of-birth of deceased individuals of known birth records.

This presentation will impact the forensic science community by exploring new methods and techniques to aid in human identification.

Researchers have investigated the possibility of acquiring the year-of-birth and year-of-death dates by using radiocarbon (¹⁴C) measurements from a broad range of human tissues. This is possible due to high concentration of radiocarbon in the earth's atmosphere during the thermonuclear bomb testing carried out between 1953 and 1963, and its propagation into the food chain through photosynthesis. Measuring the magnitude of this ¹⁴C concentration allows year-of-birth determinations for individuals that were born in this period. Recently, Hodgins (2009)¹ studied human tissues of 36 deceased individuals of known birth dates. To estimate the year-of-birth, Hodgins measured ¹⁴C of tooth enamel. More than 50% of his results were consistent with the true birth dates, and uncertainties for most were as good as 1.5 years. However, a significant percentage of the measurements yielded estimated birth dates off as much as 4 years. Since diet life histories of individuals were unknown, Hodgins speculated that a ¹⁴C depleted marine diet may have played a role in explaining some of these date deviations. Since some human non-turnover tissue, such as eye lens crystalline and tooth

enamel, start forming while *in utero* and stop at approximately age of 3 and 17 years, respectively, this notion raises the question of how much an individual's childhood diet can affect the age determinations. To examine this possibility isotopes d13C, d15N, and ¹⁴C in fingernails collected from breast milk fed infants and their mothers from before birth through the weaning period were measured. In this study, the mother-infant pairs were from the same region in the United States and their protein diet was recorded during the course of sampling. Samples that would most likely show some differences from one another since they were from individuals with different protein dietary preferences were chose, but in this preliminary investigation no significant variability was observed. This may be attributable in part to the fact that the individuals sampled were from the same region, and so a more diverse population would possibly produce more variability. To further investigate the outliers that were observed by Hodgins, and to determine the magnitude of any dietary biases on ¹⁴C measurements to estimate the year-of-birth, future research should be done directly on non-turnover tissue of individuals of varied recorded diets from different locations.

Isotopes, Diet, Fingernails

G47 The Effect of Cultural Cranial Deformation on Neurological Development: A Beneficial or Disadvantageous Practice?

Anna Williams, PhD, and Mitzi A. Richards, MSc, Cranfield University, Defence Academy of the UK, Shrivenham, SN6 8LA, UNITED KINGDOM*

After attending this presentation, attendees will gain an appreciation of the different methods of cultural cranial deformation and the existing medical conditions that cranial deformation simulates. There are clear similarities between cranial development in individuals with culturally-induced cranial deformation and individuals with different forms of the congenital condition craniosynostosis. Attendees will understand the implications of cranial deformation for the neurological development of the individual, and these will be compared with those with craniosynostosis. Ethnographic material written through participant observation amongst societies that practice cranial deformation, and medical reports of function in craniosynostotic individuals will be examined to determine whether the practice has a beneficial or disadvantageous affect on individuals' neurological function.

This presentation will impact the forensic science community by detailing the effect of artificial or culturally-induced cranial deformation on the neurological function of the individuals. This is of significance to forensic anthropologists as it is a method of body modification that has implications for the survival of the participants. Neurological conditions are known to affect bone morphology, for example bone atrophy due to paralysis. It also allows an appreciation of cranial growth processes and the interrelationships between the cranial vault, base, and face, as well as the foramina that conduct the cranial nerves. An analysis of the morphological changes to the nerve foramina, coupled with an examination of ethnographic accounts of the physical symptoms exhibited by the individuals has not been attempted before, and constitutes a novel contribution to our understanding of cranial deformation in past and existing societies. The modern condition of craniosynostosis can inhibit neurological development, and can offer the forensic anthropologist insight into the physiological consequences of the social practice. This has implications for investigations of human rights violations and the recognition of how social and cultural practices can dramatically affect human physiology.

This project builds on previous research conducted by Dingwall,¹ Schijmane,² and Cheverud *et al.*,³ among others, to determine whether or

not artificial cranial deformation practiced by past and extant peoples has an effect on neurological function. It aims to refute or support the hypothesis that cranial deformation must have an effect on the development of the brain and the skull and therefore affect neurological function in an observable way.

Intentional artificial cranial deformation, practiced for a variety of cultural reasons, is of great interest to anthropologists due to its value for reconstructing aspects of past and contemporary social systems, as well as understanding modern medical conditions. Deformations have been carried out for many social and aesthetic purposes, ranging from increasing perceived beauty to encouraging obedience in infants. It is associated with instilling ethnic identity and social stratification. This paper addresses the question of whether artificial cranial deformation of infant skulls, as practiced with boards, pads, stones, or bandages, had any adverse or beneficial consequences for neurological development, and whether these were ignored or embraced by the societies practicing the tradition.

Previous research has not made links between cranial modification and ethnographic evidence of abnormal neurological function (whether impaired or improved); however, papers written comparing the skull morphology of modern pathological specimens and ethnographic examples of artificially deformed specimens have shown that some features appear different to un-modified skulls, for example, the patterns of venous sinuses and meningeal vessels, which may affect neurological function.⁴ The resulting consequences of possible neurological change have not been compared to ethnographic data. The paucity of such research may have implications for wider anthropology, as cultural or social phenomena such as tribal demise or proliferation, or shared spiritual experience may be attributed to neurological modification as a result of artificially-induced cranial deformation. Some traits and idiosyncrasies peculiar to distinct peoples may have a neurological foundation.

A study was conducted using two types of artificially deformed crania from the Natural History Museum, London, to examine whether changes in cranial foramina morphology could explain some of the symptoms observed in ethnographic accounts. Cephalic indices and ethnographic accounts of observed effects of artificial cranial deformation were collated, and compared to measurements and documented symptoms and CT scans of individuals exhibiting the medical condition craniosynostosis which appears to express similar morphological changes to the skull. The cephalic indices of artificially deformed skulls were found to be similar to those of skulls with craniosynostosis, which is known to cause an increase in intracranial pressure and precipitate conditions such as strokes and 3rd, 4th, and 6th cranial nerve palsies. This supports the hypothesis that the symptoms exhibited by individuals with artificial cranial deformation would be similar to those with craniosynostosis, and the explanations for the observed symptoms of cranial deformation substantiate the theory that brain function is affected.

This study represents original research that has not been undertaken elsewhere, and constitutes a valuable contribution to anthropological knowledge. It will further the understanding of the nature of cranial deformation, neurological development and pathology, with significant implications for socio-cultural anthropology, forensic anthropology, and medicine.

Cranial Deformation, Neurological Function, Craniosynostosis

G48 Morphological Identification of Right Ventricular Ischemia Determining Right Heart Failure in Cases of Fatal Pulmonary Thromboembolism

Tony Fracasso, MD, University Center of Legal Medicine, CMU - CURML, Rue Michel-Servet 1, Geneva, 1211, SWITZERLAND; Heidi Pfeiffer, PhD, University Hospital Münster, Röntgenstr 23, Münster, 48149, GERMANY; Cristina Sauerland, University of Münster, Domagstr 9, Münster, 48149, GERMANY; and Andreas Schmeling, PhD, University Hospital Münster, Röntgenstr. 23, Münster, 48149, GERMANY*

After attending this presentation, attendees will be aware of the possibility of detecting right ventricular failure due to ischemia in cases of pulmonary thromboembolism

This presentation will impact the forensic science community by making the public aware about the possibility of detecting morphological signs of right ventricular failure due to right heart ischemia.

Pulmonary thromboembolism is a medical emergency that may potentially determine right ventricular failure. Even if the pathophysiology of this phenomenon has been widely investigated, no morphological demonstration of right ventricular ischemic damage determining right ventricular failure in cases of fatal pulmonary embolism has been reported till now.

An immunohistochemical investigation was performed with the antibodies against Fibronectin and C5b-9 in 26 cases of fatal pulmonary thromboembolism (16 ♀, 10 ♂, mean age 56.4 years) as well as in 25 cases of acute myocardial infarction (16 ♀, 9 ♂, mean age 60.8 years) and 20 cases of hanging (3 ♀, 17 ♂, mean age 40.8 years). In each case at least one tissue slide from both cardiac ventricles (wall of the right ventricle, anterior and/or posterior wall of the left ventricle) was available. The reactions were semi-quantitatively classified and the expressions in the groups were compared. In cases of pulmonary thromboembolism the occurrence of positive reactions at the right ventricle was significantly higher than in cases of myocardial infarction and global hypoxia due to hanging. This may indicate the primary ischemic involvement of the right ventricle and be interpreted as morphological sign of right ventricular failure.

Right Ventricular Failure, Acute Pulmonary Hypertension, Immunohistochemistry

G49 Autopsy Performance in Transfusion Recipient Fatalities Reported to the United States Food and Drug Administration (FDA) During Fiscal Year 2008

Stephen L. Sgan, MD, District 2 Medical Examiner's Office, PO Box 14389, Tallahassee, FL 32317*

After attending this presentation, attendees will learn recent updates regarding the classification of fatal transfusion reactions, review recent transfusion-recipient fatality data relevant to forensic practice, especially regarding autopsy performance and medical errors, consider approaches to the investigation of deaths potentially related to transfusion of blood products, and learn how to contribute to the national investigation of transfusion-associated fatalities through the FDA transfusion fatality program.

This presentation will impact the forensic science community by sharing how findings suggest that ME/C systems can provide important contributions to the investigation of transfusion-related fatalities through increased awareness, vigilance, autopsy performance, and reporting.

This presentation will inform attendees of something they do not know: (1) classification of fatal transfusion reactions; and, (2) recent

transfusion-recipient fatality data relevant to forensic practice, especially regarding autopsy performance and medical errors. This presentation will inform attendees of something they do not know/do: (1) how to approach the investigation of deaths potentially related to transfusion of blood products; and, (2) how to contribute to the national investigation of transfusion-associated fatalities by the FDA transfusion fatality program through increased awareness, vigilance, autopsy performance, and reporting.

Background: Many deaths investigated by medical examiner/coroner (ME/C) systems are associated with a blood transfusion shortly before death. Complications of transfusion may occur and are occasionally fatal. The transfusion service is required to report fatal complications of transfusions to the FDA Center for Biologics Evaluation and Research (CBER). A CBER Medical Officer (CMO) reviews submitted information and determines to what extent, if any, the transfusion may have contributed to death. CBER publishes an annual summary of the reported fatalities. As part of its investigation, FDA requests the reporting facility to provide information on whether or not an autopsy was performed, but autopsy data have never been published in the annual summary.

Hypotheses: (1) Transfusion-associated fatalities reported to the FDA are under-reported to ME/C systems, despite the fact that several of these deaths are due to medical errors and therefore likely be certified as Accidental in manner of death; (2) a significant number of these cases would also otherwise typically fall under ME/C jurisdiction, such as cases involving transfusion for traumatic injuries; (3) there is a very low autopsy rate in these cases; and, (4) for the group of fatalities in which the FDA could not rule out transfusion as contributing to the death, a higher autopsy rate could have potentially helped to determine the cause of death with a higher degree of certainty and therefore allowed more definitive classification of some of these cases as either transfusion-related or not.

Methods: After review of the 2008 U.S. FDA Annual Summary report of fatalities following transfusion, the most recent year for which data had been published at the initiation of the project, a Freedom of Information Act request was submitted to CBER for the "Table of Final Conclusions" prepared by a CMO for each of the 72 reported transfusion-recipient deaths. Sixty-nine individual reports with some data redacted were received, as three cases had been withdrawn prior to CMO review. Available documents were mined for data that would address the hypotheses and potentially be of interest to participants of death investigation systems.

Results: Of the transfusion-recipient deaths reported (N=69), there were 35 males (51%), 33 females (48%), and 1 sex unspecified. Age ranged from 6 weeks to 97 years (median=66 years). The overall reported autopsy rate was 26% (18/69). Performance of an autopsy was reported in 24% (11/46) of cases in which transfusion was determined by the CMO to have contributed to the death and in 43% (6/14) of cases in which transfusion was determined to be unrelated to the death, but in only 11% (1/9) of cases in which transfusion could not be ruled out or confirmed as contributing to the death. Human errors in pre-transfusion specimen collection, compatibility testing or blood administration accounted for 30% (14/46) of transfusion-related deaths; all of these were due to hemolytic transfusion reactions (HTRs). Ninety percent (90%, 9/10) of the deaths due to ABO incompatibility (ABO HTRs) occurred when Type A donor red blood cells were erroneously transfused to non-A recipients, 89% (8/9) of whom were Type O. Of the deaths due to incompatibility of non-ABO red blood cell antigens (non-ABO HTRs), 71% (5/7) were due to errors that occurred in the blood bank during compatibility testing. Autopsy performance was reported in only 14% (2/14) of the deaths due to human error. Trauma patients accounted for 6% (four cases) of all reported deaths, and for each of these a transfusion complication was determined to contribute to the death (three cases) or could not be ruled out (one case). For five of the eight deaths without an autopsy in which transfusion could not be ruled out or confirmed as a contributing factor, the CMO listed a differential

diagnosis that suggested autopsy findings may have helped with further classification.

Conclusions: In this study, a significant number of reported transfusion-related deaths were due to human error. Transfusion complications may cause or contribute to death in cases that would typically otherwise fall under ME/C jurisdiction, including trauma cases. Lack of autopsy findings may impede the determination of whether or not a transfusion contributed to death and thereby prevent definitive classification.

Transfusion, Fatal, Autopsy

G50 A Case of Atypical Chronic Subdural Hematoma: A Spontaneous Rupture of Dural Lymphoma Nodule?

Renaud Clement, MD*, 1 Rue Gaston Veil, Nantes, FRANCE

After attending this presentation, attendees will understand the call for creating an entity of spontaneous chronic subdural hematoma.

This presentation will impact the forensic scientist community by presenting a case report about chronic subdural hematoma (SDH) and the different causes of bleeding beneath the *dura*.

Introduction: SDH is usually associated with brain injury following trauma. Hemorrhage resulted from the rupture of the cerebral bridge veins of the meninges, from a tear of superficial cortical arteries or from a focus of intraparenchymal hemorrhage associated with an overlying contusion such as in temporal lobe which ruptures through the contused cortical area. Acute SDH is due to direct impact trauma or sudden acceleration-deceleration of the head without injury of the head. Chronic SDH may be traumatic or may rise spontaneously.

Case Report: A 40-year-old Caucasian woman traveled to an African country. Her medical history included local radiation therapy, several years beforehand, for the treatment of breast cancer. She had been in complete remission for more than a couple of years. This woman's status of health presented no constitutional or acquired hemostasis disorders. She was completely free of medicine. She had no known addictive tendencies. Several days after her arrival, she presented paroxysmal hyperthermia, accompanied a few hours later by photophobia, difficulty in walking and confusion. Neurological state worsened with the appearance of coma (Glasgow score of 6). She was hospitalized and resuscitation measures did not prevent the patient's death. Following cold storage, the victim's body was repatriated to France, where an autopsy was performed to determine the primary cause of death because liability could be assigned against insurance (transfer with delay time between neurological deterioration and hospitalization). On opening the cranial space, a subdural hematoma forming a right hemispheric biconvex lens was discovered. It weighed 90 grams, was wine red in color and consisted of an encased fluid mass. No traumatic lesion was found during external or internal examination of the skull. Histological investigations then uncovered a multi-organ generalized lymphoid infiltration. Examination of the cerebral cortex showed these lymphoid infiltrations as well. A small-cell lymphoid nodule, disrupted by erythrocytes was found in the falx cerebri of the meninges. Following these additional investigations the main cause of death was a chronic right circumferential SDH. This hematoma could originate with the "spontaneous" hemorrhagic rupture of a nodule of lymphoid infiltrate in the meninges of the falx cerebri. This nodule was a dural metastasis of a multi-organ lymphoma.

Discussion: Chronic SDH is well known as incidental finding during forensic autopsy. In forensic medicine, the formation of chronic SDH is always linked to trauma. The entity of spontaneous SDH doesn't exist in forensic medicine. Chronic subdural hematomas occur more frequently in men, in the elderly, and in patients using anticoagulant or platelet aggregation inhibiting drugs. The consumption of alcohol is also

a predisposing factor. In these circumstances, the development of a SDH involves necessary the intervention of trauma. It can be minimal such as some encountering in the impacts of everyday life. In the medical literature, several cases of atypical chronic SDH characterized by the presence of pre-existing pathological dural lesions, especially cancerous ones, have been described. These tumors of the dura mater can result from primitive neoplasias of the central nervous system in the meninges or from dural metastases of cancers. In the present case history, several forensic medical elements contributed to the atypical nature of this chronic SDH: no major or minor traumas were identified in this young woman of forty years; she was non-menopausal; and she was not a chronic or acute consumer of alcohol and/or medications that could interfere with hemostasis or coagulation. In some previous published cases, the hypothesis of trauma, even if minimal, leading to displacement of the brain within the cranial space was suggested and could not be excluded. And spontaneous chronic SDH have been described. This presentation will review the possible mechanisms which rupture the lesion and will discuss the fact that if trauma could not be completely excluded, the entity of spontaneous chronic SDH could be created in forensic medicine.

Subdural Hemorrhage, Forensic Medicine, Spontaneous

G51 A Comparison of Trauma Associated With Manual and Automated Cardiopulmonary Resuscitation

Deborah C. Pinto, PhD*, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Kathryn Haden-Pinneri, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054; and Jennifer C. Love, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054

After attending this presentation, attendees will be able to associate certain injury distribution patterns with the type of CPR administered.

This presentation will impact the forensic science community by assisting medical examiners in identifying fracture distribution patterns associated with automated CPR specifically ZOLL AutoPulse® Noninvasive Cardiac Support Pump use. Posterior fractures such as those observed with AutoPulse® CPR are generally noticed in cases of inflicted trauma. By understanding the fracture pattern associated with AutoPulse® CPR, a potentially erroneous interpretation of therapeutic injuries as inflicted can be avoided.

This presentation will detail the results of a retrospective study of the effects of therapeutic intervention with manual cardiopulmonary resuscitation (CPR) compared to the effects of automated mechanical CPR device use. After this presentation, attendees will be able to associate certain injury distribution patterns with the type of CPR administered.

In 2007, Houston TX was selected as a test site for the ZOLL AutoPulse® Noninvasive Cardiac Support Pump. According to ZOLL, the benefits of this device include continuous CPR without fatigue, relief for EMS personnel who are then free to perform other life-saving tasks, and improved blood flow for patients with cardiac distress. The purpose of this study was to identify the trauma associated with AutoPulse® use, particularly how it compares to standard manual CPR. Expanding on previous research that found upper body skin abrasions associated with AutoPulse® use, this study also included the occurrence of hard tissue trauma between the two forms of CPR. It is well established that manual CPR can result in rib and sternal fractures. A comparison of the distribution and frequency of manual CPR fractures to AutoPulse® fractures as well as abrasion occurrence can potentially help rule out erroneous interpretations of inflicted trauma.

Autopsy records from 137 decedents brought to the Harris County Institute of Forensic Science, Houston TX, between the years 2006 to

2009 were analyzed. According to the sample records, manual CPR was performed on 49 individuals (24 males, 25 females) and AutoPulse® CPR was used on 88 individuals (52 males, 36 females). The median age for the manual CPR group was 48 years and the AutoPulse® CPR group was 54 years. The distribution of rib fractures from the anterior, lateral, and posterior compartments as well as sternal fractures and skin abrasions were recorded. Kruskal-Wallis ANOVA comparisons between fractures from the manual CPR group and the AutoPulse® CPR group demonstrated a statistically significant difference ($p<0.05$) between the number of anterior fractures, lateral fractures, posterior fractures, sternal fractures, and skin abrasions. In manual CPR, anterior fractures had the highest frequency followed by lateral fractures. Posterior fractures were only found in one case, secondary to body placement during manual CPR. In AutoPulse® CPR, anterior fractures had the highest frequency followed by posterior fractures and lastly, lateral fractures. Sternal fractures were found at a higher frequency in the manual CPR group than the AutoPulse® group. Skin abrasions were more common in the AutoPulse® CPR group, located primarily along the anterior chest, lateral chest, and shoulder. In the few cases that abrasions were observed in the manual CPR group, they were located along the sternum.

The results of this study identify the distribution patterns of fractures associated with manual and automated CPR. When rib fractures are found in the anterior or lateral rib cage in association with sternal fractures, they are consistent with manual CPR. When rib fractures are found in the anterior and posterior compartments with chest skin abrasions, they are consistent with automated CPR resulting from AutoPulse® use (and not other types of devices, which were not included in this study). It should be noted that it is mandatory for Houston EMS personnel to initially administer manual CPR before AutoPulse® use and this combination may account for the anterior rib fractures observed in the AutoPulse® CPR group. During manual CPR, chest compressions are administered for an extended period of time, thus causing sternal fractures. The small number of sternal fractures seen in AutoPulse® CPR is likely due to the short duration of manual CPR. The significance of this study to the forensic community is in the importance of identifying fracture distribution patterns associated with AutoPulse® use. Posterior fractures such as those observed with AutoPulse® CPR are generally noticed in cases of inflicted trauma. By understanding the fracture pattern associated with AutoPulse® CPR, medical examiners can avoid a potentially erroneous interpretation of therapeutic injuries as inflicted.

Trauma, Cardiopulmonary Resuscitation, Fractures

G52 Sudden Unexpected Death Associated With Undiagnosed Lymphocytic Thyroiditis: Report of a Case and Literature Review

Silvia Tambuschio, PhD*, University of Verona, via Rezzonico, 24, 35131, Padova, ITALY; Jennifer Pascali, PhD, University of Verona, Piazzale L.A. Scuro 10, Verona, IL 37100, ITALY; Andrea Galassi, MD, S.Bortolo Vicenza Hospital, via Rodolfi 37, Vicenza, IL, ITALY; Federica Alessandrini, PhD, Università Politecnica delle Marche, via Conca 6 Torrette, Ancona, IL 60126, ITALY; and Fiorella Calabrese, MD, University of Padova, via A.Gabelli 61, Padova, 35121, ITALY

After attending this presentation, attendees will have a better understanding of the significance of pathological changes in the thyroid gland in determining the cause of death, since in many patients thyroid dysfunction remains undetected during life, due to the lack of clinical signs and symptoms characterizing some nosographic entities, such as silent (painless) thyroiditis, or the Hashimoto disease.

This presentation will impact the forensic science community by emphasizing the importance of taking all natural diseases into proper account when investigating sudden deaths, even if clinical records are not indicative or when the anamnesis is poor.

In this perspective a careful gross examination and an adequate sampling of the thyroid gland are mandatory. Findings obtained by histology and updated tissue analyses should be always interpreted in relation to complex data coming from a multidisciplinary approach, finally leading *per exclusionem* to the diagnosis of sudden death due to an episode of transient thyrotoxicosis. Silent (painless) thyroiditis is regarded as follicular destruction-induced hyperthyroidism resulting in the release of stored thyroid hormones in the circulation. The above mentioned disease is characterized by a transient hyperthyroidism with spontaneous resolution in two to five months, even though cases of relapse can occur quite often. The thyrotoxic phase of this syndrome is short and requires no, or only symptomatic therapy, but it is assumed that untreated thyrotoxicosis might lead to sudden death by several mechanisms (cardiac arrhythmia, hyperpyrexia, electrolyte disturbances, and epileptic seizures). Macroscopically the thyroid glands are normal sized and non tender; histologically, focal, or diffuse lymphocytic thyroiditis is present. In some cases anti-thyroid antibodies can be detected, indicating an autoimmune pathogenesis and postmortem dosage of thyroid hormones, when interpreted in relation to the histological findings, can provide further information about the functional status during life.

In the present case a previously healthy 18-years-old woman was found dead prone near the entrance of her house, where she was living alone. The crime scene investigation did not offer any significant finding, and external examination of the body showed a single contusion at the forehead, consistent with an accidental fall from the standing position. Clinical history was unremarkable, but information regarding a possible family history of thyroid disease was not available.

Full autopsy was carried out including a detailed macroscopic/microscopic cardiac examination, tissue molecular analyses for viral detection, chemical analyses, and toxicology. At the autopsy all internal organs were unremarkable and the thyroid gland was macroscopically normal. The one relevant pathological finding was a prominent lymphocytic infiltration with follicular disruptions, rare oxyphilic changes and low grade fibrosis. Since the histological picture was consistent with lymphocytic thyroiditis, immunophenotype characterization and lymphocyte clonality analyses were performed in order to rule out the diagnosis of hematologic malignant neoplasm.

In this case the lymphocytic thyroiditis could by exclusion offer a reasonable explanation of the sudden unexpected death occurred during an episode of transient thyrotoxicosis, cardiac arrhythmia being the most likely mechanism of death.

In consideration of the autopsied findings, further investigation into the medical history was carried out, revealing that the deceased a few days before death complained chest pain to the general practitioner; moreover, three months before she required the prescription for psychoactive drugs, due to the recent onset of insomnia and unexplained anxiety; contemporaneously, she was noticed loosing weight.

Since the young woman had one sister and one brother, at the end of the medico-legal investigation a clinical diagnostic protocol on the relatives was recommended to the general practitioner.

In conclusion: the presented case highlights to forensic pathologists the importance of sampling and careful studying the thyroid gland to evaluate the possible role of a thyrotoxic episode related to a silent thyroid disease, as a cause of sudden death in otherwise unexplained fatalities. Review of the literature reported only a few cases of lymphocytic thyroiditis as a possible cause of death, but in such cases a full multidisciplinary approach (with special regard to biomolecular and chemical analyses) was not carried out.

Furthermore, the present case investigation, first aiming to the solution of forensic concerns, also represented the start up for diagnostic protocol on the relatives, at that time still asymptomatic, with final possible positive outcome on their health care.

Silent Thyroiditis, Sudden Death, Thyrotoxicosis

G53 The Pattern of Immunoreactivity for von Willebrand Factor in a Variety of Thrombotic States

Stacey A Simons, MD*, Miami Dade County Medical Examiner Department, Number One on Bob Hope Drive, Miami, FL 33136; Paul E. Swanson, MD, University of Washington Division of Anatomic Pathology, 1959 Northeast Pacific Street, Seattle, WA 98195; and Aldo J. Fusaro, DO, King County Medical Examiner's Office, 908 Jefferson Street, Seattle, WA 98104

After attending this presentation, attendees will understand the role of von Willebrand Factor (vWF) in thrombotic thrombocytopenic purpura (TTP) and recognize variations in patterns of immunohistochemical staining against von Willebrand Factor antigen in thromboemboli from thrombotic thrombocytopenic purpura, hemolytic uremic syndrome, disseminated intravascular coagulation, non-bacterial thrombotic endocarditis, renal allograft vascular rejection, and stasis thrombosis.

This presentation will impact the forensic science community in cases of precipitous deaths with little or no antemortem workup that are characterized by a thrombotic state. Although previous reports have discussed the value of immunohistochemical staining against von Willebrand Factor antigen in deaths where thrombotic thrombocytopenic purpura is suspected, this is the first case report to provide images that demonstrate the staining patterns of several other entities within the differential diagnosis.

Although previous reports have detailed the value of this stain in deaths where TTP is suspected, this is the first case report to provide images that demonstrate the staining patterns of several other entities within the differential diagnosis. The variations appear to reflect the etiology of the thromboemboli and their relative content of vWF. The visual references included here will be especially helpful to the medical examiner in cases of precipitous death when there has been little or no antemortem workup.

TTP is a thrombotic microangiopathy, historically requiring a pentad of symptoms for clinical diagnosis: microangiopathic hemolytic anemia; thrombocytopenia with or without purpura; acute renal insufficiency; fever; and neurologic abnormalities. It is now understood that few patients present with all features; however, the presence of neurologic abnormalities is often helpful in distinguishing TTP from hemolytic uremic syndrome (HUS).

The case of an adult male is presented with microangiopathic hemolytic anemia, thrombocytopenia, and an episode of hematuria two days prior to hospital admission. The patient did not report diarrhea or fever, and did not exhibit neurologic symptoms. Pulseless electrical activity and renal failure were present at the time of admission. The patient had a rapid clinical decline and died before a diagnosis could be made. Autopsy did not reveal significant gross pathology. Histologic sections contained myocardial necrosis with relatively widespread microthrombi in small cardiac vessels and, less frequently, microthrombi within glomeruli and renal arterioles. Vascular lesions also included intimal thickening and disruption, and fragmented red cells.

TTP is currently thought to be driven by a deficiency in ADAMTS-13, a metalloprotease that cleaves vWF to render it ineffective in its role in intravascular platelet aggregation. Deficiencies may be inherited or acquired, and may lead to unchecked formation of vWF-rich thrombi in those vessels subject to shear stress (including arterioles and capillaries). Because vWF is produced in arterial endothelial cells and megakaryocytes, thrombotic lesions in TTP, non-bacterial thrombotic endocarditis (NBTE) and allograft vascular rejection will demonstrate immunoreactivity to vWF antigen. The characteristically fibrin-rich thromboemboli formed in states that are not mediated by vWF will exhibit minimal-to-no immunoreactivity.

Tissue controls in the current report included a single example of each aforementioned disease entity, including a mixed immune-TTP

control case, internal positive controls (arterial endothelium), and internal negative controls (hepatic veins and sinusoids). In TTP, there was dense, relatively homogeneous staining of the entire vWF-rich thrombus. In NBTE, there was variably dense, granular staining of characteristically platelet-rich bland vegetations (both on valves and in embolized material). In renal allograft rejection, there was heterogeneous staining, most dense in areas of vascular damage, with only minimal peripheral staining of the thrombi.

In HUS, there was minimal peripheral staining of thrombi. In disseminated intravascular coagulation (DIC), and in stasis thrombosis (the latter secondary to a myocardial infarct), there was focal dense staining only within the more cellular "layered" regions of organizing thrombi, where platelets may become entrapped.

Tissue from the presented case demonstrated vWF-rich thrombi in cardiac and renal vessels as well as in rare small cerebellar vessels, and looked most similar to the mixed immune-TTP control tissue, supporting myocardial necrosis secondary to TTP as the cause of death.

Overall, this case with its corresponding array of tissue controls represents a spectrum of patterns that correlates well with the pathophysiology of each specific pathologic entity. In conclusion, when interpreted in combination with anatomic findings at autopsy, vWF staining provides support for a diagnosis of TTP even when the clinical history is limited or atypical.

TPP, von Willebrand, Hemolysis

G54 Giant Cell Myocarditis as a Cause of Sudden or Unexpected Death: A Report of Two Cases and a Review of the Literature

Steven M. White, PhD*, Mitra B. Kalelkar, MD, and James A. Filkins, JD, PhD, Office of the Medical Examiner, County of Cook, 2121 West Harrison Street, Chicago, IL 60612

After attending this presentation, attendees will have an awareness of giant cell myocarditis as a cause of sudden or unexpected death and its diagnosis.

This presentation will impact the forensic science community by increasing knowledge and awareness of an uncommon cause of sudden or unexpected death with two case presentations.

Giant cell myocarditis (GCM), formerly known as Fiedler's myocarditis, is an inflammatory process of unknown etiology restricted to the heart, typically occurring in young and middle-aged adults. There is no clear gender predilection, but the prevalence of GCM is higher in Caucasians than in other races. Because of its isolation to the heart and fulminant clinical course resulting in sudden or unexpected death, GCM is usually diagnosed at autopsy, and therefore may be encountered in a forensic setting. Gross findings at autopsy are variable. Microscopically, there is myocyte necrosis associated with an infiltrate composed of histiocytic giant cells, lymphocytes, and scattered eosinophils. The differential diagnoses of GCM include other forms of granulomatous myocarditis, such as sarcoidosis and infectious etiologies. In contrast with sarcoidosis, GCM is typically localized to the heart and has a fulminant clinical course. Infectious etiologies can be excluded with the use of special stains. GCM is a rare cause of sudden or unexpected death with a very low prevalence as reported by other studies.

A search of the records of the Cook County Medical Examiner's Office identified 72 cases in which myocarditis was the principle or contributing factor to death in adults aged 18 and older. The search covered the period from January 1, 2000 through July 15, 2010. Of these 72 cases, only two were cases of giant cell myocarditis. The remaining 70 cases consisted of neutrophilic, lymphocytic, or mixed inflammatory infiltrates.

The first case is a 39-year-old African-American female with a history of hypertension and obesity, who presented to the emergency

* Presenting Author

room with shortness of breath and sinus tachycardia. Two days prior to this event, she was seen in the emergency room with fever, malaise, and an elevated white blood cell count, and was discharged. Soon after presentation to the emergency room, she developed pulseless ventricular tachycardia despite pharmacologic therapy. Following synchronized cardioversion and a brief period of asystole, she developed sinus bradycardia. Transcutaneous pacing was attempted, but she progressed to ventricular fibrillation, then asystole. She died within two hours of admission. At autopsy, the heart was enlarged, weighing 487 grams. Grossly, there was concentric left ventricular hypertrophy and the myocardium was uniformly red/brown with the exception of the papillary muscles of the left ventricle, which were pale yellow/gray. Microscopic examination of the heart revealed foci of myocyte loss, fibrosis, and chronic inflammation with scattered giant cells predominantly in the papillary muscle. Other findings at autopsy included cerebral edema, splenomegaly, and chronic passive congestion of the liver. Toxicologic studies were negative for ethanol, opiates, or cocaine.

The second case is a 33-year-old African-American female with no prior medical history, who collapsed suddenly at a nightclub. At autopsy, her heart was enlarged, weighing 426 grams. Grossly, there were geographic areas of pallor from base to apex involving the myocardium of the anterior, lateral, and septal walls of the left ventricle. Microscopically, there was extensive fibrosis and inflammation with numerous giant cells and only small islands of preserved myocardium. Other findings at autopsy included pulmonary congestion and an incidental ovarian teratoma. Toxicologic studies were negative for opiates or cocaine.

These cases are reported to demonstrate the variation in clinical presentation and autopsy findings of GCM, as well as to illustrate that GCM remains a rare cause of sudden or unexpected death even in a busy, urban medical examiner's office.

Myocarditis, Sudden or Unexpected Death, Heart Disease

G55 Death Due to Atrial Septum Defect Repaired by Transcatheter Closure: Who Failed?

Eugenio Di Stefano, MD, Via Raffaello N°9, Palermo, 90100, ITALY; Filippo Maria Cascino, MD*, Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via del Vespro 129, Palermo, 90127, ITALY; and Graziana Farina, MD, Roberto Guarino, MD, Nunzia Albano, MD, and Emiliano Maresi, Via Del Vespro 127, Palermo, 90100, ITALY*

After attending this presentation, attendees will learn about the role of the forensic pathologist in transcatheter procedures and professional liability.

This presentation will impact the forensic science community by showing a case report regarding a bronchial lesion following transcatheter procedure.

A 13-year-old Caucasian male, with past medical history of ostium secundum atrial septal defect previously treated using septal occlusion device with no success.

After a period of time, a new surgical access procedure was performed on the young man using transcatheter closure procedure. The device should be placed in the atrial septum via catheter introduced into femoral vein. The access was monitored with transesophageal echocardiography. The medical record states that twenty minutes after the start of surgery, a sudden decrease of oxygen saturation, and contemporaneous sub-cutaneous emphysema occurred. In spite of cardio-pulmonary resuscitation maneuvers and following placement of the trocar and thoracic drainage system, the young man died, because of a contemporaneous ventricular fibrillation.

External examination revealed a drainage located in left hemithorax in the first intercostal space; another one in the right hemithorax in the fifth intercostal space, two needle marks in the left third intercostal space and in the right second intercostal space; cyanosis of finger nails of both hands was present.

Internal examination revealed emphysema in subcutaneous soft tissue of the thoracic and abdominal regions, in greater omentum and in the visceral adipose tissue. Also observed marked mediastinal emphysema, bilateral pneumothorax and reduced volume of the lungs.

The macroscopic examination of the heart showed collapse of the fossa ovalis, redundant, with diameter of 2.5 centimeters and with two perforations: the first one with maximum diameter of 1 centimeter and the second one of 0.5 centimeter, divided by fibro-muscular biceps. The right ventricle was dilated with thin walls (0.3 centimeter maximum thickness), left ventricle slightly dilated with a free wall of 1.5 centimeters.

The observation of air breath showed in the right intermediate bronchus an "S"-shaped laceration with frayed margins slightly that involved, in the point of the bifurcation with medium lobe, in the extraparenchymal intrapleural tract, half circumference of the bronchus.

The dissection of the lungs revealed congestion and hemorrhagic edema. There was hypoxic ischemic multiorgan damage.

Histologic assays showed massive right endo-bronchial bleeding and the site of the bronchial lesion was characterized by incomplete breakup of a cartilaginous ring in correspondence of one of the extremities; the adjacent pulmonary vein with massive blood infiltration of the nearest soft tissues. The borders of the vascular breakup were irregularly dissected and infiltrated by blood cells; in the context of the vascular wall other breaches were observed with partial tonaca media's dissection. Hemorrhagic edema was found in pulmonary parenchyma with red cells infiltration of the nearest soft tissues and sub-pleural tissues, in association with emphysematous blebs.

On the macro-microscopic evidences the cause of the death has been attributed to an acute respiratory insufficiency by severe pneumothorax following bronchial breakup; the typology of death is attributable to "therapeutic complication."

Along with the histological assays, the authors have verified the iatrogenic nature of the breakup; besides, using the classic forensic criteria the pathologists have attributed the professional liability to one of the professional figures (echocardiographist, hemodynamist, anesthetist) involved in the management of the young patient.

Transcatheter Closure, Atrial Septum Defect, Bronchial Lesion

G56 Dissecting Intramural Hematoma of the Esophagus: A Rare Case of Sudden Death

Cristoforo Pomara, PhD, University of Foggia, Department of Forensic Pathology, Viale Degli Aviatori 1, Foggia, 71100, ITALY; Alessandra De Salvia, PhD, University of Verona, Department of Forensic Pathology, Policlinico G. B. Rossi, Verona, 71100, ITALY; Antonio Nieddu, MD, University of Sassari, Department of Forensic Pathology, Sassari, Sassari, ITALY; and Stefano D'Errico, PhD, University of Foggia, Department of Forensic Pathology, Viale Degli Aviatori, Foggia, 71100, ITALY*

After attending this presentation, attendees will learn that dissecting intramural hematoma of the esophagus is a rare condition with excellent prognosis when treated conservatively. Spontaneous ruptures of hematoma are rarely described as well as sudden death due to DIHO.

This presentation will impact the forensic science community by presenting the rarity of the fatal events due to DIHO and the autopsy technique performed in visualizing rupture, preserving anatomical relationship between cervic-thoracic organs.

Dissecting intramural hematoma of the oesophagus (DIHO) is a rare condition in which intramural hemorrhage leads to submucosal

dissection of the oesophageal wall. It is usually associated with a rapid increase in intraoesophageal pressure, trauma or a coagulation disorder. The clinical presentation is with chest pain, hematemesis and dysphagia/odynophagia and an accurate history is vital to help distinguish it from other causes of acute chest pain, such as myocardial infarction, aortic dissection or oesophageal perforation. The three different types of acute oesophageal injury are a mucosal tear (Mallory–Weiss syndrome), full-thickness rupture (Boerhaave's syndrome) and dissecting intramural hematoma. Neither the Mallory–Weiss nor the Boerhaave lesions are associated with submucosal hematomas or dissections. In some cases the first event may be hemorrhage into the submucosa with secondary rupture into the lumen. The differential diagnosis includes other causes of central chest pain and it is vital to obtain an accurate history of both gastrointestinal and cardiovascular symptoms. Analysis of the precipitating factors suggests that there are three main subgroups. Firstly, a sudden pressure change in the oesophagus (e.g., swallowing, vomiting) perhaps associated with a temporary disruption in the normal co-ordinated opening mechanism of the upper and lower oesophageal sphincters. Secondly, direct injury following an endoscopic therapeutic intervention (e.g., oesophageal dilatation). Thirdly, about one fifth of patients appear to have a truly spontaneous origin although this may be associated with an underlying predisposition to abnormal pressure changes within the oesophagus (e.g., achalasia) or a bleeding disorder (e.g., due to anti-platelets, anti-coagulants or thrombolytics). The pathophysiology is characterized by submucosal hemorrhage that dissects the submucosa and classically occurs in the distal oesophagus because this region is least supported by adjacent structures such as the trachea or heart.

A rare case is presented of sudden death due to spontaneous rupture of DIHO occurred in a 42-year-old woman presented at local emergency department with a 24 hour history of sudden onset severe central chest and interscapular pain associated with dysphagia and odynophagia. There was no history of vomiting, hematemesis or trauma. There was little previous medical history of note and he was not taking any regular medication. On examination, vital signs were: blood pressure, 104/49 mmHg with no differential between arms; pulse, 125 beats/min; respiratory rate, 24 breaths/min; body temperature was normal. There was no abdominal tenderness and no maelena. EKG was unremarkable as well as cardiac enzymes. Clinical conditions suddenly got worse; the woman collapsed and resuscitation maneuvers were unsuccessful. Autopsy was performed the day after death. Massive hemothorax was recorded. Thoracic and abdominal organs were removed en masse according to Letulle technique and fixed in 10% buffered formalin for a detailed macroscopic examination. All other organs examination was unremarkable except for cerebral oedema. Vessels were poor of blood. Lungs were increased in volume and size, with few subpleural hemorrhagic spots. Mild white foam on the main bronchi was also detected. Heart was normal in size and volume, with conical shape. Coronaries examination was unremarkable. A large bluish/red intramural haematoma of the posterior wall of the oesofagus extending from just below the cricopharyngeous to the gastro-oesophageal junction was recorded with a complete rupture of the oesophagus wall in the proximal third. Mild cerebral oedema and focal pulmonary oedema were observed at histological examination with standard H&E staining. Histological examination of heart was unremarkable except for few foci of contraction band necrosis. Sample of oesophagus dissection was collected excluding recognizable abnormality in the muscle layers, except for rupture. A complete immunohistochemical panel has been performed on esophagus samples. Genetic investigations had been performed also.

DIHO, Spontaneous rupture, Sudden Death

G57 Anaphylactic Shock and Postmortem Exam – A Systematic Approach

César L. Santos, MD, and Beatriz S. Silva, MD, Portuguese National Institute of Legal Medicine, Delegação do Centro do INML, IP, Largo da Sé Nova, 3000-213, Coimbra, PORTUGAL; and Duarte N.P. Vieira, PhD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL*

After attending this presentation, attendees will have an insight about the efforts being made by the Portuguese National Institute of Legal Medicine in order to harmonize the methodology of forensic autopsies, since not all the medical forensic experts have the specialty of legal medicine.

This presentation will impact the forensic science community by informing attendees of the attempt to establish specific rules concerning the approach of fatal cases of suspect anaphylactic reactions.

The anaphylactic shock is classified as a type I of hypersensitivity reaction that occurs due to the release of biologically active agents, among them, histamine. It is due to exposure to allergens of different types, like drugs, food, animal sting, animal fur. If not promptly reversed, the outcome can be fatal.

The relevance of available circumstantial information, namely context and symptoms prior to death, previous medical history and possible life support procedures applied will be discussed.

The need for a thorough external examination of the corpse is also addressed, in order to search, for instance, for possible sting marks or hives-like lesions that may help to support the diagnostic.

Overall, postmortem findings, either in the external and internal examination, are usually nonexistent or nonspecific, the forensic expert should collect all body samples that may be needed later on to reach a more accurate diagnosis.

Therefore, besides the routine histology (heart, lungs, liver and kidneys), the collection of samples from other organs with known increased mastocyte cells population is recommended. Toxicological exams should contemplate drugs, abuse drugs and/or pesticides, according to the specificity of the case.

Also highlighted is the relevance of collecting peripheral blood for IgE and tryptase concentration levels and that this task should be undertaken as soon as possible after the judiciary's authorization for the autopsy.

Because of the lack of relevant findings, death by anaphylactic shock is considered a diagnosis of exclusion, that is achieved through the evaluation of the available circumstantial information, the findings (or their nonexistence) in the external and internal examination and results of ancillary investigation, namely, histology, in some cases complemented by immunohistochemical techniques (anti-tryptase and anti-CD117), toxicology and serology (IgE and tryptase).

Based on the most recent scientific knowledge, a comprehensive protocol was designed with the purpose of being applied to this situation and serve as a guideline to forensic autopsies.

Forensic Autopsy, Anaphylaxis, Protocol

G58 Spontaneous Pulmonary Arterial Dissection: A Case Report

Margherita Neri, PhD, Stefania Bello, MD, Raffaella Bisceglia, MD, and Carmela Fiore, MD, Department of Forensic Pathology, University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY*

The goal of this presentation is to present a fatal case of spontaneous pulmonary arterial dissection with a wide immunohistochemical study about alteration of pulmonary wall.

This presentation will impact the forensic science community for the rarity of the deaths due a spontaneous dissection of the pulmonary trunk.

Unlike dissection in systemic arteries, pulmonary artery or main pulmonary branche dissection, is usually lethal. So the diagnosis of this condition is very rarely made during life and most commonly diagnosed at autopsy in cases of sudden and unexpected death. Hemorrhagic pericardial effusion and cardiac tamponade usually follow the outward rupture of the proximal main pulmonary artery.

With regard to pathogenesis, pulmonary artery dissection is strongly associated with primary and much more frequently, secondary pulmonary hypertension. Secondary pulmonary hypertension most often results from congenital cardiac lesions, above all with various forms of left-to-right shunting, most commonly patent ductus arteriosus, or congenital ventricular septal defect. These cardiac conditions predispose individuals to the development of pulmonary artery aneurysm by generating sustained high pulmonary flow rates and pulmonary artery pressure. However, other possible causes are Marfan syndrome and other connective tissue diseases, infectious processes and inflammatory conditions, such as Behcet disease. Anyway pulmonary artery dissection is exceedingly rare in the absence of pulmonary hypertension or other pathologic conditions.

The clinical presentation of pulmonary artery dissection is highly variable and the symptoms are nonspecific, most frequently chest pain, dyspnea, cyanosis, and hemodynamic compromise. Diagnostic instruments for this condition are noninvasive imaging techniques, including echocardiography, CT, and magnetic resonance imaging (MRI).

The vascular histopathologic changes associated with the majority of pulmonary artery dissections involve medial degeneration, with fragmentation of elastic fibers. These changes may represent an intrinsic weakness in the vessel wall which is compounded by the increased hemodynamic shear stresses of pulmonary hypertension, thereby predisposing an intimal tear. The pathogenetic mechanism of dissection in absence of histopathologic alterations remains substantially unclear.

The case presented concerns sudden death due to spontaneous pulmonary artery dissection.

A 72-year-old woman was admitted to the Emergency Department for chest pain, spread to mandible, dyspnea, and jugular tightness, and she referred these symptoms after bleach inhalation during housecleaning.

Physical examination, ECG and CT were unremarkable. Cardiac ultrasonography showed concentric ventricular hypertrophy and ascending thoracic aorta ectasia (50 mm). Laboratory blood values demonstrated neutrophilia, lymphopenia, moncytosis and increased erythro sedimentation rate. Two days later she died.

A postmortem examination was performed and revealed a large hemorrhagic area in left posterior mediastinum and pericardial sac containing approximately 150 ml of blood and 250 g of clotted blood. The source of hemorrhage was readily identified as a 2 cm tear in the wall of the pulmonary trunk and so dissection and rupture of the artery.

Microscopic sections of the pulmonary artery revealed regular morphology of the wall layers. The medial layer showed fragmentation of elastic fibers, marked fibrosis and copious erythrocytes. In a section the intimal tear was identified as initial site of dissection.

The immunohistochemical investigation of the pulmonary artery samples in whole artery wall and in laminar dissection was performed with antibodies anti TGF-beta-1, TGFBR1 (ALK-5) e TGFBR2, ALK-1, fibrillin and endoglin. Fibrillin showed a massive and diffuse positive reaction of the whole pulmonary artery near the dissection, but it showed negative reaction in laminar dissection; Endoglin showed a weak positive reaction in the whole artery and a negative reaction in the laminar dissection; TGF-beta1 revealed a weak positive reaction in the whole pulmonary artery and a strong reaction in the laminar dissection; TGFBR1 and ALK-1 showed a moderate positive reaction in the whole pulmonary artery wall and a massive positive reaction in laminar dissection; TGFBR2 revealed a massive positive reaction of the whole pulmonary artery, but it showed moderate reaction in laminar dissection.

A fatal hemopericardium caused by spontaneous pulmonary artery dissection was recorded as the cause of death. The histological investigation of the pulmonary artery samples revealed the absence of hypertensive arterial changes and the immunohistochemical showed the absence of any connective tissue disease of the pulmonary trunk. So the presented case illustrates a very rare cause of sudden death in a spontaneous dissection of a normal pulmonary trunk.

Spontaneous Pulmonary Dissection, Sudden Death, Immunohistochemistry

G59 Inherited Cardiac Diseases and Molecular Autopsy: Perspectives and Limitations

Katarzyna Michaud, MD*, Centre Universitaire Romand de, Medecine Legale, Rue du Bugnon 21, Lausanne, 1005, SWITZERLAND; Florence Fellmann, PhD, University Service of Medical Genetics, Lausanne, 1010, SWITZERLAND; and Patrice Mangin, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND

After attending this presentation, attendees will understand the importance of postmortem genetic testing, as well its limitations for the diagnosis of sudden cardiac death in young adult or in sudden infant death syndrome (SIDS) cases.

This presentation will impact the forensic science community by presenting the practical approach to a new diagnostic tool in cases of sudden death in the forensic context.

Cardiac diseases of genetic origin are often the cause of sudden death, especially in young individuals. Postmortem genetic testing, also known as molecular autopsy, is recommended in cases of sudden cardiac death with a negative autopsy. These deaths are currently considered to be due to sudden arrhythmic death syndrome, and are reported in up to 40% of sudden cardiac deaths of young adults. The studies performed on cases of sudden infant death syndrome (SIDS) indicate that approximately 5–10% of SIDS is due to defective cardiac ion channels.

Rhythm disturbances observed in genetically determined cardiac diseases are not always lethal, but can have dramatic consequences if the individual is driving or swimming, for example.

Several cases of sudden death resulting from different genetically determined cardiac pathologies will be presented. In some cases, a morphological substrate, such as arrhythmogenic right ventricular dysplasia cardiomyopathy (ARVD/C) or hypertrophic cardiomyopathy (HCM) was observed at autopsy and confirmed by histological examination. In others cases without any pathology observed during standard autopsy procedures, and after a negative toxicological analysis, mutations in the three genes most frequently implicated in inherited arrhythmias SCN5A, KCNQ1, and KCNH2 were found. In the remaining cases even the molecular autopsy was negative.

The first case is a 33-year-old man who died after losing control of his vehicle. ARVD/C was found at autopsy. No traumatic lesions were observed and it was determined to be a natural death. The second case is an 18-year-old man who died after a football match. The only significant finding at autopsy was the ARVD/C. In this case, an electrocardiogram recorded a few weeks before his death showed pathological patterns pathognomonic for the ARVD/C. In one SIDS case, the molecular autopsy showed mutations in the KCNH2 gene and in another SIDS case a genetic variant in the SCN5A gene. Both have been described in long QT-cases. In the last presented SIDS case, molecular autopsy was negative but a positional asphyxia was evoked after scene investigation and a cartilaginous meta-hyperplasia of the cardiac conduction system was observed.

The major limitations of the molecular autopsy in forensic practice are the cost of the analyses, the accessibility of a competent laboratory and the legal aspects of postmortem genetic testing. The interpretation

of the results and their transmission to the families can also prove to be problematic. Due to the heritability of genetically determined cardiac disease, the autopsy diagnosis is very important for any living relatives. Collaboration with cardiologists and geneticists allows proposing multidisciplinary consultations to them.

In conclusion, the molecular diagnosis of cardiac arrhythmias represents a very useful and attractive tool in cases of sudden death. However, even if the case is presumed to be related to a hereditary cardiac disease the classical guidelines of autopsy practice should be respected (scene investigation, histological examination, toxicological analyses etc.) to avoid the over interpretation of the results of the molecular autopsy. Moreover, due to the heritability of genetically determined cardiac disease, the potential implications for living relatives must be taken into consideration and genetic counseling should be proposed to the family.

Molecular Autopsy, Sudden Cardiac Death, Channelopathies

G60 Sudden, Unexpected Death Due to Glioblastoma: Three Fatal Cases

Irene Riezzo, PhD*, University of Foggia, Osp D'Avanzo, Department of Forensic Pathology, Viale Degli Aviatori, 1, Foggia, 71100, ITALY; Santina Cantatore, Benedetta Di Battista, MD, Ruggero Parente, MD, and Francesco Ventura, MD, University of Genova, Department of Forensic Pathology, Via de' Toni, 12, Genova, 16132, ITALY

The goal of this presentation is to present three cases of sudden, unexpected death due to glioblastoma, with different brain localization and expression.

This presentation will impact the forensic science community by discussing how a complete methodological forensic approach by means of autopsy, histological and immunohistochemical examinations let us to conclude for an acute central dysregulation caused by glioblastoma and relative complication with rapid increase of intracranial pressure as cause of death.

Glioblastoma is the most common malignant primary brain neoplasm, representing about 12-20% of all intracranial tumors and accounting for about 50-60% of all astrocytic gliomas. In the most European and North American countries, the incidence is approximately 2-3 new cases per 100,000 people per year. The incidence of sudden death due to undiagnosed primary intracranial tumor is low in forensic autopsy and is an uncommon event. In fact only 12% of all cases of sudden unexpected death due to primary intracranial tumors are due to glioblastomas.

Three cases of sudden unexpected death due to glioblastoma according to WHO grade IV are reported.

Case 1: a 43-year-old Polish man was found dead in a slope near the track of the railway. Death scene investigation was unremarkable. A complete autopsy was performed 48 hours after death. The external examination revealed only same abrasions and bruises on the face, and the upper and lower limbs. The internal examination revealed polyvisceral stasis, heavy lungs and reddish colored foam on trachea and the main bronchi. The skull was entire. The examination of the brain (cm 21x16x6, g 1630) after fixation in buffered formalin revealed a cerebral edema and an increase in volume of the left frontal lobe. On coronal sections, the cerebral hemispheres were asymmetrical with deviation of midline structures from left toward right. In the left frontal lobe a spherical mass (cm 3.5x3x1.5), with variegated appearance and contained regions of necrosis and hemorrhage was found. The blood alcohol concentration was 0.8 g/l.

Case 2: a 79-year-old Caucasian man, with a history of ischemic heart disease and hypertension, was brought to the hospital in the neurological unit for symptoms such as confusion, slackening, sleepiness, and tremor of the upper limbs start few days before. The brain CT scanner examination shows a large hypodense mass in the left

temporal lobe with massive oedema and compression phenomena on occipital and temporal lobe and midline shift. The patient was then referred for neurosurgical consultation, but the day before surgery he suddenly died. General autopsy performed 48 hours after death was unremarkable. The brain weighed 1600 g and measured (cm 22x16x6.5) showed diffusely swollen cerebral hemispheres and an increase in volume of the left temporal lobe. There was no herniation of the temporal lobe uncus or cerebellar tonsils. On coronal section, after fixation, the left temporal lobe showed a large mass lesion, which measured 3x2.5x2.2, hemorrhagic and surrounded by necrotic and oedematous tissue.

Case 3: a 71-year-old-Caucasian man, with a past history of hypostenia of the right arm, cervical spine surgery, chronic kidney disease, and hepatic steatosis. During his detention, showed headache, confusional state, and difficulty in walking therefore he was transferred to the local hospital. The neurological examination revealed poor general condition, marked weight loss, ataxia and ideomotor slowing, depressive syndrome, apathy, fatigue, and lack of initiative. The laboratory examination of blood and liquor was negative for infection-inflammatory disease. To diagnose a multi-infarct dementia the patient was scheduled for TC and magnetic resonance imaging of the brain and the entire spine, but suddenly died prior to the imaging. At autopsy a moderate pulmonary edema and polyvisceral stasis were observed. The brain weighed 1550 g and showed massive edema. A spherical gelatinous solid mass, measuring 1 cm in diameter was attached in the right medulla. On coronal sections, the right temporal lobe showed a reddish-rusty mass lesion, measuring 1x2 cm and the third ventricle was compressed and dislocated.

The etiopathogenetic definition was outlined by histological examinations performed on brain tissue samples using haematoxylin-eosin (H&E) and Perl's and revealed the presence of diffuse and marked cytotoxic and vasogenic brain edema, and in samples taken from left frontal lobe (case I), left temporal lobe (case II), right medulla and temporal lobe (case III) foci of central necrosis surrounded by neoplastic cells with nuclear pleomorphism, pseudopalisading, multinucleated cells ("giant cells glioblastomas") and vascular proliferation. Areas of extensive haemorrhage near tumor cells were also observed.

The immunohistochemical examination of the brain specimens revealed a positive reaction for antibodies anti-GFAP (glial fibrillary acidic protein), CD68, vimentin and S-100; NSE (neuron-specific enolase), smooth muscle actin, CD34, cytokeratins MNF 116, EMA (epithelial membrane antigen), synaptophysin, HMB45 (Human Melanoma Black) were negative. The positive reaction for GFAP was confirmed by Western blotting. The other organs showed signs of central dysregulation (pulmonary oedema).

The death was attributed in the first and second case to brain edema and massive hemorrhage into the glioblastoma from arrosion of vessels, with an increase in intracranial pressure and compression of cerebrospinal fluid circulation, whereas in the third case death can be explained by distortion and compression of the medulla by the tumor with consequent acute central dysregulation due to glioblastoma corresponding to WHO grade IV.

Glioblastoma, Sudden Death, Immunohistochemistry Stains and Western Blotting

G61 Postmortem Tryptase Levels of Anaphylactic and Non-Anaphylactic Deaths

Marc D. Bollmann, MD, Centre Universitaire Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND; Olaf Drummer, Noel W.F. Woodford, MD, Victorian Institute of Forensic Medicine, 57-83 Kavanagh Street, Southbank, Victoria, 3006, AUSTRALIA; Bettina Schrag, MD, University Center of Legal Medicine Lausanne-Geneva, Bugnon 21, Lausanne, 1011, SWITZERLAND; and Dimitri Gerostamoulos, Victorian Institute of Forensic Medicine, 57-83 Kavanagh Street, Southbank, Victoria, 3006, AUSTRALIA*

After attending this presentation, attendees will understand the importance and some limitations of the analysis of serum tryptase in the postmortem diagnosis of anaphylactic shock.

This presentation will impact the forensic science community by helping the forensic pathologists in the interpretation of postmortem serum tryptase levels. In addition to that, the number of anaphylaxis cases presented here is big, given the rarity of this cause of death.

Introduction: Anaphylactic reactions are encountered very rarely as cause of death in forensic practice and the postmortem diagnosis can be difficult, given the unspecific autopsy findings. The diagnosis is usually based on several criteria, including an elevated serum tryptase level. The established clinical normal values for serum tryptase can however not be used in the postmortem setting and need to be adapted for postmortem cases. The interpretation of postmortem serum tryptase levels may be tricky. So it is well known that some conditions other than anaphylaxis can lead to high tryptase levels and also false negative results can be encountered.

Aims: The presented study is aimed at describing the diagnostic criteria, including serum tryptase levels that were used to diagnose twelve anaphylactic deaths. Moreover, a postmortem normal value for serum tryptase from controls is computed and compared to the published data in the literature.

Methods: Twelve anaphylactic deaths, investigated in the Victorian Institute of Forensic Medicine in Melbourne (AUS), have been retrospectively analyzed concerning the diagnostic criteria, autopsy findings and postmortem serum tryptase levels. The findings and the serum tryptase levels were compared to those of a control group consisting of 33 cases with identified, non-anaphylactic causes of death. To better represent the reality of forensic practice, the control group has been increased by 17 individuals with unascertained causes of death, for a second comparison. The obtained cut-off level was compared to the published data.

Results: The postmortem diagnosis of anaphylaxis in the 12 cases was mainly based on the circumstantial information surrounding the death, the medical history, and the exclusion of other causes of death. Laryngeal oedema was found in 83% of the anaphylaxis cases and in 17% of the controls. None of them had a skin rash. The tryptase levels of the controls will be presented with known causes of death and of the increased control group after including unascertained cases. Some cases with surprisingly high or low levels will be discussed.

Conclusion: Serum tryptase obtained from peripheral blood is the strongest aid in the diagnosis of anaphylaxis as a cause of death. The majority of anaphylaxis cases have tryptase levels of well above 100 μ g/l, whereas the other causes of death had tryptase levels generally under 41 μ g/l. A grey zone clearly exists, and a number of elements should be present to make the diagnosis of anaphylaxis. Even a strongly positive tryptase result should not automatically lead to the diagnosis of anaphylactic shock. In most cases, other elements can be found to support or reject the diagnosis. Other conditions with elevated tryptase levels exist and should be considered in cases with high levels.

Tryptase, Anaphylaxis, Postmortem

G62 Murder-Suicide in Fulton County, Georgia: 1992-2006

Randy L. Hanzlick, MD, and Stacey L. Smith, MD, Fulton County Medical Examiner's Office, 430 Pryor Street Southeast, Atlanta, GA 30312*

After attending this presentation, attendees will understand the characteristics of murder-suicides occurring during a 15-year-period in Fulton County, Georgia, with emphasis on circumstances and relationships of perpetrators and victims.

This presentation will impact forensic science community by detailing the features of murder-suicide events and reviewing relevant literature, with the goal of providing information relevant to prevention strategies.

Background: Murder-suicide typically involves one or more homicides followed shortly thereafter (usually at the same time but sometimes later) by suicide of the perpetrator. The Fulton County Medical Examiner's Office previously reported a series of twelve murder-suicide cases which occurred in the years 1988-1991. This report is a follow up study of murder-suicide cases in Fulton County, Georgia, which occurred in the 15-year period of 1992 through 2006. Current data are compared with data from the earlier study and other studies reported in the literature.

Methods: The Fulton County Medical Examiner's Office maintains a comprehensive database which includes data items to record companion cases and for the past seven years, indication of whether death was part of a murder-suicide event. The data base was searched to detect murder-suicide events and to collect demographic, cause of death, and circumstantial information for each case. Results are compared with our previous study, the literature, and the incidents are classified in the context of a previously published classification scheme.

Results: 40 incidents occurred during the 15-year period. There were 40 suicides and 46 homicides for a total of 86 decedents. The number of incidents per year ranged from 1 to 6 with an average of 2.6, and the number of decedents per year ranged from 2 to 17 with an average of 5.5 per year. There were two decedents in 38 of the incidents, three decedents in one incident, and seven decedents in one incident. There was at least one murder-suicide event each year.

In every case, the perpetrator was male. Fourteen of the perpetrators (34%) tested positive for ethanol, five of the homicide victims (11%) tested positive for ethanol, and in three cases (7%), both the perpetrator and victim were positive for ethanol. In 8 cases (26%), the perpetrator was positive for stimulant drugs such as cocaine or methamphetamine.

In 34 incidents (85%), the perpetrator and victim were both shot. One incident involved sharp force injuries of both decedents, another incident involved thermal burns of both decedents, and in four incidents a combination of methods was used. 27 (66%) incidents occurred in or on the property of the perpetrator's place of residence. The most common circumstance was a boyfriend killing a girlfriend (n=13) or ex-girlfriend (n=3). The second most common was a husband killing his wife or ex-wife (n=11). An employee killed a coworker in three incidents. In two incidents, one male killed another male during an argument.

Of the perpetrators (all male), 9 (23%) were White, 6 (15%) were Hispanic/Latino, and 25 (63%) were Black. Both Hispanics and Blacks were overrepresented in comparison with their prevalence (43% and 8% respectively) in the county population while whites were underrepresented (account for about 50% of the population). In 37 incidents (93%), all decedents were of the same race. In three cases, the perpetrator was Hispanic/Latino and the victim was White (non-Hispanic). A male killed one or more females in 34 of the 40 incidents (85% of cases).

The number of days between incidents ranged from 12 to 483 with a median of 125 days and a mean of 142 days. Thus, evidence of short term clustering was minimal except for two incidents in late June and

* Presenting Author

early July of 1999. The same year which had the maximum number of incidents (n=6).

Comparison of the present study to our previous study shows only slight differences in the trends observed, which may relate mainly to the much larger size of the most recent case series.

Using the classification scheme of Marzuk, Tardiff, and Hirsch, the most common type of incident (71% of incidents) was "Spousal or Consortial" (in which we included spouses, former spouses, girlfriends, and ex-girlfriends) and the most common motive (27% of incidents) was "Amorous Jealousy." A similar portion of cases involved some form of argument or relationship problem which was not further clarified. Of note, 12 cases (30% of incidents) involved motives that were not apparent. This finding points out the difficulty in clarifying the motive when the people who might be able to explain what happened are dead and further specific information cannot be determined.

All but three incidents involved circumstances in which the deaths of the victims and perpetrators had a close temporal relationship. In one case, the perpetrator died in the hospital after a two months stay for his self inflicted gunshot wound. In a second and atypical case, the perpetrator committed suicide in jail several months after being arrested for the murder of the victim. In the third case, the homicide victim died about five months after the incident from ongoing complications of her gunshot wounds.

Conclusions: Similar to other studies, murder-suicides in Fulton County, Georgia show a low but stable rate of occurrence with a predominance of male perpetrators, female homicide victims, same-race victims, two deceased persons, a victim-perpetrator relationship such a spouse or girlfriend, and causes of death which predominantly involve gunshot wounds.

Murder-Suicide, Homicide-Suicide, Violent Death

G63 Homicidal Deaths in the Western Suburbs of Paris: A 15-Year-Study With Special Focus on Survival Time

Jérôme Cros, MD, AP-HP, Jean-Claude Alvarez, PharmD, AP-HP, Raymond Poincaré Hospital, 104, Bd Raymond Poincaré, Garches, F-92380, FRANCE; Emilie Shidian, MD, AP-HP, Department of Clinical Research and Public Health, Henri Mondor Hospital, 51 av du Maréchal de Tassigny, Crétteil, F-94010, FRANCE; and Philippe Charlier, PhD, AP-HP, and Geoffroy Lorin de la Grandmaison, PhD*, AP-HP, Raymond Poincaré Hospital, 104, Bd Raymond Poincaré, Garches, F-92380, FRANCE

After attending this presentation, attendees will understand homicide trends in an area around Paris and the value of Injury Severity Score (ISS) for the estimation of survival time.

This presentation will impact the forensic science community by helping forensic pathologists in homicide case investigations when questions about victim's survival time are raised.

The goal of this study was to analyze the homicide pattern in the western suburbs of Paris and its evolution between 1994 and 2008. ISS was also assessed to see if it was correlated with the survival time of homicide victims.

All autopsy reports regarding homicides from January 1, 1994 to December 31, 2008 were retrospectively reviewed. All autopsies were performed in the Department of Forensic Medicine and Pathology of Garches. Out of 4,842 autopsy cases reviewed, 511 homicide cases were selected. The following data were recorded: assailants' and victims' characteristics, crime scene location, homicide motive, cause of death, postmortem toxicological results, ISS, and estimated survival time.

Homicide rate steadily declined over the period at the exception of the number of homicide-suicide per year which remained constant. Homicide victims remained unidentified after medico-legal investigations in 2% of the cases. Child and elder homicide cases

represented respectively 10.7% and 8.2% of the cases. Offenders were male in 88% of the cases. Male and female assailants showed distinct homicide patterns: females were involved more frequently in familial quarrel and child abuse. They never killed a stranger and committed homicide exclusively in a private place with a predominance of sharp weapons. Males in contrast assaulted almost equally a stranger or an acquaintance, often in a public place with a predominance of firearm. The victim knew the assailant(s) in 57% of the cases. Homicides mostly took place at the residence of the assailant or the victim. Homicide motive was clearly determined in 71% of the cases. Argument was the most common motive in 44% of the cases. Sexual assault was rarely found (ten cases). Gunshot wounds were the most common cause of death (37%), followed by stab wounds (27%), blunt trauma (19%) and asphyxia (13%). A decrease of gunshot wounds as a cause of death was found over the studied period. Alcohol was the most common toxic detected in blood victim, in 48.5% of the cases when toxicological results were available. Blood alcohol concentration ranged from 1 to 500 mg/dL with a mean value of 150 mg/dL. Survival time was determined in 162 cases and ranged from 0 minute to 25 days. The mean ISS was different according to the cause of death: 3.4 for deaths by asphyxia, 38.6 for deaths by stab wounds, 39.6 for deaths by blunt trauma and 60 for deaths by gunshot wounds. ISS and survival time showed a significant correlation ($r=-0.56$; $p<0.05$) only for short survival time (less than three hours) and after exclusion of deaths by asphyxia (n=58). Correlation was weaker when there was a long time of resuscitation.

In conclusion, this autopsy series research pointed out that homicide pattern strongly differed according to the sex of the victim and of the assailant. ISS could be used to help in estimating the victim's survival time, taking into account the compounding factor of resuscitation.

Homicide, ISS, Survival Time

G64 Pattern of Limb Lesions in Suicidal Hanging: A Criteria Tool in the Distinction of Suspicious Cases

Anne Desjarlais, BSc*, 7101 De La Roche, Montreal, QC H2S2E6, CANADA; Anny Sauvageau, MD, Office of the Chief Medical Examiner, 7007 - 116 Street, Edmonton, AB T6H 5R8, CANADA; and Jean-Pierre Guay, PhD, University of Montreal, CP 6128, Succ. Centre-ville, Montréal, QC H2S 2E7, CANADA

After attending this presentation, attendees will have a better understanding of the usual pattern of lesions in suicidal hangings and will be aware of the pattern of lesions to be considered suspicious.

This presentation will impact the forensic science community by providing tools to improve the screening of suicidal hangings for possible suspicious cases.

Introduction: In this era of limited resources, hanging cases are investigated in several jurisdictions by a limited scene analysis and a rapid external examination of the body. Full body autopsies are becoming less and less frequent in these cases, based on the assumption that hangings are virtually always suicide. Homicidal hangings are therefore at serious risk to be missed, particularly since they are difficult to detect. However, to recommend a full body autopsy on all hanging victims is not realistic considering the limited human and financial resources.

In a recent six-year retrospective study on the pattern of limb bruises in hanging conducted in the Province of Quebec, Canada, it was suggested that the presence of bruises on the anterior upper limb and the presence of bruises on both the upper and lower limbs were two criteria that should alert the pathologist to be more cautious. The presence of bruises on the posterior lower limb was initially proposed as an additional criterion of suspicion, but failed to reach statistical

significance. The present study aims at evaluating the validity of these criteria on a different population and to further investigate the usual pattern of limb lesions in suicidal hangings.

Material and Methods: A total of 214 suicidal hangings, investigated at the Office of the Chief Medical Examiner in Alberta, were reviewed for the presence and localization of bruises, abrasions and lacerations. An age- and gender-matched control group of non-hanging homicidal strangulations, composed of 51 cases, was similarly studied.

Results: Incidence of limb lesions: Bruises were found in 6% of suicidal hanging victims, abrasions in 5% and lacerations in 1%. Compared to homicidal strangulation victims, suicidal hanging victims are less likely to present bruises ($\chi^2=84.301$; $p=.000$; $\Phi=.564$), abrasions ($\chi^2=75.231$; $p=.000$; $\Phi=.533$) and lacerations ($\chi^2=8.123$; $p=.023$; $\Phi=.175$).

Usual pattern of limb bruises in suicidal hanging: The usual pattern of limb lesions in suicidal hanging victims was confirmed to be the following: bruises and abrasions are mostly found on the posterior part of upper limbs, on the anterior aspect of lower limbs, and on either the upper or lower limb but not to both in a single case. It was also found that bruises are commonly found on the anterior part of upper arms, but not on the anterior part of forearms. The comparative pattern in homicidal non-hanging strangulation does not display this preferential concentration.

Suspicion criteria for limb bruises: Three criteria were statistically confirmed to be in favor of an homicidal strangulation: the presence of bruises and/or abrasions (i) on the anterior forearms (bruises: $\chi^2=16.500$; $p=.001$; $\Phi=.250$; abrasions: $\chi^2=16.224$; $p=.001$; $\Phi=.247$), (ii) on the posterior aspect of lower limbs (bruises: $\chi^2=39.092$; $p=.000$; $\Phi=.384$; abrasions: $\chi^2=25.642$; $p=.000$; $\Phi=.312$), and (iii) on both upper and lower limbs in a single case (bruises: $\chi^2=51.043$; $p=.000$; $\Phi=.439$; abrasions: $\chi^2=24.682$; $p=.000$; $\Phi=.305$).

Conclusion: In the evaluation of a given case, the presence of the following distribution of bruises or abrasions should alert the pathologist to be more cautious and to further investigate the case: the presence of bruises or abrasions on the anterior forearms, on the posterior legs, or on both upper and lower limbs in a single case. Of course, the localization of bruises and abrasions is not to be interpreted without all other scene elements and autopsy findings.

Hanging, Bruise, Abrasion

G65 Decubitus Ulcers and Ligature Marks as Evidence in a Homicide Case

Miran Coklo, PhD, Valter Stemberga, PhD, Drazen Cuculic, PhD*, and Alan Bosnar, PhD, Rijeka University School of Medicine, Department of Forensic Medicine, Brace Branchetta 20, Rijeka, 51000, CROATIA

After attending this presentation, attendees will better understand the application of medicolegal investigation, specifically the role of forensic pathologist during homicide investigation. In addition, attendees will become familiar with the relatively rare injury patterns in forensic practice.

This presentation will impact the forensic science community by providing knowledge to medicolegal investigators, especially in deciding cause and manner of death in equivocal death investigations. This presentation will increase the competence of the medicolegal examiners and forensic pathologists in examination of complicated cases, when the autopsy findings may become unique evidence in the following legal action and adjudication.

The 30-year-old woman was found dead in the house where she was living with her fiancée and her mother-in-law. At initial inspection, bad condition and exhaustion of the body suggested natural death by malignant disease with no preview of medical history. Some unusual circumstances aroused suspicion. The victim was isolated in the dark room with no possibility to call for help, because her private cell phone

was taken away. Crime police found adhesive tapes and linen strap near the bed. Insensitive behavior of the household aroused suspicion and demanded careful pursuit of the following medicolegal investigation.

External examination of the body revealed three different types of injuries: decubitus ulcers (pressure sores), scabs (as ligature marks), and bruises of various ages. The decubitus ulcers stage II and III of the coccyx-sacrum region and on the both sides of the buttocks, ulcers stage II of the left elbow and the left ankle, ulcers stage I of the left trochanter and over the pectoral spine near the left shoulder blade were described. The circular scabs around the neck, and both wrists indicated ligature marks, so as the necrosis of the II-III fingers on the left hand. The bruises of various colors were presented on the left hand and upper arm, as well as along both medial femoral regions. The autopsy findings showed that the sacro-coccygeal ulcers extended into the subcutaneous tissue and secondary resulted in bronchopneumonia with purulent effusion into the left thoracic cavity. The lipofuscin pigmentation of hepatocytes and myocytes as histopathological changes indicated a state of long time deprivation of food. The forensic pathologist pronounced the cause of death violent death by bronchopneumonia caused by infected decubitus ulcers.

It is believed that no similar cases described in the recent literature have been found. Homicide of a young woman by the infliction of decubitus ulcers caused by immobility and fixation of the victim's body with ligature (tapes and strap) including elements of social and physical separation combined with starvation has not yet been described in the criminal records in Croatia.

The forensic psychiatry expert determined the specific relations between the victim and the perpetrators. This study concluded that the perpetrators didn't act alone. The male perpetrator was a drug addict who had permanent schizotypal disorder of personality, with characterization of egocentrism, latent aggression, lower tolerance threshold and emotional coldness. His mother was a person with dominantly narcissistic and dissocial personality disorder, with an intention to control the life of her son. The victim was a person with predominantly passive-dependent personality disorder, psychologically and socially predetermined to victimization. Forensic psychiatrist concluded that the perpetrators planned the crime together, carried on by the motive of jealousy.

According to Croatian Penal Code the perpetrators of a criminal offence were convicted of intentional murder to 30 years imprisonment.

The case presented shows the importance of a detailed crime investigation and close cooperation between crime police and forensic pathologist, especially if the presumed course of events is ambiguous. Recognition of the relatively rare injury patterns and understanding the mechanism of death seems to be the most important factor in elucidation of the presented homicide case.

Decubitus Ulcers, Ligature, Homicide

G66 Soccer Scams, Search Engines, Scientists, and Slaughter: Investigating a Complex Double Homicide in North-East England

Stuart J. Hamilton, MB ChB*, 9 Troon Close, Consett, DH8 5XF, UNITED KINGDOM

After attending this presentation, attendees will see the value of using relevant subspecialty expertise in forensic pathology and the benefits of good communication between the various experts and investigating authorities in ensuring that evidence given in court is reliable and supported by validated scientific principles.

This presentation will impact the forensic science community by showing how a complex case can be brought to a satisfactory conclusion by methodical examination of the available evidence.

In 2008, two Chinese nationals who had been students at Newcastle University were found dead in their home. They had clearly been the victims of homicide and a pet had also been killed. There was virtually no evidence at the outset as to when or why the murders had occurred and no suspect existed. Scene examination showed that both victims had been bound and suffered significant blunt force trauma. At autopsy, evidence of incised wounds was identified in one victim and signs of asphyxia in the other.

The brains were submitted to a forensically experienced neuropathologist who provided valuable evidence with respect to the survival period after injury. The meal that one of the victims had eaten when last seen alive had been at the restaurant where she worked. The nature of this meal was known and the gastric contents of this victim were examined by both the pathologist and a scientist to attempt to identify the components of the stomach contents and the degree of digestion.

Although a national appeal was made on television for information, a suspect was developed by an unusual method. A strong case including DNA evidence was made and ultimately this individual was convicted on two counts of murder.

Good communication between the experts and police led to the development of a powerful and reliable case assisted by relevant subspecialist expertise.

Blunt Trauma, Homicide, Organized Crime

G67 Death Certification of “Suicide by Cop”

Amber R. Neitzel, BS, 550 East Van Buren Street, Phoenix, AZ 85004, and James R. Gill, MD, Office of the Chief Medical Examiner, 520 First Avenue, New York, NY 10016*

After attending this presentation, attendees will understand the concept of “suicide by cop” and the criteria used to certify these deaths as suicides.

This presentation will impact the forensic science community by discussing examples of “suicide by cop” and why suicide (and not homicide) is the appropriate manner for these deaths.

A death certification of “suicide by cop” is controversial among some medical examiners and coroners (ME/C). These are often complex investigations and the opinions of the medical examiner must take into consideration all relevant issues. Five such deaths are presented that were certified as suicides and discuss the medicolegal issues involved with these certifications. In order to certify such a death as a suicide, certain criteria should be met. The five criteria used to make this certification include evidence of: (1) suicidal intent; (2) intent to be shot by law enforcement; (3) possession of a lethal weapon or facsimile; (4) intentional escalation of the encounter; and, (5) legal use of force by law enforcement. These legal actions of law enforcement are what distinguish these deaths from other instances of “assisted-suicide” that would be certified as homicides if they involved the illegal actions of another.

All of the decedents were male and their average age was 34 years (range 26 to 43). Both ethanol and cocaine were detected in two of the decedents and the other three had a history of psychiatric illness. All of the decedents possessed weapons or a facsimile of a weapon. There were three handguns, two knives, and one silver cigarette lighter in the form of a gun.

Suicide by cop is a circumstance that involves the completion of intentional acts that may result in dichotomous determinations of the manner of death. In some jurisdictions, these deaths are certified as homicide. Since these deaths occur at the hand of another, the invoked reasoning is that homicide therefore dominates the certification. But what if there was reliable evidence that a person wanted to die and committed an intentional act to further that goal? If the death was the result of an intentional act to do self harm or cause death of one’s self,

then the manner of death is more appropriately certified as “suicide” in these instances despite the fact that the decedent did not pull the trigger.

For police shootings, the conventional certification remains “homicide” in the absence of other compelling circumstances. But just because these deaths occur at the hand of another, there should not be an automatic homicide determination in all instances. Suicide should be considered in these deaths. Despite the absence of direct self-infliction, there is overwhelming evidence that these five individuals intended to end their own lives. Their use of an unusual method to accomplish this goal may inappropriately result in a reflexive certification of homicide. Instances of suicide by cop and contend that these types of deaths are best certified as suicides will be presented.

Suicide, Police, Manner

G68 Study of Lethal and Non-Lethal Filmed Hangings: New Insight Into the Pathophysiology of Hanging

Anny Sauvageau, MD, Office of the Chief Medical Examiner, 7007 - 116 Street, Edmonton, AB T6H 5R8, CANADA*

After attending this presentation, attendees will have a better understanding of the pathophysiology of hanging, of the effect of the type of suspension and ischemic habituation on the agonal sequence, and on the appropriate scientific answer to the time to die by hanging.

This presentation will impact the forensic science community by providing new insight into the pathophysiology of hanging, based on the ongoing study of the working group on human asphyxia.

Introduction: Contemporary understanding of the pathophysiology of hanging is still largely based on old writings and experimentation from the end of the 19th century and beginning of the 20th. Apart from a few animal studies that gave very limited information on the pathophysiology of hanging in human, there was little new development on this issue until the creation of the Working Group on Human Asphyxia in 2006. Here presented are the newest results from this ongoing study.

Material and Methods: Fourteen lethal filmed hangings (nine autoerotic accidents, four suicides, and one homicide) were analyzed, as well as three non-lethal filmed hangings by an autoerotic asphyxia practitioner.

Results and Discussion: *Lethal filmed hangings:* In the fourteen lethal filmed hangings, the following sequence of agonal responses was observed: rapid loss of consciousness in 10 s ± 3 s, mild generalized convulsions in 14 s ± 3 s, decerebrate rigidity in 19 s ± 5 s, beginning of deep rhythmic abdominal respiratory movements in 19 s ± 5 s, decorticate rigidity in 38 s ± 15 s, loss of muscle tone in 1 min 17 s ± 25 s, end of deep abdominal respiratory movements in 1 min 51 s ± 30 s, and last muscle movement in 4 min 12 s ± 2 min 29 s.

Effect of the type of suspension: A comparison of time delay for agonal responses in complete suspension and incomplete suspension do not reveal impressive differences. These results suggest that the type of suspension may not be an important factor in the timing of agonal responses and therefore in the time to irreversible damage and death.

Effect of ischemic habituation: Considering that autoerotic practitioners might develop over time a certain ischemic habituation over time, it is theoretically possible that these cases present a deceleration of the sequence. On the other hand, since they often play for a longer period with the hanging process before the final hanging, it could be argue that on the contrary, their hanging sequence will be accelerated. Overall, the time delays for the early responses to hanging seem to be relatively similar between both groups, with the exception of an accelerated start of deep abdominal respiratory movements in the autoerotic practitioners. As for the late responses to hanging, they seem to be decelerated in autoerotic practitioners.

Non-lethal filmed hangings: In the three non-lethal filmed hangings, a loss of consciousness was observed in 8 to 16 seconds, followed by convulsions in 9 to 26 seconds. Decerebration rigidity was observed in one non-lethal filmed hanging (at 20 seconds). The ligature, which was not tied tightly to the shower rod, then detached from it, causing the fall of the man and the interruption of the hanging. Upon interruption of the hanging, the man quickly regained consciousness and seemed to present a full recovery without any noticeable symptoms.

Estimation of the time to irreversibility and to die by hanging: The scientific basis for the generalized assumption that death by hanging occur in three to five minutes will be reviewed. There is no forensic study to sustain this estimate of five minutes to die. In fact, this number seems to be based on three types of studies: a series of near-hanging victims in emergency medicine, studies of carotid endarterectomy, and physiopathological studies of brain ischemia. Though this estimation of the time is certainly precise and accurate enough for the needs of clinicians, it will be demonstrated that scientific evidence are not strong enough to be used in court. So how long does it take to suffer irreversible damage by hanging or by strangulation? The only honest and scientifically valid answer is not known.

Asphyxia, Hanging, Pathophysiology

G69 Pitfalls in the Interpretation of the Hyoid and Thyroid Fractures in Strangulation: The Importance of Anatomical Variations

João S. Pinheiro, MS, Instituto Nacional de Medicina Legal, Delegação do Centro, Largo da Sé Nova, Coimbra, 3000, PORTUGAL; and Anny Sauvageau, MD, Office of the Chief Medical Examiner, 7007 - 116 Street, Edmonton, AB T6H 5R8, CANADA*

After attending this presentation, attendees will have a better knowledge of the importance of anatomical variations in the interpretation of fractures of the hyoid bone and thyroid cartilages.

This presentation will impact the forensic science community by developing and increasing awareness of the pitfalls associated with anatomical variations of the hyoid bone and the thyroid cartilage in strangulation cases.

Strangulation is defined as asphyxia by closure of the blood vessels and/or air passages of the neck as a result of external pressure on the neck. Three subtypes are recognized: hanging, ligature strangulation, and manual strangulation.

A proper neck dissection is a key element in the investigation of these deaths. Despite the usefulness of x-ray and computed tomography as ancillary techniques, manual dissection of the neck structures remains the most widely used technique to assess the integrity of neck structures. Considering the relative complexity of the neck dissection, it is important that it is performed by a trained forensic pathologist.

Apart from basic anatomical background and technical skills, forensic pathologists are in general well trained in recognizing postmortem artifacts encountered during the neck dissection. Unfortunately, anatomical variations as pitfalls in the interpretation of fractures of the hyoid bone and thyroid cartilage are however unknown to most. This comes to no surprise considering that forensic textbooks and the forensic literature have failed to pay any attention to these anatomical variations.

The anatomists have described several anatomical variations of the hyoid bone and thyroid cartilage that are of great interest to forensic pathologists. The triticea, a very small cartilage located in the thyroid-hyoid membrane, is encountered in approximately 13 to 16% of individuals. This cartilage can easily be mistaken as a fracture of the superior horns of the thyroid cartilage. Asymmetrical length of the superior horns of the thyroid cartilage, morphological differences between horns, and unilateral absence of one horn are all variations that

also constitute pitfalls in the interpretation of fractures of the thyroid cartilage. In the hyoid bone, the forensic pathologist should be aware of the following possible variations: unusually long great horn, uncommonly long lesser horns, difference in the fusion time of the greater horns to the body, and calcification of the stylohyoid ligament. The consistency of the hyoid bone and thyroid cartilage in relation to the victim's age should also be taken into consideration in the interpretation of autopsy findings.

Forensic pathologists should be aware of the anatomical variations of the hyoid bone and thyroid cartilage and should be trained in recognizing them, in order to avoid erroneous interpretation of autopsy findings. The role of x-ray and computed tomography as ancillary techniques will be discussed, but the importance of a proper manual dissection, with palpation of the fractures, will be reinforced. After removing the viscera from the chest and abdominal cavities and removing the brain (dry neck dissection), it is recommended to dissect *in situ* the muscles layers and then to remove the neck organs from the mouth and cervical column, in order to perform a dissection *ex-situ* of the hyoid and thyroid cartilage. Ultimately, the hands and eyes of the pathologist constitute an invaluable tool, provided there is proper training and knowledge. The dissection technique to assist in the discrimination of anatomical variations versus fractures of the neck structures will be further described.

Despite the tremendous importance of correct interpretation of anatomical variations in the identification of fractures of the neck structures in strangulation, this issue has not been properly discussed in the forensic literature so far. This presentation is aimed to fulfill this gap.

Hyoid, Thyroid Cartilage, Strangulation

G70 A Comparison Study of Homicides Between Beijing, China and the State of Maryland, United States

Lin Chang, MD, China University of Political Science and Law, 116 Lugu Road, Shijingshan District, Beijing, 100040, PEOPLES REPUBLIC OF CHINA; Li Liu, MD, Beijing Municipal Public Security Bureau, No.1 Qinghe Longgang Road Haidian District, Beijing, 100192, PEOPLES REPUBLIC OF CHINA; and Xiang Zhang, MD, David R. Fowler, MD, Eleanor J. Thomas, and Ling Li, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will have learned the epidemiological characteristics of homicides in Beijing, China and the state of Maryland, United States.

This presentation will impact the forensic science community by illustrating the differences in the pattern of homicides between China and the United States, and by discussing the influence of cultural dimensions and socioeconomic development on violent crime.

A retrospective comparison study was conducted on homicides occurring in 2008 comparing Beijing, China and the State of Maryland, United States. Beijing, the capital of China, with a population of 16,950,000, covering 6.489 square miles, is made up of two suburban counties and 16 urban districts. Maryland, with a population of 5,633,597 and a total area of 12,407 square miles, comprises twenty-three counties and Baltimore City. In 2008, a total of 398 homicides occurred in Beijing. The homicide rate was 2.34 homicides per 100,000 population. Maryland, however, had 536 homicides (9.51 per 100,000 population), which was more than four times as high as the homicide rate in Beijing. Males were much more likely to become homicide victims than females in Maryland (Male: Female = 5.2:1, based on the rate), when compared with homicides in Beijing (Male: Female = 1.4: 1). The age distribution of homicide victims was similar between Beijing and Maryland, with the majority of the victims in their 20's to 40's.

The most common cause of homicide in Beijing was sharp force

injury (52.8%), followed by blunt force injury (24.1%), asphyxia due to suffocation/strangulation (17.8%). Only two deaths were caused by firearm injury combined with sharp force injury. On the other hand, the most common cause of homicide in Maryland was firearm injury (74.8%), followed by sharp force injury (10.3%), blunt force injury (5.0%), and suffocation/strangulation (3.5%). There was a significant difference between Beijing and Maryland regarding the homicide death scene location. More than 71% of the homicide victims in Beijing were found inside of buildings, such as residential houses (44.2%), business/government offices (10.0%), stores (7.5%), night clubs (6.5%), and other facilities (2.8%). However, only 37.9% of the homicide victims in Maryland were found inside of buildings with fewer than 30% of the victims found in residential houses. The majority of Maryland homicide victims were found either on the street (42.9%), or in the park/wood/field (12.9%), or other outside locations. The possible motives of homicide in both regions will also be discussed.

Forensic Science, Homicide, Epidemiology

G71 Blood at the Scene of Death Due to Hanging: Artifact or Antemortem

Surendra K. Kumar, MD, Army College of Medical Sciences, Delhi Cantonment, New Delhi, 110010, INDIA*

After attending this presentation, attendees will understand the distinctive difference between antemortem and postmortem collection of blood, the dynamics of blood collecting at the scene, principles of artifacts, importance of determining that the blood at the scene of crime was not antemortem but was a postmortem phenomenon, correlating the blood with the injuries, and example of dubious presentation of suicidal and homicidal deaths due to asphyxia.

This presentation will impact the forensic science community by showing how suspicion and or allegations of not reporting injuries or reporting incorrectly are related to the evidence of blood at the scene of crime. Blood oozing out of injuries sustained during medical treatment needs to be differentiated from those injuries that were inflicted after the death of an individual. Misinterpretations can be reduced and scope and diagnostic accuracy could be enhanced by the exclusion of antemortem nature of blood at the scene of occurrence.

In India, those who do autopsies are generally not supposed to visit the crime scene. Autopsy opinions about cause and manner of death are sometimes in conflict with the opinion of those who had observed blood at the scene. In order to set aside an autopsy opinion of "suicidal hanging" and to believe that of "ligature strangulation" in three different cases, proving how blood at the scene could be postmortem was a big challenge.

Manner in which the blood at the scene had been perceived during the investigation or even some time after the occurrence and investigation was significant. Such a perception formed the basis to confront the autopsy opinion in three controversial cases. Baring the truth that blood at the scene was not that had oozed out of the injuries sustained during life in these cases makes an interesting case. In the first case of suicidal hanging, bleeding was from the injury that was inflicted after the death by the tip of a scissors used to cut ligature material around the neck. The second case relates to a probe into the reinvestigation of a suicidal death of a hanged victim who had been discovered dead on the fifth day. Earlier investigation and autopsy opinion of hanging were considered botched. The contention was that the victim had injuries; these injuries were not reported and had been missed deliberately both by the investigators and in the autopsy. The blood at the scene was the result of collection from constant dribbling due to postmortem hypostasis. It was not as was being presumed to have collected at the scene from some missed injury on the front of the body of hanged victim. The third case was of a lady found dead in her own house. Co-existence

of a thread like ligature mark around her neck with the fresh bleeding cut throat injury and bleeding sharp weapon injuries on both the wrists remained a mystery. One of these or both of these were the cause of deaths remained the issue. Death was due to ligature strangulation became the diagnosis that blood had come out of the injuries which were caused by shaving blade after the death.

Antemortem looking postmortem blood raised issues to challenge the credibility of the autopsy opinion and or police investigation in three cases. A case study to show how misinterpretations of blood at the scene discredited family version as well as autopsy opinion of hanging in the case of two suicidal deaths will be presented. Inference indicating ligature strangulation appeared weak and ineffective so long as antemortem appearing injuries were found to be postmortem cuts in the third case. It is recommended that death investigators be familiar with the sensitivity to exclude the probability of blood at the scene being postmortem and unrelated to the actual mechanism of death.

Antemortem, Postmortem, Blood

G72 The Influence of the Meteorological Factors on Occurrence of the Suicide Cases

Zalina Muzaferova, Main Bureau of Forensic Medicine, Mirakhmedov Street, 143, Tashkent, UZBEKISTAN*

The goal of this presentation is to demonstrate the correlation of the dependency between meteorological factors in defining the reasoning in suicides for forming training for prevention and alertness.

This presentation will impact the forensic science community by assisting in increasing the understanding of suicide.

During the investigation of suicide cases, the focus is ordinarily on the location of the event, the type of death, personal information and additional documents but it is also important to study other factors influencing the death, factors like meteorological conditions. Full-fledged suicide has many affects on society and many scientists pay very close attention to it, but most of the significance is that suicide is a social and medical problem.

Meteorological and heliophysics factors as well as socio-economic events have a great influence on the emotional state of an individual, and may also be factors in the occurrence of several diseases. Moreover, they may also increase the occurrence of suicide.

Factors such as atmospheric pressure, air temperature, humidity, and solar radiation have been fully analyzed with respect to the influence on suicide. Reports from suicide cases with conclusions of medical examiners for a five-year period were provided by the Main Bureau of Forensic Medicine in Tashkent, Uzbekistan. Information about temperature, humidity, atmospheric pressure, rain, and magnetic storm indices in Tashkent city were obtained from Uzhydromet, the Hydrometeorological Services Center in Tashkent.

Study results were analyzed for significance using the Student t-test method.

The results of the analysis of both suicide cases and meteorological factors have been combined and adequate statistics had been created. After certain procedures it had been highlighted that the correlation between two types of factors is indirect. This correlation was worked out by Health Institute of the Ministry of Health of the Republic of Uzbekistan for early prognosis of suicide occurrences affected by many factors.

This study of the effects of meteorological factors on suicide rates showed a strong correlation only with atmospheric pressure and air temperature. The method of direct correlative relationship (2, 3) worked out by the Republican Information Analytical Center was applied to this data to study the effect of many meteorological factors on suicide rates. The results of this study allowed for the creation of a formula for predicting the number of suicides cases as a function of air temperature

and atmospheric pressure: $X = 0.014198 \{ T (^{\circ}C) \} - 0.0000708 \{ P (GPa) \} + 0.65990$; where, X= number of expected suicides per day; T= expected air temperature; P= expected atmospheric pressure. According to given equation, the average fluctuation of the number of expected occurrences is ± 0.05 , at a confidence of 95%.

The above study shows that there is a certain relationship between meteorological factors such as air temperature and atmospheric pressure with the occurrence of suicide cases. The developed formula based on the combination of meteorological factors makes it possible to predict the expected suicide states and take preventive measures.

Forensic Pathology, Suicide, Meteorological Factor

G73 Complex Suicide: An Unusual Case With Six Methods Applied

Stojan Petkovic, PhD, Miljen Maletin, MD, MSc, and Maja Durendic-Brenesel, PhD, Klinicki Centar Vojvodine, Department of Forensic Medicine, Clinical Center of Vojvodina, Hajduk Veljkova 5-7, Novi Sad, 21000, SERBIA AND MONTENEGRO*

After attending this presentation, attendees will be acquainted with complex suicide, potential methods applied, determination of main-dominant cause of death, and will be provided with more details about traumatic brain injury caused by screwdriver.

This presentation will impact the forensic science community describing six methods in committing complex suicide that should be of great interest in common forensic practice.

Complex suicides are committed by using more than one method. They account for 1.5% to 5% of all suicides. Depending on the time delay between the employed suicidal mechanisms they can be defined as “primary complex suicides” if the mechanisms are applied simultaneously and “secondary complex suicides” if the mechanisms are applied in quick chronological sequence.

The report presents a case of complex suicide of a 44-year-old male, found dead in the vicinity of his car, in a deserted frozen field few kilometers away from the nearest town. The doors of the car were opened, and victim's head and clothes were soaked in blood. Blood spots were found on both front car seats. Neither weapons nor any tools were found around his body outside the car. A farewell letter was handwritten on two sheets of paper and was found on the dashboard of the car. The motive for committing suicide was not given in this letter. On the right front car seat there were blood spots, a screwdriver handle, an automobile crane, one razor blade, one cell phone, car keys, a pencil, and a woolen hat. In front of this seat there were two half-emptied red plastic bottles with hydrochloric acid, and one almost empty transparent plastic bottle with traces of liquid of unknown origin. A single receipt from the nearby town supermarket was found in the car. One screwdriver, pack of razor blades, and two bottles of concentrated hydrochloric acid were listed in the receipt. Police investigation excluded homicide and no medical data confirmed mental illnesses.

The autopsy revealed wrist cuts, neck cuts, acid burns in the GI tract, multiple stab wounds to the head by screwdriver, and several uncertain signs of hypothermia. In the parietal region, along the midline, there was an epidural hematoma measuring 5x1 cm in diameter. The brain was swollen, with flattened gyri and narrowed sulci, measuring 1.64 kg. Marked indentations on the ventral surface of cerebellum, indicating tonsillar herniation were found. The brain tissue along all wound tracts was debrided, but there were no diffuse injuries in white matter, nor were concentric zones of necrosis around the tracts noticed. Toxicology analysis (GC-MS) of gastric and intestinal content revealed Cypermethrin (synthetic pyrethroid used as an insecticide in commercial agricultural applications), while analysis of blood, urine and bile was negative. The same substance was identified in liquid from transparent plastic bottle, taken from the scene.

The stab wounds to the head were determined to be the cause of death, while external hemorrhage and hypothermia were contributing factors. This is the first case of complex suicide reviewed in literature where six suicide methods were applied. This particular case is interesting because the victim used a screwdriver as a tool for inflicting stab wounds to the head, which is a rare suicidal method.

Complex Suicide, Traumatic Brain Injury, Screwdriver

G74 Bitten by Snake Shot: Attempted Homicide and Successful Suicide With Multiple Gunshot Wounds

Todd M. Luckasevic, DO, and Baiyang Xu, MD, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222; and Abdulrezak M. Shakir, MD, and Karl E. Williams, MD, MPH, Office of the Medical Examiner - Allegheny County, 542 Fourth Avenue, Pittsburgh, PA 15219*

The goal of this presentation is to illustrate an unusual case of an attempted homicide and successful suicide with a revolver and multiple snake shot cartridges.

This presentation will impact the forensic science community by illustrating the need for close collaboration between the forensic pathologist and the firearm examiner when dealing with cases of unusual gunshot wounds.

Introduction: Suicide is one of the most important public health issues in the United States. Suicide represents the eleventh leading cause of death in the United States. Suicides comprise approximately 12% of the caseload of the Allegheny County Medical Examiner's Office in Pittsburgh, Pennsylvania. Suicide rates for this country have been relatively stable over the past decade averaging approximately ten per 100,000 populations. The most common method of suicide in the United States is the use of a firearm.

Homicide-followed-by-suicide (referred to as “homicide-suicide”) incidents are rare events but can have a profound impact on families and communities. The National Violent Death Reporting System based on 2003-2005 data, revealed 408 homicide-suicide incidents in 17 participating states. Most incidents were committed with a firearm (88.2%) and perpetrated by males (91.4%), those over 19 years of age (97.6%), and those of white race (77.0%). Over 55% of male homicide-suicide perpetrators had prior intimate partner conflicts.

Materials and Methods: The case involved a 53-year-old Caucasian male and his wife with a long standing history of domestic violence. The couple began to argue when suddenly the decedent pulled out a revolver and shot his wife in the face several times. The wife ran downstairs, exited the house, and ran to the neighbor's house for help. She was transported to a local hospital, treated for three gunshot wounds to her face and then subsequently released weeks later.

The decedent was found in the upstairs bedroom in bed with a revolver lying on his left leg. Two wounds were noted to the left and right sides of his head.

Results: The external examination revealed a Caucasian male with two contact penetrating gunshot wounds to both sides of his head. Dense soot deposits were present on the skin and within the wound tracks. Faint muzzle abrasions with micro-stretch lacerations were identified surrounding the entrance wounds. Gunpowder residue was grossly visible on both the left and right hands. Radiographs of the head revealed two separate aggregates of pellets. Autopsy revealed a gunshot wound of entrance just lateral and slightly superior to the right orbit. The path of the pellets was leftward through the orbital rim, posterior, and inferior to the orbital globe and came to rest in the sphenoid sinus. The second entrance wound entered superior and anterior to the left ear. The path of the pellets was rightward through the frontal bone and frontal lobe of the brain where they were recovered.

The firearm used by the decedent was a revolver made in West Germany chambered in 22 long rifle. The ammunition in the revolver consisted of five spent rounds and one live cartridge of .22 caliber long rifle shotshells loaded with number (size) 12 shot.

Conclusions: Collaboration between the pathologist and firearms examiner concluded that the decedent shot himself near his right orbit first and then changed hands and shot the lethal round into the left frontal region of his head. This is supported by gunshot residue on both hands and autopsy evidence that the path of the pellets on the right side of the head did no major damage. A literature review revealed only two published papers pertaining to the use of snake shot or shot shells. This case report offers to further build upon the knowledge of terminal ballistics of handgun shot shells.

Snake Shot, Handgun, Suicide

G75 Survived Strangulation: A Case Report

Paula C. Oliveira, MD, Portuguese National Institute of Legal Medicine, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; Ana R. Pereira, MD*, Ladeira das Alpenduradas nº13A, Coimbra, 3030-167, PORTUGAL; Rosario L. Silva, MD, and Graca Santos Costa, MD, Portuguese National Institute of Legal Medicine, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; and Duarte N.P. Vieira, PhD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL*

The goal of this presentation is to analyze and discuss the injury pattern potentially associated with situations of survived strangulation and the various consequences that may result from them, based on real cases. This presentation will also attempt to determine, if findings and symptoms of victims can be intensity of the assault and the severity of strangulation and if general evaluation criteria can be established on the basis of objective findings.

This presentation will impact the forensic science community by presenting severe survived strangulation cases researched, and introducing other cases described in literature. Difficulties usually exist in clinical forensic medicine regarding the interpretation of the findings in reference to the intensity and duration of the assault and, ultimately, the threat it represented for victim's life. This assessment is particularly important when conclusions must be drawn in the context of penal law, in order to allow the court to decide about the life risk involved in situations of aggression.

Cases Report: Several cases are presented involving different situations, from victims of assault to incidences of accidental self-inflicted strangulation. The majority the cases presented are of severe life-threatening strangulation that is cases with petechial bleedings on conjunctivae, mucosal surfaces and facial skin, as well as otorrhea, loss of consciousness, loss of urine, vomiting, etc.

Conclusions: The interpretation and significance of the injury pattern is discussed as well has the contribution that this pattern may give to a differential diagnosis between assault and self-inflicted strangulation and to the evaluation of the severity of the situation and the threat to life. Also stressed is the fact that forensic assessment must be as detailed as possible, due to the fact of a rapid change of the lesions pattern, with the risk of becoming impossible a correct interpretation of the facts. Finally, the transitory physical consequences of these situations and of the permanent results that may result from them, as well as of their contribution to an appreciation of the severity of the aggression will be discussed. The analysis of these cases also stress the importance, as previously stated by Plattner et al (2005), of a clinical and radiological examination in addition to the forensic examination. It also shows that applicability in forensic practice of the classification in three different degrees of severity of these situations, proposed by Plattner et al (2001).

Strangulation, Injury Pattern, Survival

G76 Cause of Sudden Death Due to Cardiac Rhabdomyoma in an 11-Month-Old Baby

Sabina Di Donato, PhD, University of Foggia, Department of Forensic Pathology, Viale Aviatori, 1, Foggia, 71100, ITALY; Michele Nolè, A.O.R. "San Carlo" Hospital, Via Potito Petrone, 6, Potenza, 85100, ITALY; Irene Riezzo, PhD, University of Foggia, Osp D'Avanzo, Department of Forensic Pathology, Viale degli Aviatori, 1, Foggia, 71100, ITALY; Sara Vita, MD, University of Foggia, Department of Forensic Pathology, Viale Aviatori, 1, Foggia, 71100, ITALY; and Rocco A.G. Maglietta, MD, San Carlo Hospital Potenza, Section of Legal Medicine, via P. Petrone n.6, Potenza, 85100, ITALY*

After attending this presentation, attendees will become familiar with the possibility that a completely asymptomatic benign cardiac tumor may induce sudden death in a previously healthy infant.

This presentation will impact the forensic science community by making attendees aware of the insidious development of benign cardiac tumors also in infants and children, focusing the possible responsible mechanisms of sudden death in such cases and providing a reference for additional study on these subjects.

Neoplasms of the heart can be characterized as primary and secondary. Primary cardiac neoplasms occur infrequently in both adult and pediatric age groups. In the general population, their incidence ranges between 0.17% and 0.19% in unselected autopsy series. In infants and children, cardiac tumors were reported at a frequency of 0.027%. Approximately 75% of primary cardiac tumors are benign, and 25% are malignant, in the general population. Benign lesions usually predominate, making up more than 90% of all pediatric tumors. Approximately 50% of the benign tumors are myxomas, and about 75% of the malignant tumors are sarcomas.

Rhabdomyoma is the most frequently occurring cardiac tumor in children. It usually presents during the first few days after birth. It is associated strongly with tuberous sclerosis, a hereditary disorder characterized by hamartomas in various organs, epilepsy, mental deficiency, and sebaceous adenomas. Fifty percent of patients with tuberous sclerosis have rhabdomyoma, but more than 50% of patients with rhabdomyoma have or will develop tuberous sclerosis. The exceptional patient is one with a solitary, single rhabdomyoma who does not have or develop tuberous sclerosis.

Over 90% of rhabdomyomas are multiple and occur with approximately equal frequency in both ventricles. The atrium is involved in fewer than 30% of patients. Pathologically, these tumors are firm, gray, and nodular and tend to project into the ventricular cavity. Micrographs show myocytes of twice normal size filled with glycogen and containing hyperchromatic nuclei and eosinophilic-staining cytoplasmic granules. Scattered bundles of myofibrils can be seen within cells by electron microscopy.

The most common presentation is heart failure caused by tumor obstruction of cardiac chambers or valvular orifice flow. Clinical findings may mimic valvular or subvalvular stenosis. Arrhythmias, particularly ventricular tachycardia and sudden death, may be a presenting symptom. Atrial tumors may produce atrial arrhythmias. The diagnosis is suggested by clinical features of tuberous sclerosis and is made by echocardiography.

Benign cardiac tumors in childhood have an excellent prognosis when completely excised and appear to have a good short-term prognosis even when excision is incomplete. Symptomatic tumors often are both multiple and extensive, particularly in patients with tuberous sclerosis, who unfortunately, have a dismal long-term outlook. In such circumstances, surgery offers little benefit.

Case Report: A mother was bathing her 11-month-old baby. Suddenly the infant showed a worsening dyspnoea. Parents accompanied the baby to the emergency room immediately, but despite the reanimation manoeuvres, the doctor could only pronounce the death. The infant had a negative obstetric, remote and recent pathological

anamnesis, except for a documented fall two days before. Also the familiar history was negative for sudden death.

A complete postmortem examination was performed within 48 hours after death. The body was that of a regularly developed 11-month-old infant. External examination was insignificant, except for the presence of a little and superficial wound on the sternal region.

The internal examination revealed a pedunculated mass at the cardiac apex, a second superficial subepicardial neoformation at the posterior wall of the left ventricle and a third transmural nodule of the posterior wall of the left ventricle. A polyvisceral congestion, cerebral and pulmonary oedema, with a massive increase in lung weight were also evident.

The histological examination of cardiac specimens, stained with haematoxylin–eosin, showed a demarcation and separation of the three masses from the surrounding regular parenchyma. The striated muscle cells appeared diffusely vacuolated, enlarged, with round to oval slightly irregular nuclei and variable cytoplasmatic clearing. There were occasional spider cells; muscular tissue residues were also visible. The immunohistochemical studies documented a positive expression of myoglobin, Actin, Vimentin, Desmin, CD34. The result with antibodies Anti-Ki67, -S100 was negative. This microscopic examination was consistent with rhabdomyoma.

Cultural tests and toxicological screening resulted negative. There were no signs of sclerosi tuberosa.

It was concluded that the infant had three cardiac lesions consistent with a primary cardiac tumor, the rhabdomyoma, which caused the sudden death. In particular one tumoral mass occupied almost the whole posterior wall of the left ventricle, rising from the apex to the valvular level, so compromising the regular contraction of the left ventricle. The neoplasms probably had caused two days before a near syncopal episode that the parents erroneously referred as a fall.

Sudden Infant Death, Cardiac Rhabdomyoma, Benign Cardiac Tumors

G77 Suicide by Table Saw — A Slice of Interpretation

Jeffrey Racette, MD*, Baiyang Xu, MD, Todd M. Luckasevic, DO, Allegheny County Medical Examiner Office, 1520 Penn Avenue, Pittsburgh, PA 15222; and Abdulrezak M. Shakir, MD, Allegheny County and Karl E. Williams, MD, Office of the Medical Examiner - Allegheny County, 542 Fourth Avenue, Pittsburgh, PA 15219

The goal of this presentation is to illustrate an unusual means of suicide with a home radial arm circular table saw.

This presentation will impact the forensic science community by illustrating the need for close collaboration between the forensic pathologist and the scene investigators (in combination with careful photography) to elucidate the sequence of events and to rule out the involvement of other individuals in unusual cases involving violent, non-firearm related, means.

Introduction: Suicide represents a common manner of death in the United States. A painful means (with or without the expectation of a rapid loss of consciousness) are uncommon. The use of a electrical saws for suicidal purposes is documented in the literature, but remains a very rare event. The use of violent means of suicide is even more uncommon in individuals with no significant prior history of psychological disorder(s).

Case Presentation: The subject of this case is a 50-year-old Caucasian male who became recently depressed due to debt problems. The man and his wife had discussed the possibility of dying together in a murder-suicide. It is in question whether the wife reported a domestic assault on the same morning which she managed to escape from her husband, before calling the police. The decedent was found dead in his garage shortly thereafter on the morning of November 24, 2009.

The investigation of the scene revealed a plugged in table saw. The body was lying on a large pool of blood about five feet away from the table saw. The walls of the garage were extensively covered with blood spatter in a pattern of arterial spray. The table saw itself had been overturned and had blood on both the saw blade, and on the upper and lower surfaces of the saw.

The autopsy on the decedent noted an oblique, Y-shaped incised wound in the right side of his neck. The wound was located on the superior anterolateral aspect of the neck, beneath the right mandible and measured 14 cm in total length, 0.4 cm in width, and 3.5 cm in maximal depth. The edges of the wound are abraded along the superior margin and smooth along the inferior margin. The wound transected the right jugular vein and the right external carotid artery and penetrates into the right sternocleidomastoid muscle. The cause of death was exsanguinations due to the incised wound of the neck. Postmortem toxicology study was negative.

Discussion: Investigation was emphasis on ruled out the wife or others might have been involved in the death of her husband due to the initial findings at the scene, the absence of a suicide note and the unusual means used. Further interview of the wife revealed that decedent and his wife had a discussion of ending their own lives with a murder-suicide fashion. The 6-14 inch table circular saw used in this case had double protective features to prevent self injury. Further study indicated there is the possibility that the saw can be used by self to produce the similar injury as the decedent sustained. It can also be explained that people keep consciousness and moving their bodies within short of time after sudden loss of large amount of blood.

Conclusions: Suicide itself is much more common in individuals with long standing psychological problems, including bipolar mood disorders, depression, and schizophrenia. Violent means of suicide have been more closely associated with bipolar disorders with tendency towards self mutilating behavior. A differential thought process must be considered to interpret the pattern of events surrounding the scene of a death by violent means. Cooperation between the forensic pathologists, the police and crime scene investigators made it possible to reconstruct the unusual situation and to exonerate a third party.

Suicide, Forensic Pathology, Table Saw

G78 The Significance of Gross Adrenal Hemorrhage — Undiagnosed Waterhouse-Friderichsen Syndrome: A Case Series

Lee M. Tormos, MD*, Medical and Forensic Autopsy, Pathology and Laborat Medicine, 171 Ashley Avenue, Suite 309, MSC908, Charleston, SC 29425-9080; and Cynthia A. Schandl, PhD, Medical University of South Carolina, 171 Ashley Avenue, Suite 309, MSC-908, Charleston, SC 29425

After attending this presentation, attendees will understand the importance of finding gross adrenal hemorrhage at autopsy, and that further laboratory studies and clinical-pathologic correlation is warranted to identify the signs and symptoms of pre mortem adrenal dysfunction.

This presentation will impact the forensic science community by addressing how bilateral adrenal hemorrhage can complicate severe sepsis of various origins, not only severe meningococcemia. Clinical suspicion of sepsis and septic shock warrants clinical studies to diagnose adrenal hemorrhage and insufficiency. Undiagnosed adrenal hemorrhage will result in an unfavorable outcome despite adequate treatment.

Adrenal hemorrhage and clinical adrenal insufficiency is classically associated with meningococcemia as part of the Waterhouse-Friderichsen syndrome. It is proposed that non-traumatic adrenal hemorrhage in cases of sudden unexplained death are associated with

bacterial sepsis of various etiologies and that undiagnosed adrenal insufficiency may contribute to the fulminant clinical course.

Adrenal hemorrhage and resultant clinical adrenal insufficiency has been reported in literature as an uncommon complication of bacterial sepsis and is generally associated with an unfavorable outcome in the majority of cases. Other causes named in the literature include stress, anticoagulation therapy, and hypotensive events. Therefore, the finding of adrenal hemorrhage at autopsy is not necessarily associated with sepsis and premortem functional adrenal insufficiency, as is seen in Waterhouse-Friderichsen syndrome. Four cases of non-traumatic gross adrenal hemorrhage are identified in 800 consecutive forensic autopsies and are described and analyzed, with particular attention paid to the patient's signs and symptoms possibly secondary to adrenal failure and the clinical course. It was found that patients with this grossly identifiable adrenal hemorrhage die suddenly as a consequence of acute illness of several days duration. All subjects were males, of different ethnicities, and with ages ranging from 2 to 47. All subjects have a clinical history suggestive of sepsis. At autopsy the most relevant findings are in the lungs, where findings range from heavy, congested lungs to gross findings of necrotizing pneumonia with abscess formation and empyema. Postmortem cultures yielded positive results in three out of four cases, with *Staphylococcus aureus*, *Streptococcus pneumoniae*, and *Pseudomonas aeruginosa* determined to be the definitive agent and the underlying cause of death in each case respectively. The fourth case had a positive culture with yeast and a coagulase negative staphylococcus. No cases had a positive culture for *Neisseria meningitidis*. In each case, signs and symptoms compatible with premortem adrenal insufficiency were reported; in no instance was the adrenal hemorrhage clinically identified. The precise mechanism(s) of adrenal hemorrhage in sepsis or other initiating condition(s) is unclear. However, once adrenal hemorrhage ensues, significant morbidity and mortality may result from adrenal crisis including shock and death. The pediatric population is statistically at increased risk for this complication. In light of the clinical information and autopsy findings, a component of adrenal failure may have contributed to the grave consequences of infection. Herein, the causes and potential consequences are discussed of adrenal hemorrhage by reviewing a series of four cases in light of the available published literature and conclude that additional autopsy and clinical studies may be warranted to determine the clinico-pathologic correlation of this postmortem finding.

Adrenal Hemorrhage, Waterhouse-Friderichsen, Sepsis

G79 Metastatic Calcification of AV-Node as a Cause of Complete Heart Block and Death

Joseph K. White, DO, University of Colorado Denver School of Medicine, 660 Bannock Street, Denver, CO 80204; and Amy Martin, MD, Denver Office of the Medical Examiner, 660 Bannock Street, Denver, CO 80204*

After attending this presentation, attendees will have a better understanding of the mechanism, and the common and uncommon complications associated with dialysis-associated myocardial calcification.

This presentation will impact the forensic science community by increasing awareness of some of the possible complications of renal failure, such as myocardial calcification and conduction abnormalities, in individuals on dialysis.

Metastatic calcium deposition into soft tissue is a well documented phenomenon that occurs rarely in people treated with dialysis. The pattern of calcification and the organs involved is highly variable and thus the symptoms are myriad. A case is presented of a 37-year-old woman on nightly ambulatory peritoneal dialysis for 20 months. She had stage 4 renal failure due to uncontrolled hypertension. She presented to the hospital complaining of shortness of breath and cough of two days'

duration. She had not been feeling well enough at home to perform her dialysis for the past two days. At admission she had a GFR of 2, was hyperkalemic (6.3 mEq/L), anemic with thrombocytosis and leukocytosis (23.5 K/uL) and a left shift. She had developed a new third-degree heart block with a ventricular rate in the 30's. Her troponin-I was elevated at 1.56 ng/mL. Her total calcium was 9.4 mg/dL and her phosphorus was also elevated at 18.6 mg/dL for a calcium x phosphorus product of 174.8 mg²/dL². She was transferred to the ICU where she became asystolic for 5-6 seconds, but had a spontaneous return of circulation. A transvenous pacemaker was placed emergently with good capture and effective right ventricular pacing. However, she quickly became hypotensive, lost consciousness, and became pulseless. After 35 minutes of unsuccessful resuscitative efforts she was pronounced dead. The case was referred to the Office of the Medical Examiner due to her sudden and somewhat unexpected clinical decline.

At autopsy, the left ventricle demonstrated a uniform mottled pail-yellow process. The coronary arteries had thin, pliable vascular walls with widely patent lumina. Microscopic exam revealed widespread calcium deposits in the myocardium including the conduction system. There was also evidence of acute myocardial ischemia. Cardiovascular complications are the leading cause of death in patients with end-stage-renal-disease (ESRD). Derangements of calcium and phosphate metabolism are known to lead to soft tissue calcification. The calcification of the coronary arteries in patients with ESRD is a common cause of morbidity and mortality. The National Kidney Foundation recommends that the calcium-phosphate product be maintained below 55 mg²/dL² to minimize the risk of metastatic calcification of soft tissue and vasculature. In patients with a severely elevated calcium-phosphate product the deposition of calcium can be rapid. If the deposition occurs in the cardiac conduction system sudden cardiac death can occur without the presence of coronary artery calcification.

Pathologists should be aware of this potential complication of ESRD in cases of sudden death in patients with elevated calcium and phosphate or in cases in which the values were not obtained near the time of death or known at the time of autopsy.

Dialysis, Calcification, AV-Node

G80 Postmortem Interval and Cardiac Troponin Effect

Ziya Kir, MD, and Coskun Yorulmaz, MD, Istanbul University Cerrahpasa School of Medicine, Department of Forensic Medicine, Cerrahpasa, Istanbul, 34099, TURKEY; Murat Bolayirli, MD, Istanbul University Cerrahpasa School of Medicine, Department of Biochemistry, Cerrahpasa, Istanbul, 34099, TURKEY; Haluk Ince, PhD, Council of Forensic Medicine, Chairperson of the Council of Forensic Medicine, Istanbul, 34197, TURKEY; and Mete K. Gulmen, PhD, Cukurova University School of Medicine, Department of Forensic Medicine, Adana, 01330, TURKEY*

The goal of this presentation is to show the cardiac troponin effects in PMI and its value in daily forensic use.

This presentation will impact the forensic science community by demonstrating the statistical data of the cardiac troponins experimentally and the estimation of PMI accordingly and also the daily use of it.

In clinical practices, cardiac troponins (cardiac myofibril-specificproteins) are specific markers of myocardial damage. In addition, measurements of cardiac isoform of troponin are recognized as important tests in the postmortem diagnosis of myocardial necrosis when such a lesion is suspected but cannot be established. Previous studies have suggested the possible application of these markers in the postmortem diagnosis of acute myocardial infarction. However, some reports showed that elevated postmortem cardiac troponin I (cTnT) levels in cardiac tissue and pericardial fluid may reflect postmortem interval. Postmortem interval may provide valuable information for

evaluation cases in both criminal and civil law pursuits, for their elucidation as well. Time-since-death markers have lagged behind the progress in technology of the past years. Since the earlier attempts, failed to meet the definite postmortem interval, for variable reasons with much success, the postmortem biochemical changes in various body fluids and tissue have been tried for the estimation of time of death. The degradation of cardiac Troponin I in myocardial tissue and pericardial fluid has been investigated. The goal of this study is to investigate the potential use of myocardial tissue and pericardial fluid cTnI level as an estimator of postmortem interval. Cases selected from routine necropsies performed in the Council of Forensic Medicine, Istanbul. Samples were obtained from 98 deceased, where exact postmortem interval was known. Isolation of cTnI from heart tissue and pericardial fluid was chosen because it is found in a highly protected internal location.

The findings were elucidated according to patient records, scene of death, autopsy, and complementary toxicological and histological studies, depending on the probable intensity of myocardial damage and cause of death. No statistically significant difference was found between cause of death and titration alterations of cTnI in cardiac tissue and pericardial fluid specimens ($p>0.05$). On the other hand, alteration in the level of cTnI in the pericardial fluid dependent on the period of time after death showed statistically significant positive correlation ($r=0.523$ $p<0.0001$). Especially differentiation between period of first 12 hours after death and interval beyond could be established within confidence interval of 95% using the estimation of pericardial fluid cTnI level. Meaningful statistical correlation in between the pericardial effusion and cardiac tissue cTnI titrations ($r=0.427$ $p<0.0001$) was noticed. This result shows us the protein degrading effect of the PM autolysis to the pericardial effusion. This is a similar finding with the similar studies and it is very valuable to show the autolytic degradation instead of the reflection of the tissue necrosis. The positive correlation between the level of pericardial fluid cTnI and the postmortem interval and discriminative property of this marker for estimation of the postmortem interval should provide a superior tool for this purpose. The data presented demonstrates that this technique represents a major advance in time since death determination providing reliable quantitative biochemical markers from a protected organ versus estimates such as those based on direct temperature measurements.

Furthermore, it could be shown that cardiac tissue is not influenced by autolytic changes in the postmortem interval to a considerable extent. Although previous forensic pathological studies have suggested the possible application of cardiac troponins in the diagnosis of myocardial infarction, there appears to be insufficient data with regard to its influence of postmortem interval. These results suggest that immune enzymatic studies concerning postmortem differential diagnosis of myocardial infarction may provide considerably reliable data with probability of false positive results on a negligible level. In forensic medicine, there is a need for more sensitive biochemical markers for estimation of postmortem interval and diagnosis of myocardial injury. A study of the distribution of biochemical markers in different fluids is of great significance in postmortem diagnosis, because their distribution depends on the location of tissue damage and release kinetics. Further studies are required to compare these results and create the possibility for new conclusions.

Postmortem Interval, Cardiac Troponin I, Forensic Autopsy

G81 Ante- and Postmortem In-Human Cocaine Packs Detected by Computed Tomography

Patricia Mildred Flach, MD, and Steffen G. Ross, MD, Institute of Forensic Medicine, Center of Forensic Imaging "Virtopsy", Buehlstrasse 20, Bern, 3012, SWITZERLAND; Garyfalia Ampanozi, MD, Ulrich Preiss, MD, Tanja Germerott, MD, Gary M. Hatch, MD, and Michael Thali, MD, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND; and Michael Patak, MD, University of Bern, Radiology, Freiburgstrasse, Bern, 3010, SWITZERLAND*

After attending the presentation, attendees will understand how to detect intra-corporal cocaine packs on CT. The differences of body packing, stuffing, or pushing will be elaborated and the varying appearance of the packs in CT will be demonstrated. Further, the necessity of a tight collaboration of the custody ward, the forensic institute, and the radiology department will be shown.

This presentation will impact the forensic science community by raising awareness of the difficulties and pitfalls on CT imaging of drug mules, understanding the variety of drug containers, and the upcoming medicolegal issues.

Purpose: The goal of this presentation is to depict the findings on computed tomography (CT) in detection of concealed cocaine – filled packs in the alimentary tract of living and dead human transporters.

Materials and Methods: The study population consisted of 15 antemortem and one postmortem CT exams with detected intra-corporal cocaine containers. The images were assessed retrospectively by investigators with special training and experience in reading images of drug carriers. Radiological findings were compared with listed evidence in the feces or alimentary tract of each detained suspect or deceased victim.

Results: Cocaine-filled containers were detected by CT in each case. The appearance and morphologic shape were compared to the evidence secured on a custody ward or during autopsy. Window leveling from abdominal window to lung window of the CT images was crucial and allowed for correct diagnoses.

Conclusion: Reading CT images of drug mules needs special knowledge of the appearance of the various drug containers and of the important window leveling in order to detect even hypodense or tiny packs within the alimentary tract. A reliable and fast method such as CT is needed due to the limited space at custody wards to triage holding, discharge or transfer to regional prison. During the last years, forensic and medical issues have lead to an increasing number of if needed, judicially warranted CT examinations. Pre-autopsy postmortem scans allow for exact localization of incidental or suspected findings of foreign bodies such as in-human drug containers. Obviously, the radiologist needs to be well schooled in the appearance of the drug containers in order to diagnose those correctly – therefore a tight collaboration with the custody ward, the associated forensic institute and the radiology department is desirable.

Body Packer, Cocaine, CT

G82 Decomposition in a Closed Vehicle Environment in Southern Ontario

Shari L. Forbes, PhD, Helene LeBlanc, PhD*, Katelynn Perrault, BSc, and Alicia Bueter, BSc, University of Ontario Institute of Technology, 2000 Simcoe Street North, Oshawa, ON LIH7K4, CANADA*

After attending this presentation, attendees will understand the importance of chemical and entomological evidence associated with decomposing remains concealed in a closed vehicle environment. This

presentation will impact the forensic community by providing new information regarding the decomposition process in a vehicle trunk in southern Ontario and providing more accurate estimates of time since death in this unique environment.

A body placed in a closed vehicle environment will undergo a distinctly different process and rate of decomposition than a body placed in an outdoor environment. A closed vehicle has the potential to significantly affect decomposition processes by reducing entomological access to the body, increasing ambient temperatures, and promoting desiccation and mummification of the remains. In Canada, there is currently no published literature which has studied the effect of a closed vehicle environment on entomological activity and the chemical processes which occur during soft tissue decomposition. This information would be valuable to forensic pathologists and coroners when estimating time since death in forensic investigations involving decomposed remains recovered from a vehicle.

The goal of this study was to investigate the chemical process of soft tissue decomposition and the entomological evidence associated with a body placed in the trunk of a vehicle. The study was conducted in the southern region of Ontario, Canada during the summer months of June and July. Two pig carcasses of similar biomass were used in the study. The experimental carcass was placed in the trunk of a dark-colored vehicle and sealed. The control carcass was placed on the soil surface approximately ten meters from the vehicle. A data logger was placed in the vehicle to record temperature and humidity. A weather station was placed near the control carcass to record ambient temperature, humidity, and rainfall. Soft tissue samples were collected from the upper and lower torso region of the carcasses. Entomological evidence was collected directly from the carcasses and from pitfall traps surrounding the carcasses. Samples were collected at regular intervals until the carcasses reached the skeletonization or dry remains stage.

Decomposed soft tissue was analyzed using gas chromatography-mass spectrometry to determine the lipid degradation process and resulting fatty acid content within the samples. Unsaturated and saturated long-chain fatty acids were identified at all stages of the decomposition process. Variations in the lipid degradation pathways were evident between the experimental and control carcasses. Adult and immature insects were collected from the carcasses in order to determine the succession throughout decomposition. An important delay of insect colonization was observed in the vehicle as well as a significant decrease in species composition.

Observational measurements confirmed that the decomposition process was distinctly different in the closed trunk of the vehicle when compared to the decomposition process on the soil surface. The chemical, entomological, and environmental data provided additional confirmation of the distinct process in which a decomposing body will undergo in a closed vehicle environment. This information will be valuable to law enforcement agencies and forensic pathologists and may aid in providing more accurate estimations of time since death.

Forensic Entomology, Decomposition Chemistry, Closed Vehicle Environment

G83 Child Abusive Head Trauma in Portugal

Agostinho Santos, PhD, North Branch of the National Institute of Legal Medicine, Jardim Carrilho Videira, Porto, 4050-167, PORTUGAL; Liliana Santos, MD, Jardim Carrilho Videira, Porto, 4050-167, PORTUGAL; Teresa Magalhães, PhD, North Branch of the National Institute of Legal Medicine, Jardim Carrilho Videira, Porto, 4050-167, PORTUGAL; Francisco Corte-Real, PhD, Center Branch National Institute of Legal Medicine, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL; Jorge C. Santos, PhD, South Branch National Institute of Legal Medicine, R. Manuel Bento de Sousa, nº 3, Lisboa, 1150-219, PORTUGAL; and Duarte N.P. Vieira, PhD, Rua Antonio Jose de Almeida, No 117, Coimbra, 3000-044, PORTUGAL*

The goal of this presentation is to better understand how child Abusive Head Trauma (AHT) is managed in Portugal.

This presentation will impact the forensic science community by filling the void of epidemiology background concerning fatal AHT in Portugal, and will allow comprehensive knowledge of the Portuguese experience on this issue. Only then will it be possible to develop assertive and coordinated policies and strategies for action in this field in order to minimize the number of cases as well as its consequences. Until now, in Portugal, only isolated and non-articulated studies have been made on this issue, reflecting only loco-regional incidences or even only the numbers of one organization. For these reasons, it is not possible to infer what is really going on at a national level.

The absence of a systematic approach on child abuse (CA) makes it impossible to have the real knowledge of the prevalence and incidence of this problem in the Portuguese population. Currently there are no more than estimates of certain entities, certainly underestimating, from the Ministry of Justice, the *National Commission for the Protection of Children and Young People at Risk* (CNCJR), the *National Institute of Legal Medicine* (INML), the criminal police forces, the victims' support associations, or the health care services. Furthermore, the most important problem is that the referred data represents only a portion of incidences because frequently cases are not reported. However, gathering such sort of data is vital in order to find the proper and most suitable approach to these situations in Portugal.

In AHT cases, it was verified that in the last years there has been an important increase in the number of published reports in the international medical literature describing AHT (Hymel KP, 2002) and considering that it represents the most frequent cause of death due to CA, the main cause of traumatic death in children under 1-year-old (Duhaime AC e col, 1999) and the cause of significant morbidity, with up to 50% of survivors having permanent neurologic sequelae (Duhaime AC e col, 1996). Between 24% and 33% of traumatic brain injuries (TBI) hospital admissions in children under 2-years-of-age are from AHT (Duhaime AC e col, 1987; Dashti SR e col, 1999). The incidence of severe inflicted TBI in Scotland is 24.6 infants per 100 000 person-years which is comparable with epidemiologic data in the United States, where this incidence is 29.7 infants per 100 000 person years (Barlow KM, Minns RA, 2003; Keenan HT e col, 2003). In fact, it is known that for AHT up to 30% of the cases are difficult to be initially recognized (Jenny C e col, 1999), mainly because victims, almost under 2-years-of-age, cannot describe the abuse (Bechtel K e col, 2004), and because many cases are of mild or moderate severity (Berger RP e col, 2004).

However, in spite of all these difficulties, the various forms of AHT (including shaken baby syndrome (SBS)) are now well recognized and diagnosed in most countries (Barlow KM e col, 2005) which cases are being identified and reported; however, doesn't seem to be the case in Portugal. The intervention in a situation of CA can be initiated by multiple kinds of professionals of different institutions. Among those professionals teachers, childhood educators, physicians (mostly pediatricians, practitioners, and gynecologists), nurses, psychologists, policemen/women, and social workers are highlighted. According to the Portuguese Criminal Law these professionals are mandatory reporters

and according to the Protective Law and the Deontological Code (in what physicians concern), they have the duty to report suspected cases. The problem is that there are numerous initial referral sources, multiple professionals (with different formations and awareness, presenting possible "prejudices" and non-official instructions and forms for reporting cases.

In Portugal there are no published data concerning non-fatal AHT, and this work represents the first national approach regarding fatal cases due to this kind of abuse. Analyzing the fatal cases of suspected CA observed in the medico-legal services of Portugal, between 2005 and 2008, it has been verified that AHT represented only 12.5% of the suspected CA causes of death (1.2 infants per 100,000 person years), despite in the literature, AHT represents the most frequent cause of death due to CA. The single diagnosed case of SBS will be presented.

These Portuguese results must be carefully analyzed and compared with other foreign studies, which are completely different. According to the facts, it is presumed that an important number of cases of AHT is still undiagnosed or underdiagnosed in Portugal (being diagnosed only when specifically looked for), or remain unreported or underreported by the health professionals.

Child Abuse, Abusive Head Trauma, Shaken Baby Syndrome

G84 Gravesoil Microbial Community Structure During Carcass Decomposition

Amy E. Maile, BS, and David O. Carter, PhD, University of Nebraska, Lincoln, Department of Entomology, 202 Entomology Hall, Lincoln, NE 68583-0816; and Rhae A. Drijber, PhD, University of Nebraska-Lincoln, Department of Agronomy and Horticulture, 279 Plant Sciences Hall, Lincoln, NE 68583-0915*

After attending this presentation, attendees will understand that there is potential for the use of fatty acids to characterize gravesoil microbial community with the ultimate goal of estimating postmortem interval (PMI).

This presentation will impact the forensic science community by the development of an additional method to determine extended PMI. This additional method can be used in conjunction with other methods to estimate PMI, such as forensic entomology.

Estimating PMI is important for every death investigation. It allows for the acceptance or rejection of alibis as well as helping to identify victims. At present forensic entomology is arguably the most reliable means to accurately estimate PMI at outdoor death scenes. However, active blowfly larvae, which are critical to insect based estimates of PMI, can leave a body as early as ten days postmortem. When active blowfly larvae are not present at a death scene, forensic science is often ill equipped to estimate PMI accurately.

A controlled laboratory experiment was conducted to determine if soil microbial ecology has the potential to be used as an estimator of PMI. To do this incubation units were constructed that comprised petri dishes (150 mm x 25 mm) filled with 360 grams (g) of washed sand inoculated with 40 g of Pawnee clay loam soil. Soil was collected from Nine Mile Prairie, a natural tall-grass prairie ecosystem, which is located approximately nine miles northwest of Lincoln, Nebraska. Soil of the Pawnee series is a fine, montmorillonitic, mesic Aquic Argidoll (Mollisol). These incubation units were calibrated to a water holding capacity of 55% and left to equilibrate for seven days in plastic containers (20 cm x 34 cm x 11 cm) that contained methanol washed pea gravel and distilled water (100 ml) to regulate humidity.

After seven days, a mouse carcass (killed with carbon dioxide) was placed on its left side on the inoculated sand within 30 minutes of death. Nylon mesh (0.1 mm x 0.1 mm) was then used to cover the plastic container to prevent insect colonization. The temperature was kept at approximately 20°C during the experimental period and the water

content of the inoculated sand was maintained at 55% every 3-4 days by adding distilled water. Carcass decomposition was monitored every 24 hours for 35 days using a decomposition scoring system. In addition, carcass mass loss was measured at 7, 14, 21, 28, and 35 days postmortem. A destructive harvest design was used to avoid the influence of carcass disturbance on the rate of decomposition. Following carcass harvest, inoculated sand was collected and analyzed for lipid phosphorus, fatty acid methyl esters, pH, total nitrogen, and total carbon. This experiment was replicated four times and controls (inoculated sand with no carcass) were used. Results and discussion will be presented to demonstrate the effectiveness of soil microbial ecology to act as an estimator of PMI.

Forensic Taphonomy, Extended Postmortem Interval, Ecology

G85 Laceration of the Inferior Vena Cava Following Blunt Abdominal Trauma in a Case of Child Abuse

Carlos F. Chavez-Arias, MD, Puerto Rico Institute of Forensic Sciences, PO BOX 11878, Caparra Heights Station, San Juan, PR 00922-1878; and Javier G. Serrano, MD, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921*

The goal of this presentation is to describe and discuss a child abuse case with multiple blunt injuries that include blunt abdominal trauma with laceration of the inferior vena cava (IVC).

This presentation will impact the forensic science community by demonstrating an uncommon finding resulting from blunt trauma in a child abuse case.

The majority of injuries to the IVC are due to penetrating trauma. Only 10% of these injuries will be caused by blunt trauma. This may be due to the fact that the IVC is a retroperitoneal organ and is therefore relatively protected from injury. Injury as a result of blunt trauma would only result from a force of great magnitude.

This case involved a 22-month-old, Hispanic, male infant who arrived dead to the emergency room. The stepfather stated that he witnessed the infant falling to the ground while walking and hitting his head against the adjacent wall. The stepfather tried to resuscitate the child but he continued to lose consciousness. He waited for the infant's mother to arrive home and they took the child to the emergency room. His social history revealed that he lived with his mother and the stepfather and there was no family history of child protective services involvement. At the time of the event, he was under the stepfathers' care. The stepfather denied any physical abuse against the child.

At autopsy the body corresponded to a well-developed and well-nourished male infant. He was 33 inches tall and weighed 31 pounds. External examination of his face and head showed multiple recent contusions and abrasions over the face and scalp. Multiple foci of subgaleal hemorrhage were present over the skull. The brain had mild subarachnoid hemorrhage over the left parietal and occipital lobes. Examination of the brain disclosed no other trauma. The head had no fractures. The torso also revealed multiple recent contusions. The abdomen was moderately distended. After entering the peritoneal cavity, 150 mL of liquid blood and 35 grams of blood clots were noted. There was a laceration to the proximal suprahepatic segment of IVC with presence of blood clots adjacent to the laceration. Moderate hemorrhagic infiltrate was present in the subintimal layer of the IVC along the supradiaphragmatic segment of the vein extending to the right atrium of the heart. Gross examination of the abdominal viscera found no other source of bleeding. The right pleural space had 40 mL of liquid blood. The right and left lungs had multiple contusions. Small lacerations were present next to the hilum of the right lung. Examination

of the extremities showed multiple recent contusions and no fractures. Toxicological evaluation was negative for alcohol, cocaine, opioids, and cannabinoids. The cause of death was blunt force injuries and the manner of death was ruled a homicide.

Intra-abdominal hemorrhage is most commonly associated with a clear history of trauma. In young children, the liver and spleen are the most common abdominal viscera to sustain a traumatic injury. Lacerations of the inferior vena cava resulting from blunt trauma are relatively rare, but extremely serious with a high mortality and may be difficult to repair. The majority of injuries of the IVC are due to penetrating trauma and only a small percentage is caused by blunt trauma. Lacerations to the IVC are uncommon injuries in the pediatric population. Lacerations of this vessel indicate a force of great magnitude with a profound level of injury. The presented case has evidence of blunt trauma in multiple regions of the body. The abdomen and thorax were the most severely affected regions. The unique feature of this case is the finding of IVC laceration with no other abdominal viscera involvement. In this case intr-thoracic and intra-abdominal tensional forces produced by blunt trauma to the torso could explain the lacerations of the IVC and hilar area of the right lung.

Laceration of Inferior Vena Cava, Blunt Trauma, Child Abuse

G86 Inferior Vena Cava Compression: A Possible Mechanism for Arrest Related Death

Jeffrey D. Ho, MD, Hennepin County Medical Center, Department of Emergency Medicine, 701 Park Avenue South, Minneapolis, MN 55415; Donald M. Dawes, MD, Lompoc Valley Medical Center, 1515 East Ocean Avenue, Lompoc, CA 93436; and Johanna C. Moore, MD, and James R. Miner, MD, Hennepin County Medical Center, Department of Emergency Medicine, 701 Park Avenue South, 1431 Lakeview Avenue South, Minneapolis, MN 55415*

After attending this presentation, attendees will understand a potential pathophysiologic mechanism of arrest related death (ARD) not previously studied or discussed in the literature.

This presentation will impact the forensic science community by providing a possible explanation for sudden, arrest-related death that is not yet established in the literature.

The physiology of sudden ARDs proximal to restraint has not been elucidated. Prior work has not suggested a relationship between position, restraint, or thorax compression up to 50 lbs with regard to clinical impact on respiration. However, the impact of these variables on Central Venous Return (CVR) has not been studied. Decreased CVR is a theoretical concern in a subject with tachycardia from resistive exertion, mental excitement, or sympathomimetic ingestions. A sudden change in CVR could cause an acute decrease of cardiac preload leading to possible decreased coronary artery perfusion pressure and ischemia or the induction of a maladaptive neuro-cardiogenic reflex. This, in turn, could lead to a brady-asystolic cardiac arrest. This study used ultrasound to measure the size of the Inferior Vena Cava (IVC) as a surrogate marker of CVR when positional change and thoracic compression occurs.

This was a prospective study of human volunteers. Subjects had ultrasounds of their IVC in transverse and longitudinal planes performed in four positions. Maximum and minimum measurement values were obtained in each position after accounting for respiratory variability. The four positions were: (1) standing; (2) lying prone; (3) lying prone with 100 lbs of weight applied uniformly to the upper back; and, (4) lying prone with 147 lbs of weight applied uniformly to the upper back. The weight was meant to simulate thoracic compression during a restraint procedure. A custom table and weight mechanism was used to allow access to visualize the IVC in the prone position and to apply the weight

uniformly to all subjects. IVC values were measured with a handheld ultrasound with a phased array (5-2MHz) transducer, operated by an RDMS sonographer. Data were analyzed using descriptive statistics and k sample for equality of medians test.

There were 24 subjects that completed the study protocol. The median (interquartile range) IVC measurements for all positions are as follows:

- Longitudinal maximum was 1.86 cm standing (1.57-2.16), 1.67 cm prone (1.05-2.26), 1.205 cm with 100 lbs compression (0.83-1.58), and 0.805 cm with 147 lbs compression (0.46-1.29), ($p < 0.0001$).
- Longitudinal minimum was 1.21 cm standing (1.01-1.51), 1.14 cm prone (0.64-1.61), 0.70 cm with 100 lbs compression (0.45-1.02), and 0.28 cm with 147 lbs compression (0.0-0.79), ($p < 0.0001$).
- Transverse maximum was 1.63 cm standing (1.43-1.93), 1.45 cm prone (1.17-2.02), 1.12 cm with 100 lbs compression (0.76-1.65), and 0.74 cm with 147 lbs compression (0.46-1.13), ($p < 0.0001$).
- Transverse minimum was 1.18 cm standing (0.93-1.39), 1.01 cm prone (0.77-1.47), 0.38 cm with 100 lbs compression (0.0-1.15), 0.31 cm with 147 lbs compression (0.0-0.52), ($p < 0.0001$).

There was significant difference between the IVC size in the longitudinal and transverse planes at maximum and minimum between all positions. The IVC size was greatest while standing. It became sequentially smaller with prone positioning and application of weight force. It was smallest while lying prone with 147 lbs of thorax compression. These findings support a possible pathophysiologic mechanism of ARDs that has not previously been reported. Further study in this area is recommended.

Arrest Related Death, In-Custody Death, Sudden Death

G87 Intra-Abdominal Hemorrhage Associated to an Intrapartum Rupture of the Umbilical Cord: A Case Report

Carlos F. Chavez-Arias, MD, Puerto Rico Institute of Forensic Sciences, PO BOX 11878, Caparra Heights Station, San Juan, PR 00922-1878; and Javier G. Serrano, MD, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921*

The goal of this presentation is to describe and discuss a case of an intrapartum rupture of the umbilical cord leading to an intra-abdominal hemorrhage and newborn death.

This presentation will impact the forensic science community by demonstrating an uncommon case of intra-abdominal hemorrhage and death of the newborn as a complication of the rupture of the umbilical cord in a precipitous delivery.

Intra-abdominal hemorrhage in the newborn is uncommon. Bleeding from umbilical vessels in the cord can occur in the perinatal period, the predisposing factors being a short cord, varices, velamentous insertion of the cord, or true knot of the cord. Even more uncommon is bleeding secondary to rupture of the umbilical cord.

A 25-year-old gravida 6, para 4, came in active labor at 36 6/7 weeks of gestation. The mother had a late prenatal care and vaginal infection. The case was complicated at delivery due to violent expulsion of the baby girl who was caught by the physician attending the delivery. The umbilical cord ruptured causing hemorrhage to the baby and the mother. Apgar scores were 1, 4, and 6 at 1, 5, and 10 minutes, respectively. The baby was in respiratory distress, pale with poor response to bag-mask ventilation. Neonatologist intubated the baby in delivery room and she was transferred to Neonatal Intensive Care Unit (NICU). Initial work up showed blood gases results as follows: PH 7.35, pCO₂ 32 mmHg, and pO₂ 54 mmHg. Hemoglobin was 15.7 and

Hematocrit 44.1%. Skeletal survey was negative and Head Ultrasound showed mild left ventricle dilation and no evidence of intraventricular hemorrhage. The next day the baby continued with respiratory distress with significant anemia, Hb was 10.9 and Hct 30.4%. Despite blood transfusions and other therapeutic measures the baby remained critically ill with marked hypoxia and poor perfusion. On the 3rd and 4th days at NICU, a tense abdomen was noted with paleness below the level of the diaphragm and plethoric upward, suggestive of compartment syndrome secondary to aortic compression due to hemoperitoneum. A Penrose drain was placed for abdominal decompression but patient did not improve and died.

At autopsy the body corresponded to a female preterm baby. She was 18.7 inches tall and weighed 6.2 pounds. External examination did not show signs of trauma. Among the medical intervention there was an umbilical arterial catheter in place without disruption of the artery. After entering the peritoneal cavity, 30 ml of liquid blood was noted and some blood clots in the right subdiaphragmatic area. As the peritoneal cavity was entered, it was noted that the umbilical vein and falciform ligament were disrupted. A hematoma was noted at the site of disruption adjacent to the peritoneal surface. The liver had a non-ruptured subcapsular hematoma at the anterior and superior surfaces of the left lobe without lacerations of the parenchyma. The rest of the thoracic and abdominal organs had no signs of trauma. The brain had no hemorrhages or lesions. The placenta weighted 509 grams with a centrally inserted umbilical tri-vascular cord that measured 11 x 1.3 cm. On microscopic examination revealed acute chorioamnionitis. Toxicological evaluation was negative for alcohol, cocaine, heroin and cannabinoids.

The normal umbilical cord resists trauma, the forces of normal delivery, and does not bleed. However, in dysmature infants the cord is thin and weak and liable to rupture. In precipitous delivery, a rapid increase in cord tension can rupture the fetal aspect of the cord. Short or entangled cords may rupture, as may abnormal cords, such as those with velamentous insertion on the placenta. Although birth trauma involving intra-abdominal organs is also uncommon, it must be suspected in the newborn with pallor, abdominal distension, anemia, and shock without evidence of external blood loss, intracranial hemorrhage, or gastrointestinal bleeding. The size of the infant and the presentation at delivery are important risk factors for abdominal trauma. The liver is the abdominal organ most commonly injured in the birth process. Subcapsular hematomas rather than hepatic lacerations are more apt to occur.

In this case, several recognizable factors increased the risk of umbilical cord rupture, such as prematurity of the infant combined with a precipitous delivery. Disruption of the umbilical vein represented the source of intra-abdominal bleeding. The subcapsular hematoma could be attributed to the abdominal birth trauma or be part of the tensional injury secondary to the rupture of the umbilical cord.

Umbilical Cord Rupture, Intra-Abdominal Hemorrhage, Subcapsular Hematoma

G88 Aortic Aneurysm Rupture Into the Lung With Formation of Pseudoaneurysm

Carlos F. Chavez-Arias, MD, Puerto Rico Institute of Forensic Sciences, PO BOX 11878, Caparra Heights Station, San Juan, PR 00922-1878; and Javier G. Serrano, MD, and Edda Rodriguez, MD, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921*

The goal of this presentation is to describe and discuss a case of aortic aneurysm rupture into the lung parenchyma with formation of pseudoaneurysm.

This presentation will impact the forensic science community by demonstrating a rare complication of a thoracic aortic aneurysm.

Rupture of thoracic aneurysm into the lung with formation of pseudoaneurysm is rare. There are few reported cases discussing the diagnostic approach and management of this complication. In the researched literature there are no reports of this complication as an autopsy finding.

This case involved 72-year-old, black Hispanic male with history of poorly controlled arterial hypertension and two cerebrovascular accidents. He was a heavy smoker and occasional alcohol drinker. He was found lying supine on the street. The paramedics pronounced him dead at scene after evaluation. There were no signs of violence or foul play at scene.

At autopsy the body corresponded to a well-developed and well-nourished adult male. He was 66-inches tall and weighed 152 pounds. External examination showed no significant evidence of trauma. Reflection of the skin over the anterior thorax showed no significant hemorrhagic infiltrates or fractures. On internal examination the left thoracic cavity contained 700 grams of clotted blood and 600 ml of liquid blood. Examination of the thoracic organs revealed that the source of bleeding was a ruptured aneurysm of the middle third of the descending thoracic aorta. The aortic aneurysm ruptured into the parenchyma of the lower lobe of the left lung forming a pseudoaneurysmatic structure that contained a fusiform mural organized thrombus that measured 16.5 x 6.5 x 5.0 cm. Cut sections of the affected pulmonary parenchyma demonstrated that the cavitary lesion was surrounded by a well formed and circumscribed wall. Sections of the thrombus showed a surface with a multilayered arrangement. Focal areas of hemorrhage were present in the pulmonary parenchyma surrounding the cavity. The aorta showed severe atherosclerosis with calcification and focal ulceration of the atherosclerotic plaques. Histopathologically the aorta had no evidence of inflammation; however, degenerative changes were recognized near the possible rupture site. The heart weighed 300 grams and had mild left ventricular hypertrophy. The rest of the thoracic and abdominal organs had no remarkable macroscopic pathology. Postmortem toxicological evaluation was negative for alcohol, cocaine, opioids, and cannabinoids. Serological test for syphilis was negative.

Reports of patients with aortic aneurysm rupturing into the lung with formation of pseudoaneurysm are few. There are no reported cases in the researched literature describing the presence of this condition as an autopsy finding. An aortic aneurysm or dissection that ruptures into the lung parenchyma or erodes into a bronchus can lead to acute, massive hemoptysis, hemothorax and death. This case is particular because the aneurysm ruptured into the visceral pleura and lung parenchyma forming a pseudoaneurysmatic structure where the blood lodged. Two factors appeared to combine and contribute in the formation of this pseudoaneurysmatic structure, delaying the free extravasation of blood to the pleural cavity and imminent death. First is the anatomic location of the aortic aneurysm. In this case the aneurysm was located in the mid portion of the descending segment, adjacent to the medial aspect of the lower lobe of the left lung. The second factor is the elasticity of the lung parenchyma that cushioned the aortic aneurysm wall, allowing a slow passage of blood with formation of the cavity. Rupture and extravasation of blood to the pleural cavity occurred when the intracavitary pressure exceeded the elastic capacity of the tissues surrounding the pseudoaneurysmatic structure. Fibrous tissue attachment between the lung and aorta could have also played a role, but it was not clearly demonstrated at autopsy.

Aortic Aneurysm, Pseudoaneurysm, Lung Parenchyma

G89 Is DNA Purified From Forensic Autopsy Material Suitable for Molecular Biological Studies?

Iana Lesnikova, PhD*, Department of Forensic Pathology of University of Aarhus, Denmark, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Jakob Hansen, PhD, Department of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; and Jytte B. Lundemose, Department of Forensic Pathology, University of Aarhus, Denmark, Brendstrupgaardsvej 100, Aarhus N, AK 8200, DENMARK

After attending this presentation, attendees will understand more about the suitability of DNA, purified from forensic autopsy samples for advanced molecular research.

This presentation will impact the forensic science community by providing information about how decomposition and time from death to autopsy affects the usability of DNA for molecular studies. Knowledge about the degree of DNA fragmentation and degradation is an important tool for planning of future molecular biological studies.

The quality of molecular-biological studies obviously depends on the tissue in which the markers must be investigated. At forensic laboratories, a large number of frozen, biological samples are stored (collected at the autopsies), which can be used as templates for molecular biological studies. These samples are extremely valuable for all types of molecular biological studies in both diagnostic and research purposes. The decomposition and thereby the following changes in quality of DNA occur shortly after death. Degradation and fragmentation of DNA purified from autopsy material depends on several factors, such as time since death to autopsy, the degree of postmortem changes, the keeping of the corpse, external and environmental influences, storage of samples, and the addition of the chemicals to blood samples and other tissues for storage. It is believed there are no studies on this issue. The current study is a pilot for a major project, which is to define the molecular biological markers for sudden unexpected death. The suitability of purified DNA from tissues taken at autopsies including frozen blood with or without additional chemicals and paraffin embedded and frozen tissue is validated, as template for molecular biological studies in order to define the main risk factors for DNA fragmentation and degradation. By using PCR primer sets that amplify DNA fragments of varying length and DNA extracted from tissue samples with different degree of postmortem decomposition. Using the internal autopsy database the study group is defined consisting of tissue samples without signs of decomposition of tissue, with moderate decomposition of tissue and with severe decomposition. Frozen tissue samples of the detected cases (blood samples and muscle tissue) are available as well as frozen blood samples with the addition of potassium fluoride. DNA from tissue samples were purified using commercially available kits. Ten different PCR primer sets were designed to amplify 100 to 1000 basepair long fragments of human genomic DNA. PCR products were analyzed by agarose gel electrophoresis and ethidium bromide DNA staining.

Preliminary results suggest that the degree of fragmentation and degradation of DNA after death increases corresponding to grade of decomposition of tissue. The lengths of DNA fragments in samples with high grade of decomposition are significantly shorter than in samples without decomposition of tissue. It was possible to generate DNA fragments of at least 1,000 basepair lengths from samples taken from individuals that died within one week before autopsy was performed. On the other hand DNA samples from individuals that died at least two weeks before autopsies only could generate PCR product up to 600 basepair long.

Validation, DNA Fragmentation, Tissue Decomposition

G90 Evaluation of a New Approach for Estimating the Postmortem Interval Based on the Direct Skin Surface Analysis Using FTIR Spectroscopy

Liliana Santos, MD*, Jardim Carrilho Videira, Porto, 4050-167, PORTUGAL; João Lopes, PhD, Faculty of Pharmacy, Rua Aníbal Cunha 164, Porto, 4050-047, PORTUGAL; Agostinho Almeida, PhD, 2REQUIMTE, Department of Chemistry-Physics, Faculty, Rua Aníbal Cunha 164, Porto, 4050-047, PORTUGAL; and Agostinho Santos, PhD, and Teresa Magalhães, PhD, North Branch of the National Institute of Legal Medicine, Jardim Carrilho Videira, Porto, 4050-167, PORTUGAL

The goal of this presentation is to determine with accurate methods the Postmortem Interval (PMI).

This presentation will impact the forensic science community by facing one of the main issues in forensic sciences, the estimation of time since death (postmortem interval). Most methods currently employed have considerable inaccuracy. To be able to determine PMI is one challenge that can change a forensic investigation, and give answers, that until now were not properly supported in court.

The estimation of postmortem interval is a main issue in forensic sciences. Most methods currently employed have considerable inaccuracy.

Most of these methods are based on medical knowledge. With this work we intend to solve a forensic problem with the help of other areas of science not usually involved in medical studies.

The interaction of infrared (IR) electromagnetic radiation with the matter is a widely established technique to probe the chemical composition of materials.

The IR spectrum is divided into three zones; near- (14000-4000 cm⁻¹), mid- (4000-400 cm⁻¹) and far-infrared (400-10 cm⁻¹). The mid-infrared (MIR) region is used to analyze the fundamental vibrations of molecules and is strongly absorbed so materials have to be analyzed as thin films or in small path length cells (e.g., milk analysis).

Near-infrared (NIR) spectroscopy is based on molecular overtone and combination vibrations, which are forbidden by the selection rules of quantum mechanics. This means that NIR can penetrate much further into materials than MIR. This makes NIR very useful in probing bulk material with little or no sample preparation.

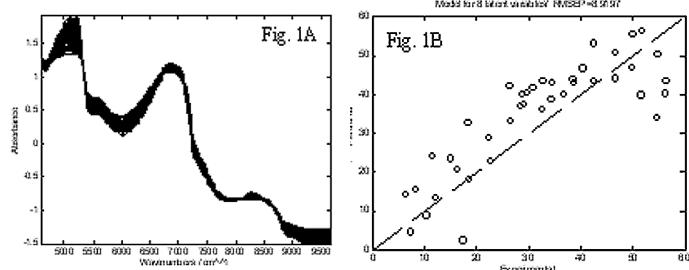

Because NIR probes the overtone and combination bands the spectra are usually very complex. Individual bands can not be assigned to specific features as with MIR. This means multiple wavelength (multivariate) calibration techniques are used to extract structural information. The design of powerful software packages, such as PLSplus/IQ, allows users with minimal chemometric experience the opportunity to generate and maintain their own calibration models without relying on general models from a third party that are not specific to their materials.

The increased processing power of computers has allowed the introduction of Fourier Transform (FT) infrared analyzers. Prior to this technology instruments either had to either use filters to look at the absorption of specific wavelengths or use diffraction gratings to scan through the wavelengths and measure the changing absorptions. FT technology uses interferometers that allow all the information at all wavelengths to be collected simultaneously. This means much more information can be collected in a shorter time.

Fourier transform near-infrared (FT-NIR) spectroscopy is an analytical technique that has gained great popularity in recent years. It is an effective tool for investigating chemical changes at molecular level and its major strengths include fast and easy equipment operation, good accuracy and precision, and the potential to perform nondestructive analyses. In its reflectance mode, FT-NIR spectroscopy is widely used to study, for example, the human skin and other tissues. And in the last

few years, using fiber-optic technology, the direct real-time in situ analysis became possible.

The utilization of FT-NIIR spectroscopy is being studied here to directly test the human skin in order to, in combination with chemometric data analysis (PCA – principal component analysis; PLS – partial least-squares models), look for possible surface chemical changes occurring after death that may correlate with PMI. Studies performed to date (20 cases) showed promising results. Figure 1A shows typical spectra obtained from six corpses in the 48 hours postmortem period and Figure 1B shows the correlation between the predicted PMI versus the known (real) time since death.

This study shows the usefulness of coupled with chemometric data analysis for estimating PMI, and the importance of the interaction between different areas of knowledge.

Postmortem Interval, FTIR Spectroscopy, Accuracy

G91 Unusual Style Cut Throat Injury: A Case Report

Suresh K. Shetty, MD*, Kasturba Medical College, Light House Hill Road, Mangalore, 575001, INDIA

After attending this presentation, attendees will understand the circumstances and possibilities of injuries in a rare case of self-inflicted cut throat injury.

This presentation will impact the forensic community by helping officials responsible for the maintenance of law and order to administer justice.

Suicide is one of the leading causes of death in the world. The incidence and pattern of suicide vary from country to country where cultural, religious, and social values play a vital role. Hanging, poisoning, drowning are the common methods of committing suicide. Suicide by incising one's own throat without hesitation marks remains a rare, and only few cases have been reported in forensic literature. An unusual and rare case of self-inflicted cut throat injury of a 45-year-old ex-military man without tentative cuts over the neck, which has resulted from a curved sharp weapon is presented.

A case report of self-inflicted cut throat injury without tentative cuts, a rare event is presented. Such cases are rare to be reported in forensic literature. It is recommended that medico legal death investigators be aware and familiar with such injuries in a detailed autopsy, which may ultimately prove or disprove the case, which may be of significant value to the investigating authority.

Self-Inflicted, Cut Throat Injury, Hesitation Marks

G92 Mass Fatality Management: A Multi-National Perspective

Ann H. Ross, PhD, North Carolina State University, Department of Sociology & Anthropology, Campus Box 8107, Raleigh, NC 27695-8107; and Jason H. Byrd, PhD*, Maples Center for Forensic Medicine, University of Florida, 4800 Southwest 35th Drive, Gainesville, FL 32608

After attending this presentation, attendees will understand the challenges faced a multi-national recovery and identification effort.

This presentation will impact the forensic science community by presenting lessons learned from the field in a multi-national mass fatalities incident, which can be applied to a future incidence response.

In response to the Haiti Earthquake, several international organizations responded to assist in fatality management and repatriation of non-Haitian human remains. Each of the fatality management and response organizations was dispatched by a governmental agency, but with little coordination between the organizations. Initially, the prohibitive conditions of an entire Haitian infrastructure in disarray and the extreme difficulty of providing for the logistical requirements of supporting a deployable morgue unit without local support was the primary factor limiting human identification efforts. However, difficulty in determining jurisdiction and logistics of repatriation of multi-national citizens became one of the primary difficulties in the response effort. A major complexity in the recovery and victim identification of foreign nationals was the number of independent countries on the ground attempting to identify their own citizens for repatriation. Another major factor was the actual recovery of the victims that were buried under tons of rubble, which were a safety hazard for recovery personnel.

Not only was the logistical aspect of this operation complex, but the recovery and initial identification of the multi-national victims was extremely difficult. This is the first global mass fatality incident where an attempt had to be made to determine the nationality of the victims prior to recovery to ensure accurate identification, repatriation and disposition of the remains. The coordination of antemortem biological information was crucial to this effort and it took a great deal of coordination between countries.

This presentation will discuss how to more effectively coordinate a mass fatality response in the event of future disasters involving multi-national populations from multiple countries with varying capabilities for fatality response as well as the complexity of victim identification in this scenario.

Fatality Management, Mass Disaster, Mortuary Operations

G93 Improving Evidence and Victim Recovery Protocols at the Mass Fatality Incident

Dennis C. Dirkmaat, PhD*, Luis L. Cabo-Pérez, MS, Michael W. Kenyhercz, MS, Allison M. Nesbitt, MS, Alexandra R. Klales, MS, and Erin Chapman, MS, Mercyhurst College, Department of Applied Forensic Sciences, 501 East 38th Street, Erie, PA 16546

After attending this presentation, attendees will understand problems faced by coroner and medical examiners relative to their responsibility to properly recover and identify plane crash victims. Attendees will be presented with effective strategies and protocols for dealing with these scenes.

This presentation will impact the forensic science community by describing efficient and effective evidence and victim recovery protocols applicable to large-scale, widely-dispersed mass fatality scenes.

The crash of a major airliner results in an extremely chaotic situation. After the first responders have dealt with survivors and fire resulting from the crash, the processing of the scene can commence. The primary goals of this processing effort are: (1) determining the cause of

the crash; (2) comprehensively recovering the victims and their personal effects; (3) determining the identity of all of the biological tissue; and, (4) removing all of the debris from the site.

With respect to the first goal, in the United States; if the cause is likely accidental (vehicular malfunction or human error), the National Transportation Safety Board (NTSB) will be in charge of the investigation. If it is instead determined that criminal intent may have been involved, the Federal Bureau of Investigation (FBI) will take custody of the scene.

The efforts of both the NTSB and FBI are focused on the non-human evidence at the scene. The recovery, identification and interpretation of the human remains (Goal 2) are the province of the Medical Examiner/Coroner (ME/C). While nearly all ME/C offices can deal with the morgue component of victim identification on their own or, they can request the services of federal groups such as DMORT, most offices do not possess the training, expertise, experience, or protocols to deal with a large scale scene containing the highly fragmented and commingled remains of large numbers of victims. This presentation will demonstrate that the best approach to the processing of outdoor crime scenes, especially large-scale scenes such as a plane crash, is to employ forensic archaeological methods. A new set of protocols for the processing of large-scale disaster scene will be presented.

The new protocols are based on the Weldon Spring protocols developed during the past decade (Dirkmaat and Hochrein 2000). The Weldon Spring Protocols are based on a systematic sequence of search, documentation, and recovery methods that is intended to result in the most efficient and effective scene processing effort. By effectiveness we refer to the proportion of physical and contextual evidence identified, documented, and recovered at the scene, while efficiency relates to the time and personnel required for effective recovery completion under a particular protocol. The goal of the present study was to optimize these two factors through the logistic and technological enhancement of the Weldon Spring protocols. To attain this, different technological configurations, affecting all the components of the protocol, from evidence location to data acquisition and recordation, were developed and tested in terms of their efficiency and effectiveness at real forensic cases and realistic mock scenes. Comprehensive guidelines for needs assessment and decision-making, targeting the identification and resolution of trade-offs related to technology availability and amortization, budgetary and personnel constraints, and training were also developed, in an attempt to offer different configuration alternatives to fit the needs and resources of a wide array of agencies without significant effectiveness losses.

The technological enhancements include high-resolution GPS units for the quick recordation of precise spatial recording, bar code scanning for data entry and sharing, and the utilization of wireless networks at the scene. The combination of these elements resulted in a reduction of recording times from minutes to just a few seconds, higher data integrity, with a standardization of evidence codes and the virtual elimination of any risk of reference duplication. This translates into an almost automatic coordination of all the recovery teams involved, in a manner that not only reduces the amount of time required by each team to locate, map, document and recover each evidentiary item, but also allows more teams to be deployed simultaneously at the scene.

Mass Fatality Incident, Forensic Archaeology, Victim Recovery

G94 Telluric Movements of Death: The Cemetery of Gargano's Mafia Inside the Ravine of Zazzano (Foggia, Italy)

Cristoforo Pomara, PhD, and Gianpaolo Di Peri, MD, University of Foggia, Department of Forensic Pathology, Viale Degli Aviatori, Foggia, 71100, ITALY; Giuseppe Guglielmi, PhD MD, University of Foggia, Department of Radiology, Viale Pinto, Foggia, 71100, ITALY; Emilio Nuzzolese, DDS, PhD, Viale J.F. Kennedy 77, Bari, 70124, ITALY; and Stefano Derrico, PhD, University of Foggia, Department of Forensic Pathology, Via Luigi Pinto, 1, Foggia, 71100, ITALY*

The goal of this presentation is to offer a multidisciplinary approach in forensic investigation that presents identification of victims as belonging to victims of local criminal organization. Skeletal remains of four different cadavers were recovered in a ravine, a surprising movie of this recovery completes the peculiarity of the case.

This presentation will impact the forensic science community by discussing how skeletal remains recovery requires a multidisciplinary approach in forensic activity, and identification of missing represents the principal aim.

The Gargano, also known as Spur of Italy is a subregion of Italy which coincides with the headland stretching in the North of Puglia and corresponds to the East of the Province of Foggia. It is entirely surrounded by the Adriatic Sea except in the West, bordering the Tavoliere. The frequent and constant carsic erosions in this area produced cavities that, in time, due to telluric movements created grottoes, dolins, and ravines hundreds meters underground. A ravine is a small valley—almost like a canyon but narrower—which is often the product of stream cutting erosion. Ravines are typically classified as larger in scale than gullies, although smaller than valleys. A ravine is generally a slope landform of relatively steep (cross-sectional) sides, on the order of twenty to seventy percent in gradient. Ravines may or may not have active streams flowing along the down slope channel which originally formed them; moreover, often they are characterized by intermittent streams, since their geographic scale may not be sufficiently large to support a perennial watercourse. The ravine of Zazzano is located on the Gargano area. The ravine is a 30 meter large ravine, 107 meters deep underground which was used in the past as abusive rubbish dump. Old and wrecked cars were also put down the ravines, stacking on each other in column. During a cleaning operation, local authorities, a team of speleologists found human skeletal remains and activities were interrupted. A prosecutor was immediately alerted and forensic pathologists were called for scene investigation, skeletal remains recovery, and identification. In a wrecked car, one completely skeletonized cadaver was found with its clothes; a reddish rope still tied to the arms bones and the head found inside a plastic bag. A second completely skeletonized cadaver was found later in another wrecked car some meters down the previous one. Bones of a third cadaver were recovered on the ground of the ravine, partially covered by mud. The cadaver lying in a prone position; head, thorax, and upper arms were found inside a jute bag, a reddish rope still tied lower arms. A fourth cadaver, completely buried under the mud was found, lying in supine position; the head was found inside a plastic bag. Recovery activities were completed in three days. A video recording of recovery was performed and is presented. Local authorities identified the owners of recovered wrecked cars. Forensic activities involved radiological investigation by means of standard approach and total body multislice TC scan contributing in determining causes of death: suffocation, gunshot wounds and efforts of mutilation, variously combined. Anthropological investigation determined sex and race of skeletons; dental records and dental casts were performed by forensic odontologists. DNA profile has been developed for identification. At the end of forensic examination all the fourth cadavers were identified as

belonging to men suddenly missed in the nineties, suspected as victims of the local criminal organization. The gravine is now famous with the name of cemetery of the Gargano's mafia.

Skeletal Remains, Ravine, Homicide

G95 Use of Multidetector Computed Tomography (MDCT) in the Evaluation of Gunshot Wounds

Edward L. Mazuchowski, PhD*, and Philip J. Berran, JD, Office of the Armed Forces Medical Examiner, 1413 Research Boulevard, Building 102, Rockville, MD 20850; and Howard T. Harcke, MD, Armed Forces Institute of Pathology, 6825 16th Street Northwest, Washington, DC 20306

After attending this presentation, attendees will understand the process used by the Armed Forces Medical Examiner System (AFMES) to integrate MDCT into the evaluation of gunshot wounds. Attendees will be able to describe the advantages and limitations of utilizing MDCT in the evaluation of gunshot wounds.

This presentation will impact the forensic science community by detailing a novel approach to overcome the limitation of the visualizing entrance and exit gunshot wounds with MDCT.

Postmortem forensic imaging is a critical tool in the evaluation of gunshot wounds. Traditionally, fluoroscopy and digital/plan film x-rays have been utilized to document and locate bullets and bullet fragments in cases of gunshot wounds. In the last several years, traditional imaging techniques in conjunction with postmortem MDCT has made it possible to obtain precise three-dimensional localization of bullets and bullet fragments. In addition, this technique has been shown to be an effective method for aiding in the documentation of gunshot wound paths and evaluation of internal organ injury prior to autopsy.

One of the main limitations of utilizing MDCT in the evaluation of gunshot wound paths is the inability of MDCT to precisely locate the surface entry and exit wounds. Although the presence of gas in the soft tissue and disruption of tissue surfaces may be helpful in the precise location of these wounds, the collapse of the temporary cavities, compression of soft tissue defects and the position of the body on the scanning table can limit the detection of the entry and exit wounds.

In order to overcome this limitation, a novel technique was developed utilizing radio-opaque markers. Briefly, the body is first imaged by digital x-rays to identify any bullets or bullet fragments in the body or clothing. Next, digital photographs of the body and gunshot wounds are taken and the locations of the gunshot wounds are marked with a 1.5 millimeter radiopaque marker. The body is then imaged with MDCT. The resulting images are processed with imaging software to produce a three-dimensional image of the body with the precise location of the entry and exit wounds on the skin surface. Reconstructed images are manipulated to obtain any desired orientation of the body and wound pathway. These images can then be used to demonstrate the gunshot wound pathways in medicolegal proceedings. It must be noted that this technique does not overcome the limitation of MDCT in distinguishing entrance gunshot wounds from exit gunshot wounds. This distinction is made by combining the postmortem forensic imaging with the findings from the external inspection and internal dissection of the body.

Computed Tomography, Gunshot Wounds, Virtual Autopsy

G96 Gunshot Wounds Covered by Different Textiles: Determination of GSR Through Micro-CT Analysis

Giovanni Cecchetto, MD*, Alessandro Amagiani, MD, Guido Viel, MD, and Paolo Fais, MD, University of Padua, Via Faloppio 50, Padova, 35121, ITALY; Giampietro Feltrin, MD, Via Giustiniani 2, Padova, 35121, ITALY; Santo Davide Ferrara, PhD, University of Padua - Section of Legal Medicine and Forensic Toxicology, Via Faloppio 50, Padua, 35121, ITALY; and Massimo Montisci, PhD, University of Padua, Via Faloppio 50, Padova, 35121, ITALY;

After attending this presentation, attendees will have novel information on the role of Micro-CT analysis of gunshot wounds for estimating the firing range.

This presentation will impact the forensic science community by adding new data on the estimation of the firing distance of intermediate-range gunshot wounds in clothed victims, through a micro-CT analysis of the gunshot residue.

Estimation of the firing range is often critical for reconstructing gunshot fatalities, where the main measurable evidence consists of the gunshot residue (GSR). Several techniques and methods have already been used for characterizing GSR, such as Atomic Absorption Spectroscopy, Neutron Activation Analysis, Autoradiography, Routine-CT, Scanning Electron Microscopy, and Histochemistry. Recently, a novel approach, based on the use of Micro-CT, proved to be an objective, reliable, rapid, and inexpensive tool for estimating the firing range in intermediate-range shots.

Aim of the Study: It is well known that the presence of clothes covering the body heavily affects the distribution of GSR on the entrance wound, hindering the estimation of the firing range on the basis of the sole macroscopic inspection.

The goal of the present study was to evaluate the differential distribution of GSR, with regard to the different kinds of textiles covering the skin, by means of micro-CT analysis, with the final purpose of reconstructing the firing distance.

Materials and methods: Human legs, surgically amputated, were cleaned of dried blood and any other contaminants, and cut into sections of approximately 6 cm in length.

A total of 60 sections were selected; each section was covered with a single type of textile, chosen among cotton fabric ($n = 15$), jeans ($n = 15$), leather ($n = 15$), and waterproof synthetic fabric ($n = 15$). Bare skin sections were used as controls ($n = 15$).

Firing was carried out perpendicularly at distances of 5, 15, and 30 cm, using a .32 pistol loaded with full-jacketed bullets. A total of 75 shots were performed (five replicates for each distance). After each firing test, the gunshot wounds were photographed and formalin fixed.

The skin specimens, comprising the epidermis, dermis, and subcutaneous fat, were cut into parallelepipeds (height 1 cm, side 1 cm) with a lancet. Samples were scanned following standard processing procedures, using a high resolution scanner.

The acquired raw data were reconstructed with reconciliation software, which uses the back-projection algorithm to reconstruct axial subsequent images saved as bitmap format. The bitmap images were analyzed by a CT analysis software: the selected volume of interest (VOI side of 1 cm and height of 3.8 mm) was focused in the centre of the specimen in order to have the entire entry wound positioned in the middle. All the samples were binarized using the same parameters.

The percentage of GSR deposit was calculated analyzing all particles with a density higher than 1000 Hu (particles with a density lower than 1000 Hu were excluded to reduce iron artefacts). The 3D images were reconstructed through a Ct-Vox Software.

Results: The visual inspection of the skin did not allow the estimation of the firing distance for the covered gunshot-wounds; the

morphological features of the entrance wounds (blackening and tattooing) were, indeed, not discernible.

The micro-CT analysis revealed that:

- GSR particles were less represented in cases compared to controls;
- In cases GSR particles were distributed inside the cavity and the fatty tissue of the entrance wound, while in controls they were present mainly on the skin around the hole; and,
- Increasing the firing range, the radiological detection of GSR progressively decreased in both cases and controls, allowing a good discrimination of the firing distances tested in the present study.

Conclusions: Micro-CT analysis might be useful for the forensic assessment of the firing range, particularly when the morphological features of intermediate-range wounds are not visually discernible (i.e., black people or clothed victims).

Forensic Pathology, Gunshot Wounds, Firing Range

G97 Child Abuse vs. Cachexia: Do Healing and Acute Rib Fractures Trump a Diagnosis of Probable Cardiac Dysrhythmia Due to Electrolyte Abnormalities

Steven A. Symes, PhD, Mercyhurst College, 501 East 38th Street, Erie, PA 16546-0001; and Dianne R. Vertes, PhD, MD, Erie County Medical Examiner's Office, 462 Grider Street, Buffalo, NY 14215

After attending this presentation, attendees will gain an awareness of potential differential diagnoses between forensic anthropologists and medical examiners/coroners on child deaths becomes evident.

This presentation will impact the forensic science community by informing attendees of the difficulties that accompany medical/anthropological diagnoses of child abuse, and the complications that arise when specialists attempt to contribute to cause and manner of death in infants.

One of the most difficult tasks confronted by forensic pathologists is the determination of cause and manner of death in suspected child abuse cases. In the last 15 years, forensic anthropology has demonstrated a potential for contributing to the cause of death, by systematically examining questionable skeletal areas after processing the skeletal elements free of soft tissue for a close look. Certainly, an accurate analysis of acute and healing fractures contributes immensely to a final diagnosis of infant's deaths. But do the two professions, with different approaches and diverse responsibilities, ever conflict in diagnoses? Of course they do. Below is a case where such a conflict arises.

An unembalmed body of a well developed, poorly-nourished female was examined and autopsied. The body appears younger than the reported three-months. Inanition is evidenced. The pale skin shows no acute injuries, or scars, nor were there any indications of trauma from the external exam. A V-shaped incision was performed previously by a tissue harvest team to remove the heart and proximal aorta. The clavicle and first rib on the right side were sectioned for this procedure. The first indication of skeletal injuries is first discovered during the internal examination of the ribs, where hemorrhage, acute, and possible healing rib fractures are visible.

Pathologic diagnoses documents small body size, where height and weight are diagnosed as in the 3rd percentile for age. Morgue examination weight is 7 lbs 6 oz, where birth weight was 6 lbs 3 oz. This presents neglect or failure to thrive. Also noticed is documented dehydration and small organ weights. Finally, blunt force skeletal injuries are present, with acute, chronic, and acute-on-chronic rib fractures. History indicates that aunt called 911 at 15:30 after last seeing the child alive at 8:30 that morning. The aunt is the legal guardian.

The anthropologist was called in at the first recognition of skeletal trauma. At that point it was decided to remove all ribs, both clavicles, and vertebrae C-7 through L-4 after extensive photographic documentation. These were processed free of obvious soft tissue, but preserved in anatomical position to give a better idea of three dimensional relationships of the complicated trauma to bone.

Dry bone examination combined with faxitron radiographs indicate numerous rib fractures as listed in Table 1.

Table 1. Summary of rib fractures in 3-month-old infant.

RIB FRACTURES				
Acute	Chronic	Stable Chronic	Acute On Chronic	Other Procedure
15*	6	10 (3 questionable)	2	1 (tissue bank)

*All rib head apex tears

As one would guess, the anthropological report documents and describes the 33 insults to bone that clearly point to non-accidental trauma, with the history as reported. However, from a medical examiner point of view, this case was everything but a clear case of child abuse.

It is ruled the death of this 3-month-old as attributed to probable cardiac dysrhythmia due to electrolyte abnormalities. Postmortem testing for calcium and vitreous sodium yielded abnormally low levels. Multiple blunt force injuries in the form of acute and chronic rib fractures were also noted at autopsy. No external signs of trauma are seen on the body. Differential diagnoses of the infant's abnormalities include natural and non-natural causes. Neglect and child abuse cannot be ruled out, however, nor can a natural cause such as a metabolic disorder be eliminated. To complicate issues, the infant had been taken to the pediatrician regularly and they were treating the low body weight. The last physician visit was 16 days before death. In view of these issues, the manner of death is best certified as "Undetermined."

Maybe the question in this case should be formulated, "Do diagnoses of probable cardiac dysrhythmia due to electrolyte abnormalities trump healing and acute rib fractures?" To the anthropologist perspective, this is an unsettling thought. To the medical examiner/coroner, while still unsettling, their responsibilities are medical interpretations of cause and manner of death, not simply biomechanic interpretations of bone fracture. The repercussions of a homicide ruling without a traumatic cause of death are immense. Thus, the debate goes on.

Child Abuse, Cachexia, Healing Rib Fractures

G98 The Identification of French Victims in the Massive Earthquake on January 12, 2010 in Haiti

Stephane Malbranque, MD*, French-DVI, Chu Fort-De-France, Hop. La Meynard, BP 632, Fort-De-France cedex, 97261, MARTINIQUE

The goal of this presentation is to give attendees a clear understanding of France's structure and procedures in terms of identification of its nationals in the event of a major natural disaster and to demonstrate that the international response is as efficient and effective as it is at a national level.

This presentation will impact the forensic science community by showing the successful collaboration between a forensic scientist and a first response rescue team. To illustrate this, the French national team of identification was followed on site at Port-Au-Prince from January 13, 2010 until April 1, 2010. It also demonstrates that an early intervention is key to optimizing the effectiveness of the identification process and to achieving the overall success of the operation.

The earthquake that struck Haiti's capital Port-au-Prince caused more than 200,000 deaths. The major contributing factors to such high casualties were primarily its incredible strength and secondly the

instability of the existing infrastructure. The challenges that had to be overcome were the significant increase of sanitary requirements and the issue of corpses' management. Identifying such a high number of victims proved extremely difficult firstly because of such a large volume of corpses and secondly because of their high levels of depreciation. The success of this operation was only made possible due to a thorough preparation combined with a structured and systematic approach.

In response to similar events, France has a national DVI team (Unité Nationale d'Identification des Victimes de Catastrophes – UNIVC) since 1992. It was established by the Criminal Research Institute of the National Gendarmerie (IRCGN). The team is made up of specialists from the Criminal Identification Department who are able to be deployed on site very quickly and are trained to be adaptable and responsive to any given situation.

Since 2006, authorities based in the French island of Martinique, in the West Indies, have been focusing on contingency and emergency plans due to the island's major exposure to natural risks and its remote location. These revised response procedures were put into practice for the first time in Haiti in 2009 to such great effect that it has subsequently brought about modifications of the national strategy (plan ORSEC). This strategy encompasses a forensic scientist, with expertise in mass deceased management, as part of the initial first aid response team.

The first evaluation reported at least 70,000 deceased in PORT-AU-PRINCE 24 hours after the earthquake. The police's chief of the United Nations and the Haitian Prime Minister, who were actually themselves survivors of the disaster, were immediately contacted to organize the clearance and logistic requirements, as well as the coordination of the mass burial of corpses in common graves commencing 36 hours after the earthquake.

Communication was a key factor in this operation not only with the population, to dispel the myth that corpses in a disaster can cause the rapid spread of diseases, but also with the international nursing staff to reiterate that sanitary precautions in the movement of bodies.

The second major objective was to perform an accurate census of the deceased French nationals by locating and collating their position at the time for the purposes of identification and repatriation to families. This was achieved by setting up an "antemortem" unit at the French embassy for the registration of missing persons and reported fatalities.

Between 72 and 96 hours, 30 names were indexed. Survivors were then contacted and advised on the best practices for the storage of the deceased prior to burial. These instructions also gave details on how to preserve vital evidence i.e. ensuring personal effects of the corpses were not removed, drawing up an accurate map to locate corpses, collecting local and national coordinate.

As a result, all French deceased nationals (33 of approximately 1,200 present) were identified by the end of March 2010 and placed in a temporary mortuary at the French embassy with thanks to the close cooperation of the American and Canadian DVI.

Identification, Mass Disaster, Earthquake

G99 Comparison of Methods for Measuring Decomposition of Submerged Carrion in Fresh Water

Michael K. Humphreys, MS, Yolo County Sheriff/Coroner Office, 2500 East Gibson Road, Woodland, CA 95616; Edward Panacek, MD, MPH, University of California - Davis, Department of Emergency Medicine, 4150 V Street, Patient Support Services Building, Suite 2100, Sacramento, CA 95817; William Green, MD, California Clinical Forensic Medical Training Center, University of California - Davis Medical Center, 3671 Business Drive, Sacramento, CA 95820; and Elizabeth A. Albers, MD, Sacramento County Coroner's Office, 4800 Broadway, Sacramento, CA 95820*

The goal of this presentation is to determine a method for measuring submerged decomposition experimentally that limits contamination to the carrion.

This presentation will impact the forensic science community by discussing how, currently, there is no standard for measuring submerged decomposition *in situ*. This study compared current proposed methods for experimentally measuring the amount of decomposition undertaken by carrion underwater, and hopefully, the results may guide future underwater decomposition research, using more standardized techniques that limit contamination of the decomposition process.

Continuous monitoring of decomposition and calculations of the postmortem submersion interval (PMSI) of carrion at depth can be problematic for forensic investigators due to risk contamination of the carrion caused by the extraction from the experimental environment and weighing processes. Underwater photography and evaluation utilizing the Heaton et al. total aquatic decomposition (TAD) score at depth was compared to weighing the carrion before and after submersion, as well as full forensic necropsies. The actual time of submersion was known for each carrion. Perinatal piglets were used as human analogues for experimental purposes. This study suggests that weighing the piglets after they have been submerged in fresh (stagnant) water yields inconsistent results due to the unpredictability of algae growth in water ecosystems with high algal contamination. In addition, while underwater photography does reveal some evidence of decomposition *in situ*, usefulness is limited by required training, expensive equipment, and further algal growth issues which can obscure the visual data. The results of this study indicate that in order to objectively measure decomposition over time, the carrion should be examined either at depth using the TAD scoring system, or a set of piglets should be submerged with one piglet harvested from the experimental environment over set periods. This piglet should then undergo a pathological examination (with histological sampling and TAD scoring, as was done in this study), rather than relying on underwater photography. This allows for normalization between piglets and excludes weight and algal growth issues, thereby showing the amount of decomposition over time. The acquired TAD score can then be used with the calculated Accumulated Degree-Days (ADD) to determine an approximate PMSI. These results may not be generalizable to other submersion conditions in water ecosystems with different salinity, temperature, degree of algae growth, and amount of other animal activity.

Underwater Decomposition, Postmortem Submersion Interval, Visual Scoring System

G100 Fatal Sexual Violence Against Women: Normative, Baseline Studies of Postmortem Genital Anatomy — What Can We Say About Normal?

Sharon R. Crowley, MN*, FCNS, 122 Emeline Avenue, Santa Cruz, CA 95060

After attending this presentation, attendees will better understand the nature and appearance of the postmortem anogenital tissues; be able to discuss findings from control groups of normative, baseline studies for comparison with cases of fatal sexual violence; and discuss taxonomy, examination adjuncts, and database variables useful in the postmortem sexual assault evaluation.

This presentation will impact the forensic science community by improving the diagnostic acumen of the forensic examiner, helping avoid ambiguity of interpretation of clinical findings in postmortem genital examinations, and improving knowledge about fatal sexual violence against women.

Until recently, a paucity of data existed on the “normal” appearance of the genital anatomy during the postmortem interval. There is a lack of data from scrutiny and photodocumentation of the postmortem anogenital tissues. The use of colposcopy is well established for both adult and child *living* victims. During the autopsy, gross visualization alone may not allow the detection of the more subtle findings that usually constitute genital trauma in sexual assault (Crowley-AAFS: 2003). Comparisons to either living sexual assault victims or postmortem cases of non-sexual etiology were extremely difficult.

This presentation proposes to describe ongoing research on postmortem genital anatomy. These cases constitute the first normative, baseline data on the anogenital tissues during the postmortem interval. The focus of the present discussion is to describe the findings from two normative, baseline control groups, with a total sample of 48 female cases.

Group I consists of 30 female cases drawn from the Body Donation Program, at the University of California, Davis, California. Most donors are received \leq 24 hours of death. All cases selected for this baseline study are fresh, or fresh-frozen, vs. embalmed. Cases are examined based upon availability, i.e., female gender and received by the program in a time frame compatible with access by the primary investigator.

Group II consists of 18 coroners’ cases, from another jurisdiction. These were also examined using the mobile colposcopy and examination system described by Crowley (JFS: 2004). The manner of death was accidental in seven cases and natural in 11.

Materials and Methods: This research project is an observational study, with a cross-sectional design. The examination methodology employs photocolposcopy at 7.5X, 15X magnification, or both, plus 35 mm photography via the colposcope. In most cases, additional photographs are taken with a 35mm single lens reflex (SLR) manual or digital camera, for comparison to colposcopy. Inspection and photodocumentation of specific anogenital sites is employed, prior to manipulation of the genital tissues. On select cases, concomitant application of a 1% solution of toluidine blue dye has also been incorporated, in order to evaluate the reliability of this general nuclear stain as an adjunct to the postmortem examination. The same 12 anatomic sites are visualized, inspected, and photographed in both controls and sexual homicide cases. These include the labia majora, peri-clitoral area, peri-urethral area, labia minora, hymen, vagina, cervix, perineum, fossa navicularis, posterior fourchette, anus, and rectum.

There are some core data elements germane to both control and sexual homicide groups. These include age and reproductive status, (pre-pubertal, reproductive age, peri-menopausal, and post-menopausal) and genital examination techniques. Other common variables include the unique case identifier, date and time of the examination, interval from death to arrival in forensic science morgue, general condition of

body, race and ethnicity per CDC definitions, cause and manner of death, and contributory and/or concomitant medical and gynecological conditions, especially those presenting lesions.

The 30 female cases from Group I range in age from 60-99 years. The mean age is 83.1 years old. This is a largely homogeneous group; 93% of the sample is Non-Hispanic/White. The majority of Group I presented to the forensic science morgue within 24 hours. Postmortem mucosal autolysis was present at a minimum of one out of the 12 anatomic sites in 80% of the sample. Postmortem skin slip in the anogenital area was present in 16.6%. A 1% Toluidine blue dye solution was applied and decolorized with a dilute acetic acid solution in 21 of the 30 body donor cases. There was a false positive uptake in 100% of the cases. This was true regardless of the anatomic site of dye application.

The age range for the 18 cases in Group II was 32 months to 89 years of age. The mean age was 47.87 in this Group. The ethnicity and race distribution was as follows: Non-Hispanic/White (66.6%); Non-Hispanic/Asian Pacific Islander (5.5%); Hispanic/White (11%), and African American (16.6%). The postmortem interval to arrival at the forensic science morgue was \leq 24 hours in 88.8%, 96 hours in 5.5%, and \geq 5 days (active decay) in 5.5%. Postmortem mucosal autolysis was present in greater than 50% of Group II. Toluidine blue dye was not applied to any in this sample.

Discussion: The postmortem arena superimposes a unique set of factors. Many were not previously studied or documented in the literature. Analysis of results from baseline studies allows eventual comparison to genital injuries sustained by both sexual homicide victims and living sexual assault victims. A relational database was described (Crowley, AAFS: 2010) as a method to simplify and quantify data for interpretation, analysis, and linkage to other cases.

Taxonomy germane to the postmortem arena should incorporate salient terms that will be consistent and universally applicable and acceptable within the forensic community (Crowley & Peterson: AAFS, 2004). Postmortem artifact, such as *mucosal autolysis* and *skin slip*, visualized in the anogenital tissues, is documented for each anatomic site. Inclusion into case documentation permits aggregate summaries of individual and population-based summaries. Appropriate taxonomy and correct identification of “normal” will help improve our diagnostic acumen and increase the reliability of our methodology.

The significantly false positive results obtained from application of Toluidine Blue dye on the postmortem anogenital tissues should preclude any recommendation for its use in the postmortem sexual assault examination. It appears to be consistently picked up by the shedding tissues that comprise part of the normal artifact. The inexperienced examiner might misconstrue this for a significant finding.

It is certainly true that in equivocal cases, the forensic pathologist can simply remove en bloc, for dissection and microscopic evaluation, the tissues germane to genital findings. However, it may prove to be beneficial to have an initial *in situ* examination of the anogenital anatomy, via colposcopy. The ultimate goal of this research is to improve our understanding of what is normal, and what is not, during the postmortem interval for the anogenital tissues. In this manner, the capacity and understanding of fatal sexual violence against women will continue to grow.

Fatal Sexual Violence Against Women, Body Donation Program, Colposcopy

G101 The Effects of Household Chemicals on Blow Fly Oviposition and Development Using Human Cadavers

Kristi N. Bugajski, MS, 929 King Street, Lafayette, IN 47905; and Ralph E. Williams, PhD, Purdue University Department of Entomology, 901 West State Street, West Lafayette, IN 47907*

After attending this presentation, attendees will have a better understanding of the effects that household chemicals have on the insect's role in the decomposition of the human body. This research was inspired from a murder that occurred in Lafayette, Indiana where the perpetrator sprayed Raid® on the body of the victim. This led researchers to question what effects Raid® and other household chemicals have on blow fly activity and subsequently estimations of the postmortem interval (PMI).

This presentation will impact the forensic science community by exploring the hypothesis that bodies treated with the chemical ammonia would not significantly vary from bodies with no treatment and bodies treated with Raid® would significantly vary. This hypothesis was based on the results of previous research conducted on swine.

Six human bodies, (four male and two female), were obtained for use in this study and frozen prior to placement in the field. This research was conducted at the Anthropological Research Facility at the University of Tennessee in Knoxville. The field research started on July 18, 2010 and concluded on August 6, 2010. The bodies were placed in the field in sealed body bags and allowed to thaw for a period of 48 hours prior to treatment with chemicals. After the bodies were removed from the bags they were checked for any evidence of insect activity and none was observed. Two bodies (male) were not treated with chemicals and served as controls. Two bodies (one male, one female) were coated with 1275 g (3 cans) of Raid for Flying Insects, (active ingredients 0.05% permethrin, 17.5% tetramethrin, 0.05% d-cis/trans allethrin). Coating involved spraying the bodies with Raid until runoff occurred. Two bodies (one male, one female) were coated with 9.45 L (5 bottles) of Great Value brand household ammonia. The ammonia was poured onto the body until runoff occurred. Treatments were randomly assigned using a random number generator. The bodies were monitored and photographed twice daily and notes were taken to document blow fly activity. The following major stages of insect activity were noted: adult flies, fly eggs, fly larvae, migrating fly larvae, presence of beetles, and the end of maggot migration (characterized by the absence of observable larvae on the body). This allowed researchers to document differences in development time as well as the initial onset of blow fly life stages. Adults and larvae were collected following standard operating procedures outlined in Haskell and Williams (2008) each day to document any differences in species composition or development among treatments. Larvae were collected in KAA (composed of 95% Ethanol (77%), Acetic Acid (15%) and Kerosene (8%)) and adults in 70% EtOH.

The research was still in progress during the writing of this abstract, but the results and conclusions of the study will be discussed during the presentation.

Forensic entomologists are often asked by law enforcement agencies to provide an estimation of the PMI using insects. If chemicals are applied to a body and that has an effect on the blow fly activity, then the estimation of the PMI is therefore compromised. The data obtained from this research will impact the forensic science community by helping to overcome this obstacle when chemicals are involved and yield more accurate assessments by forensic entomologists.

Forensic Entomology, Chemicals, PMI

G102 Mass Disaster Procedures: Forensic Pathology and Genetic Techniques Used to Locate Nine Missing People in the Calabria Region (Southern Italy)

Paola A. Magni, MS, F.E.LAB ASL TO1, c/o Civico Obitorio di Torino, Via Bertani 112/A, Torino, 10137, ITALY; Giulio Di Mizio, PhD, Policlinico Universitario Camp, Germaneto, Edificio Clinico, Sec. Foren Med, Viale Europa, Catanzaro, 88100, ITALY; Federica Colosimo, MD, Magna Graecia University of Catanzaro, Viale Europa Loc. Germaneto, Catanzaro, 88100, ITALY; Sergio Schiavone, PhD*, RIS Carabinieri, S.S. 114 Km 3,400, Messina, 98128, ITALY; Carlo G. Romano, MSc, RIS Carabinieri, S.S. 114 Km 6,400, Messina, 98128, ITALY; Ciro Di Nunzio, Institute of Legal Medicine, School of Medicine, Magna Graecia University, Viale Europa Germaneto, Catanzaro, 88100, ITALY; Ian Dadour, PhD, Centre for Forensic Science, University of Western Australia, 35 Stirling Highway, Nedlands, 6009, AUSTRALIA; and Pietrantonio Ricci, MD, Università degli Studi Magna Graecia Catanzaro, Viale Europa - Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will understand the importance of a unified and well organized multidisciplinary approach resulting in a set of guidelines useful during a mass exhumation.

This presentation will impact the forensic science community by documenting the management of the first mass exhumation and DNA identification of one hundred corpses. This procedure will be useful in the future following an actual mass disaster event.

The Public Prosecutor's Office of the city of Paola (CS, Calabria Region, Southern Italy) opened an investigation into a number of criminal offenses that have repeatedly occurred in aged care facilities where people with physical and psychological handicaps are managed.

The aged care facility manager was a suspect and due to his irregular management was arrested.

In different periods over recent years nine residents had gone missing from the house. The resident's families reported this to the legal authorities about their missing relatives to the legal authorities. Moreover the families expressed concern that during the last meeting when they saw their relatives, they were all injured.

An investigation was organized in order to find the missing patients. This was concentrated in the local cemetery where the police found unmarked graves without any identification.

The public prosecutor gave permission to the Legal Medicine Department of Magna Graecia University of Catanzaro to exhume the unmarked graves and examine each corpse so they could be identified.

In a period of 15 days, 101 corpses were exhumed for identification using DNA and to determine if any trauma had occurred either antemortem or perimortem.

The medico-legal task force which was multi-disciplinary consisted of three phases: a planning phase; a pre-analytical phase; and, an analytical phase.

Planning Phase: During this phase mass disaster operative procedures were enacted. A medico-legal camp was built close to the cemetery area. Briefing meetings were organized to coordinate the schedule of pathologists, molecular biologists, entomologists, mechanical engineers, computer scientists, physics, and law enforcement agents (Arma dei Carabinieri and fire brigade).

Pre-Analytical Phase: Under the direction of the coordinating pathologist, pneumatic tents were positioned courtesy of the fire brigade. Each tent had its own purpose (external inspection, x-ray, autopsy, biological laboratory). The camp site was powered by portable electric generators. Moreover, the camp set up was established in order to prevent the infestation of insects attracted by human remains which would complicate or invalidate the medico-legal analyses. Approximately 40 people worked each day in the camp.

Analytical phase: This phase was developed in the Genetic Laboratory of the RIS, Carabinieri Messina. The methodology was previously validated at the Forensic Genetic Laboratory of Magna Graecia University where techniques had been previously established to extract DNA from old and badly preserved bones. The main difficulty of this work was the DNA extraction from corpses in colliquative, corification, and skeletonization stages.

A piece of femur diaphysis (4 cm length) was sampled from each corpse and fixed in alcohol. Subsequently all muscle tissue and internal trabeculae (if present), was removed from the bone. The bone was then washed in water-alcohol-ether, then pulverized and demineralized.

The pulverization of 0.5 g of bone was achieved by impact and friction using 30 Hz frequency and spun together with a single tungsten carbide ball inside a cylindrical steel container.

The bone powder demineralization was obtained using an EDTA solution 0.5 M pH 8.0.

After chloroform extraction, the DNA purification was completed using silica gel columns.

The quantity of obtained DNA was determined by REAL-TIME PCR technique.

The DNA personal profiles were obtained with multiplex amplification and subsequent separation in capillary electrophoresis.

The results obtained allowed the DNA identification of the corpses regardless of their stage of decay. The obtained DNA profiles were compared with relatives to confirm the identity of the exhumed bodies.

Mass Disasters, Forensic Pathology, Forensic Genetics

G103 Variance in Growth Rates of *Calliphora vomitoria* on Different Tissue Types: Mass Raised vs. Single Raised

Bridget R. McSweeney, BA*, 1629 South Shenandoah Street, Los Angeles, CA 90035; and Tal Simmons, PhD, School of Forensic & Investigative Sciences, University of Central Lancashire, Preston, PR1 2HE, UNITED KINGDOM

After attending this presentation, attendees will have a better understanding of the variances in growth rates for *Calliphora vomitoria* that occur not only when raised on differing tissue types, but also when raised in mass versus single.

This presentation will impact the forensic science community by demonstrating the need for further understanding of larvae activity and growth rates on differing tissue types.

Without a more thorough understanding of larvae species and their possible species specific growth rates and interactions with tissue types, the use of them in determining postmortem intervals (PMI) is suspect.

Recent studies show that there are significant differences in maggot growth rates depending on what type of tissue they consume. While previous studies have determined that the structure of the tissue didn't make a difference, what exactly causes the variation in growth rates has not yet been discovered. Since most comparison studies have been conducted using lab raised larvae (commonly grown on cow liver or pig liver), there may be significant problems with using such larvae to determine PMI in real cases. To better understand the implications of the variation in growth and development, development rates of larvae raised on various tissue types need to be explored more completely. This raises the question of whether the specific tissue consumed, or a change within the mass's activity, causes a change in growth rate.

A comparison between single raised larvae and mass raised larvae was used to judge the possible connection between being raised in mass and differences in growth rates on varying tissue types. If the difference in growth rates between different tissue types was not related to being mass raised, then single raised larvae and mass raised larvae from the same tissue type would show the same variations in growth rates.

This experiment examined the growth rates of single versus group raised maggots (N=100) on various tissue types. Growth rate differences were measured in two ways: mean maggot size, and instar stage. Larvae were procured from eggs laid in the lab by a mixture of wild caught and lab raised *C. vomitoria*. Larvae were laid on kidney, liver, heart, lung, or brain before being transferred within an hour of hatching to the tissue on which they were to be raised. All larvae were transported from the tissue on which they were laid to either a piece of the same tissue type or a different tissue type. By this means, it could be seen if a variation in origin tissue and sustenance tissue for a larvae during the first instar stage had an effect on the rate at which it matured.

Each tissue type had three replicates of masses being born and raised on the same tissue type and three replicates of larvae being born and raised on differing tissue types, for six replicates in total. Single raised larvae were replicated in groups of twenty for each origin tissue, resulting in batches of forty replicates total per a raising tissue type. All larvae were killed approximately six days after hatching and were measured by length from mouth to instar markings to the nearest .01 µm.

Whether the tissue type on which a larva was born was switched during first instar was not statistically significant. However, the relationship between size, tissue type, and whether a larva was mass grown or single grown was significant. In PMI studies larvae are used to determine PMI based on length at time of death, or time needed to grow them to adulthood in a laboratory setting combined with accumulated degree days. The variations in growth seen in this study differ from those seen with previously studied species, signifying that tissue based variations in growth rates are species specific. The wider variance in lengths noted in mass raised larvae as compared to single raised larvae indicates that size is not the best determinant of age as previously presumed. These results could mean a significant change in the way fly larvae are viewed and utilized in the field of taphonomy and forensic entomology for determining PMI.

Development Rate, Forensic Entomology, Postmortem Interval

G104 Identification of Two Homicide Victims and Linking of Separate Crimes Solved by Radiographic Discovery of a Healed Bullet Wound.

William C. Rodriguez III, PhD*, and Laura A. Regan, PhD, Armed Forces Medical Examiner System, 1413 Research Boulevard, Building 102, Rockville, MD 20850; and Humphrey H. Germaniuk, MD, Trumbull County Coroner's Office, 1863 East Market Street, Warren, OH 44483

The goal of this presentation is to provide details on the investigation, and forensic examination of two separate homicide cases which were solved based on the radiographic discovery of an old healed bullet wound. A primary point of discussion of this presentation will be how the smallest and least suspected piece of evidence can be utilized to solve a difficult case or cases. The importance of detailed forensic anthropological examination in skeletonized or badly decomposed cases will be noted during the presentation.

This presentation will impact the forensic science community by providing present and future forensic investigations insight as to the forensic analysis of decomposed and skeletonized remains so as determine the identity of deceased as well as the possible cause and manner of death. The forensic audience attending the presentation will become more aware of the importance of old healed injuries in the identification process as well as possibly identifying past activities or linking criminal activity.

In the summer of 2006 near Warren, Ohio skeletonized remains of an adult individual were discovered in a heavily vegetated area near a water treatment facility. The remains of the deceased were noted to be without any associated clothing or foot ware. Forensic anthropological

examination of the remains found them to be consistent with that of a Negroid male who was in his fifth decade of life at death. Based on the environmental conditions at the scene and the decompositional state of the remains a postmortem PMI of approximately six to eight months was assigned. The lack of soft tissues, absence of skeletal trauma in addition to the absence of clothing and location of the remains were noted as extremely suspicious by the coroner's pathologist.

Approximately two years passed while the remains of the deceased remained unidentified. In June of 2008, another set of skeletonized remains were discovered near Warren, Ohio. The remains discovered were recovered from several plastic garbage bags that were located along a highway. Each of the garbage bags recovered contained various portions of a highly decomposed body that had been dismembered. Forensic anthropological examination of the dismembered remains revealed them to represent a single individual that of a Negroid male who was in his mid to late twenties at death.

Detailed examination of the remains revealed that the dismemberment had been accomplished with a saw. The sawing dismemberment was noted as unusual as the cuts were made along the longitudinal/saggital plane of the body. A major portion of the middle and lower vertebral column had been cut longitudinally including a near perfect halving of the sacrum. A single gunshot wound was noted on the skull and considered to be the probable cause of death.

While conducting an examination of the innomates for aging and sexing purposes a very slight and almost unnoticeable small depression was noted along the inferior side of one of the innomates. The slight depression which was adjacent to the inferior side of the sciatic notch at first appeared to represent a simple skeletal anomaly attributed to human skeletal variation. Radiographic examination of the innominate revealed the presence of a fairly intact nine millimeter bullet. The bullet was removed from the innominate utilizing a small craft saw and submitted as evidence of an old healed bullet wound.

The discovery of the old healed bullet wound served as a key lead to the identification of the homicide victim. Identification of the victim led police on an investigation that in turn resulted in the identification of the prior unknown remains discovered near the water treatment facility. Further investigation of this case revealed that the earlier death was also a homicide and led to the arrest of the killer.

Anthropology, Ballistics, Human Identification

G105 Utilizing Multi-Detector Computerized Tomography to Evaluate Concrete-Encased Human Remains

Robert A. Kurtzman, DO, Community Hospital, 2021 North 12th Street, Grand Junction, CO 81501; and Casey P. Bitting, BS, 1700 Bassett Street, #2114, Denver, CO 80202*

After attending this presentation, attendees will recognize the value of postmortem multi-detector computerized tomography (MDCT) evaluation of an unusual case of human dismemberment followed by encasement in concrete; appreciate the value of MDCT osseous examination and documentation; learn methods to utilize MDCT analysis of concealed biologic remains and review procedures utilized for orientation and extraction of human remains from concrete.

This presentation will impact the forensic science community by expanding the scenarios in which the use of MDCT may be utilized to improve postmortem evaluation and will demonstrate opportunities to utilize MDCT in medical examiner/coroner facilities where MDCT is reasonably available.

The Mesa County Coroner's Office is situated in rural Western Colorado at Community Hospital in Grand Junction, Colorado. Because the morgue is located within the hospital, state of the art radiographic equipment and ancillary staff are available.

Case Report: the decedent is a 41-year-old male homicide victim whose dismembered remains were concealed with concrete in two five-gallon plastic buckets. According to police reports, the decedent was killed by his son who later confessed and led police to his father's remains which had been stored in a shed for approximately two months following the homicide and dismemberment. Unable to determine the veracity of the reported circumstances, the presence of human remains was confirmed using MDCT. The remains were limited to the decedent's head with cervical spine, hands, feet, and heart. The imaging also served to establish preliminary forensic findings, namely the presence of a bullet in the left orbit. In addition, fractures of the left and right orbital plates were noted, while the remainder of the calvarium was intact. Other osseous findings include a fracture of the left distal second metacarpal and left distal first phalange, as well as a metal plate in the left orbit. In order to remove the remains from the buckets with minimal damage, the outside of the buckets were marked to indicate the orientation of the remains. A circular saw with a concrete cutting blade was used to cut into the concrete along predetermined planes of predetermined depth. The properly oriented concrete incisions allowed for coronal separation around the head providing anterior and posterior intact concrete mold halves. External examination of the head revealed that the skin and portions of soft tissue had been removed prior to encasement. The ears and eyelids were missing, and the eyes were sunken and softened due to decomposition. A small caliber, slightly deformed bullet was recovered from the left frontal sinus/superior orbital ridge. Due to the intentional removal of the decedent's facial skin and postmortem change, the entry wound was not visible and range of fire could not be determined; however, absence of soot from sections around the remaining soft tissue likely exclude a contact gunshot wound. In the absence of postmortem MDCT or conventional radiographs, it is entirely possible that the presence of a gunshot wound could have been overlooked. While the extent of brain decomposition precluded its examination, the MDCT and gross examination findings indicate that the bullet did not penetrate the cranial cavity. Examination of the outer table of the left orbital ridge of the calvarium revealed hemorrhage in the soft tissue. Neck and throat examination indicate the unlikelihood of strangulation based on the presence of an intact hyoid bone, thyroid cartilage, and thyroid cornu and absence of hemorrhage of the laryngeal mucosa. Because of the limited amount of remains available for examination, trauma to the remainder of the decedent's body could not be evaluated and therefore the cause of death was classified as undetermined. The manner of death was classified as homicide. Positive identification of the remains was established by comparison with antemortem dental records and confirmation of an orthopedic metal plate in the left brow.

In summary due to the location of our morgue facility, MDCT is readily available and was utilized to confirm the presence of human remains concealed in concrete. Furthermore, MDCT permitted orientation of the remains for optimal removal, documented orthopedic devices to augment identification, and assisted in the evaluation of injury. This defendant pled guilty and the case did not appear in court. If court proceedings had ensued, the use of a three dimensional volumetric MDCT rendering would have been utilized to present information to the jury. It is believed, a three dimensional volumetric rendering provides objective detailed visual imagery without the graphic, frequently repulsive appearance of wound photographs, and MDCT is useful in the evaluation of selected postmortem examinations.

Multi-Detector Computerized Tomography, Gunshot Wound, Homicide

G106 Use of Multidetector Computed Tomography (MDCT) in the Medicolegal Investigation of Human Remains After a Natural Disaster

Howard T. Harcke, MD, Armed Forces Institute of Pathology, 6825 16th Street Northwest, Washington, DC 20306; and Edward L. Mazuchowski, PhD, and Philip J. Berran, JD, Office of the Armed Forces Medical Examiner, 1413 Research Boulevard, Building 102, Rockville, MD 20850*

After attending this presentation, attendees will understand the process used by the Armed Forces Medical Examiner System (AFMES) to integrate multi-detector computerized tomography (MDCT) in the handling of human remains recovered from the natural disaster in Haiti. Attendees will be able to describe strengths and limitations of the process model employed.

This presentation will impact the forensic science community by offering one alternative for processing human remains following a natural disaster or other mass casualty event.

A disaster mortuary is established both to identify victims and determine cause and manner of death. Conventional radiography has been routinely used to screen for foreign bodies, personal effects and anatomic, dental, or surgical findings. MDCT has proved to be a useful technique in support of forensic examination in military and civilian mortuaries. The disaster in Haiti provided the AFMES the opportunity to utilize MDCT in the processing of victims of that event.

The three step processing model used employed: (1) digital radiography and whole body MDCT; (2) visual external inspection of the body; and, (3) forensic autopsy if steps one and two did not establish reasonable explanation for cause and manner of death or produced findings that required internal examination (e.g., ballistic fragments, external wounds).

There were 28 cases received and 27 processed using the model (one case did not have MDCT). In 20 cases MDCT and visual inspection showed evidence of blunt force injury and no suspicious findings. The medical examiner did not perform an autopsy and cause/manner of death was "blunt force injury/accident." In 19 of 20 non-autopsied cases MDCT gave more information than digital radiology, the exception being a case where disarticulated bones were received. Key findings were skeletal injuries to the head/neck, spine, thorax, and pelvis. In seven cases MDCT and visual inspection was judged inconclusive and complete autopsy was performed. These cases were signed out as "probable positional asphyxia/accident" (2), "cardiac arrhythmia/natural" (2), "blunt force injury/accident" (2) and "complications of a natural disaster/accident" (1). None of the 27 cases showed internal metallic fragments or suspicious external wounds. In 23 of 27 cases, moderate to severe decomposition was present and our prior forensic experience was helpful in distinguishing changes related to postmortem decomposition, recovery and handling from acute injury sustained during the event.

In conclusion, the use of MDCT together with external visual inspection by a medical examiner provided sufficient information to establish cause and manner of death in 74% of the cases sent to the AFMES during recovery operations in Haiti. This related directly to the ability of MDCT to determine findings consistent with blunt force injury not apparent on digital radiographs. This model using MDCT and visual inspection offers a rapid alternative for investigating human remains recovered after a natural disaster. It is believed that MDCT alone without external visual inspection by a medical examiner would not be adequate. It is also recognized that a medical examiner may deem a full autopsy to be required for a variety of other reasons (e.g., statutes, policy directives).

Computed Tomography, Natural Disaster, Virtual Autopsy

G107 Evaluation of the Randox Whole Blood Drugs of Abuse (DOA) Microchip Arrays for Use With Alternative Postmortem Samples as a Rapid Near-Body Screen

Poppy McLaughlin, MSc, Bournemouth University, Fern Barrow, Talbot Campus, Poole, BH12 5BB, UNITED KINGDOM; Derrick J. Pounder, MB, University of Dundee, Department of Forensic Medicine, Dundee, DD1 4HN, UNITED KINGDOM; and Michael D. Osselton, Bournemouth University, Fern Barrow, Talbot Campus, Poole, BH12 5BB, UNITED KINGDOM*

The goal of this presentation is to illustrate a rapid and simple tissue preparation method which allows drugs of abuse (DOA) to be screened using the Randox whole blood DOA microchip arrays.

This presentation will impact the forensic science community as the entire process can be undertaken and results obtained in the mortuary whilst the postmortem is taking place. Also the quantity of sample needed to screen may obviate the need to remove large tissue samples for laboratory analysis, saving time and costs, especially in negative cases.

A procedure is described that allows small aliquots of postmortem samples of blood, urine, vitreous humor, liver, and psoas major muscle to be analyzed for the following drugs, simultaneously: acetaminophen, amphetamine, barbiturates, benzodiazepines, benzoylecgonine, buprenorphine, cannabinoids, fentanyl, ketamine, lysergic acid diethylamide (LSD), methadone, methaqualone, methylamphetamine, methylenedioxymethamphetamine (MDMA), opioids, phencyclidine (PCP), propoxyphene, tricyclic antidepressants, zaleplon, zolpidem, and zopiclone.

Femoral blood, urine, vitreous humor, liver, and psoas muscle were obtained from forensic autopsies, ranging from suicides to natural causes. Tissue samples were cut into 1 centimeter cubes and homogenised with 1 millilitre SPE diluent. The homogenates were centrifuged for ten minutes at 3000 rpm and 70 microlitres of supernatant transferred to Eppendorf tubes. The samples were then diluted 1:3 with SPE diluent. Femoral blood, urine and vitreous humour were prepared and applied to the assay following the manufacturer's protocol for whole blood. Femoral blood from each case subsequently underwent confirmatory analysis using high performance liquid chromatography with diode array detection (HPLC-DAD) and liquid chromatography tandem mass spectrometry (LC-MS/MS).

Over 100 postmortems were screened for a combination of the previously mentioned drugs of abuse. A good agreement was obtained between the Randox assays and HPLC-DAD and LC-MS/MS analyses. Of the positive cases, urine and liver samples had a greater percentage agreement with confirmatory analyses than femoral blood, vitreous humor, and psoas muscle. The discrepancies between assay screening and confirmatory analysis may reflect differences in drug distribution between tissues as well as confirmatory analyses detecting concentrations below the assay's cut-offs.

In conclusion, the Randox whole blood DOA arrays can be used to alternative postmortem samples rapidly and simply. The simple procedure will benefit the forensic community as the entire process can be undertaken and results obtained in the mortuary while the postmortem is taking place. Also the quantity of sample needed to screen may obviate the need to remove large tissue samples for laboratory analysis, saving time and costs, especially in negative cases.

Drug Screening, Postmortem, Alternative Samples

G108 Postmortem Vitreous Beta-Hydroxybutyrate: Interpretation in a Forensic Setting

Michael Heninger, MD, Fulton County Medical Examiner's Office, 430 Pryor Street, Atlanta, GA 30312*

After attending this presentation, attendees will be aware of the range and frequency of postmortem vitreous beta-hydroxybutyrate (BHB) levels likely to be encountered in a forensic setting.

This presentation will impact the forensic science community by providing a more thorough basis for interpreting vitreous BHB levels.

Beta-hydroxybutyrate is one of three ketone-related substances commonly measured in the clinical laboratory and is also useful in postmortem testing. Ketones increase when the primary metabolic fuel source switches from glucose to fatty acids. Ketones are most useful as a marker for diabetic ketoacidosis and are also increased in alcoholic ketoacidosis, starvation states, and severe infectious disease processes. They can be measured in many body fluids including blood, urine, and vitreous fluid during postmortem investigations.

The medical examiner is often faced with an elevated vitreous BHB level that appears to have little or no bearing on the case. When can elevated vitreous ketones be safely ignored? This retrospective study was undertaken in order to gain a better understanding of the frequency and usefulness of postmortem vitreous BHB levels in the forensic setting. Moderately elevated levels were common and were not often related to the cause of death. More severely elevated levels of BHB were related to the cause of death with increasing frequency as the levels increased. Markedly elevated vitreous BHB coupled with elevated vitreous glucose usually indicated diabetic ketoacidosis. When vitreous BHB was elevated and the vitreous glucose was low, an alcohol related death was common.

A computer database was searched for postmortem vitreous beta-Hydroxybutyrate (BHB) levels measured in 1,795 forensic cases over a six year period (2003 to 2009) in the normal course of death investigation. Levels ranged from 0 to 22.7 mmol/L and averaged 1.2 mmol/L. 562 (31.3%) were less than 0.4mmol/L . 637 (35.5%) were between 0.4 and 1.2 mmol/L. 439 (24.5%) were between 1.2 and 2 mmol/L. 105 (5.85%) were between 2 and 6 mmol/L. 52 (2.9%) were greater than 6 mmol/L. Comparison of vitreous BHB with vitreous glucose levels in 1,781 cases showed moderately good correlation $r=0.731$. Comparison with blood alcohol levels in 1,561 cases showed no correlation $r= -0.053$. Diabetic ketoacidosis was diagnosed in 76.9% of the cases with vitreous BHB above 6 mmol/L; 37.5% to 13.5% of cases with decreasing BHB levels from six to two mmol/L and less than 2% of cases with BHB less than 2.0 mmol/L. Alcoholic ketoacidosis appeared in only 4 cases. Conditions thought to be ketogenic (diabetes, alcoholism, severe infections) were found in over 92% of the cases with BHB above 6 mmol/L and a third of the cases with BHB levels below 2.0, 1.2, and 0.4 mmol/L. Cases of sudden violent death, age 20-40 and less than 90 minutes from incident to pronouncement time, and with no obvious reason for elevated BHB amounted to 11 cases and showed vitreous BHB levels closer to normal with an average of 0.57 mmol/L. The BHB level was elevated (0.4 – 1.72 mmol/L) in 32 of 34 SIDS-like cases included in the study.

Beta-Hydroxybutyrate, Death Investigation, Sudden Infant Death Syndrome

G109 The Rising Trend of Ecstasy and Mimic Drugs Among Teenagers in Santa Clara County, California — A Guide and Awareness for Medical Examiners, Coroners, and Toxicologists

Larry Silveira, MS, Santa Clara County Department of Alcohol and Drug Services, 2101 Alexian Drive, Suite 110, San Jose, CA 95116; and Michelle A. Jorden, MD, Santa Clara Medical Examiner, 850 Thorton Way, San Jose, CA 95128*

The goal of this presentation is to educate the forensic community about the rise of ecstasy use and mimic drugs in California.

This presentation will impact the forensic science community by presenting a comprehensive report detailing the current growing trend of illicit pill ingestion among teenagers in Santa Clara County to include ecstasy, as well as, other mimic drugs (phenylpiperazines) which may escape detection in a basic toxicologic analysis. At the end of the presentation, attendees will be introduced and will be able to appreciate the new trend of "thizzin" and "popping" by teenagers in this county as well as nationwide. This presentation will also reiterate the importance of complete toxicologic screens on fatal overdoses to help identify common and not so common drugs of abuse and/or cutting agents.

According to 2001 data collected by the Substance Abuse and Mental Health Services Administration (SAMHSA), there have been approximately 100 deaths resulting from ecstasy overdoses in the United States. Nationwide, ecstasy abuse seems to outweigh methamphetamine abuse and only lags behind alcohol, marijuana, and cocaine as a popular drug of abuse among 12th graders. What is most disturbing is the indiscriminate ingestion of different colored and shaped pills ("thizzin") advertised to teenagers as ecstasy, when in reality, some of the ecstasy pills may be cut with cocaine, heroin, phenylpiperazines, and talc, just to mention a few agents. In Santa Clara County, a rise is being seen in teenagers abusing ecstasy and ingesting pills which may be composed of various drugs, some which may evade the basic toxicology screen. In the past year, Santa Clara County has seen two deaths resulting from ecstasy intoxication or complications thereof. Recently, a male who attended a rave party in a surrounding county died of an acute ecstasy overdose.

A retrospective search over the past nine years at the Santa Clara County Medical Examiner/Coroner Office disclosed a total of five ecstasy overdoses, two within the past year. In April 2009, a 22-year-old female was found deceased in a motel room after partying all night and ingesting ecstasy. During the course of the evening, she complained of headaches and began vomiting. Her friends left her alone in the motel room only to find her deceased hours later. The autopsy examination revealed a morbidly obese woman with an unremarkable internal examination except for marked brain swelling and pulmonary edema. Toxicology revealed the peripheral blood was positive for MDMA at 140 ng/mL (non-lethal) and its metabolite MDA at 20 ng/mL. Vitreous electrolytes revealed a profound electrolyte abnormality that consisted of hyponatremia. The cause of death was attributed to ecstasy-associated hyponatremia.

In January 2010, a 16-year-old adolescent was ingesting ecstasy with friends and had ingested a total of four tablets along with energy drinks when she became unresponsive shortly thereafter. Autopsy examination revealed that both coronary ostia arose from the same semi-lunar cusp but the coronary arteries pursued a normal anatomic course, along with findings of marked pulmonary and cerebral edema. Toxicology revealed the peripheral blood was positive for MDMA at 3200 ng/mL (fatalities arise at 1000 ng/mL) and its metabolite MDA at 140 ng/mL. Death was attributed to an ecstasy overdose.

After this period of recent fatalities, a survey of 1,852 students was conducted at two large comprehensive high schools and two continuation high schools located in Santa Clara County. A one-page anonymous

questionnaire to identify use of various mind altering substances was administered from March 24, 2010 to May 12, 2010 to students ranging from ages 14-19.

In all, 25.32% of all respondents admitted to “ever use” of ecstasy (469 out of 1852) which is 390% higher than the teens responding to the national 2009 Monitoring the Future Survey (MTF) and nearly twice the level from the national 2009 Parents and Teens Attitude Tracking Study Report (Partnership for a Drug Free America) (PATS). Additionally, 8.48% of the teen respondents admitted to the use of ecstasy in the past 30 days; 471% higher than the MTF results and 41% higher than the PATS results. Students who had taken ecstasy admitted to maximum doses ranging from one to ten tablets with an average of four tablets. Results from the review of pictures of pills from www.ecstasydata.org by a smaller subgroup of 30 students confirmed that 70% contained phenylpiperazines

For at least local teen populations and perhaps growing geographical regions, it is hypothesized that the drug's ease of availability, reduction in its cost, limited awareness of the risks and risk of death, growing teen permissive attitudes and enabling behaviors from their social subculture, appear to have pushed this drug to their third most frequently used drug surpassed only by marijuana and alcohol. Complete toxicological screens are suggested in this population given their extreme dosing behaviors and the apparent frequent presence of phenylpiperazines.

Ecstasy, Mimic Drugs, Rise in Use

G110 Laboratory Variation and Postmortem Redistribution in the Interpretation of Postmortem Fentanyl Levels

Clarissa Krinsky, MD, University of New Mexico School Of Medicine, MSC11 6030, 1 University of New Mexico, Albuquerque, NM 87131; and Sarah Lathrop, PhD, DVM, and Ross E. Zumwalt, MD, University of New Mexico, Office of Medical Investigator, MSC 11 6030, 1 University of New Mexico, Albuquerque, NM 87131-0001*

After attending this presentation, attendees will understand the principles of postmortem redistribution and interlaboratory variation and how to best utilize those concepts when evaluating postmortem fentanyl levels in central and peripheral samples.

This presentation will impact the forensic science community by providing an understanding the importance of using caution when interpreting very small, quantified fentanyl levels in postmortem samples.

The concept of postmortem redistribution has been extensively studied in some drugs, such as amitriptyline. The concept has also been looked at in regards to fentanyl, which due to its transdermal delivery mechanism, has interesting and unique pharmacokinetics and likely undergoes postmortem redistribution. It is hypothesized that fentanyl levels drawn from peripheral samples in the field, hours before autopsy, would be significantly lower than fentanyl levels in peripheral and central blood samples drawn at autopsy.

For this study, ten cases had fentanyl levels drawn in the field by investigators. The fentanyl level in this sample was compared to the level of fentanyl in peripheral and central samples taken at autopsy 15-24 hours later. Fentanyl levels are measured in very small quantities, ng/ml. At these very small amounts, the standard laboratory error could also greatly impact the values reported by the laboratory. In the process of comparing field and autopsy specimens and autopsy peripheral and central samples, we also sent most samples to a second accredited forensic toxicology lab. The ratios between the field and autopsy specimens and the heart and femoral blood levels were compared, and the interlaboratory variation was evaluated as well.

The spearman correlation coefficient was similar (0.41) for the field and autopsy specimens from a single case analyzed at laboratory #1 as the coefficient for a single heart blood sample run at laboratory #1 and laboratory #2 (0.62) and a single autopsy peripheral blood sample run at laboratory #1 and laboratory #2 (0.57). Thus, the variation in values was similar between the same specimen analyzed at two different laboratories and between samples drawn from different sites and at different times. Other evaluations of the heart:femoral blood ratio of fentanyl and measurements of correlation and variation will be discussed.

Fentanyl, Postmortem Redistribution, Interlaboratory Variation

G111 Toxicology and Pathology of 149-Methadone-Related Deaths

Sébastien Prat, MD, Service de Médecine Légale, Hôpital Troussseau, Centre Régional Hospitalier Universitaire de Tours, Tours, MB 37000, FRANCE; Patrice Mangin, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND; Marc Augsburger, PhD, University Center of Legal Medicine, Bugnon 21, Lausanne, 1010, SWITZERLAND; and Katarzyna Michaud, MD, Centre Universitaire Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, 1005, SWITZERLAND*

After attending this presentation, attendees will understand that careful interpretation of methadone related deaths in the presence of concomitant drug intake and pathological changes is very important.

This presentation will impact the forensic science community by illustrating the difficulty of interpreting postmortem methadone blood levels due to the possible interaction with other drugs acting on the QT-interval or on the cytochrome P450, as well as the presence of pathological changes.

Methadone-related deaths are often difficult to interpret, especially in the presence history of chronic drug use, concomitant intoxications and if pathological changes are observed. Historically, the presence of methadone was often considered to be an incidental finding of the postmortem examination, unrelated to the cause of death. It was recently reported that methadone may prolong the QT interval, resulting in torsade de pointes. Sudden deaths with therapeutic levels of this synthetic opioid have been reported. Moreover, clinicians are increasingly aware of interactions between methadone and other drugs that prolong the QT interval or decrease the elimination rate of methadone.

The goal of this study was to evaluate methadone related deaths by dividing them into three groups according to the peripheral blood level of methadone: lower than 200 µg/L, 200 to 1000 µg/L, and higher than 1000 µg/L. The primary purpose of the study was to determine whether differences exist between the presence of illicit drugs, drugs acting on QT interval and drugs metabolized by cytochrome P450. This study also aimed to determine whether there are differences between the cardiac, hepatic and pulmonary pathology of the three groups.

Materials and Methods: Methadone-related cases were reviewed retrospectively. The age of the victims ranged between 17 and 65 years. Most of the cases were male (109 cases). For all cases the complete autopsy, including histological examination and a full toxicological screening, was performed.

Results: The methadone blood levels were lower than 200 µg/L in 37 cases; between 200 and 1000 µg/L in 89 cases; and higher than 1000 µg/L in 23 cases. In the last group methadone was detected in hair for all victims. Hair analysis was performed in 61 cases: 49 cases tested positive for methadone (80.3%) and 39 cases were positive for cocaine. Higher methadone blood levels were observed in men (p -value 0.052) and did not differ significantly by age.

Only in five cases methadone was alone, in 90 cases other drugs metabolized by cytochrome P450 were found, without significant

differences between the three group (*p*-value 0.81). Illicit drugs were found in 62 cases (*p*-value 0.29), drugs acting on QT interval in 79 cases (*p*-value 0.07) and respiratory depressant drugs, mostly benzodiazepines, in 139 cases (*p*-value 0.38).

Different pathological changes (cardiac, pulmonary, hepatic) were observed in 97 cases (*p*-value 0.24). Coronary disease was observed in 60.6% of chronic methadone or cocaine abusers.

Discussion: This study illustrates the difficulty of interpreting postmortem methadone blood levels due to the possible interaction with others drugs acting the QT-interval or on the cytochrome P450, as well as the presence of pathological changes. The various interactions between drugs remain unclear and do not appear to be related to the methadone blood level. Genetic variability may exist in the response of sub-group of individuals to the drug and its metabolism, making them more susceptible to an overdose. More postmortem studies should be performed in order to further understand and prevent fatalities which are mostly often observed during substitutive programmes or during illicit intake.

Methadone, QT Interval, Overdose

G112 Deaths in Unlicensed Alcohol Rehabilitation Facilities

Lawrence Nguyen, MD, Los Angeles County Department of Coroner, 1104 North Mission Road, Los Angeles, CA 90033; and Christopher B. Rogers, MD, Los Angeles County Medical Examiner's Office, 1104 North Mission Road, Los Angeles, CA 90033*

After attending this presentation, attendees will be aware of the risk of death in unlicensed alcohol rehabilitation facilities.

This presentation will impact the forensic science community by making pathologists aware of a series of deaths of alcohol abusers in unlicensed facilities, and making the public aware of the risks of alcohol withdrawal without medical intervention.

A series of 17 deaths in alcohol rehabilitation facilities occurred in Los Angeles County between 1996 and 2010. In each an intoxicated Spanish-speaking alcoholic man was dropped off at an alcohol rehabilitation group by his family. The individuals remained at the facilities for varying periods of time and underwent several procedures for detoxification.

Reported treatment methods have included use of restraints, forcing the victim to drink ethanol or isopropanol, restraint with forced ingestion of alcohol, application of onions to the feet, and inserting a spoon in the victim's mouth.

In three cases there was a history of restraint use. Two additional decedents had both ethanol and isopropanol in the blood, although it was unclear whether the isopropanol was given at the facility. The causes of death included alcohol overdose, alcohol withdrawal, hemoperitoneum due to cirrhosis and a ruptured splenic vein, and diabetic ketoacidosis related to chronic pancreatitis. Most cases were closed as accident or natural, although three cases involving restraint were ruled homicide. In some cases, other members of the group were charged with involuntary manslaughter and false imprisonment.

The police are familiar with these groups and are able to close the facilities. However, new groups often form at the same addresses, requiring additional police action. Los Angeles County has disseminated a public health warning about these centers and has published a list of 57 alcohol treatment centers using non-medical methods of detoxification. However, it has been difficult to eradicate these groups.

It is recommended that medicolegal death investigators be aware of this information, as similar groups may exist in other areas.

Alcoholism, Investigation, Detoxification

G113 Was This Drug Overdose Due to Intravenous Injection or Oral Ingestion of Heroin — Can You Tell?

Johan A. Duflou, MM, Department of Forensic Medicine, PO Box 90, Glebe, Sydney, 2037, AUSTRALIA; Shane Darke, PhD, National Drug and Alcohol Research Centre, University of New South Wales, Sydney, 2052, AUSTRALIA; and Jennifer Easson, BSc, Division of Analytical Laboratories, Sydney West Area Health Service, Joseph Street, Lidcombe, 2141, AUSTRALIA*

After attending this presentation, attendees will be alerted to and understand potential pitfalls associated with interpreting opioid levels in various body fluids and other matrices. This will be illustrated by presentation of a recent case where a question requiring an answer was whether heroin had been taken intravenously or orally. Research data will be presented followed by an explanation of the various mechanisms thought to cause these apparently anomalous findings.

This presentation will impact the forensic science community by informing attendees of the pharmacokinetics of opioids in the gastrointestinal system, and alerting them to the dangers of not fully understanding the behavior of these drugs in the body.

Death due to heroin overdose is almost always the result of intravenous injection of the drug in Australia. A case is described where a heroin overdose was initially thought to be the result of oral ingestion of the drug, primarily as a result of higher concentrations of morphine in stomach contents than in blood. During the subsequent criminal trial and investigation, however, the issue of the entero-hepatic circulation of morphine was raised as a possible reason for the presence of morphine in the stomach contents.

For many drugs and poisons, a simple way of making the distinction between oral and parenteral administration is to analyze the stomach contents and compare the levels of the drug in the stomach with those in blood; a higher stomach contents concentration of the drug would generally be strong supportive evidence for the assertion that the drug or poison was administered orally. Morphine; however, in common with a range of other drugs, undergoes entero-hepatic circulation as part of the metabolism and elimination of the drug. The entero-hepatic circulation is a complex mechanism whereby chemicals that have undergone conjugation reactions in the liver, such as morphine, once in the gastrointestinal tract, may be subject to passive re-uptake, entering the circulation via the hepatic portal vein, returning to the liver where the chemical can be biotransformed again and then re-eliminated. Morphine may undergo several cycles of entero-hepatic circulation resulting in a significant increase in the retention time and its consequent duration of action. Further, both during life and in the perimortem and postmortem period, the pyloric sphincter offers at best a partial barrier to reflux of morphine-containing gastrointestinal contents from the duodenum to the stomach.

These mechanisms would explain the presence of significant concentrations of morphine in the stomach contents of intravenous heroin users and we hypothesised that such physiological mechanisms can result in higher concentrations of morphine in stomach contents than in blood, despite the drug having been administered intravenously.

This study reports on the distribution of opioids in blood, stomach contents, urine, liver and bile in 29 deaths due to intravenous heroin overdose. The mean total and free blood morphine concentrations were 0.60 mg/L and 0.32 mg/L, respectively, and the mean stomach contents total morphine concentration was 1.16 mg/kg. All cases had detectable morphine in the stomach contents, and 24 of 29 cases had higher concentrations of total morphine in stomach contents than in blood. The mean total morphine concentration in bile was approximately 100 times that in blood, and the liver total morphine concentration averaged twice that of blood levels.

Morphine was detected in the stomach contents in all cases in this study, and in 83% of cases the stomach morphine level was higher than that in blood. This would indicate that the entero-hepatic circulation materially affects morphine levels in the body, and that reflux of morphine from the duodenum into the stomach appears to be the norm, at least after death. Furthermore, even if the gall bladder had been removed surgically at some prior time, stomach morphine concentrations can still be higher than the blood total morphine levels, as illustrated in one case.

It's concluded that the current study demonstrated that stomach morphine levels cannot be relied upon to determine whether heroin had been orally or intravenously administered. Given the large number of drugs and poisons which undergo entero-hepatic circulation, it would appear prudent to not make comment on route of administration of such drugs unless definite evidence of oral ingestion of the drug can be obtained, for example through visualization of appropriate pill fragments.

Heroin Overdose, Illicit Drug Use, Pharmacokinetics

G114 First Reported Case of Bromo-Dragonfly Fatality in the United States, San Jose, California, County of Santa Clara

Michelle A. Jorden, MD, Santa Clara Medical Examiner, 850 Thorton Way, San Jose, CA 95128; Lee M. Blum, PhD, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090; and Joseph Corvo, BS, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090*

The goal of this presentation is to educate the forensic community of overdoses with rare chemicals used by young adults.

This presentation will impact the forensic science community by illustrating and emphasizing the importance of a thorough scene investigation, keeping an open mind to the curiosity of young adults and drug experimentation, and good communication with the consulting laboratory.

Like LSD, Bromo-DragonFLY is a psychedelic hallucinogenic drug that is extremely potent. In 1998, Matthew Parker synthesized Bromo-DragonFLY and because the molecule's structure resembled a fly, it was nicknamed FLY. Bromo-DragonFLY is a psychedelic phenethylamine and a non-subtype selective 5-HT2 (serotonin) agonist, considered less potent than LSD, but exhibits a longer duration of action and can last for up to two to three days.

The drug is ingested and the mechanism of drug toxicity is unclear, but based on numerous reports from individuals experimenting with this particular drug and their side effects, the mechanism of action appears to involve a severe peripheral vasoconstriction. Delayed onset of seizures, gangrenous extremity involvement, and extremely bad trips have been reported with one drug trip being described as "It was like being dragged to hell and back again many times. It is the most evil thing I've ever tried. It lasted an eternity."

In September 2009, the Santa Clara County Medical Examiner Office was called to the scene involving the sudden death of an otherwise healthy 18-year-old white male. According to the investigation, he was experimenting with and ingesting a new drug called 2C-B-FLY, which had been purchased through the internet, with his brother and his brother's girlfriend. The decedent's brother stated that the decedent ingested the least amount of the drug. Over the next two to three hours, the decedent appeared to be having a "difficult trip" then underwent seizure-like activity and became unresponsive. The decedent could not be resuscitated by emergency services and expired. The autopsy examination revealed an unkempt white male whose autopsy was unremarkable except for marked pulmonary edema, a non-specific finding seen in drug overdose cases and a thymic cyst. Because the medical examiner had no experience with 2C-B-FLY, additional insight

to the drug and its effects was gained by searching a online library, a website suggested by the decedent's father. During this time, the comprehensive toxicology screen on the peripheral blood reported the presence of phentermine at a concentration consistent with therapeutic levels, marijuana, nicotine and cotinine, and atropine, most likely due to resuscitative attempts. The medical examiner remained suspicious that this death represented an acute drug overdose, especially in light of the circumstances surrounding the death, and consultation with a toxicologist was pursued.

Further information gathered later in the course of the investigation revealed that in October 2009, a batch of Bromo-DragonFLY, purchased from Denmark, was distributed as the less active compound 2C-B-FLY, with a packaging label of "batch b1," one of which was purchased by the decedent's brother. Toxicological analysis specifically for 2C-B-FLY and Bromo-DragonFLY was undertaken. The analytical technique used for this work was gas chromatography/mass spectrometry (GC/MS). 2C-B-FLY was not detected in any of the specimens. Only Bromo-DragonFLY was detected in each of the specimens at the following concentrations: in peripheral blood 22 nanog/mL; in gastric fluid 38 nanog/mL; in urine 28 nanog/mL; and in bile 350 nanog/mL. Bromo-DragonFLY levels in beta-glucuronidase treated urine and bile were 49 ng/mL and 470 ng/mL, respectively. Review of the literature revealed one paper from Denmark in 2009 of an 18-year-old woman who died of a fatal Bromo-DragonFLY overdose and the reported femoral blood concentration was 4.7 ng/mL (MF Andreasen et al., 2009).

Since October 2009, rare lethal overdoses were reported from the distributed batch and to our knowledge this case represents the only United States fatality resulting from Bromo-DragonFLY. The decedent's brother and his girlfriend were admitted to the hospital for observation, and luckily recovered from their drug trip, although both were experiencing effects of the drug hours later. Both parties reported the drug trip was long lasting and not a comfortable experience.

In summary, this case illustrates the combined efforts of the medical examiner-coroner office and the toxicologist to identify the substance which led to the sudden death of a young adult experimenting with a purchased, non-controlled drug from overseas. Although our case represents the only reported fatality from Bromo-DragonFLY in the United States, it serves to illustrate and emphasize the importance of the combined efforts of different agencies to help render a cause and manner of death.

Bromo-Dragonfly, Overdose, Drug Experimentation

G115 Sudden Unexpected Infant Death: Lymphocytic Meningoencephalitis With Multiple Retinal Hemorrhages

Patrick E. Lantz, MD, Wake Forest University, School of Medicine, Department of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072; Amy M. Durso, MD, Professional Pathology Services, One Science Court, Suite 200, Columbia, SC 29203; and Ryan T. Mott, MD, Department of Pathology/Wake Forest University Health Sciences, Medical Center Buolevard, Winston Salem, NC 27157-1072*

After attending this presentation, attendees will learn how multiple retinal hemorrhages extending to the ora serrata are not diagnostically specific for abusive head trauma (shaken baby syndrome).

The presentation will impact the forensic science community by expanding the list of conditions in infants associated with multiple retinal hemorrhages that extend to the periphery of the retina.

This presentation will inform attendees of something they do not know—multiple retinal hemorrhages, involving the peripheral retina and extending to the ora serrata in infants, are not specific for abusive head trauma (shaken baby syndrome).

Numerous authors contend that specific ophthalmological findings in infants and young children with abusive head trauma (AHT) include numerous retinal hemorrhages that extend far into the periphery of the retina. Listed non-traumatic causes of retinal hemorrhages—coagulopathy, sepsis, meningitis, vasculopathies, increased intracranial pressure, and cardiopulmonary resuscitation—reportedly do not result in the multiplicity and peripheral distribution of the hemorrhages associated with AHT.

This case presents a 7 $\frac{3}{4}$ -month-old male infant with multiple retinal hemorrhages extending to the ora serrata who died suddenly and unexpectedly from severe, diffuse lymphocytic meningoencephalitis. He had had rhinorrhea and upper respiratory congestion for about two weeks. His mother had been giving him acetaminophen every four hours. Otherwise, he had been healthy. He was placed down for a nap around 2:30 p.m. and was found unresponsive at about 3:00 p.m. Resuscitative efforts were begun immediately. A call was made to 911 at 3:05 p.m. and EMS arrived at 3:13 p.m. He was transported to the emergency department (ED) and arrived at 3:35 p.m. He was pronounced dead at 4:07 p.m. following 32 minutes of resuscitative efforts in the ED.

The medicolegal autopsy was performed 17 hours after he was pronounced dead. There was no evidence of trauma, skull fractures, intracranial hemorrhages or injury of the brain or spinal cord. Microbiological cultures of blood, trachea and lung were non-contributory. A skeletal survey did not reveal any evidence of acute or healing fractures. Subsequent toxicological analysis did not detect any licit or illicit drugs that caused or contributed to his death.

Postmortem monocular indirect ophthalmoscopy detected multiple retinal hemorrhages. The fundal hemorrhages in the left eye were over the posterior pole extending past the equator and abutting the ora serrata in all four quadrants; three small retinal hemorrhages were in the right globe.

His calvarial *dura* was smooth with areas of hyperemia and congestion of dural vessels, but no subdural extravasated blood or membranes were present. The dural venous sinuses were patent and the leptomeninges had no areas of extravasated blood. The cerebrum had a well-defined grey-white junction with no lesions in the cortex, white matter, or subcortical nuclei. The cerebral ventricles were of normal caliber and the ependymal lining of the ventricles appeared normal for age. The brainstem was normally developed with no gross abnormalities. The cerebellum exhibited normal folia, white matter, and dentate nuclei. The spinal cord had no areas of hemorrhage or exudates.

Microscopically, the cerebrum, brainstem, and cerebellum showed a multifocal lymphocytic infiltrate with numerous microglial nodules and neuronophagia. The inflammatory process involved the cerebral grey and white matter (including the basal ganglia), brainstem grey matter, and cerebellar white matter. The brainstem involvement was diffuse, with inflammatory foci in the midbrain, pons, and medulla; the spinal cord was not involved. No viral inclusions or areas of necrosis were seen. There was lymphocytic involvement of the cerebral leptomeninges and small perivascular lymphocytic collections were just deep to the ependyma. No significant ventriculitis was present. Immunohistochemical (IHC) stains for CD4 and CD8 showed a multifocal T-cell inflammatory infiltrate within the cerebral parenchyma and around blood vessels. An IHC stain for CD20 highlighted a smaller number of B-cells around blood vessels and within the parenchyma. The ICH stain for CD68 highlighted the microglial nodules and IHC stains for CMV, HSV-1, and HSV-2 were negative. The Centers for Disease Control performed IHC testing for panentero viruses and EV71 plus polymerase chain reaction (PCR) for enterovirus and parechovirus—all were negative.

Meningoencephalitis is a rare complication of common infantile viral infections. Most viral infections with central nervous system manifestations cause either meningeal involvement, namely aseptic meningitis, or a mild clinical syndrome of meningoencephalitis rather than a fatal form of encephalitis. The causative agent in this case was not

apparent despite IHC and PCR testing for enteroviruses and parechoviruses. Of particular interest, this infant had numerous retinal hemorrhages in the left globe distributed posteriorly, equatorially, and peripherally—a finding considered by many authors unique to AHT and indicative of repetitive acceleration-deceleration injury (shaken baby syndrome). It is imperative that forensic pathologists not equate multiple retinal hemorrhages with a peripheral distribution exclusively with AHT. Postmortem ocular findings must not be interpreted in isolation, but correlated with the circumstances of the death plus the anatomic and histopathologic findings.

Retinal Hemorrhages, Lymphocytic Meningoencephalitis, Abusive Head Trauma

G116 Parietal Pseudofracture in Children Suggesting Non-Accidental Trauma: A Report of Two Cases and Review of the Literature

Pauline Saint-Martin, MD, and Camille Rerolle, MD, Hopital Troussseau, Service de Medecine Legale, CHRU TOURS, TOURS, 37000, FRANCE; Thierry Lefrancq, MD, Le Vauban, BP 549, 16 rue Clerget, NEVERS, 58009, FRANCE; and Patrick O. Byrne, MD, Service de Medecine Legale, Hopital Troussseau, CHRU TOURS, TOURS, 37000, FRANCE*

After attending this presentation, attendees will learn the characteristics of variation in sutures of the pediatric skull that may make it difficult to distinguish from real fractures based on imaging criteria alone.

This presentation will impact the forensic science community by emphasizing the legal complications caused by mistaking normal variation of the pediatric skull for fracture and by aiding in better understanding of these pseudofractures of the skull in infants.

Introduction: Two cases of infants who died at home are reported. Both were previously healthy and had no history of trauma according to the parents. As in all suspected cases of SIDS, a complete autopsy was performed. For both cases, radiographic or computed tomography (CT) scan findings were initially interpreted as parietal fractures and raised the possibility of non accidental trauma.

Case reports: The first case was a 3-month-old female child who was found dead at home by her mother. An autopsy was performed the same day. A skeletal radiographic survey showed two linear radiolucencies in the parietal region mimicking a fracture of the right parietal bone. At autopsy there was an H-shaped abnormality of the right parietal bone with no associated soft tissue swelling. The brain was normal. There were severe pulmonary lesions and a test for the respiratory syncytial viral antigen was positive. Histological sections of the parietal bone showed two vertically unossified membranous strips linked by a horizontal membranous strip. Death was attributed to pulmonary infection. The second case was a 6-month-old male child who was found dead at home by his mother. An autopsy was performed. A bone window CT scan showed a linear defect in the left parietal bone. At autopsy, no scalp swelling or bruising was noted. The rest of the autopsy was normal. Microscopic sections of the decalcified parietal bone demonstrated neither inflammatory infiltrate nor periosteal reaction. The findings were consistent with an unossified membranous strip. Cause of death was not identified.

Discussion: According to the literature, the parietal bone is the most common fracture site in children, in both accidental and non-accidental trauma. However, an extensive study of the embryogenesis of the parietal bone was made by an author who discovered a variety of anomalous parietal suture, described as failure of ossification of a strip of membranous parietal tissue. These normal variations or pseudofractures are rare and may simulate skull fractures, especially in live infants when histological examination is not available. Overlooking

a fracture of the pediatric skull is a serious situation, but to mistake normal variation for a skull fracture may cause legal complications as well. Awareness of differential diagnosis such as vascular markings, sutures, and artifacts that may masquerade radiographically as skull fractures in infants is essential for the forensic pathologist.

Membranous Unossified Strip, Skull Fracture, Non-Accidental Trauma

G117 Methadone and Cocaine Related Death in A Young Boy: A Case Report

Francesco Ausania, MD, Institute of Forensic Medicine, Catholic University, School of Medicine, Ro, largo Francesco Vito 1, Rome, ITALY; Massimo Senati, PhD, Largo Francesco Vito 1, Rome, ITALY; Nadia Fucci, PhD, largo francesco vito 1, Rome, ITALY; Antonio Oliva, PhD, Institute of Forensic Medicine, Catholic University, School of Medicine, Ro, Largo Francesco Vito 1, Rome, ITALY; and Pietrantonio Ricci, PhD, Università degli Studi Magna Grecia Catanzaro, Viale Europa - Località Germaneto, Catanzaro, ITALY*

After attending this presentation, attendees will learn of the possibility of cases where a synergic effect of cocaine and methadone could be assumed as the cause of death.

This presentation will impact the forensic science community by the discussion regarding pharmacokinetic and pharmacodynamic drug interactions between cocaine and methadone.

Background and Learning Objective: In recent years, a significant increase in the number of fatal intoxications with methadone has been reported in Italy. The abuse of methadone is most frequently seen in conjunction with the abuse of other drugs. Cocaine and methadone are rarely co-intoxicants in cases of combined drug toxicity. The interpretation of blood methadone concentrations alone or combined with other psychoactive drugs requires careful and accurate consideration of the subject's potential chronic use of and tolerance to the drug. Moreover, determining the cause of death in methadone and cocaine positive cases requires a strong correlation with autopsy results and investigative findings. The goal of this study is to discuss the possible mechanisms and eventually the synergic effect of cocaine and methadone in causing the death of a young boy.

Case Report: A 15-year-old young man was found dead during the early morning in his bed at home. Police investigations ordered by the public prosecutor revealed that the young boy, the night before, had used cocaine and methadone for the first time.

Results: At the autopsy, lungs were edematous and congested with absence of major diseases. Main findings at the histological investigation were widespread myocardial interstitial edema and focal vascular congestion. Toxicological analysis detected cocaine, methadone, and related metabolites at the following concentrations.

Blood: benzoyllecgonine = 50 nanograms/ml; cocaine=40 nanograms/ml; methadone=274 nanograms/ml; EDDP = 166 nanograms/ml. **Urine:** benzoyllecgonine = 9000 nanograms / ml, cocaine = 153 nanograms / ml methadone = 300 nanograms/ ml; EDDP = 200 nanograms/ml. Traces of cocaine were also found in the nasal mucosa.

Conclusions: It is well known in forensic field that it can be very difficult to determine what mechanism(s) are responsible for drug interactions especially in cases as such, where the deceased cannot be considered as habitual drug-user. Moreover, it should be taken into account that the presence of methadone is often an incidental finding during postmortem examination which is unrelated to the cause of death and that postmortem measurements of methadone or its metabolite cannot be used in isolation to identify which deaths are associated with methadone toxicity. Very little information is available from the literature regarding methadone-cocaine co-intoxications. In our case we can only hypothesize an interaction between these drugs on different organs, such as heart and central nervous system. Pharmacokinetic and

pharmacodynamic drug interactions mechanism and the possible explanation in determining the cause of death in this case will be discussed.

Methadone, Cocaine, Synergic Effect

G118 Sudden Death Due to Dengue Fever in an 8-Month-Old Baby

Mohd Shafie Bin Othman, MD, Forensic Department Hospital Raja Permaisuri Bainun, Jalan Hospital 30450, Ipoh, 31350, MALAYSIA; and Santina Cantatore, Dania De Carlo, MD, and Margherita Neri, PhD, Department Forensic Pathology, University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY*

The goal of this presentation is to present a case of postmortem diagnosis of dengue related death in a suspect sudden infant death syndrome.

This presentation will impact the forensic science community for the postmortem diagnosis of dengue fever like cause of death in a suspect case of SIDS.

Dengue virus (DENV) infection is caused by one of four antigenically distinct but related single stranded, positive-sense RNA viruses in the family Flaviviridae. This virus is transmitted by mosquito vectors, primarily *Aedes aegypti*. Four serotypes (DENV-1, DENV-2, DENV-3, and DENV-4) circulate worldwide. Dengue fever is one of the most significant re-emerging tropical diseases; it is now endemic in more than 100 countries in Africa, the Americas, the Eastern Mediterranean, South-East Asia, and the Western Pacific. South-East Asia and the Western Pacific are the most seriously affected. Dengue causes a severe flu-like illness and sometimes a potentially lethal complication called dengue hemorrhagic fever (DHF). Dengue hemorrhagic fever (DHF) is a potentially deadly complication that is characterized by high fever, often with enlargement of the liver, and in severe cases circulatory failure. The illness often begins with a sudden rise in temperature accompanied by facial flush, and other flu-like symptoms. The fever usually continues for two to seven days and can be as high as 41°C, possibly with convulsions and other complications. Frequently fatal cases of dengue death occur in the hospital. The clinical features of dengue fever vary according to the age of the patient. Infants and young children may have a fever with rash. Older children and adults may have either a mild fever or the classical incapacitating disease with abrupt onset and high fever, severe headache, pain behind the eyes, muscle and joint pains, and rash. Some cases develop much milder symptoms which can be misdiagnosed as influenza or other viral infection when no rash or retro-orbital pain is present. When dengue infections proceed to DHF symptoms, DHF causes vascular leak syndrome which includes fluid in the blood vessels leaking through the skin and into spaces around the lungs and belly. This fluid loss and severe bleeding can cause blood pressure to fall, then Dengue Shock Syndrome (DSS) sets in, which has a high mortality rate. In babies a pauci-symptomatic fatal case could be confused with a SIDS or a homicide. The case presented concerns an 8-month-old male infant was found unresponsive during a nap in his nursery school. The baby was quickly taken by ambulance but was declared dead on arrival at the hospital. Body was cold. The police took information by the nursery school teacher: three hours prior to death, the child was given plain water through a bottle before being put to sleep on a mattress on the floor, the baby frequently slept in prone position. The infant had been cared for by the nursery school since the age of three months. There was a history of mild fever illness for the previous weeks before the death and he was being treated with antipyretic drugs. The prosecutor began an investigation of the nursery school, arranged the autopsy on the body to clarify the exact mechanism of death: SIDS, accident, or homicide? The autopsy was performed six hours after death. The infant was well hydrated and well nourished, with body length of 68 cm and weighed 6920 g. He was pale with mild peripheral cyanosis

noted. Faint lividity was still noticeable at front part of body. There was blood-stained fluid oozing out of the nostrils and mouth on turning the body. There wasn't a rash or petechial hemorrhages on the skin. Fundal ophthalmoscopic examination didn't show retinal hemorrhage. No signs of external injury were detected, with the exception of puncture marks at the dorsum of both hands in a tentative of resuscitation. All the internal organs were congested. Pleural cavities contained 12 cc of yellow fluid. The lungs were edematous with areas of hemorrhage mainly seen on the right side. The upper airway was filled with froth and admixed with blood-stained fluid. Pericardial cavity contained 2 cc of yellow fluid. The heart showed few epicardial petechiae. Abdominal cavity contained 15 cc of yellow fluid. Stomach was empty. Liver was congested and had beefy appearance on cut sections. Other organs were unremarkable except of edema. Histopathologic examination showed in heart samples wide foci of early contraction bands necrosis, colliquative myocytolysis grade II, perivascular and interstitial infiltration of lymphocytes, monocytes and plasmacells. Lungs present alveolar septa mildly thickened by edema and capillary congestion, alveolar edema; lymphocytes, monocytes and plasma cells infiltrates septa and bronchial walls. In some fields, also numerous endoalveolar erythrocytes were observed. In liver, kidney, and spleen samples, there were perivascular mononuclear cells infiltration. An immunohistochemical study using antibody anti CD 3, CD4, CD 8, CD 20 and CD68 for the tipization of leucocytes infiltrations was performed. Serological dengue screening using captured ELISA was positive for IgM but negative for IgG. The case showed that dengue infection may be asymptomatic or paucisymptomatic before a sudden death, so dengue fever should be included in the differential when a forensic pathologist must discern between a SIDS a homicide or a death related-dengue, particularly in endemic areas for dengue, like Malaysia.

Dengue Fever, Histological Findings, Postmortem Diagnosis

G119 Sudden Death in the First Year of Life: The Importance of Pancreatic Histomorphological Analysis

Francesco Paolo Busardo, MD, Institute of Legal Medicine, Via Del Vespro, 129, Palermo, 90100, ITALY; Stefania Zerbo, MD, Institute of Legal Medicine, Via Del Vespro, 127, Palermo, 90100, ITALY; Antonina Argo, Via Del Vespro 127, Palermo, 90100, ITALY; Liliya Gutsul, MD, Instituto, Via Del Vespro, 127, Palermo, 90100, ITALY; Paolo Procaccianti, Palermo University, Via Del Vespro, N. 127, Palermo, 90100, ITALY; and Emiliano Maresi, Via Del Vespro 127, Palermo, 90100, ITALY*

After attending this presentation, attendees will be able to better understand the importance of pancreatic histomorphological examination after a complete autopsy in sudden infant death, to discriminate between the explained natural sudden death and natural idiopathic sudden death (SIDS).

This presentation will impact the forensic science community by discussing the role of endocrine/metabolic pancreas disease as cause of sudden infant death, providing valid evaluation parameters to the diagnosis.

Material and Method: From 1990 to 2009, 175 autopsies (137 males and 43 females) were performed on infants suddenly dying of natural causes within the first year of life. The diagnosis of sudden natural death has been established through a complete autopsy and investigation including scene examination, review of family, social and medical history and toxicology studies. The age ranged between 2 and 273 days (median 42 days).

In 19 cases, death was unexplained (SIDS) while in 156 cases, it was due to congenital or acquired diseases (explained sudden infant death), primarily involving different systems: cardiovascular (121

cases); respiratory (15 cases); endocrine/ metabolic (12 cases); gastrointestinal (4 cases); central nervous system (4 cases).

Autopsy protocol were based on Perinatal Autopsy Manual. Washington, D.C.: Armed Forces Institute of Pathology, 1983, and on Paediatric Autopsy Techniques - Enid Gilbert-Barness and Diane E. Debich-Spicer in Handbook of Pediatric Autopsy Pathology, Humana Press pp.7-74, 2005. From a histological point of view, according to 2,875 fetal and pediatric autopsies, the following morphological pancreatic parameters were examined: (1) lobular architecture; (2) interstitial thickness; (3) number, branch and volume of ductular-acinar units; (4) number, size and cytology arrangement of islet (quantitative relation between α , β , and δ cells); (5) inflammatory infiltrates; and, (6) heterotopic erythropoiesis.

This analysis was performed on serial sections stained with hematoxylin-eosin, Alcian-PAS, Mallory's trichrome and Giemsa and partly investigated immunohistochemistry using antibodies anti-insulin and anti-glucagon.

Results: In the context of explained sudden natural death in the first year of life, pancreatic histological examination has allowed us to identify 11 cases related to endocrine/metabolic disease, of which, in nine cases, were interested the islets of Langerhans (endocrinous pancreas), and in two cases ductular-acinar units (exocrine pancreas).

The endocrine/metabolic diseases involving endocrinous pancreas were: glycogenosis (type 1b and 2)(five cases); maternal diabetes (2 cases); nesidioblastosis (2 cases (1 case in monochorionic twin)). The endocrine/metabolic diseases involving the exocrine pancreas were: cystic fibrosis (2 cases) macronesia and polynesia were observed in pancreas of both patients with glycogenosis and in children of diabetic mothers, these aspects were due to hyperplasia of the α -cells in patients with glycogenosis, and β -cell hyperplasia in children of diabetic mothers.

In these cases also present were cytoatipism of β -cell and eosinophilic granulocyte infiltration of the islets. In subjects with nesidioblastosis there was only a diffuse polynesia neoformation of islet from duct epithelium.

The cystic ectasia of the ductular-acinar structures associated with pink inspissated secretion was observed in cystic fibrosis.

Discussion and Conclusion: A complete autopsy is essential to establish the causes of sudden explained death in the first year of life. This approach allows to sample, for histomorphological examination, organs such as the pancreas that are almost always free of macroscopically visible changes.

The results of the study show that, in addition to the consolidated sampling of pancreas in autopsy, a complete and focused histomorphological study as suggested, allowing the identification of endocrine-metabolic anomalies, such as glycogenosis, nesidioblastosis, and cystic fibrosis, only rarely reported in the literature as a cause of sudden death in the first year of life.

This research demonstrated that, glucose postmortem levels in plasma and vitreous are not reliable for identifying potential endocrine-metabolic diseases, certainly the histomorphological data of the pancreas is the most reliable.

Glycogenosis, Nesidioblastosis, Sudden Infant Death

G120 Isolated Coronary Anomalies and Sudden Death in the Young

Emiliano Maresi*, and Livio Milone, PhD, Via Del Vespro, N. 127, Palermo, 90100, ITALY; Paola Pugnetti, MD, Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via Del Vespro, n. 129, Palermo, 90127, ITALY; Francesco P. Busardo, MD, Institute of Legal Medicine, Via Del Vespro, 129, Palermo, 90127, ITALY; Nunzia Albano, MD, Pierangela Fleres, MD, Via Del vespro 127, Palermo, 90100, ITALY; and Paolo Procaccianti, Palermo University, Via Del Vespro, n. 127, Palermo, 90100, ITALY

After attending this presentation, attendees will be able to better understand the importance of coronary examination (origin, course, and lumen canalization) during autopsy of young people suddenly dead, to identify coronary artery anomalies.

This presentation will impact the forensic science community by improving knowledge of natural causes of juvenile sudden death (SD).

Background: Coronary artery anomalies (CAAs) had been some of the most confusing, neglected topics in cardiology. In the 1990s, the subject of CAAs underwent to profound evolution related to substantive methodological changes regarding the definition, incidence, morphology, clinical presentation, diagnostic work-up, prognosis, and treatment. CAAs are most frequently found in association with congenital heart diseases (great arteries transposition, tetralogy of Fallot, common artery trunk) and hypertrophic or dilated cardiomyopathy, but can also occur in the absence of other cardiovascular diseases ("isolated coronary artery anomalies"). Isolated CAAs are rare, found in: 0.2–2.2% of autopsies of all ages; 0.5% of pediatric autopsies; 0.6–1.3% of coronary angiograms in adults. CAAs represent common causes of exercise-related sudden death (SD) in young people (≤ 35 years of age). The mechanism of SD is believed to be episodic myocardial ischemia.

Objectives: The goal of the current study is to detect the frequency, type, and possible pathophysiology due to "isolated" CAAs in an autopsy population of the young, suddenly dead for cardiovascular diseases (CSD).

Methods: In the time interval from January 1990 to December 2009, 236 consecutive cases were collected of cardiovascular sudden death in young people. In all of the cases, the analysis of death circumstance (*most of the deaths analyzed were testified*), the complete autopsy and the toxicological essays let us establish that death was: natural, violent, sudden. The juvenile CSD was defined as unexpected death as a result of natural cardiovascular causes within one hour of initial symptoms in persons ≤ 35 years of age.

Results: Forty nine sudden deaths in young people were reported, identified solely at autopsy and due to: right coronary artery from the left sinus ($n = 15$); right coronary artery above anterior commissure ($n = 11$); left coronary artery from right coronary sinus ($n = 3$); intramyocardial course ($n = 10$); obstructive valve-like ridge in the Valsalva's sinus and intra-right coronary ostium ($n = 9$); left anterior descending artery from right coronary sinus ($n = 1$). The CAAs was either isolated ($n = 43$, 87.8%) and associated to hypertrophic cardiomyopathy ($n = 6$, 12.2%). In all patients (43 males and 6 female, age ranging from 13 months to 35 years; median, 22.6), sudden death was the first manifestation of the disease and familial history was negative. The fatal outcome occurred after physical effort ($n = 27$, 55%), at rest ($n = 16$, 32.6%), or after emotional stress ($n = 6$, 12.4%). Unquestionable ischemic damage within the related myocardium, in the absence of obstructive coronary atherosclerosis or other cardiac diseases, was observed in all cases: acute myocardial infarction ($n = 29$, 59.2%), healing myocardial infarction ($n = 4$, 8.2%), healed myocardial infarction ($n = 16$, 32.6%). In this study of Juvenile CSD, death was precipitated by isolated CAAs in 21% of cases.

Conclusion: Data from this collection confirms that isolated CAAs may account for juvenile CSD and that fatal event is frequently the

manifestation of the disease, it is precipitated by effort and depends on ischemic damage within the related myocardium. Recognition during life of these anomalies, by the use of non-invasive procedures, is mandatory to prevent the risk of SD and to plan the screening in competitive athletes.

Coronary Artery Anomalies, Juvenile Sudden Death, Forensic Pathology

G121 Pathologic and Anthropologic Manifestations of Documented Repetitive Blunt Trauma in a Child Abuse Case

Pramod Gumpeni, MD*, Jason M. Wiersema, PhD, and Luis A. Sanchez, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054

After attending this presentation, attendees will see the pathologic and anthropologic manifestations of repetitive blunt trauma to the ribs of child.

This presentation will impact the forensic science community by illustrating the utility of a collaborative effort in the interpretation of repeated injury.

The child had been in the care of the birth mother for the first six years of his life and had reached all appropriate mental and physical developmental milestones. The mother placed the decedent in the care of the decedent's father (with whom the child had no prior contact) fifteen days prior to his death in the interest of fostering a paternal relationship.

The decedent presented to the Harris County Institute of Forensic Sciences (HCIFS) following his demise at a local hospital. The terminal history, provided to the HCIFS investigator by the father's girlfriend was that the decedent had been repeatedly beaten about the chest by the father for an approximate 8-hour-period. The beating was apparently precipitated by the child's refusal to go to sleep. The father reported that the child began exhibiting seizure-like activity after which emergency medical services were contacted. The unresponsive decedent was transported to the hospital, where he was pronounced six minutes after arrival.

The birth father and his female acquaintance ultimately confessed that the child was beaten in a similar manner for the duration of the two week period during which he was in their custody. They stated that the decedent would be made to sit on his knees, with his arms held up while the father would repeatedly punch him in the left axilla and chest. After several days, the child exhibited pain, and the father began punching the decedent in the right axilla and back. In addition, the female acquaintance admitted to the use of a belt to strike the decedent on the back. The father ultimately stated that he pushed the decedent forcibly into the shower, striking the back of the decedent's head against the wall immediately prior to the onset of his seizure-like symptoms.

Autopsy of the child showed numerous confluent contusions over the decedent's torso, predominantly in the left and right axilla extending down to the flank, the upper chest, and over the mid and lower back. There were numerous abrasions over the extremities. Several contusions were present over the scalp, with brain contusions identified on internal examination. A large fibrous mass lesion consisting of resolving hematoma, granulation tissue, and early callous formation was found in the left upper axilla involving the anterior bodies of left ribs 2-4. There were also bilateral pleural effusions, with 550 cc of serosanguinous fluid in the left pleural cavity, and lacerations of the liver and right adrenal, with marked retroperitoneal hemorrhage. Initial x-rays of the chest showed a heterogeneous mass lesion in the left upper chest.

Per HCIFS protocol, the decedent underwent a complete skeletal examination in search of skeletal injury. This process involved resection of the muscle and periosteum overlying the long bones, ribs, and

scapulae. Skeletal trauma was limited to the ribs, and the rib cage was recovered for anthropological analysis. There were multiple series of serial rib fractures displaying morphology consistent with direct impact(s) at the site(s) of the fractures. The fractures were in varied stages of healing, ranging from acute fractures with sharp margins and no visible callus formation to the presence of large, disorganized soft calluses overlying complete transverse fractures. The array of skeletal injuries was consistent with repeated impacts to the anterior and lateral chest.

This case provides a unique view of the effects of repetitive blunt injury directed to specific regions of the body over the span of two weeks, and the physiological consequences of such trauma to both bone and soft tissue. It also illustrates the utility of a detailed terminal history in the interpretation of blunt force injury.

Repetitive Injury, Blunt Trauma, Child Abuse

G122 Pregnancy, Caesarean, and Pheochromocytoma: A Case Report With a Fatal Outcome

Isabelle Plu, PhD, Denis Barres, MD, and Dominique Lecomte, PhD,
Institut Médico-Légal, 2 place Mazas, Paris, 75012, FRANCE*

After attending this presentation, attendees will be aware of the clinical, physiological, diagnostic, and therapeutic features of pheochromocytoma during pregnancy.

This presentation will impact the forensic science community by explaining how pheochromocytoma can cause sudden death (maternal and fetal death) in pregnant women if the condition is undiagnosed and left untreated. From this case report, attendees will be able to identify the clinical milestones which can indicate medical malpractice and which can determine whether the fatal outcome was predictable.

The subject of this presentation is a 43-year-old full term pregnant woman who was scheduled for a cesarean delivery in October 2009. At the start of the C-section, she developed a sudden and malignant high blood pressure with hemoptysis, sweat, and tachycardia. The C-section delivered a dead newborn who was successfully resuscitated. The mother died after persistent cardiac arrest.

A judicial autopsy was requested. It revealed an acute pulmonary edema which explained the death and a voluminous tumor of the left adrenal gland which was necrotic and hemorrhagic suggesting a pheochromocytoma. The diagnosis of pheochromocytoma was confirmed by pathological analyses.

The magistrate requested the obstetrical records of the patient be studied. The patient's first pregnancy was in 2005-2006 and her last pregnancy was in 2009. According to these medical records, the woman had a no serious medical history:

- During her first pregnancy (2005-2006), the patient developed gestational diabetes mellitus which was successfully treated by controlling diet. Throughout the follow-up during the pregnancy, blood pressure and cardiac rhythm were stable. At 31 weeks of pregnancy + 5 days, the patient had an episode of malaise during a fetal ultrasound, which resolved spontaneously.
- The baby was delivered by C-section before labor in January 2006. C-section was performed because of low fetal heart rate and failure to induce labor. The newborn was healthy and the patient's diabetes mellitus disappeared after the delivery.
- During her second pregnancy (2009), the patient developed gestational diabetes mellitus which was treated by controlling her diet and insulin (16 weeks of pregnancy). In July 2009 (at 29 weeks of pregnancy + 6 days), the patient had a drop in blood pressure with hypoglycemia and a low fetal heart rate was detected. The patient was admitted to hospital for further

investigations and medical supervision for three days. All medical investigations were normal and all abnormalities disappeared spontaneously. A delivery by C-section was scheduled at 37 weeks of pregnancy because of previously scared uterus and gestational diabetes mellitus. The woman was admitted to the hospital one day before. The C-section delivered a dead newborn who was successfully resuscitated. The mother died after resistant cardiac arrest.

This case is interesting from both a medical and medico-legal point of view.

Pheochromocytoma is a rare tumor of the adrenal glands which secretes catecholamine. It can be diagnosed by the classic triad of symptoms —headache, sweating, and tachycardia— which result from arterial hypertension, paroxysmal high blood pressure, acute pulmonary edema, and fatal cardio-pulmonary failure. In pregnant women, the incidence of pheochromocytoma is very low, and its symptoms can mimic gestational hypertension, preeclampsia, or eclampsia. Diabetes mellitus can be due to pheochromocytoma in pregnancy, but is seldom the only symptom. Because of the low incidence of pheochromocytoma in pregnancy, any systematic/mass screening by urinary catecholamine measurement is not requested in pregnant women, except in cases of refractory hypertension.

From a medico legal point of view, we can presume, with hindsight, that the gestational diabetes mellitus was a symptom of the pheochromocytoma, as was the malaise and the low blood pressure which happened during the gestations. However these features are not specific to pheochromocytoma, and are frequent in pregnancy, which explains the difficulty in diagnosis.

Conclusion: This case is unusual. First, it led to maternal death; and, second, the diagnosis of the tumor was postmortem, being unnoticed during the management of pregnancy. It can also be presumed that the pheochromocytoma was asymptomatic between the two pregnancies of the patient since no medical history was reported in her medical records.

Pheochromocytoma, Cesarean, Maternal Death

G123 Infant Death Evaluation: What is the Constellation of Abusive Injuries?

M.G.F. Gilliland, MD, Brody School of Medicine at East Carolina University, Pathology & Lab Medicine, Brody 7S-10, Greenville, NC 27858-4354*

After attending this presentation, attendees will be able to identify components of a constellation of abusive injuries that can be used to reliably identify a subset of abusive injuries.

This presentation will impact the forensic science community by providing knowledge of components of a constellation of abusive injuries that can be used to reliably identify a subset of abusive injuries allowing them to more competently perform determinations of cause and manner of death.

Hypothesis: No single finding is pathognomonic of abusive injuries to infants and children. Findings suggestive of abusive injuries must be used in conjunction with other information to reliably determine that a death is the result of abusive injuries. Additional investigative information about the reliability or number of histories provided by caregivers has been described as useful in this regard. Investigative information about delays in seeking medical attention has been seen more commonly in abusive injuries.

Materials: Information about the circumstances surrounding collapse or death, medical treatment, past medical history, law enforcement investigation, and social service information (when available) was used in a prospective study of 169 child deaths with autopsy and postmortem ocular examinations to make cause and manner determinations. The patterns of ocular and systemic injuries in children

dying as the result of non-accidental injury were compared with those found in injuries from motor vehicle accidents, falls, asphyxia and in natural disease. The immediate causes of death included: 76 (45%) intentional injuries, 36 (21%) inadvertent injuries, 47 (28%) natural causes, and 10 (6%) undetermined causes.

Results: The triad of findings of subdural hemorrhage, brain edema, and retinal hemorrhages was seen in 47 of the total 76 (62%) non-accidental injury deaths and in eight inadvertent injury deaths of the total 36 (22%). The triad was not seen in any of the 46 natural deaths or any of the ten classified as undetermined deaths. Treating these three findings (the “triad”) as a “laboratory test” to identify abusive injuries did not meet criteria for reliability of diagnosis. The sensitivity of the presence of the triad was only 62% in detecting non-accidental injuries. The specificity of the absence of the triad in inadvertent injuries was 78%.

Histories of the circumstances of change of status have been important in identifying abusive injury. The original recognition of the “battered baby” followed inquiry into the phenomenon of absent or changing histories in the presence of subdural hemorrhages and extremity fractures. In this population, the sensitivity of finding inconsistent histories with the presence of the triad was 80%. The negative predictive value of finding a consistent history when the triad was absent was 88%. The relative risk of the triad being found with an inconsistent history was 4.56 with confidence limits of 2.53-8.20 and a value << 0.01.

Delay in seeking treatment has also been identified as a marker of abusive injuries. In this population information was available to identify the interval between onset of symptoms and presentation for medical attention in 127 deaths. This information was then used to look at the deaths with the triad of retinal hemorrhages, subdural bleeding, and brain swelling.

Triad	< 24 hours	24-72 hours	> 72 hours	Total
No triad	55	14	4	73
Triad	38	13	3	54
Total	93	27	7	127

Additional investigative information was used to determine the cause and manner of death to distinguish abusive injuries from accidental injuries. Among children having the triad, delay in seeking treatment was only seen with abusive injuries.

Manner	< 24 hours	24-72 hours	> 72 hours	Total
Abusive	30	13	3	46
Non-abusive	8	0	0	8
Total	38	13	3	54

Summary: Deaths with an inconsistent history, delay in seeking medical attention, and autopsy findings including the triad of subdural hemorrhage, brain edema, and retinal hemorrhages can be reliably used to identify deaths which are more likely to be the result of inflicted injury. Thorough investigation and complete autopsy findings must be used to establish whether or not a particular child’s death was caused by inflicted injuries.

Review of the findings and investigative information in this study allows identification of a constellation of reliable markers of abusive injuries, and components of the constellation needed to avoid wrongful accusations of injury. The components include: triad of retinal hemorrhages, subdural bleeding, and brain swelling; inconsistent or multiple histories; and delay in seeking medical attention.

Abusive Injuries, Wrongful Accusation, Child Deaths

G124 Utility of Whole Body Postmortem Computed Tomography Imaging in Detection of Elder Abuse: Comparison With and Potential Substitution for Standard Autopsy

Zabiullah Ali, MD*, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Barry Daly, MD, and Nancy Knight, PhD, University of Maryland Medical Center, Radiology Department, 22 South Greene Street, Baltimore, MD 21201; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201

After attending this presentation, attendees will be familiar with the value of CT Imaging in the detection or exclusion of injuries associated with elder abuse.

This presentation will impact the forensic science community by demonstrating how whole body CT imaging can be an efficient triage tool that assists the medical examiner’s decision on whether to proceed to conventional autopsy in suspected cases of elder abuse.

Elder abuse (EA) contributing to death is a crime that is difficult to exclude without a full conventional autopsy (CA), even where allegations of abuse are limited to non-physical issues. The potential for use of whole-body postmortem CT (PMCT) as a triage tool to determine the need for CA based on detection of injuries suggestive of physical abuse was investigated.

Method and Materials: Fifty-two decedents (12 M, 40 F; mean age 76 y, range 52-93 y) with associated allegations of EA had PMCT and subsequent CA by state medical examiners within 24 hours of death. PMCT scans were interpreted by radiologists experienced in forensic imaging. Sensitivity of PMCT for injuries suspicious for abuse and other major findings were determined with CA as the standard of reference.

Results: PMCT was concordant with CA for evidence or absence of elder abuse in all cases. PMCT demonstrated multiple previously unreported fractures of varying age consistent with EA in only 1/52 cases. Recent fractures consistent with cardiac resuscitation (CPR) or typical accidental trauma were noted on PMCT in 18/52 (35%) and 5/52 (10%), respectively, but at CA were undetected in 7/18 (39%) and 4/5 (80%), respectively. PMCT misinterpreted an undisplaced cervical fracture in the setting of severe degenerative disease. Cause of death was determined by PMCT in 24/52(46%) and by CA in 50/52(96%) cases.

Conclusion: PMCT is reliable for the detection or exclusion of skeletal injuries suspicious for elder abuse and may be used in correlation with history and external examination to determine the need for CA where allegations or suspicion of abuse are raised. Acute upper anterior bilateral rib fractures were noted in all decedents who underwent full CPR, likely related to osteopenia/osteoporosis. PMCT was not reliable for determination of specific cause of death in this decedent group.

Elder Abuse, Computed Tomography, Autopsy

G125 Findings of the Examinations of Suspected Animal Cruelty Cases Submitted to the Birmingham Jefferson County Animal Control

Ubicelio Martin-Orozco, EDV, Ciudad Juarez Autonomous University, Benjamin Franklin# PRONAF Zone, Juarez, 32315, MEXICO; Barbara Benhart, DVM, Jefferson County Animal Control, 6227 5th Avenue North, Birmingham, AL 35212; and Elizabeth A. Gardner, PhD, University of Alabama Department of Justice, UBOB 210, 1530 3rd Avenue, South, Birmingham, AL 35294-4562*

After attending this presentation, attendees will understand some of the basic principles of the elements necessary in the investigation of animal cruelty, including characteristic injury patterns and examples of the practical application of comparative forensic pathology.

This presentation will impact the forensic science community by shedding new light on an old technique by showing how both macroscopic and microscopic injuries are a key aspect of an animal cruelty or animal abuse investigation. The techniques developed in this project have the potential to be applied in crime profiling to track animal abuse, which may be a predictor for child abuse or domestic violence.

The objective of this project was to establish routine performance of medical examinations, necropsies, and histopathology as the first step in establishing a solid case of animal abuse.

Comparing the changes in the morphology of the lesions observed in this study with the ones that are in current forensic pathology provided a unique opportunity to record the differences between human pathology and animal pathology. The increase in knowledge in the field of forensic veterinary medicine gives this study merit, because those differences are currently underdeveloped in veterinary science.

In general pathology, it is assumed that humans and animals often exhibit similar physiopathology. For example, in gunshot cases, there are many similarities in the entrance and exit wounds in humans and animals. However, differences occur because of the animal's fur, which can hide a wound, and the structure of the blood vessels, which can change the bleeding patterns. In the case of a dog with an embedded collar, there will be edema in the cervical area above the collar. By combining the principles of general pathology with special veterinary pathology, animal abuse can be accurately documented.

As part of this project, medical examinations, necropsies, and histopathology were performed on more than 50 animals at Birmingham Jefferson County Animal Control during the summer of 2010.

Animal Abuse, Comparative Pathology, Necropsy

G126 Fatal Tiger Attack on a Zoo Patron: Patterns and Types of Injuries in Large Predatory Cats

Ellen Moffatt, MD, City & County of San Francisco Office of the Medical Examiner, 850 Bryant Street, San Francisco, CA 94103; Gregory L. Mar, DDS*, Hall of Justice, 850 Bryant Street, Room 442, San Francisco, CA 94103; Duane E. Spencer, DDS*, 1855 San Miguel Drive, Suite 9, Walnut Creek, CA 94596-5282; John K. Berk, DDS, 20652 Redwood Road, Castro Valley, CA 94546; James D. Wood, DDS, 102 South Main Street, Cloverdale, CA 95425; Freeland Dunker, DVM, California Academy of Sciences, Steinhart Aquarium, 55 Music Concourse Drive, San Francisco, CA 94118; and Jacqueline Jencek, DVM, San Francisco Zoological Society, 1 Zoo Road, San Francisco, CA 94132-1098*

After attending this presentation, attendees will gain a better understanding of fatal attacks on humans by large predatory cats.

This presentation will impact the forensic science community by emphasizing the expected wound locations and patterns inflicted by large members of the cat and dog families.

On December 25, 2007, a four-year-old Siberian female tiger escaped its enclosure in the San Francisco Zoo and focused its attack on two young males. One of the males was fatally mauled while his companion was injured. Responding San Francisco Police Department officers came in contact with the escaped tiger and used their service pistols to subdue it.

The victim was autopsied at the San Francisco Medical Examiner's Office and showed evidence of large animal bites and crushing trauma typical for a large cat attack including biting of the posterior upper body/neck, fracturing of the neck, and "abrasion rings" surrounding the incisor wounds. Toxicology was positive for cannabinoids and ethanol.

A necropsy of the tiger was done by the San Francisco Zoo veterinarian, with pertinent body parts (head, paws, stomach contents, and tail) delivered to the San Francisco Medical Examiner's Office. The stomach contents contained no body parts, and the back claws showed evidence of shredding of the nails which most likely occurred as the tiger propelled itself up the textured cement wall of the enclosure. It was determined that the tiger was struck three times by gunfire (once in the left frontal sinus, twice in the thoracic cavity with one of the shots being the fatal strike to the heart and lung). The bullet in the frontal sinus was recovered at the San Francisco Medical Examiner's Office before impressions were taken of both the maxillary and mandibular jaws. Plaster casts of the jaws were made for metric comparison to the patterned injury of the deceased young man.

Large feline attacks on humans are quite rare, with the most common attacks by mountain lions in the western United States. This presentation will demonstrate features typical of large predatory cat attack, as well as techniques used in taking impressions of the tiger's jaws to fabricate study models. Also briefly compared will be large cat attacks to large dog attacks.

This is the first known attack by a captive large cat at a zoo in the United States on a zoo patron not in the animal's enclosure. A second documented large cat fatal mauling occurred in 2008 at the Denver Zoo on a trained keeper by a jaguar.

Fatal, Tiger, Attack

G127 The Utility of Skeletal Examination in Recognition of Occult Skeletal Injury

Jason M. Wiersema, PhD, Jennifer C. Love, PhD, Sharon M. Derrick, PhD, and Luis A. Sanchez, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

The goal of this presentation is to illustrate the effectiveness of the skeletal examination method at locating otherwise obscure fractures in children.

This presentation will impact the forensic science community by illustrating particularly to forensic pathologists the effectiveness of the skeletal examination method in the recognition otherwise occult fractures in children.

The Harris County Institute of Forensic Sciences (HCIFS) has been conducting skeletal examination, an autopsy method for recognizing skeletal fractures in children, described by Love and Sanchez in 2009, since March of 2007. The method involves incising and reflecting the skeletal muscle and periosteum overlying the long bones, scapulae, and ribs of infants and children with medical history and/or soft tissue injuries that are suspicious for inflicted trauma. The current study is a retrospective analysis of the utility of this method in the recognition of subadult skeletal injury.

The method is intended to expose occult fractures typically not recognized during standard radiograph surveys and autopsy (Love and Sanchez 2009). The traditional autopsy protocol provides good visibility

* Presenting Author

of the skull and thoracic skeleton but not the appendicular skeleton. For this reason, an increase in the number of long bone fractures, particularly classic metaphyseal lesions, was expected in cases that have undergone this method, relative to those that predate it. However, a significant increase in the number of either skull or rib fractures was not expected.

Following HCIFS protocol, a skeletal examination is performed on all children with a history, or autopsy findings suspicious for inflicted injury aged three years and younger. Fifty-four total cases have undergone the procedure since March of 2007. This presentation considers only those cases that were ultimately classified as homicides with blunt injury included in the cause of death. HCIFS anthropologists have completed 41 such cases (experimental sample). These cases were compared to the same number of consecutive cases with the same criteria (41) that predate adoption of the method (control sample). All cases in the control sample underwent complete autopsies as defined in the National Association of Medical Examiners standards, but were not subjected to anthropological skeletal examinations.

Of the 41 cases that have undergone skeletal examination, skull fractures were noted in 22 (53%), compared to 20 (49%) in the control sample. Seventeen (41%) of the 41 cases in the experimental sample had thoracic fractures (ribs, vertebrae, clavicles or scapulae), compared to 16 (39%) of the 41 in the control sample. Both of these numbers are expectedly similar between the control and experimental samples. However, the number of long bone fractures recognized per case since the method was adopted has increased significantly. Long bone fractures were noted in 17 of the 41 (41%) cases in the experimental sample, as compared to 6 of the 41 (14%) in the control sample. Worth noting is the fact that the fractures noted in four of the six cases in the control sample were complete fractures mentioned in the medical records prior to autopsy. The fractures recognized in the experimental sample are predominantly classic metaphyseal lesions. In addition, both the number of cases with multiple fractures and the number of fractures per case is appreciably higher in the experimental sample than in the control sample. The average number of rib fractures identified in cases with multiple rib fractures is 13 for the control sample and 22 for the experimental sample. The average number of long bone fractures identified in cases with at least one long bone fracture is one for the control sample and four for the experimental sample.

These preliminary results indicate that skeletal examination affords the anthropologist or pathologist the means to better recognize fractures that are difficult to appreciate on radiographs, and has increased the degree to which fractures in infants and young children, particularly of the long bones can be recognized, described, and interpreted. An additional benefit of skeletal examination is that it also facilitates interpretation of the degree of healing and the forces associated with individual fractures.

Skeletal Examination, Child Abuse, Fractures

G128 Interpretation of Anogenital Findings in Forensic Autopsy: Problems and Challenges

Patrícia Jardim, MD, José M. Fernandes, MD, Dina Almeida, MD, Liliana Santos, MD, MSc, Agostinho Santos, PhD, and Teresa Magalhães, PhD, North Branch of the National Institute of Legal Medicine, Jardim Carrilho Videira, 4050-167, Porto, PORTUGAL*

The goal of this presentation is to highlight the difficulties in anogenital examination during autopsy and in interpretation of sexual violence signs.

This presentation will impact the forensic science community by raising awareness of the difficulties in establishing the medical legal diagnosis of sexual crimes on deceased victims, and to outline the importance of scientific research in postmortem genital and anal changes.

* Presenting Author

Sexual violence is a current topic that has been thoroughly studied, leading to numerous publications. However, these papers deal, almost exclusively, with the study of living victims. The few publications about postmortem anogenital examination and related findings advocate that this expertise and related injuries interpretation should be similar to the one performed in living victims. However, in daily practice, the major difficulty for medical legal experts in the interpretation of sexual violence injuries, lies in the fact that currently there are no published studies allowing us to obtain a rigorous differential diagnosis between these injuries and anogenital tissues appearance in the postmortem interval caused by postmortem phenomena, like, cadaveric lividity, dehydration, and putrefaction which could lead to over or misinterpretation of macroscopic sexual violence signs in anogenital area.

Autopsy case reports of five female homicide victims, performed in the North Branch of the Portuguese National Institute of Legal Medicine between June 2009 and June 2010 are reported.

The victims' age ranged from 9 to 89 years old. In all of the cases, anogenital injuries with multiple severity degrees, from bruises to vaginal and uterus perforation, were found. Depending on the type and severity of the injuries:

- a) Two different postmortem technical approaches were performed: macroscopic anogenital examination (four cases); and abdominopelvic amputation (one case). The colposcope was not used in any of the cases and blue toluidine coloration was performed in one of the cases;
- b) Several complementary procedures were performed: toxicological, in five cases; genetic, in five cases; and histological, in three cases.

Photographic documentation was performed in all cases.

Complementary procedures results revealed drugs intoxication in two cases, a male profile in three cases and uterus and vaginal vital laceration in one case.

In autopsy daily practice, medical legal doctors have many difficulties, especially in technical, methodological, and interpretation areas.

Postmortem phenomena, as rigor mortis often make the cadaver manipulation and positioning difficult, not allowing adequate anogenital view. Cadaveric lividity, dehydration and putrefaction phenomena could mimic sexual violence injuries, as abrasions, bruises, hematomas, among others or even hide them, leading to over or misinterpretation of macroscopic sexual violence signs.

To overcome these difficulties, autopsy should be performed as soon as possible, before washing the corpse by a medical legal doctor with expertise in sexual violence in order to prevent loss of biological evidence.

The forensic examination must follow the methodology for the same type of examination in living victims, through: the use of suitable materials, such as the speculum and anoscope; techniques for image magnification macroscopic, such as colposcopy; staining techniques, such as blue toluidine, and photographic documentation.

There must be collected histological and biological samples, in order to exclude various disorders that can mimic signs of inflicted genital trauma or sexually transmitted infection and rule out postmortem artifact and to search for heterologous biological material (DNA profile).

If evidence of trauma is found, special dissection is necessary so that the rectum, anus and perianal tissues are removed *en bloc* with the perineum, uterus, vagina and vulva being included in the female.

Given the paucity information on the nature and appearance of the anogenital tissues in the postmortem interval, the opinion here is that scientific research is essential to improve knowledge about genital anatomy and variants, sexual violence physical indicators and their lesional mechanisms, differential diagnosis and, above all, interference of postmortem phenomena in these anatomical areas.

Sexual Violence, Medical Legal Autopsy, Postmortem Interval

G129 When Lightning Strikes: 17 Fatal Lightning Strikes in New Mexico

Alice J. Briones, DO*, 1107 Canvasback Lane, Denton, MD 21629; and Michelle B. Aurelius, MD, Office of the Medical Investigator, MSC 11 6030, 1 University of New Mexico, Albuquerque, NM 87131

The goals of this presentation are to describe the prevalence of fatal lightning strikes, familiarize attendees with the most frequent decedent and scene demographics identified in fatal lightning strike scenes and autopsies, and have attendees recognize the importance of thorough scene investigation and full autopsy examination with histology and specific examinations in lightning strike fatalities.

This presentation will impact the forensic science community by providing data identified in lightning strikes fatalities and suggesting investigative steps to provide the most thorough scene and autopsy examination.

Hypothesis: There are specific demographics with lightning fatalities in New Mexico that may help identify risk factors and target a population or region for preventative measures.

Methods: A retrospective review of all fatal lightning strikes in New Mexico between January 1979 and December 2009 was performed using an electronic database searching the key words “lightning” and “electrocution.” Cases of electrocution that were not from lightning were eliminated. Demographics evaluated included county of strike, underlying health conditions, month and time of day of strike, activities performed, toxicology, exam findings and the age, sex, and race of the decedent.

Results: During this 30-year time period, 17 lightning strike fatalities were identified. Full autopsies were performed on 14 cases and three were external only examinations. The cases were distributed over 14 different counties; with the highest number of cases in a single county being two. All (17/17) of the cases were male. The majority of cases (52%) of the cases fell between 31-50 years. 52.9% (9/17) of the cases had underlying health conditions. 56% percent of the cases occurred between 2:00 p.m. and 6:00 p.m. 62% of occurred in open spaces, roadways and parking lots. Exam findings included the classic arborizing Lichtenberg figures (35%), burns and singed hair (50%), and blunt force injuries (24%). Only four of the 14 full autopsies documented examination of the tympanic membranes. On cases where toxicology was performed (70.5%), no drugs of abuse or ethanol were detected.

Conclusions: Full scene investigation including weather reports, location of strike, time of day, month, activities performed, equipment used during the strike, and a thorough medical history should be collected when evaluating a fatal lightning strike. A full autopsy should include not only documentation of all external and internal injuries with evaluation of the tympanic membranes but identify natural disease. Intoxication does not appear to be a factor in the lightning deaths reviewed. To prevent lightning deaths, public service announcements in New Mexico for lightning warnings should be targeted towards males during spring and summer and emphasize the avoidance of open spaces.

The goal of this review was to compare the epidemiology of lightning strike fatalities in New Mexico to those previously described in national studies, and provide suggestions for the standardization of autopsy evaluation of lightning strike fatalities so that data may be used for prevention strategies.

Lightning, Autopsy, Prevention

G130 Drag Racing of Snowmobiles on Asphalt: A Novel Cause for Sudden Violent Death

Abraham T. Philip, MD*, Brian P. Ehret, and Robert Stoppacher, MD, Onondaga County Medical Examiner's Office, 100 Elizabeth Blackwell Street, Syracuse, NY 13210

After attending this presentation, attendees will learn about a summer activity, a variation on what was previously known to done exclusively during winter, and about the fatal consequences that it lead to.

This presentation will impact the forensic science community by providing insights on a topic about which there is almost no information in the forensic literature, as this case report details the sudden violent death of a participant in timed trials of a snowmobile which was used to race on asphalt.

Snowmobiles were initially developed to move people and supplies in regions where heavy snow prohibited the use of more conventional vehicles. Today snow-mobiling is a popular wintertime recreational lifestyle activity in several parts of the world. There are millions of registered snowmobiles users and the recreation/manufacturing complex generates billions of winter tourism dollars for the snow belt areas of North America.¹ More than 50% of snowmobile owners surveyed consider use of the vehicle as a family sport.¹ With the increasing popularity of this recreational activity, there has been an increasing incidence of injuries and deaths, the inevitable consequence of human interaction with high performance vehicles. Until the tail end of the last millennium, the snowmobile remained a stationary fixture in one's garage or side of the lawn during the months of May to November. A fact that unfortunately changed in the early 1990's with the introduction of asphalt drag strip racing for snowmobiles.

Drag racing traditionally has been an acceleration contest between two car drivers, to determine which vehicle has the better speed related performance. The vehicles start from a stationary position and takeoff usually after a signal from a set of “christmas tree lights,” and race on a track 1/8 or a 1/4 mile long. Drag racing started in the 1930s, when competitors raced along deserted stretches of roads to see who's vehicle was faster. The National Straightline Snowmobiling Racing (NSSR) is an organization started in 1986, to verify and certify results of dragstrip snowmobile races. In 1993, it included asphalt drag racing as one of the competitive classes that it arbitrated on.

The Empire State Timing Association has operated a Safety Park Dragstrip in the Central New York since the 1960s. It is a 1/4 mile racing strip, with a long stretch of road to allow cars to slow down. The time-slip booth provides the participants data about how long it took to get to various points down the track as well show data on how fast the vehicle was traveling at the half way point (1/8 mile) and at the finish line (1/4 mile) as well as who won the race, if it was a competition.

This case report is about a 24-year-old man who was operating a custom made asphalt snowmobile on a timed trial on the race track. He reportedly had been asphalt racing for the last four years. It was his first day of using his new sled, and he started his third trial run down the track. He was clocked at 161 mph at the 1/4th mile point. He unfortunately lost control of the vehicle, which struck a guardrail. He was ejected off the sled and his body came to rest in a wooded area approximately 300 feet from the initial collision point. The sled, after multiple ongoing collisions with the guardrails on either side, finally came to rest approximately 500 feet from where the body rested. The external examination, with full body x-rays, revealed devastating head injuries, despite the use of a helmet, traumatic avulsion of left forearm, open fractures of left proximal humerus, open fracture dislocation of the right ankle and closed dislocation of the left knee.

A search of the literature revealed no published information on this type of a sudden violent death.

Snowmobile Accidents, Drag Racing on Asphalt, Sudden Death

G131 Blast Overpressure After Tire Explosion: A Fatal Case

Stefano Derrico, PhD, University of Foggia, Department of Forensic Pathology, Via Luigi Pinto, 1, Foggia, 71100, ITALY; Gabriela Perilli, MD, University of Foggia, Department of Forensic Pathology, Viale Degli Aviatori 1, Foggia, 71100, ITALY; Umberto Volpe, Bari, Bari, , ITALY; Natascha Pascale, MD, University of Foggia, Department of Forensic Pathology, Viale Degli Aviatori, Foggia, 71100, ITALY; and Irene Riezzo, PhD, University of Foggia, Osp D'Avanzo, Department of Forensic Pathology, Viale Degli Aviatori, 1, Foggia, 71100, ITALY*

The goal of this presentation is to present a rare case of fatal tire explosion, the rarity of the event and the typical histopathological findings make the case peculiar.

This presentation will impact the forensic science community by presenting an integrated study in association with engineers helping to investigate damaging effects of blast overpressure, in a world where tire-blast injuries are not so common and the injuries of the nature described are quite rare and are hardly reported in forensic literature.

Blast Overpressure (BOP) is defined as the increased pressure over atmospheric pressure which is associated with a blast from explosives or weapons. BOP may cause primary, secondary, tertiary, and quaternary injuries. Primary blast injury occurs from an interaction of the pressure wave and the body. Secondary blast injury results from other object invested by the pressure wave impact against the body surface. Tertiary blast injuries occur when the body is accelerated from the blast wave at first and is then abruptly decelerated on rigid objects. Quaternary blast injuries are defined as those injuries of victims of explosions that due to the collapse of a building where the explosion took place. Tire-blast injuries are not so common and the injuries of the nature described are quite rare and are hardly reported in forensic literature. A case of a fatal tire explosion occurred after tire repair and inflation will be presented. Explosion occurred suddenly, strictly close the man who was put five meters far from his site. Rescue maneuvers were unsuccessful and death was declared. Forensic pathologist's crew investigated the crime scene: a 44 cm in length tear was recorded on tire. Blood stains on the ground and environmental structures were also detected. A complete postmortem examination was performed the day after death. Large scalp laceration was detected at external examination. Bruises on face and chest were also recorded. At gross examination, cranium vault was unremarkable except for a mild hemorrhagic infiltration of the *galea capitis*. Brain was normal in size and volume with mild cerebral edema. Diffuse subarachnoid hemorrhage was observed in both hemispheres. Linear fracture of the skull base was detected. Multiple bilateral rib fractures with mild hemothorax were recorded. Lungs were increased in size and volume, reddish colored, both; hemorrhagic foam was detected on the main bronchi. Hemoperitoneum was also recorded; multiple lacerations of liver, kidney, and spleen, deeping into the parenchyma of the viscera were detected. At histological examination with H&E subarachnoid and intraparenchimal hemorrhage were detected on brain. Acute emphysema, pulmonary edema, and hemorrhages were also described with intense congestion of the septum vessel. Venous air embolism was also recorded and investigated by means of immunohistochemistry (antibodies anti-CD 61 and fibrinogen). Capsular multiple tears and subcapsular and intraparenchimal hemorrhages were also detected at liver, spleen and kidneys microscopic examination. Polivisceral stasis was recorded. Intoxication of alcohol or drugs of abuse was excluded at toxicological investigation. Acute respiratory failure was indicated as the cause of death. A

multidisciplinary approach with engineers let us to establish blast overpressure after tire explosion. After that, impact of blast wave on the thorax produced chest and pulmonary injuries (primary blast injuries). Also abdominal viscera injuries were also attributed to blast overpressure effect. The displacement of the body on the ground and environmental structures after explosion produced scalp laceration, subarachnoid hemorrhage, and cranium fractures (tertiary blast injuries).

Blast Injuries, Tire Explosion, Overpressure

G132 TASER® XREP™: A Case Study

Ogbonna Chinwah, MD, Department of the Coroner, 1104 North Mission Road, Los Angeles, CA 90033; and Christopher B. Rogers, MD, and Lakshmanan Sathyavagiswaran, MD, Los Angeles County Medical Examiner's Office, 1104 North Mission Road, Los Angeles, CA 90033*

After attending this presentation, attendees will become familiar with the TASER® XREP™ device, a new less lethal tool for law enforcement.

This presentation will impact the forensic science community by alerting the community to the existence of a new TASER® weapon, and the need for caution in handling it.

TASER® XREP (eXternal Range Electronic Projectile) is a self-contained wireless electronic control device that deploys from a 12-gauge pump action shotgun. It delivers a neuromuscular incapacitation (NMI) bio-effect similar to that of the handheld TASER® X26™. The TASER® XREP™ can be delivered to a maximum effective range approaching 100 feet. The battery supply is incorporated into the main chassis and provides the power to propel the XREP projectile.

The TASER® XREP™ device consists of a triple-redundant incapacitation system, each part of the system generating a highly refined NMI waveform that incapacitates the subject. The system completes the circuit when the front probes make skin contact combined with the cholla electrodes, conductive hand trap, or rear facing barbs. The system is composed mainly of the following:

- a. Nose Assembly – the entire detachable nose section which includes the nose frame, frontal probes, fracture pins and reflex engagement electrodes
- b. Conductive Hand Trap Wire – connects the engine to the frontal probes (the insulated wire is wound with the conductive wire)
- c. Cholla Electrodes – electrodes attached to the chassis. The electrodes are constrained beneath the sheath during flight, extend after impact, and are conductive.

The nose assembly contains four forward-facing barbed electrodes. When the TASER® device is deployed, the nose assembly impacts the subject and the frontal probes make contact with the skin and are stuck to the body. The energy from the impact breaks a series of fracture pins that release the main chassis of the XREP projectile, which remains connected to the nose by a nonconductive tether. A conductive hand trap wire also connects the frontal probes to the TASER® XREP™ engine and has capacity to deliver NMI. The projectile autonomously generates NMI for 20 continuous seconds. As the chassis falls away, six cholla electrodes automatically deploy to deliver the NMI effect over a greater body mass. The subject instantly loses muscular control of the body and cannot perform coordinated action. The subject usually falls to the ground. After the signal stops, the subject typically regains all muscle control. Whereas other less-lethal weapons rely on pain compliance to stop the subject, with neuromuscular incapacitating weapons pain may be short-lived and may aggravate the subject even further or cause serious long-lasting injuries.

This case is that of an actor suspected of fatally stabbing a former coworker and wounding two others during a violent rampage about a week earlier. On discovering that he was a wanted suspect, the police tried to apprehend him. He fled to a nearby hill and stood on the cliff wielding a samurai sword. A 20-page handwritten suicide note was

discovered in the abandoned vehicle of the suspect. In the note he indicated sunset as the time he would end his life. A daylong standoff with police ensued with extensive news media coverage. Helicopters hovered over the scene most of the time. Crisis negotiators were called in. They joined in the efforts to get the suspect to surrender. For about eight hours (9:30 a.m. to 5:00 p.m.) he stayed on the edge of the cliff with his sword, taunting and threatening the police. With the approach of dusk, a decision was made to subdue him with a less than lethal weapon. The TASER® XREP™ device was deployed. He was hit and he plunged off the edge of the cliff to his death about 45 feet below.

Autopsy findings, mode, and health and safety issues will be reviewed.

Electronic Control Device, Neuromuscular Incapacitation, Police

G133 3D in Forensics: TIM Synthetic MRI and Virtobot – Forensic Imaging Workflow of the Future

Michael Thali, MD, VIRTOPSY Team, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND*

After attending this presentation, attendees will know the basic of virtual autopsy and the development in forensic 3D imaging of human corpses in the future.

This presentation will impact the forensic science community by covering new validated practical knowledge, and the professional practice gap in the area of virtual autopsy (CME/ACCME criteria).

Imaging has changed the world and greatly influenced modern medicine.

In the 2009 National Academy of Sciences Report, “*Medical Examiners and Coroners Systems: Current and Future Needs*” modern imaging technologies (Virtual autopsy, Virtopsy) was suggested as having a great potential to detect forensic relevant findings.

The advent of high resolution multi-detector row CT scanners and fast MRI scanners in the last decade has allowed the development of imaging techniques that have greatly enhanced the diagnostic potential of these two imaging modalities. While conventional radiographs have played a valuable role in forensic diagnosis and practice for over a century, recent investigations with both CT and MRI suggest that these imaging tools are capable of much greater contributions. A major innovation is the ability to display imaging findings in 2D and 3D planes that closely replicate the findings at conventional autopsy and make the interpretation of the studies more easily understood by non-radiologists. CT and MRI may be used to supplement traditional autopsy techniques, to provide a complete anatomic assessment prior to limited autopsy, or in certain circumstances to replace it, such as in blunt accidental trauma, or drowning deaths. These studies may also provide options in the setting of religious and cultural objections to conventional autopsy.

While CT has the advantage of providing rapid whole body imaging of great anatomic detail in a short time, the superior contrast resolution of MR provides soft tissue characterization that is not achievable by CT. MRI is less widely available and more time consuming but may be applied to the postmortem evaluation of specific body parts to aid in the diagnosis of specific causes of death that may be characterized by subtle soft tissue changes. Both CT and MRI provide a permanent pictorial record of anatomic findings that may be retained and analyzed for medical and legal purposes postmortem and offer advantages in quality assurance that may be difficult to replicate with conventional autopsy.

The forensic science and medical examiner communities have shown interest in the use of CT and MR autopsy imaging. However, while CT and MR imaging are widely available in the clinical care of the living, forensic facilities face problems of access to autopsy imaging due to financial, technical, transportation, interpretation, and related difficulties.

For the past 15 years, the Forensic Institute of the University of Bern has been concerned with imaging problems in forensics. In 2009 the robot-supported automated system integration of 3D surface scanning and multislice CT with postmortem biopsies was successful as a “Virtobot” developed. After what is now five years, the over 100 postmortem angiographies show impressive results from the research activities at the University Bern. In the early part of 2010, our Total Imaging Total Matrix TIM-MRI system that has been in operation since 2009 could be extended with the so-called synthetic MRI software. The advantage of this TIM synthetic MRI system lies in the fact that in one examination step various MRI sequences (such as T1-T2-PD, etc.) could be performed from tip to toe without any change of the surface traces. In the daily forensic service applications it has become evident that through applying this approach a increase in quality and a improvement in the forensic diagnostics can be achieved and the examination results based on the imaging are often quicker and, thanks to a more visual 3D reconstruction, can be displayed in a way that lay persons can understand and comprehend. Momentarily, in terms of workflow and process, this Virtopsy-system integration is the only forensic examination track in a forensic institute that has brought together all the modalities and technologies in this form for daily use and research. With “Axon Shadow,” the interdepartmental forensic IT structure, now being developed at our Institute, which comprises the functionalities of “ERP,” “LIMS” and document management, the forensic processes of all the IFM departments are displayed and supported in a workflow-oriented manner.

Virtopsy, Virtual Autopsy, CT and MRI

G134 Transition to Digital in the Forensic Morgue: Lessons Learned on the Pathway to Greater Efficiency

Jason M. Wiersema, PhD, Diane Logan, MBA, and Luis A. Sanchez, MD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will have a better understanding of the advantages of and obstacles to the transition to digital technology in the forensic morgue.

This presentation will impact the forensic science community by illustrating the advantages and elucidating the difficulties of the transition to digital fingerprint, radiograph, and photographic technology.

Maximizing efficiency in the postmortem examination process is critical to the daily operations of a busy medical examiner’s office, and is also of particular importance to effective mass fatality preparedness planning. The Harris County Institute of Forensic Sciences (HCIFS) uses technology to maximize the efficiency and accuracy with which it can complete the autopsy process. These technological advancements include the acquisition of a digital radiograph system, a digital fingerprinting system, and digital photography. This presentation will detail the advantages of each of these technologies as well as the obstacles that complicated the transition to each. Generally, the most significant advantages of these technologies are increased efficiency, less waste, greater security, and enhanced user benefit. The most significant obstacles involve adaptation to the specific constraints and requirements of the medical examiner/morgue setting. There is little precedent for the use of some of these technologies in the medical examiners context, and this was reflected in our effort to adopt them.

The HCIFS completed its transition from conventional film radiography to digital computed radiography in December 2009. The digital system includes a central x-ray generator and digital processor, a dedicated server, and a web-based viewing software package that is accessible from each of seven autopsy suites, and from the doctors

(pathologists and anthropologists) office and laboratory computers. The advantages of the system include: greater image quality, more functional user interface (with contrast, brightness and annotation capabilities) multi-image split screen viewing, enhanced archival security, and the elimination of the expense, waste, and space requirements associated with film radiography. The most significant obstacles to the transition to digital x-ray technology were: the lack of an existing system that was appropriately configured for medical examiner use, the consequent development of user workflow, an unfamiliar user interface and image format, and training necessary for use of the software by non-radiologists/radiographers. Additionally, the HCIFS developed a means to copy, and label the images in a format that can be accessed by the Harris County District Attorney's Office.

Digital fingerprint technology has enhanced the efficiency of the decedent identification process. The HCIFS system is essentially an extension of the Harris County Sheriff's Office (HCSO) AFIS network, and includes six AFIS stations, each comprised of two types of fingerprint scanners and a 37" all-in-one touch screen computer. The fingerprints are transferred directly to the HCSO server rather than being stored at HCIFS, and HCIFS Investigations and Morgue staff utilize a custom web-based software interface to receive and search fingerprint results. The advantages of the digital fingerprint system include: increased print quality relative to the previous method; more efficient transfer of prints and receipt of results (five minute average turnaround); infinite upgrade-ability; and more secure archiving. The primary obstacles to the transition to digital fingerprint technology were: ensuring compatibility between the HCIFS system and the databases with which it communicates; lack of an existing system that is appropriately configured for medical examiner use, and; configuring and using a system that has not yet been tested elsewhere. The HCIFS is currently incorporating satellite based scanners into the system to facilitate use of the system by HCIFS Investigators in the field.

The HCIFS transitioned to exclusive use of digital photography at the both the scene and in the morgue in 2005. Conversion from film to digital photography has increased quality control and accessibility, while reducing processing and duplication costs. The system required the acquisition of digital cameras, a dedicated photo server and the infrastructure necessary to make use of the images in a variety of settings (the morgue, daily case triage meetings, case review sessions, and pre-trials). Secure remote access was provided to the district attorney's office eliminating time and supplies required for duplication. The most significant difficulty with the digital photography system is the ever increasing need for storage, and constant oversight is needed to ensure image security and reduce unnecessary image duplication.

The conversion to these digital systems has increased the efficiency of HCIFS daily operations and has resulted in a concomitant increase in its capacity to accommodate mass fatality investigations. Each of the systems was funded by preparedness grants awarded by the United States Department of Homeland Security and the transition process can serve as a template for other medical examiner jurisdictions.

Digital Fingerprint System, Digital Radiograph System, Digital Photography

G135 Postmortem Computed Tomography as a Valuable Tool for Diagnosing Trauma Prior to Medicolegal Autopsy

Seija Ylijoki-Soerensen, MD, Department of Forensic Medicine, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Iana Lesnikova, MD, Department of Forensic Pathology of University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Lars Uhrnholt, PhD, Institute of Forensic Medicine, Department of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; and Annie Vesterby, MD, DMSc, Institute of Forensic Medicine, University of Aarhus, Brendstrupgårdsvæj 100, 8200 Aarhus N, DK-8000, DENMARK*

After attending this presentation, attendees will understand the importance of computed tomography, which provide the detailed picture of trauma before a medicolegal autopsy in traumatic deaths.

This presentation will impact the forensic science community by increasing knowledge about the benefit of the combination of whole body postmortem computed tomography with a medicolegal autopsy. This procedure gives high quality and specificity in diagnosing fractures and other traumas in a deceased. The 3D reconstruction helps to assess the extent of damage and trauma mechanisms. It is also shown how a medico-legal autopsy on a deceased with many traumas is best performed with an ancillary computed tomography. The computed tomography without medico-legal autopsy cannot provide the sufficient diagnostic information.

A case of a traffic accident with two victims is presented. A car with four people was hit from the left side by a fast-moving car with two people inside. Driver and passenger sitting in the front of the car with four people were killed instantly. Whole-body computed tomography was performed before medico-legal autopsies were performed in the Department of Forensic Medicine, Aarhus. The driver suffered fatal traumas in the form of multiple fractures on the left side of thorax, laceration of diaphragm, fractures in cervical column, contusions in the left side of the brain, pelvic fractures, and fractures in the left ankle. The passenger on his right side suffered traumas in his thorax, in column and fractures of the pelvis. The two other passengers sitting in the back got minor traumas. Driver and passenger in the other car were practically without traumas.

With this case are shown photos of the two cars involved in this accident, 3D reconstructions made from the computed tomography scanning results and the subsequent clinical photos from the medicolegal autopsies. It is shown that with these documents the trauma mechanisms can be evaluated with high reliability. Some of the diagnosis of traumas in this case could have been lost without a postmortem computed tomography scanning. Also a computed tomography scanning before a medico-legal autopsy saves time and resources for the forensic examiner and the dissection of the deceased is not necessarily as comprehensive as it can be without an ancillary scanning.

This case will be presented as an example to highlight how with a whole-body postmortem computed tomography, it is possible to achieve comprehensive information about traumas and the trauma mechanisms. It improves the quality of a medico-legal autopsy and is recommended to be used in cases of fatal traumas.

Postmortem, Computed Tomography, Trauma

G136 Traumatic Injuries in Fatal Tire Explosions

Chris Milroy, MD*, University of Ottawa, The Ottawa Hospital, 501 Smyth Road, Box 117, 4th Floor CCW, Ottawa, ON K1H 8L6, CANADA; and Alison Edgecombe, MD, The University of Ottawa, Department of Pathology and Laboratory Medicine, PO Box 117, 4th Floor CCW, 501 Smyth Road, Ottawa, ON, CANADA

After attending this presentation, attendees will appreciate the patterns of injuries from tire explosions and the circumstances where fatal tire explosions can cause danger.

The presentation will impact the forensic science community by illustrating the nature and extent of explosion injuries that may result from burst tires.

Tire explosions during servicing may cause severe trauma. The severity of injury depends on the tire size, air pressure, and distance from the blast. The blast injury has been compared to that of a grenade or land mine, but without the chemical or thermal effects. Overall mortality is significant (19-29%), mostly attributed to head injuries. Two cases of truck tire blasts in which fatal injuries were sustained are reported.

Case 1: A 29-year-old male was inflating a large truck tire which was lying flat on the ground. He was leaning over the tire when it ruptured under his chest. He was projected against a garage wall four feet away with his shoulder striking the wall nine feet from the ground. He was pronounced dead at the scene.

At autopsy, there were multiple stippled abrasions and bruises on the face, trunk, and upper and lower extremities, typical of blast injury. The right arm was almost amputated. The rib cage and sternum were extensively fractured. Contusions were seen on the lungs and the left diaphragm was ruptured. The 3rd and 4th cervical vertebrae were dislocated. At the base of the skull, there was a hinge fracture with cerebellum protruding through the fracture site. The brain stem was transected in two places.

Case 2: A 28-year-old male was testing a large truck that had reports of a faulty speedometer. A jack was placed under the third axle of the vehicle and the engine was accelerated. At 40 mph, one of the rear tires exploded. The victim's proximity to the tire blast was not witnessed but he was ambulatory briefly before collapsing. In hospital, a lacerated spleen with hemoperitoneum was managed surgically. After hemodynamic stabilization, the patient suffered cardiovascular collapse. Resuscitation was not successful.

The autopsy revealed primarily left sided trauma with left elbow, left hip, and rib cage fractures. Bilateral hemothoraces were documented. The left lower lobe of the lung was contused and the left hemidiaphragm was bruised. The left ventricle epicardial surface was bruised and traumatic rupture of the anterior papillary muscle had occurred. Subsequent examination of the spleen post-splenectomy confirmed the presence of lacerations. Lacerations were seen in the left kidney with bleeding into the perinephric fat.

Conclusion: The cause of death in both cases was attributed to multiple injuries. In case one, the brain stem transection would have been immediately fatal. In case two, acute papillary muscle rupture led to cardiovascular collapse. Tire explosions show similar injuries to bomb blasts with typical blast injuries seen. Fatalities are common; however, postmortem findings are infrequently reported in the literature.

Tire, Explosion, Fatal

PATHOLOGY/BIOLOGY

G1 Retinal and Optic Nerve Sheath Hemorrhages Are Not Pathognomonic of Abusive Head Injury

Evan Matsches, MD, Southwestern Institute of Forensic Sciences, 5230 Southwestern Medical Avenue, Dallas, TX 75235*

After attending this presentation, attendees will understand the limited value of eye evaluation in child death investigation.

This presentation will impact the forensic science community by bringing clarity to the controversial topic of retinal and optic nerve sheath hemorrhages.

For many years, the dogma of pediatric forensic pathology was “retinal and optic nerve sheath hemorrhages are pathognomonic of abusive head injury”, including especially, the Shaken Baby Syndrome (SBS). Growing controversy surrounding the existence of SBS has lead to questioning of that dogma. A retrospective review of all child deaths (≤ 36 months of age) at a metropolitan medical examiner (ME) department was undertaken to establish the spectrum of retinal (RH) and optic nerve sheath hemorrhages (ONSH) encountered in a medical examiner’s population. In this office, pediatric eye removal is routine, and all eyes are evaluated by consultant ophthalmologic pathologists. The medical Examiner’s database had 137 cases that met age criteria over a five year period; complete case files were available on 123 cases. Of those 123 cases, 18 cases (15%) had RH and/or ONSH; eight cases had both RH and ONSH, seven had only RH, and three had only ONSH. Of these 18 cases, two were certified as natural deaths, eight were certified as accidents, and eight were certified as homicides. Evaluation of the data demonstrated statistically significant relationships between RH/ONSH and: restitution of a perfusing cardiac rhythm following advanced cardiac life support (with short term survival); and cerebral edema (regardless of etiology). Of those children who died without head trauma, but with eye pathology, 6 of 7 received advanced cardiac life support. Qualitative assessment of hemorrhage severity suggests slightly more severe retinal hemorrhages in children whose deaths were ruled homicides; these children were also more likely to have more lengthy post-injury survival periods and brain swelling. In conclusion, RH/ONSH are not limited to children who die of inflicted head injuries; instead, they may be seen in a wide variety of situations, and may be linked to cerebral edema, and sequelae of advanced cardiac life support. **Retinal Hemorrhages, Shaken Baby Syndrome, Pediatric Forensic Pathology**

G2 Child Abuse vs. Accidental Falls: Judicial Outcomes in Alleged Child Abuse

James A.J. Ferris, MD, Department of Forensic Pathology, LabPlus, 85 Park Road, Grafton, PO Box 110031, Auckland, NEW ZEALAND*

After attending this presentation, attendees will learn that the incidence of accidental head injuries in infants and children is greater than previously accepted.

This presentation will impact the forensic science community by demonstrating how accidental short distance falls may simulate child abuse.

This presentation will review the trial outcomes in 14 cases from personal case files of alleged child abuse in which the defense claimed

that the head injuries were as a result of short distance accidental falls (40-120cm) or relatively minor head impact trauma.

The nature and extent of the pathology will be presented and the incidence of subdural and retinal hemorrhage will be presented. Twelve cases were found to have unilateral subdural hemorrhage and in two cases the subdural hemorrhage was bilateral. Eight cases had bilateral retinal hemorrhages and four cases had ipse-lateral retinal hemorrhages. There were three cases of skull fracture but in one case with bilateral skull fractures no retinal hemorrhages were described. In four cases there was evidence of a prior head injury.

Cerebral edema or raised intracranial pressure was documented in 12 cases. However, in one case, a six-week-old infant born seven weeks premature with several documented hypoxic episodes, who had apparently fallen 60 cm from a bed, had unilateral subdural hematoma, bilateral retinal hemorrhages and no evidence of increased intracranial pressure.

The evidential basis for the respective arguments by the prosecution and defense will be presented and the possible reasons for the verdicts will be analyzed. It may be significant to note that in two cases there was a history of minor shaking as attempt at resuscitation after the infant had exhibited signs of collapse and seizing. The defense council decided to plead his client guilty to shaking as he was afraid to expose the accused to a jury because of the widespread adverse publicity related to Shaken Baby Syndrome.

The problems relating to the presentation in court of the controversies relating to the pathogenesis and interaction of hypoxia and raised intracranial pressure on the development of subdural hemorrhage and retinal hemorrhages will be discussed.

The influence of these current controversies, particularly relating to Shaken Baby Syndrome, had on the outcome of each case will be discussed.

Child Abuse, Head Injury, Accidental Falls

G3 Pediatric Deaths in Harris County

Kathryn H. Haden-Pinneri, MD, and Sharon M. Derrick, PhD, Harris County Medical Examiner’s Office, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will gain a better understanding of the types of pediatric deaths investigated in Harris County, Texas and will be exposed to the extensive pediatric death investigation and autopsy procedures employed in our office.

This presentation will impact the forensic community through the documentation and discussion of almost 900 pediatric deaths.

Pediatric deaths pose a unique and sometimes complex set of challenges for forensic investigators. As is typical in other cases, information is gathered from family members regarding the events leading up to the death. In infant deaths, the parents must be interviewed with as much detail as possible in order to document the correct set of circumstances. This is often very difficult to do when the parents are extremely distraught and when they are the potential suspects. Because babies and small children may have injuries that aren’t apparent at the scene or emergency room, all deaths need to be thoroughly investigated beginning as soon as proper officials are notified. This can sometimes cause emotional duress and resistance to talk on the part of the parents. With experience, understanding, and a standard infant death investigation procedure, these obstacles can be overcome.

The Harris County Medical Examiner's Office (HCMEO) is located in Houston, Texas, serving a population of 3.9 million (per 2008 data from the Office of the State Demographer, Texas State Data Center). Additionally, contract services are provided to seven counties in the surrounding area. Approximately 16,000 deaths are reported each year and an average of one-fourth are brought in for either an external examination or a full autopsy. Discussed in this presentation will be the extensive investigative and autopsy procedures, including photographic documentation of the scene, special techniques and consultant assistance.

Over a four year period beginning January 2005, the HCMEO assumed jurisdiction of 870 deaths involving children 10 years of age or younger, 12.3% of which were homicides. Deaths in which an infant is found dead or unresponsive while sleeping with an adult are classified as undetermined (co-sleeping) in our office, allowing for tracking of this risky behavior. Documented wedging or overlays are classified as accidents. The diagnosis of Sudden Infant Death Syndrome (SIDS) is utilized when all investigative and autopsy findings fail to reveal a cause of death in a child under the age of one. The average rate of SIDS deaths over the four year study period is 12% (104). As expected, non-motor vehicle related accidents account for the majority of the deaths, with an average of 21.6% (188).

Statistics will be reviewed in detail for each year of the study and discuss the significance of the trends with regards to co-sleeping, asphyxial deaths, drowning, and child abuse. An unfortunate occurrence in our hot climate is the yearly cluster of heat related deaths due to children being left in motor vehicles and the increasing number of drownings. An alarming statistic discovered from this study is that the number of child deaths due to homicide is higher than those due to motor vehicles. Preventable deaths need to be targeted and all reasonable attempts need to be made to educate parents and caregivers of the dangers of leaving children in hot cars, unsupervised in swimming pools, co-sleeping with small infants, and other inappropriate sleeping conditions that may result in a child's death.

Pediatric Deaths, Homicides, Co-Sleeping

G4 What Is the Frequency of Finding Lethal Injury When a SIDS-Like Death Is Reported?

M.G.F. Gilliland, MD, Brody School of Medicine at East Carolina University, Pathology & Lab Medicine, Brody 7S-10, Greenville, NC 27858-4354*

After attending this presentation, attendees will understand how frequently lethal injuries were found in a group of infants less than one year of age initially reported to have been found dead after sleep. Attendees will also understand how important it is to thoroughly investigate infant deaths.

This presentation will impact the forensic science community by providing a scientific basis for the need to perform an autopsy, even if there is parental objection in infant deaths. Attendees will have scientific support for thorough law enforcement investigation of unexpected deaths in infancy.

Sudden unexpected deaths of infants less than a year of age are concerning to families and law enforcement. The frequency of finding evidence of lethal injury when the history is that of Sudden Infant Death Syndrome – child found unresponsive after sleep – is important in determining the extent of investigative effort required.

Method: Examination of a database of prospectively studied child death investigations from the Southwestern Institute of Forensic Sciences in Dallas, Texas from 1981-1989 identified 84 infants less than one year of age. These infants were part of a larger study of 169 children less than ten years of age. The deaths were from Dallas city and county

as well as adjacent Justice of the Peace jurisdictions in north central Texas. Investigations included: scene circumstances, medical records, investigative information from law enforcement and social services, autopsies with ocular examinations, toxicologic studies, and radiographs when indicated.

Results: SIDS-like histories were reported in 36 of the 84 infants, 42.9% of the total group. Infants with SIDS-like histories were found to have injuries playing a role or causing their deaths in eight cases of this group, 22.2%. Seven of these were attributed to non-accidental injuries when no adequate explanation was provided once internal lethal injuries were found at autopsy. Three of these non-accidentally injured infants had no external injuries. Three others had only small facial or scalp injuries which were concerning in the context of a SIDS-like history. The seventh infant of the non-accidental death group was slightly decomposed and had visible injuries in spite of the SIDS-like initial history. The accidental death occurred in an infant who had sustained a simple skull fracture when his stroller rolled down hill and crashed into a wall three days prior to death. He was treated and released and found unresponsive in the morning. He had a healing small head abrasion. Laryngeotracheobronchitis was considered a significant contributing factor in his death.

Seven of the infants' deaths in the SIDS-like history group were ruled undetermined, 19.4%. None of them had external injuries or internal injuries sufficient to cause death and none had sufficient natural disease to account for death.

Sufficient gross and/or microscopic findings to attribute death to natural diseases were found in eight infant deaths. Six died of respiratory tract illnesses and two died of other illnesses for a total of 22.2% of the total group.

The diagnosis of exclusion, SIDS, was reserved for 13 of the infants, 36.1%. None of these infants had any external injuries. At the time of the study the SIDS definition did not include extensive metabolic and radiologic studies. Scene circumstances, medical and social services information, complete autopsy, and toxicologic studies for child deaths between one month and one year of age were used to define SIDS in this study. As has been found in most studies of SIDS deaths, ten of the infants were three months old or less, 76.9%.

	Accidental	Non-accidental	Natural	Undetermined	TOTAL
Head Injury	1	7	0	0	8
Undetermined	0	0	0	7	7
Respiratory	0	0	6	0	6
Other Natural	0	0	2	0	2
SIDS	0	0	1	0	13
	1	7	21	7	36

Conclusion: Although more than half of sudden unexpected deaths of infants less than one year of age were attributed to natural causes 15 of the 36 deaths this study (41.7%) required additional law enforcement activity. Non-accidental injuries were found in 19.4% of deaths and a similar percentage could not be attributed to natural causes (undetermined cause and manner). Sudden unexpected infant deaths must be thoroughly investigated; many will be the result of natural causes, but a significant number will be unnatural deaths. Any external injury is an indication that an autopsy must be performed. The absence of external injuries did not accurately predict natural deaths. Autopsies are still necessary to exclude trauma. This study did not address high-resolution radiographic virtual autopsy techniques to allow examination in the face of parental objection to autopsy.

SIDS, Non-Accidental Injury, Infant Deaths

G5 Cardiac Channelopathies Linked to Sudden Infant Death Syndrome/Sudden Unexplained Death Syndrome

Dawei Wang, PhD*, and Donald Siegel, PhD, New York City Office of the Chief Medical Examiner, 421 East 26 Street, New York, NY; and Yingying Tang, MD, PhD, Mechthild K. Prinz, PhD, and Barbara A. Sampson, MD, PhD, Office of Chief Medical Examiner, Department of Forensic Biology, 421 East 26th Street, New York, NY 10016

The goal of this presentation is to describe the use of genetic testing to assist medical examiners in determining cause of death in undetermined cases. After attending the presentation, attendees will understand the definition of sudden infant death syndrome (SIDS) and sudden unexplained death syndrome (SUDS), the procedures of SIDS/SUDS investigations, and the SIDS/SUDS genetic testing method. An example of a SUDS case investigation will be presented.

This presentation will impact the forensic science community by emphasizing the need for and use of genetic testing in the determination of unexplained deaths. Discovery of the new mutations presented here will also enrich cardiac ion channel mutation databases and hopefully lead to better understanding of the pathogenesis of these diseases, their diagnosis and treatment.

SIDS is defined as sudden unexplained death under the age of one year. SUDS is defined as sudden unexplained death from one year of age through adulthood. In both syndromes a thorough scene investigation, complete autopsy, and review of the circumstances of death and clinical history are required.

Both environmental risk factors and genetic risk factors are believed to contribute to SIDS and SUDS. Environmental factors involved in SIDS include bedding, bed sharing, and sleeping in the prone position. SUDS can be triggered by vigorous exercise, swimming, emotional stress, and auditory stimuli. Genetic risk factors of SIDS and SUDS include genes that can contribute to arrhythmias. Studies have shown that cardiac arrhythmia may constitute up to fifteen percent or more of SIDS/SUDS cases. Since mutations on six cardiac ion channel genes- KCNQ1, KCNH2, KCNE1, KCNE2, SCN5A, and RyR2 are major causes of cardiac arrhythmias, current genetic testing for SIDS/SUDS is to sequence all exons of these six genes.

Testing of SIDS and SUDS cases in the New York City Office of Chief Medical Examiner has identified genetic variants that are consistent with a cause of death due to cardiac arrhythmias. Fifty-one SIDS cases and thirty-four SUDS cases have been tested. Thirty percent of tested SIDS cases and twenty two percent of tested SUDS cases carry possible disease causing mutations on one of the six cardiac ion channel genes described above. Among the fifty-one SIDS cases, twelve percent carry mutations on SCN5A, 8% of cases carry mutations on each KCNQ1 and KCNH2, and two percent of cases carry mutations on RyR2. Among thirty-four SUDS cases, eleven percent of cases carry mutations on SCN5A, five percent of cases carry mutations on KCNQ1, and three percent of cases carry mutations on each KCNH2 and RyR2. These results appear to confirm a link between cardiac channelopathies and SIDS/SUDS deaths.

A SUDS case investigation will be presented as an example how genetic testing could help medical examiners determine cause of death when autopsy findings are negative. It is recommended that SIDS/SUDS genetic testing become a routine procedure in undetermined death investigations.

Sudden Unexplained Deaths, Genetics, Arrhythmias

G6 Fatal Acute Intracranial Injury With Subdural Hematoma and Retinal Hemorrhages in an Infant Due to Stairway Fall

Patrick E. Lantz, MD*, Department of Pathology, Wake Forest University School of Medicine, Medical Center Boulevard, Winston-Salem, NC 27157-1072; and Daniel E. Couture, MD, Department of Neurosurgery, Wake Forest University School of Medicine, Medical Center Boulevard, Winston Salem, NC 27157

The goals of this presentation are to discuss the significance of retinal hemorrhages in an infant with a traumatic brain injury and an acute subdural hematoma and the discordance of published articles about serious injuries or fatalities in infants and young children associated with stairway or short falls.

This presentation will impact the forensic science community by emphasizing the importance of a meticulous investigation required when an infant or young child dies following a history of a short fall coupled with a critical examination of the current literature on short fall fatalities.

Mistaking a fatal accidental head injury in a young child for abusive head trauma can cause serious and protracted consequences. A case of an infant with an acute subdural hematoma (SDH) and severe hemorrhagic retinopathy due to a fatal accidental head injury from a short fall down carpeted steps will be described. The clinical, autopsy, and investigative findings of this case refute the pervasive belief of many physicians that a short fall down stairs by infants and young children are invariably trivial events and cannot cause serious intracranial injuries and extensive retinal hemorrhages.

According to the mother, her 7½-months-old son had been active, playful, and crawling on the floor when she heard a loud thud and found him supine on the basement steps' landing. He was transported by ambulance to the medical center's emergency department. The child was *in extremis* and cranial computed tomography revealed a left-sided acute SDH with a midline shift. He was taken immediately to the operating room; however, in the surgical suite he became asystolic. The neurosurgeon evacuated the blood but resuscitative efforts were unsuccessful.

Neuropathological examination verified the radiological findings of an acute intracranial injury with compressive effects from a left-sided acute SDH. He had bilateral multilayered retinal hemorrhages (left > right), optic nerve sheath hemorrhages, macular edema and microscopic retinal detachments.

The upper half of the stairway from the hallway to the landing was a flight of six carpeted steps with a carpet over hardwood landing (total units of rise = 7). The stairway pitch was 37° and the rise of each step was 0.2032 m with a total rise of 1.42 meters. The oak runners and landing were 2.0 cm thick and the synthetic carpet and pad over the steps and landing measured 1.9 cm in thickness.

The accounts of the incident by the mother were repeatedly consistent and unchanging as provided to the emergency dispatcher, paramedics, emergency department physicians and nurses, neurosurgeon, detectives, and medical examiner. A multidisciplinary team of medical professionals and law enforcement personnel reviewed the investigative reports, scene images plus clinical and autopsy findings. All concurred that his injuries were due exclusively to the stairway fall.

Published studies on stairway falls and serious injuries or fatalities from short falls involving young children are discordant. Joffe and Ludwig (1988) maintained that falls down stairs seldom result in serious injury. In contrast, Chiaviello et al. (1994) concluded that while most stairway-related injuries in young children are minor, severe head injury can occur. Hall et al. (1988) reported that falls accounted for 5.9% of childhood deaths due to trauma and 41% of the falls were minor.

Williams (1991) reported that falls witnessed by two or more people or by a non-related person were associated with less severe injuries suggesting alternate mechanisms in the unwitnessed group. Chadwick et al. (1991) described seven children who died in short falls and had other injuries (5/7 with retinal hemorrhages). They concluded that when children incur fatal injuries in falls of < 4 ft, the history is false. Reiber (1993) reviewed coroner's records (1983-1991) and analyzed relevant articles. He concluded that while children on occasion suffer fatal head injuries from short falls, such events are rare. Plunkett (2001) described 18 head injury deaths resulting from playground falls in the National Electronic Injury Surveillance System database over 12 years (1988-1999). He concluded that an infant or child can sustain a fatal head injury with retinal hemorrhages from a fall of less than three meters. Wang et al. (2001) reported on low and high-level falls in a pediatric population and found a mortality rate of 1% for low-level (<15 feet) falls. Chadwick et al. (2008) reviewed the current literature plus a statewide injury database and asserted that the best current estimate of short fall mortality rate for infants and young children was <0.48 deaths per one million young children per year.

The clinical, radiographic, autopsy and investigative findings of this case will be presented followed by a critical examination of published articles on stairway-related injuries and fatalities from short falls involving young children. Lastly, caution is urged in attributing an acute SDH and traumatic brain injury with extensive retinal hemorrhages solely to abusive head trauma in an infant or young child following a stairway or short fall based on the current medical literature.

Short Fall, Subdural Hematoma, Retinal Hemorrhages

G7 Morbidity and Mortalities Related to TV Tip Over

Marvin S. Platt, MD, JD, 5050 La Jolla Boulevard, Apartment 2G, San Diego, CA 92109; and Christina Stanley, MD, San Diego County Medical Examiner's Office, 5555 Overland Avenue, Suite 1411, San Diego, CA 92123*

The goals of this presentation is to increase awareness of incidence of injuries from TV tip over, provide guidelines for distinguishing these injuries from abusive head trauma, and emphasize risk factors and need for prevention.

This presentation will impact the forensic science community by demonstrating how the incidence of injuries related to TV tip over is increasing.

This presentation will emphasize how the incidence of injuries related to TV tip over is increasing. It will present the scene investigation and autopsy findings from three fatal cases and demonstrate how a forensic pathologist can distinguish them from abusive head injury. Recent literature of this phenomenon will also be presented.

The San Diego County Medical Examiner's Office investigated three fatal cases within a nine month interval from December 2007 to September 2008. Rady Children's Hospital in San Diego treated an additional twenty-six children with non fatal injuries from the same mechanism in the two years prior to September 2008. The workup of each case will illustrate how it was distinguished from abusive head trauma (AHT).

In the first case a 3-year-old girl attempted to reach for items on a TV and/or the dresser on which the TV was positioned. The dresser and TV tipped over impacting her face. She had a fractured orbit and subarachnoid hemorrhage as a result of a probable vertebral artery injury when her neck was hyperextended. She had a brief period of consciousness prior to transport to a hospital where she was diagnosed with nonsurvivable head injuries. The second case involved the death of a 21-month-old child in which a TV on a shelf held up by three unsecured wooden dowels in an entertainment cabinet was dislodged by

a sibling playing in the room. The TV fell on the decedent and caused multiple fractures of the calvarium and base of the skull. One posterior fracture intersected with the foramen magnum and caused atlanto-occipital hemorrhage and cerebral injuries resulting in rapid death. In the third case an 11-month-old infant was struck by a falling TV when her older siblings tried to climb a dresser serving as a TV stand. She sustained massive skull fractures, destruction of her right frontal lobe and basal ganglia, and impaired perfusion of her left cerebrum. These cases were distinguished from AHT by comparing the data obtained from the scene investigation and interviewing the parties at the scene and matching the patterns of injury with the characteristics of the TV sets and their stands and positions, and noting the absence of any prior injuries at the postmortem examination and on x-rays.

A review of the literature for the past ten years indicated that crushing head injuries and fatalities from falling TV's and standup appliances are increasing while the manufacture of larger TV's with inadequate support appliances is also increasing. However, there is a need to critically examine the reporting methods of these cases since the data may not be complete or accurate. There is also a need for better public education about this problem and for the development of standards so as to prevent these injuries. One may consider requiring manufacturers to give notice to purchasers of the dangers of TV-stand tip-over by placing warning notices on the products, developing more stable TV support appliances, and consider better ways to anchor TV's on their stands.

Television Injuries, Head Injuries, Children

G8 Hanging Deaths in Children: An Investigation of Manner of Death

Julie Adams, DO, 1234 Big Bend Crossing Drive, Valley Park, MO 63088*

After attending this presentation, attendees will understand that investigations into pediatric hanging deaths require a very thorough scene investigation, research into the decedent's psychiatric, medical, and social history, and a complete forensic postmortem examination in order to determine the manner of death. Clearly, the determination of the manner of death in these cases can be controversial and can have a tremendous impact on the child's family. Our research supports the hypothesis that hanging deaths in children aged eight to twelve years of age are less likely to have suicide as the manner of death compared to hanging deaths in those aged thirteen to eighteen years of age.

This presentation will impact the forensic science community by helping medical examiners and forensic investigators elucidate information which will help determine the manner of death in these difficult cases.

Background: Suicide in children unfortunately is not an uncommon phenomenon. Suicide is the fourth most common overall cause of death of children aged ten through nineteen years of age in the United States. However, suicide attempts and completions are rare in pre-pubertal children. The rate of suicide deaths increases with increasing age after the onset of puberty.

The number of suicide deaths in the United States for those aged fifteen through nineteen has doubled in the past 40 years, and has tripled for those in the ten to fourteen year age group. However, not all deaths by hanging in children are suicides. Asphyxial "contests" such as the "choking game" have emerged in the past few years as increasing concern with hanging deaths involving children. Additionally, many of the children whose hanging deaths are deemed accidental have histories of attention deficit disorder and impulsive behavior.

Investigations into pediatric hanging deaths require a very thorough scene investigation, research into the decedent's psychiatric, medical, and social history, and a complete forensic postmortem examination in order to determine the manner of death. Clearly, the determination of the

manner of death in these cases can be controversial and can have a tremendous impact on the child's family. Our hypothesis is that hanging deaths in children aged eight to twelve years of age are less likely to have suicide as the manner of death compared to hanging deaths in those aged thirteen to eighteen years of age.

Design: Using the medical examiner's computer registry, all hanging deaths from the past ten years involving children aged 18 years of age and younger will be identified. This will include all applicable deaths in St. Louis City and surrounding counties. All the aspects surrounding the deaths, will be analyzed including the decedent's medical, social, and psychiatric history. The results will then be compiled and presented in two groups divided by age, 8-12 and 13-18. Data will then be analyzed to show whether our hypothesis is supported.

Results and Conclusion: These findings support the hypothesis that hanging deaths ultimately ruled suicides in children aged 8-12 years of age is an unusual phenomenon and is more likely to be accidental in nature compared to hanging deaths in children aged 13-18. Since research in this area of hanging deaths in children is lacking, our goal in this retrospective review is to help elucidate information which will help medical examiners determine the manner of death in these cases. Further research will help to illuminate the issues surrounding these deaths and will assist forensic pathologists in determining the manner of death in these cases.

Hanging, Child Deaths, Asphyxial Deaths

G9 Does a Draft Really Influence Postmortem Body Cooling?

Michał R. Kaliszak, PhD*, Medical University of Gdańsk, Debowa 23, Gdańsk, 80-286, POLAND

After attending this presentation, attendees will become familiar with the process of body cooling after death in various body sites, conditions which could influence this process, and the estimation of the Time Of Death (TOD).

This presentation will impact the forensic science community by showing the possibility of estimation of the TOD by measuring the *postmortem* temperature of the eye together with the analysis of the body cooling process in different environmental conditions, including still air and the presence of draft in the experimental room.

The *postmortem* body temperature decrease is a key factor in determining the time of death in humans and temperature-based methods of the TOD estimation are deemed to be most precise during the first several hours after death. The study focused on verification of the significance of the effects of airflow (draft) present in the room where the corpse is found, on the cooling process of specific body sites, and hence on determination of the TOD. The study was carried out in pigs. The investigations were commenced 75 min after the pigs had been killed and involved computerized recording of the cooling process of the eyeball interior (the vitreous humour), soft tissues of the orbit, muscles, and the recta, measured with thermal pin probes. The first part of the study was performed in still air; the second, with airflow generated by air conditioners and a fan.

The data was processed with Matlab® Software version 7.0. The estimation was done via the least squares method implemented in Matlab's *nlinfit* function. The precision of the parameters estimated was assessed by calculating the coefficient of variation (% CV) using the *nlpaci* function. The influence of air flow on the cooling rate and the initial temperature was tested comparing the individual estimates of the cooling rate in the first and the second part of the study. A t-test was performed to test the hypothesis that individual estimates of cooling rate with and without air flow are independent random samples from the same normal distribution with equal mean and variance. Additionally, the relative difference (RD) was calculated as a difference between the mean individual estimates of both parts of the study divided by the value

of the first part of the study to assess the magnitude of the difference between the parameters. It was demonstrated that the moderate airflow (draft) present in the experimental conditions did not significantly affect the course of cooling of the investigated body sites. Despite moderate wind generated in the room, it appeared that the air movement close to the pigs bodies was in fact minimal. Therefore, in order to evaluate the TOD most precisely, one should first have reliable data on the actual velocity of air in the direct vicinity of the body rather than relying on the subjective sensation of the air velocity and using various unnecessary corrective factors.

Time of Death (TOD), Postmortem Body Cooling, Draft

G10 Forensic Medicine in Dubai, United Arab Emirates

Fawzi A. Benomran, MD*, Dubai Police, Dubai Medical College, PO Box 39844, Dubai, UNITED ARAB EMIRATES

The goal of this presentation is to present the medicolegal features of the United Arab Emirates with different culture and spectrum. Interest to the audience would include the type of cases examined compared to that of their own countries, and this presentation will contain some interesting statistical information.

This presentation will impact the forensic science community by presenting information on a topic where little information is published about this region of the world, as far as forensic science is concerned.

Various characteristics of the medicolegal scene in Dubai are described, along with an overview of all cases examined over a period of six years. During the period of study, a total of 17,683 cases were examined in the Department of Forensic Medicine of Dubai Police General Headquarters. This constituted a yearly average of (2,947). The average annual increment was 11.13%, the percentage of increase between 2002 and 2007 being 68.96%. This rate of increase represents the actual increase of referral by the prosecution and the police, as well as the increase due to population growth of 7% to 8% annually. Clinical cases of injuries were found in 10,165 (57.48%), 5,404 (30.56%) postmortem examinations, 1,525 (8.62%) clinical cases of sexual crimes, 409 (2.3%) age estimations, 58 (0.32%) medical responsibility, 20 (0.11%) criminal abortion, 61 (0.34%) civil actions, and 38 (0.21%) miscellaneous cases. Males represented 4,846 (89.7%) of postmortem examination; females 558 (10.3%). The age ranged from (0-90) years, with a mean age of 40.5 years. The peak incidence was in the age group (20-50) years, where the extremes of age were least represented. Only in 361 cases (6.68% of the grand total) the deceased was a local citizen. Autopsies amounted to 394 cases, which constituted 7.29% of the total deaths examined. The four manners of death in descending order of frequency were natural 3003 (55.57%), accidental 1,727 (32%), suicidal 498 (9.2%), homicidal 164 (3%). The manner was undetermined in 12 (0.22%) of the cases over the six-year period.

As anywhere else, interesting cases have been seen occasionally. These include all manners of death, even a natural manner of death that occurs in circumstances that puzzle the crime scene investigators. Unusual cases previously reported include a case of homicidal strangulation that was staged by the perpetrators to simulate suicidal hanging; masking and bondage in suicidal hanging; accidental death due to inhalation of sulfuric acid fumes; postmortem sole incisions in a morphine overdose; an unusual case of accidental positional asphyxia; and, accidental sand inhalation which was misdiagnosed by the doctor in the hospital. Unpublished cases of note are several: a man was found dead in the passenger seat of his own car, which was locked and his trousers and pants were half way down his thighs, which was found later to be due to massive cardiac infarction; a man alleged by his family to have been found dead in his bed was discovered later to have committed suicide by hanging and the family cut him down and put him in bed to avoid loss of life insurance policy if the fact of suicide death was known;

and in the drug scene arena, during 2008 three accidental fatalities from misuse of Tramadol (Ultram) tablets were reported for the first time. Bloody death scenes are often found when the police suspect homicide, but the forensic evidence confirmed that the death was suicidal. In one case self mutilation was so extensive that it really took some courage from the forensic medical examiner to face the suspicious and skeptical crime scene officers.

Forensic Medicine, Dubai, United Arab Emirates

G11 Injuries to Abdominal Organs in Fatal Road Traffic Crash Victims

Lars Uhrenholt, PhD, Louise Moller Andersen, and Freja Gaborit, Department of Forensic Medicine, Faculty of Health Sciences, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK*

After attending this presentation, attendees will have learned about the types and distribution of abdominal injuries detected in a study of fatal road traffic crash victims at a large department of forensic medicine. The types of injuries, their incidence, distribution, and relationship to the mode of transportation will be presented and the relevance to the forensic community will be discussed.

This presentation will impact the forensic science community by augmenting future forensic studies and supplying forensic scientific data for the purpose of improving traffic safety, injury prevention, and clinical management.

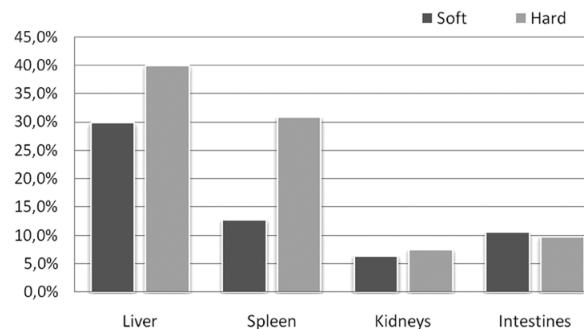

Introduction: In clinical settings, abdominal injuries can be challenging and knowledge of common topographic distribution of injuries may be helpful. There is literature suggesting that injuries to the abdominal organs are common following automobile accidents, and that the symptomatology of these injuries may range from significant to more occult clinical presentation. Abdominal injuries have been found to be common among people killed in road traffic crashes. The characteristics of fatal and non-fatal abdominal injuries are both correlated with the use of safety belts and the direction of impact. This study examined the impact of factors such as mode of transportation and type of crash scenario on abdominal injury in a group of people killed in road traffic crashes who subsequently underwent autopsy.

Methods: Autopsies performed during the period 2000-2004, involving road traffic crash victims were included. Data from autopsy and police records were retrieved from an internal database and evaluated with regard to the mode of transportation, the type of crash (i.e., passenger car, motorcycle, moped, and bicycles), and presence of injury to abdominal organs (i.e., liver, spleen, kidneys, and intestines/mesentery). Details concerning age, gender, influence of alcohol, and drugs/medication were retrieved.

Results: A total of 180 road traffic crash fatalities (133 passenger car occupants, 5 motorcycle, 19 moped, and 23 bicycles) were included. Overall, 53% of the subjects had injury to one or more abdominal organ, the liver being the most commonly affected, followed by the spleen, intestines, and kidneys. After grouping into "hard" (passenger car) and "soft" (MC, moped, and bicycle) victims, a significantly higher risk of injury to the spleen was found among car passengers *(RR=2.41 [1.10-5.32], p<0.05), whereas no statistically significant differences were found for other types of injury in relation to this grouping (Table 1). Frontal collision was the most common crash vector in passenger car crashes. For all types of abdominal organ injury lateral impact increased the likelihood of injury in passenger car victims. Injuries were more common among passenger car victims compared with other road users. Safety belt use was positively identified in 20 (36%) of a total of 55 recorded cases. Among the safety belt users, there was a higher risk of intestinal/mesentery injury, but a tendency towards a reduced risk of all

other types of abdominal injury. Alcohol test was positive in 38% of 146 tested subjects (55/146), and 39% of 46 tested subjects (18/46) were positive for drugs/medication.

Table 1 Incidence of abdominal injuries according to mode of transportation by grouping "Soft group"; MC, moped and bicycles, "Hard group"; passenger car, n=180

Discussion: Injuries to the liver and spleen were found to be the most common abdominal injuries following fatal road traffic crashes. Interestingly, only minor differences were observed in the incidence of abdominal injury in car passengers versus less protected road users (motorcycle, moped and bicycle). The significantly higher risk of injury to the spleen among passengers in motor vehicles is probably due to the generally higher energy transfer to occupants in passenger car crashes. Similarly, the increased risk of injury in lateral impact is in agreement with previous studies. The high number of positive tests for alcohol and drugs/medication in this population is similar to figures reported in the literature. Although abdominal injuries are not necessarily fatal by definition, they often contribute significantly to the cause of death. The presence, location, and severity of these injuries therefore remain of importance to the medicolegal investigation.

Conclusions: This study showed that injuries to the abdominal organs are very common following fatal road traffic crashes. Injuries to the liver and spleen were the most common types of injury affecting about a third of the deceased. The incidence rates and distribution of abdominal injuries were found to correlate to the direction of impact and mode of transportation. Future investigations into the mechanisms and pathology of abdominal injury are needed in order to improve traffic safety issues, injury prevention and clinical management.

Abdominal Injury, Fatal Road Traffic Crash, Postmortem Investigation

G12 Case Example: Cerebral Dural Venous Sinus Thrombosis Following a Motor Vehicle Accident

Ariel Goldschmidt, MD, Jackson County Medical Examiner's Office, 1700 Forum Boulevard, Apartment 509, Columbia, MO 65203; Adrian Baron, MD, and Megan Minnear, BS, 660 East 24th Street, Kansas City, MO 64108*

After attending this presentation, attendees will understand general principles related to cerebral dural venous sinus thrombosis, especially those impacting the forensic science community, including presenting signs and symptoms, risk factors, clinical diagnostic tests, potential autopsy findings, and pathophysiology. Additionally, a specific case example from the Jackson County Medical Examiner's office illustrating many of the above principles will be presented.

This presentation will impact the forensic science community by reviewing findings related to cerebral dural venous sinus thrombosis that

could easily be overlooked by medicolegal investigators, clinicians, and/or forensic pathologists unfamiliar with this potentially fatal condition.

Once familiar with this condition, medicolegal professionals will be less likely to overlook subtle diagnostic clues in a decedent's medical history and/or postmortem examination.

Among the information presented in this presentation will be anatomical diagrams and images illustrating the cerebral dural venous sinus system and potential areas of thrombosis. The potential for cerebral dural venous sinus thrombosis to cause a fatal cerebral infarct will be discussed. Risk factors including traumatic head injury and hypercoagulability from various medical conditions including dehydration from diabetes mellitus will be discussed. Images from a case example will be used to show petechial hemorrhages in the brain, a common autopsy finding in cerebral dural venous sinus thrombosis. Additional images from the case example will show scattered pulmonary thromboemboli; pulmonary thromboembolism is a rare and serious potential complication of cerebral dural venous sinus thrombosis of which many medicolegal professionals are undoubtedly unaware.

A complete case example from the Jackson County Medical Examiner's Office will be presented, including scene investigation findings, medical history including CT and MRI radiologic findings, and gross autopsy findings as described above.

Sinus, Thrombosis, Thromboembolism

G13 A Death Due to Subinvolution of the Uteroplacental Arteries: A Case Report and Literature Review

Ruth E. Kohlmeier, MD, El Paso County Coroner's Office, 2743 East Las Vegas Street, Colorado Springs, CO 80906; and Norma J. Farley, MD, Valley Forensics, 200 South 10th Street, McAllen, TX 78501*

After attending this presentation, attendees will be educated on subinvolution of the uteroplacental arteries, the risk of delayed postpartum hemorrhage with subinvolution, associated morbidity with subinvolution, and pathophysiology of subinvolution.

This presentation will impact the forensic science community by providing education as to the morbidity and mortality of the postpartum patient with subinvolution of the uteroplacental arteries.

Postpartum hemorrhage remains one of the major causes of postpartum morbidity and mortality and is defined as blood loss > 500 mL in vaginal deliveries and > 1000 mL for cesarean births. Hemorrhage within the first twenty four hours after the birth is more common, and referred to as primary or early postpartum hemorrhage. Primary and secondary postpartum hemorrhage share many of the same causes and can include uterine atony, retained placenta, placental accrete or percreta, endometrial infection, inherited coagulation disorders, consumptive coagulopathy, and lacerations of the perineum. Secondary postpartum hemorrhage, however, has received less attention, most likely because it complicates only about one percent of all pregnancies and is more frequently associated with maternal morbidity rather than mortality. However, secondary postpartum bleeding may be fatal, as is the case in this individual, and because the increase uterine bleeding occurs between one to two weeks after delivery and the patient is often home and unaware that the hemorrhage is significant.

The etiology of secondary postpartum bleeding often remains unknown if the patient can be treated conservatively; however, if bleeding is severe, a hysterectomy may be performed or the individual may not survive and require an autopsy to determine the cause of the bleeding. In subinvolution of the placental site, the uterus is grossly enlarged and boggy. Multiple microscopic sections of the placental implantation site should be taken to determine the cause of the hemorrhage and to rule out other causes of secondary postpartum

bleeding such as gestational trophoblastic disease, retained placenta, placenta accreta, and endometritis. Subinvolution of the placental site is an important cause of secondary postpartum bleeding and is defined by either a partial or complete lack of the normal involution of the superficial modified spiral arteries at the placental implantation site. Microscopically, the spiral arteries in the superficial myometrium are large and dilated and are partially occluded with thrombi. In addition, cytotoxophoblasts are identified within and surrounding the vessels and can be highlighted using low molecular cytochrome staining.

The physiologic and anatomic changes that occur in the uterine vessels during pregnancy and in the postpartum period are complex. In the beginning of pregnancy, the cytotoxophoblasts derived from the placenta invade and surround the maternal spiral arteries, transforming them into large vessels that accommodate the increased blood flow needed by the placenta and fetus. The findings are most striking at the site where the placenta has inserted into the uterus. In the normal postpartum period, involution of the arteries occurs. Involution involves the modification of the arteries back to the non-gestational state and eventual removal of the arteries from the uterus. The changes in the arteries include fibrointimal thickening, endarteritis, thrombosis, replacement of the cytotoxophoblasts within the vessels by maternal endothelial cells and regeneration of the internal elastic lamina. There is also a disappearance of the cytotoxophoblasts from the myometrium interstitium. This process, in addition to the sloughing of the decidua in the superficial endometrium and the uterine smooth muscle contraction, is necessary to avoid abnormal postpartum bleeding.

The clinical symptoms are delayed postpartum bleeding usually within two weeks of delivery. There is an abrupt onset of increased uterine bleeding that may require a hysterectomy in some cases.

The exact pathophysiology of subinvolution is not known. Some suspect an immune component leading to abnormal interaction between the maternal and fetal tissues.

Subinvolution of the uterine arteries at the placental implantation site is the result of the modified spiral arteries refusing to convert to a non pregnant state. This can lead to significant postpartum bleeding, and if not suspected, may result in death as in our case. The pathophysiology behind subinvolution is unknown but speculated that an immune etiology with miscommunication between the maternal and fetal tissues. Although it is a common suspect in delayed postpartum bleeding and can cause significant morbidity, the mortality rate due to subinvolution is unknown.

Postpartum Hemorrhage, Subinvolution, Uteroplacental Arteries

G14 Case Studies of Cranial Trepanation in Apulia (Southern Italy) Through Forensic Imaging

Emilio Nuzzolese, DDS, PhD, Ambulatorio Nuzzolese, viale J.F. Kennedy 77, Bari, 70124, ITALY; Sandro Saponetti, BSc, and Vito Scattarella, BS, Department of Animal and Environmental Biology, Università degli Studi di Bari, Bari, 70100, ITALY; and Marino Capece, MD, Imaging Department, ASL BA, Monopoli, 70100, ITALY; Nunzio Di Nunno, PhD, Università del Salento, Lecce, 73100, ITALY*

After attending this presentation, attendees will have a greater understanding and interpretation of trepanated skulls.

This presentation will impact the forensic science community by allowing a differential diagnosis between traumatic and intentional ante or postmortem trepanation.

Cranial trepanation is a practice known since prehistory in various, often geographically distant populations, from Europe to Peru. It seems to have been mainly spread during the Bronze Age and underwent a partial decline during the Iron Age. Also during the Roman Era this

practice is well attested by detailed description of specific surgical techniques and tools. It consists of several surgical treatments performed with various tools with the aim of opening a hole in the cranial vault for therapeutic purposes on living individuals. It is believed that this surgery was intended to cure cerebral disturbances related to vascular pathologies, migraines caused by intracranial pressure, or edema drainage after a severe skull trauma or as a religious ritual to drive out the evil spirit, to obtain bone powder to be used in curative potions, to obtain a bone disc as an amulet against disease, to fill the skull with incorruptible substances, or as a victory sign on dead enemies.

Differential diagnosis and the interpretation of trepanated skulls can be particularly difficult. It is necessary to distinguish between traumatic or intentional and ante or postmortem trepanation.

In case studies two early trepanated skulls who are being evaluated through radiological imaging are presented. Both skulls were found in Apulia (Italy). The first skull comes from Canosa (6th-7th AD) and the second is from Vieste (3rd BC). Both skulls present perforation, although at different stage of healing. The radiological analysis confirmed that the skull perforation was a consequence of a therapeutic operation following trauma in the Vieste skull, while the perforation was a pathologic process in the Canosa skull.

The radiological analysis was performed with a portable X-ray device (Nomad) combined with a digital sensor and computerized axial tomography with 3D reconstruction. Signs of healing reaction and bone apposition around the perforations were recognized in the Vieste skull, but not in the Canosa skull. The Vieste skull perforation can therefore be referred to as a therapeutic operation following trauma, while the lesions of the Canosa skull suggest a pathological process or a postmortem ritual practice.

The case study indicates the value of a forensic imaging approach in order to improve data analysis for a complete osteological evaluation of skulls.

Forensic Science, Cranial Trepanation, Forensic Imaging

G15 Systemic Lupus Erythematosus and Fatal Cardiac Failure Due to Pancarditis in a Young Man

Irene Riezzo, MD*, Stefania Bello, MD, Margherita Neri, PhD, and Cristoforo Pomara, PhD, Department of Forensic Pathology University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY

The goal of this presentation is to present a case of sudden cardiac failure and death in a 28-year-old Caucasian male, with reactivation of Systemic Lupus Erythematosus (SLE). A complete methodological forensic approach by means of autopsy, histological, and immunohistochemical examinations lead investigators to conclude an acute congestive heart failure due to pancarditis as cause of death.

This presentation will impact the forensic science community by discussing a definitive diagnosis of acute congestive heart failure with dilated cardiomyopathy after pancarditis was made, as a fatal and rare complication of Systemic Lupus Erythematosus.

SLE is an inflammatory, autoimmune disease of unknown etiology, characterized by the production of autoantibodies and the deposition of immune complexes in various organs. Cardiac involvement occurs frequently, although it is often mild enough not to cause clinical concern. Pericarditis is most commonly seen, with a reported prevalence of 60%. Myocardial involvement is present in only a minority of patients and valvular abnormalities can be demonstrated in an increasing number of patients. Although most of the valvular lesions will be present without any symptoms, valve incompetence can result in congestive heart failure. Myocardial involvement usually accompanies other cardiac lesions. Isolated myocarditis, or dilated cardiomyopathy, is a rare and usually late

clinical manifestation of SLE. Autopsy series in diagnosed SLE patients showed 62% pericardial involvement, 50% valvular involvement (Libman-Sacks lesions and infective endocarditis) and 40% myocarditis, but all have been underdiagnosed clinically.

A 28-year-old Caucasian man, with systemic lupus erythematosus (SLE) treated with hydroxychloroquine and systemic glucocorticoids, was admitted to the emergency department for an arm-ache after an accidental fall. Admission radiographs revealed a spiroid diaphyseal humeral fracture at the mid-distal third, which was treated by surgical internal fixation with a locked antegrade intramedullary nail, and then it was replaced by an external fixation. An ECG showed sinus bradycardia (58/min), QRS axial left deviation in the frontal plane, incomplete right bundle branch block, marked ST-T segment elevation.

After few days he was discharged to continue anticoagulant and antibiotic therapy at home, but three days later he was admitted again to the same hospital for high fever (39.5–40.5°C). The clinical examination revealed pharyngeal hyperaemia, cervical lymphadenopathy and the classical “butterfly” erythematous rash on the face and on the neck. Hematologic studies revealed anaemia, neutropenia, lymphopenia and thrombocytopenia; the morphological examination of peripheral blood and the research for viruses with cardiac and lung tropism were negative. On the eighth day the diagnosis of reactivation of SLE was made and higher doses of glucocorticoid, antipyretic, and antibiotic therapy were administered.

On the fourteenth day, an echocardiography was performed showing normal atrioventricular and semilunar valves, the ventricles were dilated and hypocontractile, with a 33% ejection fraction; the Doppler examination revealed the mitral valve regurgitation. He was transferred to the Department of Cardiology but few hours later he suddenly collapsed; blood gas analysis revealed metabolic acidosis. Vasoactive drugs (dopamine and noradrenaline), bicarbonate, and fluids were administered. The next morning he collapsed again but cardiopulmonary resuscitation was unsuccessful and the man was pronounced dead.

A postmortem examination was performed 48 hours after death. The external examination revealed only malar erythematous cutaneous rash. Internal examination was unremarkable except for heavy lungs and reddish colored foam on trachea and the main bronchi and a cerebral edema.

The heart had a normal shape (15x13x5cm) and a weight of 495g. The left ventricular wall thickness was 1.9cm and the right ventricular wall thickness was 0.8cm. The atrial chambers were normal, the ventricles ones were dilated, and the myocardium was flaccid. Cross sectioning of extramural coronary arteries showed no significant stenosis or thrombotic occlusion. The atrioventricular and semilunar valves were normal except for mitral valve, which showed abnormal leaflet thickening with a decreased mobility.

The histological examination of the heart was performed using haematoxylin-eosin (H&E) and revealed pericardial spots (lymphocytic infiltrates); the myocardium showed focal and rare lymphocytic infiltration in perivascular areas, patchy fibrosis, rare foci of irreversible hypercontraction with myofibrillar break and anomalous cross band formation, and focal interstitial hemorrhages in subendocardial layers (reflow areas). The mitral cusps showed diffuse fibrosis and lymphocytic infiltrates.

The immunohistochemical examination of the heart specimens revealed a positive reaction in cardiac myocytes for antibodies anti-TNF- α and IL-8, and a stronger positive reaction for antibodies anti-IL-15 and IL-10.

Furthermore, the expression of CD-4 and CD-8 showed a strong positive reaction in pericardium, valvular endocardium, and less positive in myocardial specimens.

Examination of the other organs was unremarkable except for cytotoxic cerebral edema, massive pulmonary edema and polyvisceral stasis.

A definitive diagnosis of acute congestive heart failure with dilated cardiomyopathy after pancarditis was made, as a fatal and rare complication of Systemic Lupus Erythematosus.

Lupus, Pancarditis, Dilated Cardiomyopathy

G16 Autopsy Investigation and Bayesian Approach to Coronary Artery Disease (CAD) in Victims of Motor Vehicle Accidents

Antonio Oliva, PhD, and Sara Meriglioli, PhD, Institute of Forensic Medicine, Catholic University, School of Medicine, Largo Francesco Vito 1, Rome, ITALY; Jose Flores, MD, Montreal Heart Institute, University, Montreal, Quebec, Canada, Montreal, CANADA; Francesca Cittadini, PhD, Sara Partemi, MD, and Vincenzo L. Pascali, PhD, Institute of Forensic Medicine, Catholic University, largo Francesco Vito 1, Rome, ITALY; and Ramon Brugada, MD, Montreal Heart Institute, Montreal Quebec, Canada, Montreal, CANADA*

After attending this presentation, attendees will understand the importance of coronary artery disease in causing motor vehicle accidents. Each year 1.2 million people die world-wide as a result of motor-vehicle accidents and the prevalence of injuries is estimated at 50 million, representing a tremendous burden to health. The objective of this study was to define the prevalence of coronary disease and its possible role in motor-vehicle accidents.

This presentation will impact the forensic science community by discussing the data regarding the important percentage of evidence of acute myocardial ischemia in traffic accidents.

Consecutive cases of non-hospital sudden death autopsies between 2002 – 2006 were examined. The research focused on those individuals victims of motor vehicle accidents. A total group of 1,260 individuals in the area of West Quebec were identified. Severe coronary artery disease (CAD) was defined as a narrowing of $\geq 75\%$ cross-sectional area or acute plaque events in major epicardial coronary arteries. In order to evaluate the probability of fatal accidents caused by the presence of significant coronary disease, a *Probabilistic Expert System* (PES) was applied.

Motor-vehicle accidents were responsible for a total of 123 deaths (63%); 100 (81.3%) were males and 23 (18.7%) were females. In individuals over 40 there was significant coronary artery disease in 64.1%, with evidence of acute myocardial ischemia in 12%. In decedents older than 60 years, the prevalence of significant coronary disease and ischemia were 84.6% and 18.18% respectively. Two-thirds of the coronary patients were identified as having erratic driving behavior by bystanders before the accident. ETOH was detected in 11.8% and drugs in 4.9% of the drivers. Statistical analysis showed that an individual affected by coronary artery disease has an accident with a probability of 0.09 (9%).

This research data shows that there is a very high prevalence of severe coronary artery disease in individuals who have suffered a motor-vehicle accident. In an important percentage there is evidence of acute myocardial ischemia. In contrast with previous statements, a large group of the coronary drivers who died, had no time to control and stop the car before the accident. This evidence has important implications for driving safety.

Motor Vehicle Accident, Coronary Artery Disease, Autopsy Investigation

G17 An Unusual “In-Custody” Death

Brian Drewry, BS, Iowa and Jerri McLemore, MD, Iowa Office of the State Medical Examiner, 2250 South Ankeny Boulevard, Ankeny, IA 50023; Dennis Klein, MD, Iowa Department of Public Health, 2250 South Ankeny Boulevard, Ankeny, IA 50023*

After attending this presentation, attendees will have learned possible symptoms related to pheochromocytomas and learn basic guidelines for investigating in-custody deaths.

This presentation will impact the forensic science community by providing basic information required by the medical examiner or coroner for deaths that occur in the presence of law enforcement officials. The presentation will also provide information of symptoms related to an adrenal gland tumor.

In-custody deaths or deaths that occur in the presence of police officers are usually high-profile cases that have the potential to become politically charged events. Scene investigation is vital to these types of deaths and should include acquisition of any video of the event, eyewitness' statements, investigation of the event by an independent agency, and autopsy of the decedent. Because of the potential for rumors of foul-play or police misconduct to be propagated within a community, an autopsy should be performed on individuals who die while interacting with law enforcement officials even if the deaths seem “straight forward.”

This presentation presents the sudden death of a woman with long-standing hypertension during detainment by a peace officer for a traffic violation. During her detainment, which caused her considerable stress, she complained of having a “panic attack,” chest pains, and shortness of breath. She became increasingly confused and would not respond to the peace officer's questions. She became unresponsive shortly after emergency medical services arrived at the scene. According to the peace officer, at no point was the woman physically restrained. Autopsy findings were remarkable for lack of trauma, cardiomegaly with left ventricular hypertrophy, hypertensive changes in the kidneys, and a tumor in the left adrenal gland that was diagnosed as a pheochromocytoma. Pheochromocytomas can produce a variety of symptoms including hypertension and have been associated with sudden death. Physical and emotional stress may precipitate hypertensive crises in individuals with these tumors. In this case, the woman's unfortunate death happened to be in the presence of a police officer. Although the death was regarded as a probable natural manner of death from the onset, an autopsy was mandated to confirm this initial impression by establishing an exact cause of death and to quell any possible accusations of misconduct by the peace officer.

In-Custody Deaths, Investigation, Pheochromocytoma

G18 Analysis of Female Firearm Homicides in King County, Washington 2000 - 2007

Janaki Warushahennadi, MD, and Richard C. Harruff, PhD, King County Medical Examiner's Office, 325 Ninth Avenue, HMC Box 359792, Seattle, WA 98116*

After attending this presentation, attendees will be able to describe distinctive features of female homicides due to firearm injuries.

This presentation will impact the forensic science community by delineating the demographics, modalities, circumstances, and motivations that characterize female homicides.

Materials and Methods: The records of the King County Medical Examiner's Office (KCMEO) in Seattle, Washington, were searched to locate homicide victims from 2000 through 2007. These records were analyzed with respect to demographics and cause of death to compare male and female homicide victims. Those cases in which the decedent

was female and the cause of death was firearm injury were analyzed in more detail and were used to construct a database comprising essential medical examiner information. Investigative records from the Homicide Investigation Tracking System (HITS) of the Washington Attorney General's Office were incorporated into this same database to include details regarding the victim, circumstances, and perpetrator of her death. Analysis of this database was the basis of the results of this study.

Results: From 2000 through 2007, there were a total of 618 homicides investigated by KCMEO; 490 were male and 128 were female. Asphyxia, blunt force injuries, sharp force injuries, firearm injuries, and mixed modalities were identified as causes of death. Considering deaths due to firearm injuries only, 334 (68.2%) of the male homicides were due to firearm injuries, compared to 52 (40.6%) of the female homicides. This difference is highly statistically significant ($p<0.0001$). In the group of 52 female firearm homicides, ages ranged from 5 to 93 years with an average of 41.7 years; 23 were married, 17 single, 8 divorced, 2 widowed, and 2 of unknown marital status; 21 were employed outside the home, 7 were homemakers, 5 students, 5 retired, and 2 unemployed. Blood alcohol levels in the decedents were positive in 21 cases and ranged from 3 to 24 mg/dL. In 34 cases, the shooting occurred inside a residence, 2 in unspecified buildings other than a residence, 8 on the street, 3 in vehicles, 2 at worksites, and 1 in a tavern. In 27 cases, the homicide was a consequence of domestic violence. Other motivations and/or circumstances included 6 reckless or unintentional shootings, 4 for financial gain, 2 in "heat of anger", 2 "mercy killings", 2 police officer involved shootings, 1 gang-related, 1 "recreational", 1 child abuse, and 1 due to ethnic hatred. Sexual assault did not appear to be a motivation in any case. Seven of the decedents were from incidents involving multiple homicides. Perpetrators were identified as 15 husbands; 17 boyfriends, ex-boyfriends, male roommates or male acquaintances; 8 family members (child, parent, or other family member); 9 strangers, unknown assailants or unspecified male; and 1 female acquaintance. In 20 cases the perpetrator shot himself immediately after killing the female.

Conclusions: In this study, firearm injuries accounted for less than half of all female homicides and occurred most commonly in a setting of domestic or intimate partner violence. Typically the decedent was a mature woman and had stable employment. Perpetrators were nearly all males with a close or intimate relationship with his victim. Most instances occurred in homes, but it was not unusual for an ex-partner to make a deliberate attack elsewhere, such as at a worksite. Although attacks were often directed at intimate partners or ex-partners, sexual assault was not a factor in any case. Nevertheless, the emotional context of these homicides was evident in that nearly forty percent of the perpetrators shot themselves after killing the female. These findings support the conclusion that domestic violence and firearms are a dangerous combination.

Firearm Injuries, Female Homicides, Domestic Violence

G19 Genetic Aspects of Sudden Death in Youth: A Retrospective Study of Familial Hypercholesterolemia

Maiken K. Larsen, MD, Department of Forensic Medicine, Brendstrupgårdsvej 100, DK-8200 Aarhus N, DENMARK; Peter H. Nissen, MSc, Department of Clinical Biochemistry, Aarhus University Hospital, Tage Hansens Gade, DK-8200 Aarhus N, DENMARK; Ingrid B. Kristensen, MD, Department of Forensic Medicine, Brendstrupgaardsvej 100, DK-8200 Aarhus N, DENMARK; Henrik K. Jensen, MSc, Department of Cardiology, Aarhus University Hospital, Skejby, Brendstrupgaardsvej 100, DK-8200 Aarhus N, DENMARK; and Jytte B. Lundemose, PhD, Faculty of Health Sciences Aarhus University, Department of Forensic Medicine, Brendstrupgårdsvej 100, DK-8200 Århus N, , DENMARK*

After attending this presentation, attendees will understand some principles of genetic heart disease and the advantage of genetic examination in selected forensic autopsies of sudden death. Preliminary results of premature ischemic heart disease will be presented as an example.

This presentation will impact the forensic science community by serving as a key aspect of sudden cardiac death investigation as it can augment traditional means of investigation by including postmortem genetic examination in order to reveal familial hypercholesterolemia (FH) in young people dying from coronary athero-thrombotic disease.

Several cases of sudden death due to basis of genetic heart disease have inspired this newly started retrospective study. The goal of the study is to examine inherited heart disease from selected forensic autopsies.

Purified DNA from blood of approximately 230 selected autopsies; aged 0-40 will be examined. The following genetic heart diseases will be emphasized: Ischemic heart disease due to FH caused by defects in the low density lipoprotein receptor (LDLR) and apo – lipoprotein B (ApoB) gene; Long QT-syndrome and Brugada syndrome due to defects in cardiac ion channel proteins; catecholaminergic polymorph ventricular tachycardia due to defects in the ryanodine receptor; arrhythmogenic right ventricular cardiomyopathy due to defects in the desmosome proteins; hypertrophic, and dilated and restrictive cardiomyopathies due to defects in the contractile proteins.

Preliminary results of the study concerning premature ischemic heart disease will be presented. Examination of approximately forty cases of death in youth due to ischemic heart disease is being examined for defects in the LDLR and ApoB gene.

Mutations in the genes of the above mentioned proteins are known to present as arrhythmia or sudden death. Diagnosed cases of sudden cardiac death in the Danish population are few, despite the estimated higher number of cases in the literature. The perspective of the study is to determine the molecular cause of sudden cardiac death in order to intervene and prevent sudden cardiac death in relatives to cases with proven genetic heart disease.

Sudden Cardiac Death in Youth, Genetic Heart Disease, Familial Hypercholesterolemia

G20 An Unusual Death of a Masochist: Accident or Suicide?

Biagio Solarino, PhD*, Sezione di Medicina Legale, Università degli Studi di Bari, P.zza Giulio Cesare, 11, Bari 70125, ITALY; Lucia Tattoli, MD, Sezione di Medicina Legale, University of Bari, Bari, ITALY; Ignazio Grattagliano, PsyD, Section of Forensic Psychiatry, University of Bari, Piazza Giulio Cesare, Bari 70124, ITALY; Claas T. Buschmann, MD, Institute of Legal Medicine and Forensic Sciences, Turmstrasse 22, Berlin 10439, GERMANY; Michael Tsokos, MD, Institute of Legal Medicine & Forensic Sciences, Turmstrasse 21, Haus L, Berlin 10559, GERMANY; and Giancarlo Di Vella, PhD, Sezione di Medicina Legale, DIMIMP, University of Bari, Policlinico, piazza G. Cesare, Bari 70121, ITALY

The goal of this presentation is to describe a very unusual case of the death of a masochist resulting from autoerotic behavior.

This presentation will impact the forensic science community by bringing attention to the unusual practice of compressing the neck and chest during masochistic activities, along with other information related to basic crime scene investigation, reconstruction of events, and autopsy findings in these type cases.

Fatal masochistic asphyxia is a relatively rare phenomenon secondary to the malfunction of apparatus used to provide sexual pleasure. The basic mechanism of sexual asphyxia is the creation of cerebral hypoxia which, according to the literature, is generally brought about by constriction of the neck by use of a ligature. In a small percentage of cases, less typical methods of sexual asphyxia involving chest and abdominal compression are also employed. In all such cases, hypotheses of suicide and homicide must not be ruled out.

A case of a 52-year-old man found dead in the house where he lived alone is reported here. The corpse was found in his study, lying supine on the floor, underneath an open chair bed with a 1.3 x 3.2 meter mattress. The victim's head protruded from under the mattress and was partially covered by two blankets. One of the legs of the chair-bed was discovered pressing perpendicularly into his throat, between which a rubber slipper was positioned, and whose sole was facing the anterior portion of his neck in midline. An iron support bar, which made up part of the bed frame, was pressed against the chest and upper abdomen, causing the bed frame to be elevated off floor. He was wearing typical men's pajamas, underneath which he wore boxer shorts with the fly open. Autopsy revealed the clear imprint of the slipper's sole on the anterior side of the neck. There was no fracture of the hyoid bone or thyroid cartilage, but several deep muscle bruises of the neck were identified. Histological analysis revealed a hemorrhage of the jugular vein and injury to the vagus nerve. An examination of the lungs revealed a large solid mass (7 cm in diameter) occupying the inferior lobe of the right lung; nodules and sclerotical patches involving the omentum were observed, along with the presence of very large adhesions of the peritoneum together with sub-obstructions of the bowel. Toxicological examination revealed no substances of abuse in the blood or urine. The cause of death was attributed to asphyxia by external compression of breathing apparatus.

Further investigation of the victims' history revealed that he was under the care of a psychologist, due to the fact that he had habit of placing heavy objects (especially books and chairs) onto his chest or abdomen with the purpose of engaging in masochistic sexual gratification. This practice interfered with his ability to become intimately involved with women, and so he sought out psychological help to free him from this behavior. The victims' medical history is unknown, including the fact that he had cancer. As far as is known, no suicidal ideation was ever expressed by the victim.

These findings suggest that the manner of death should be classified as accidental. However, the unusual circumstances involved in this case,

including the presence of cancer, does not rule out that the death may have indeed been suicidal.

Masochism, Asphyxia, Autoerotic

G21 Numerous Rhabdomyomata and Cortical Tubers in a Possible Case of SIDS

Iyare Izevbaye, PhD*, State University of New York, Buffalo, 100 High Street, Buffalo, NY 14203; and Fazlollah Loghmanee, MD, Erie County Medical Examiner's Office, 111 Lehn Spring Drive, Williamsville, NY 14221-6920

After attending this presentation, attendees will exercise different difficult possible manners of death in cases of SIDS.

This presentation will impact the forensic science community by the importance of fact findings through detailed investigations; medical, interviews with family members, etc.

Sudden Infant Death Syndrome (SIDS) is the leading cause of death for infants between the ages of one month to one year. This position has remained unchanged despite risk reduction campaigns and the resulting decline in prevalence in the past two decades. The rate of SIDS in the United States is 0.539 per 1000 livebirths in 2005, accounting for 7.8 % of all infant death. SIDS is defined as the "sudden death of an infant less than one year of age, with onset of the fatal episode apparently occurring during sleep that remains unexplained after a thorough investigation, including performance of a complete autopsy, review of the circumstances of death, and the clinical history. SIDS, a diagnosis of exclusion, can only be made after other explanations for unexpected death have been ruled out. Such explanations include Tuberous sclerosis and infantile asphyxia.

Tuberous sclerosis complex is an autosomal dominant syndrome that is occasionally the findings in these patients with unexpected infant death. Infantile asphyxiation is an important condition that results from unsafe sleeping conditions and must be ruled out before a diagnosis of SIDS can be made. Unsafe sleeping conditions include excess soft beddings, adult beds, chairs, sofas, waterbeds etc.

A case of an unexpected infant death during sleep with multiple factors that confound the cause of death will be discussed. Factors and attempts to delineate their contributions to arrive at a cause and mechanism of death will also be discussed.

Cerebral Tuberous Sclerosis Cardiac Rhabdomyomata, Undetermined Manner of Death, Final Fatal Mechanism of Death

G22 Fatal Subarachnoid Hemorrhage During Sexual Activity: A Case Report

Federica Portunato*, Maria Celeste Landolfa, MD, Manuela Botto, MD, and Francesco De Stefano, MD, Department of Legal and Forensic Medicine, Via De Toni 12, Genova, I-16132, ITALY; and Francesco Ventura, MD, Department of Forensic Pathology, University of Genova, via de' Toni, 12, Genova, 16132, ITALY

After attending this presentation, attendees will have learned about a case of sudden death immediately after coitus.

This presentation will impact the forensic science community by explaining that sexual activity, in susceptible subjects may be a trigger of medical emergencies with a real risk of sudden death.

Particularly, the anatomical and physiological responses to coitus may determine many acute and severe complications. Among these, cardiovascular, neurological and urological diseases, soft tissue and immunological consequences may arise in patients with predisposing risk factors, even if asymptomatic (A. Banerjee, 1996).

Many cases of sudden and unexpected death during autoerotic activity have been reported in literature; the majority of these may be considered accidental deaths, especially by asphyxial mechanism. Only few cases are reported as due to natural causes (*N. Beahrendt et al., 2002*).

Studies on sexual related deaths show that cardiovascular diseases and cerebral hemorrhages are the most important causes of death connected to sexual activity.

Coronary artery disease (CAD), myocardial infarction and reinfarction, dissection of aortic aneurysms along with cardiomyopathy – with or without heart failure – are more frequently associated with coital death.

Even if intracerebral bleeding during sexual activity is rare, coitus has also been considered to trigger subarachnoidal bleeding, because of the transient rise in blood-pressure.

As any form of physical exercise, sexual intercourse increases heart rate and blood-pressure. In the majority of cases of natural death combined with sexual activity, the victims are generally male (*W. Janssen et al., 2005*).

Although the gender differences in the incidence of CAD and SAH are statistically not significative, the male dominance of CAD has been showed. On the contrary, the female dominance of SAH has been demonstrated (*S. Lee et al., 2006*).

Many authors described a “malignant coital headache,” so that it can be considered a common feature of cerebral vascular accident (*M. Sutton Brown et al., 2006*).

A case of sudden and unexpected death of a homeless 45-year-old woman is described. During the questioning of the circumstances of death, the partner reported that they were on the beach, lying under a boat, around 1:00 p.m. The woman suddenly presented severe dyspnea and rigidity of the body just after sexual intercourse. Medical assistance was immediately called but the woman died despite attempts at resuscitation. According to the antemortem data obtained from the police report and relatives, it showed that the deceased was apparently healthy and did not show any prior symptoms of cardiovascular disease. No signs of serious headache were present at all in the clinical history. Because the cause of death remained unknown in order to investigate the partner’s report, a complete medicolegal autopsy was performed. The external examination was unremarkable and no signs of injuries or trauma were observed. The internal examination revealed pulmonary edema and lung congestion. There was massive subarachnoid hemorrhage due to a basilar artery aneurysm rupture. No other important pathological findings were observed. In conclusion, subarachnoid hemorrhage secondary to a cerebral aneurysm rupture is still an important cause of death despite steady advances in diagnosis and treatment. Although transient hemodynamic changes associated with sexual activity seem to play some role in the pathogenesis of subarachnoid hemorrhage, the mechanism of physical activity induced subarachnoid hemorrhage is still not completely known.

Sexual Activity, Subarachnoid Hemorrhage, Sudden Death

G23 Occurrence of MRSA in the Peritoneal Cavity Following PEG Tube Insertion

Nicole Singer, BS, 206 South 13th Street Apartment 702, Philadelphia, PA 19107; and Fredric N. Hellman, MD, Office of the Medical Examiner, Fair Acres, Route 352, Lima, PA 19037*

After attending this presentation, attendees will become familiar with the means of transmission of methicillin-resistant staphylococcus aureus (MRSA) to the peritoneal cavity, proper percutaneous endoscopic gastrostomy (PEG) tube insertion procedures, and potential pitfalls, peritonitis, and a situation that links all previously mentioned aspects.

This presentation will impact the forensic science community by explaining that the occurrence of MRSA as an isolate in bacterial

peritonitis does not increase the significant mortality for the patient to a greater extent than from mixed aerobic gram negative organisms or from anaerobic infection. It is nonetheless important for the forensic pathologist to appreciate the potential for nosocomial spread of MRSA to both the respiratory tract as well as into the peritoneal cavity, with the skin often colonized by MRSA when internal isolates of this microorganism are detected. Proper understanding of the mode of transmission will hopefully facilitate the development of guidelines to help prevent peritoneal nosocomial spread of Methicillin-resistant *Staphylococcus aureus*.

This presentation will examine the transition of MRSA as a skin commensal both to the respiratory tract of an immunologically compromised individual as well as to the peritoneal cavity following the insertion of a percutaneous endoscopic gastrostomy tube. This is the case of a 46-year-old white male who had a history of severe mental retardation/Down Syndrome and upper respiratory problems including dysphagia, being discharged from a regional hospital on January 20, 2009 after having a percutaneous endoscopic gastrostomy tube inserted for feeding. Upon returning to his place of residence, he suffered respiratory arrest, with resuscitative efforts to no avail. The decedent was pronounced dead at 9:15 p.m. on January 20, 2009, only several hours after being discharged from the hospital. Autopsy examination demonstrated a peritonitis that tested positive for Methicillin-resistant *Staphylococcus aureus*, with an excess of 300 ml of purulent tan fluid within the peritoneal cavity as well as coating visceral surfaces, and with fibrinous adhesions extending between bowel loops. Present as well was a gastrostomy tube inserted within the pyloric region of the stomach that readily slipped out of the insertion point upon removal of the viscera from the abdominal cavity. Other significant findings included chronic pancreatitis, with an extensively sclerotic pancreas, cortical contusions of the inferior orbital gyri of the left cerebral hemisphere, and extensive fenestrations of all aortic valve cusps, with extensive epicardial scarring of the surface of the heart. The cause of death was determined to be acute pneumonitis, with aspiration complicated by Methicillin-resistant *Staphylococcus aureus*-positive acute peritonitis, with significant contributing factors being inanition and dehydration, history of severe mental retardation/Down Syndrome, dysphagia, and chronic pancreatitis. The manner of death was rendered undetermined. Percutaneous endoscopic gastrostomy tubes are used to provide long term hydration and nutrition to patients who are no longer capable of receiving nutrition through oral means. Infections such as peritonitis may arise upon gastrointestinal perforation, but may also develop after percutaneous placement of gastrostomy feeding tubes in patients afflicted with commensal skin involvement by pathogenic bacteria. Typical bacteria cultured from the peritoneal cavity in circumstances of gastrointestinal perforation (e.g.,perforated diverticuli, gastric ulcerations, etc.) include mainly a mix of aerobic gram negative bacteria (primary) and anaerobes (secondary). Isolation of a pure culture of MRSA is no longer an uncommon event in cases of bacterial peritonitis, however, likely a consequence of percutaneous nosocomial transfer of these organisms. Prior MRSA infections in an individual increase the likelihood of developing future such events. The insertion of a PEG tube facilitates MRSA spread into the peritoneal cavity, presumably through nosocomial spread from the skin. Bacterial peritonitis is always a life-threatening event; MRSA as the source of bacterial peritonitis underscores both the ubiquity of this microorganism and the dangers associated with introduction of catheters into the peritoneal cavity within this context. The occurrence of MRSA as an isolate in bacterial peritonitis does not increase the significant mortality for the patient to a greater extent than from mixed aerobic gram negative organisms or from anaerobic infection. It is nonetheless important for the forensic pathologist to appreciate the potential for nosocomial spread of MRSA to both the respiratory tract as well as into the peritoneal cavity, with the skin often colonized by MRSA when internal isolates of this microorganism are detected. Proper understanding of the mode of transmission will hopefully facilitate the development of guidelines to

help prevent peritoneal nosocomial spread of Methicillin-resistant Staphylococcus aureus.

PEG Tube, Peritonitis, MRSA

G24 Two Cases of Generalized Myxedema

Meredith A. Lann, MD*, and Jeffrey J. Barnard, MD, Southwestern Institute of Forensic Sciences, 5230 Southwestern Medical Drive, Dallas, TX 75235

After attending this presentation, attendees will be able to summarize the clinical manifestations of hypothyroidism, recognize various autopsy findings associated with the hypothyroid state, appropriately utilize ancillary testing to support their diagnosis, and discuss pathophysiologic aberrancies which may lead to death in this type of case.

This presentation will impact the forensic science community by providing education about this medical condition and photographic representation of several autopsy findings, as well as underscore the diagnostic importance of performing a complete medicolegal autopsy with ancillary studies.

Hypothyroidism is rarely diagnosed in the forensic setting. Two cases of hypothyroidism with generalized myxedema were diagnosed at the SWIFS between 2006-2009 and will be discussed in the presentation.

Generalized myxedema is also known as Gull disease, as it was first linked to the hypothyroid state in 1873 by Sir William Gull. The clinical manifestations of hypothyroidism varies with age of onset. Children present with cretinism. Adults; however, suffer from relatively nonspecific manifestations such as generalized fatigue, apathy, and mental sluggishness, slowing of speech and intellectual function. Constipation, decreased sweating, cold intolerance, and weight gain are common. Skin involved by myxedema takes on a thickened and waxy appearance. The skin may become cool and pale due to decreased blood flow and/or an anemic state. Reduced cardiac output contributes to symptomatology of shortness of breath and decreased exercise capacity. The hair often becomes thinned, coarse, and dry-appearing.

There are two forms of myxedema – generalized and pretibial. Generalized myxedema is often seen in persons with hypothyroidism, whereas pretibial myxedema is associated with a hyperthyroid state. Histologic changes are similar in both forms, as the affected skin shows accumulation of matrix substances (glycosaminoglycans and hyaluronic acid), with the separation of collagen bundles in the reticular dermis. In generalized myxedema, matrix accumulation occurs in deeper subcutaneous tissues and visceral sites, therefore involvement of the heart may directly lead to death in some cases.

In cases of generalized myxedema, a thorough scene investigation and medical history should be obtained. In addition, a full medicolegal autopsy to include toxicologic and ancillary serologic analyzes should be performed. Thyroid stimulating hormone (TSH) is the most sensitive screening method for the diagnosis of hypothyroidism, and TSH levels in the serum of both adults and children are reliable up to twenty four hours after death. It is important to note that in cases of secondary or tertiary hypothyroidism (i.e., pituitary or hypothalamic disease), the TSH level will not be increased. Thyroxine (T4) levels will be decreased in all cases of hypothyroidism. Hypothyroidism is easily treatable and carries a low mortality if one is given timely and sufficient hormone therapy.

Although a diagnosis of generalized myxedema is rare in the forensic setting, it is critical for the forensic pathologist to be able to correctly identify this disease. There are many variations and subtle findings which may easily be missed by the uneducated pathologist. One must be able to recognize the various abnormalities at the time of autopsy, critically examine tissue by light microscopy, and select the

appropriate serologic studies in order to correctly determine cause of death.

Forensic Pathology, Myxedema, Hypothyroid

G25 Adipositas Cordis and Iatrogenic Death: Fatal Complication or Medical Error?

Guido Viel, MD*, and Giovanni Cecchetto, MD, University of Padua, Via Falloppio 50, Padova, 35121, ITALY; Ann S. Schroder, MD, and Nadine Wilke, MD, Eppendorf - Hamburg, Hamburg, GERMANY; Massimo Montisci, PhD, Via Falloppio 50, Padova, ITALY; and Klaus Pueschel, PhD, Eppendorf - Hamburg, Hamburg, GERMANY

After attending this presentation, attendees will learn some basic information regarding the risk of pacing maneuvers, and the role of fatty infiltration of the right ventricle in causing delayed cardiac laceration.

This presentation will impact the forensic science community by discussing the utility of an integrated analysis of clinical, radiological and histological data for identifying any eventual medical error during pacing maneuvers.

It is well-known that the hearts of most adults in western countries contain varying physiological amounts of fat, found mainly in the subepicardial region of the anterolateral wall of the right ventricle. In the normal heart the boundary between the inner myocardium and the outer subepicardial fat is usually distinct, although a slight fuzzy border may be observed. On the contrary, in the fatty infiltration of the right ventricle irregular islands of adipose tissue may extend from the epicardium to the endocardium with the interposition of only few muscle fibers.

In such cases the risk of cardiac rupture after myocardial infarction as well as the risk of ventricular laceration after cardiac surgery is notably increased.

The case of a 70-year-old woman who died of an acute pericardial tamponade due to a delayed laceration of the right ventricle after pacemaker implantation is reported. The autopsy finding of a severe fatty infiltration of the right ventricle, its causal role in determining the fatal pericardial effusion and the legal responsibilities of the physicians who performed the implantation are critically discussed under a forensic point of view.

Myocardial perforation by pacing electrodes or Implantable Cardioverter-Defibrillator (ICD) leads is a well-known and documented complication, occurring at a rate of about 0.4-2.0%. The largest part of the injuries are clearly related to the impacting maneuvers peculiar to the manipulation of pacing catheters and are recognized intraoperatively or in the early postoperative period. Even if the complication is misdiagnosed or the rupture is delayed, due to the "self-sealing" properties of the myocardium and to the fact that generally the lead closes up the ventricular perforation (avoiding a massive bleeding), life-threatening pericardial or pleural effusions are rare.

In our case, the presence of an extended fatty infiltration of the lateral wall of the right ventricle (35% of the myocardium was displaced by adipose tissue) forced the operator to move the implantation lead back and forth to obtain a valid electric signal. In that manner, because of the enhanced fragility of the right ventricle, the surgeon produced three micro-perforations, one of them localized on the lateral wall above the insertion of the anterior papillary muscle, and two of them localized near the apex. All the perforations were of small dimensions and had "self-sealed" soon after the lead damage because the echocardiography performed thirty minutes after the implantation did not reveal pericardial effusion and the patient was totally asymptomatic during the afternoon and the evening of the operative day.

Clinical and radiological data suggest that the fatal ventricular laceration has formed during the late evening or night. Indeed, the

granulocyte infiltration along the margins of the tear dates the lesion between four and six hours before death.

Considering the size and morphology of the injury as well as the extensive transmural fatty infiltration observed in that point of the ventricle, the most probable explanation is that the micro-perforation, produced by the lead, progressively enlarged due to the presence of multiple adipose cells that reduced the adhesion forces between the myocytes. Therefore, the fatty infiltration not only favored the lead-related injuries, but also played a key-role in causing the rapid and fatal pericardial bleeding.

Regarding the site and method of pacemaker implantation as well as the post-operative clinical monitoring, it is believed that several questionable choices have been made.

Attempting multiple maneuvers (i.e., making several punctures) to find a site to place an active fixation lead at the apex is extremely dangerous, above all if the patient suffers from a fatty infiltration of the right ventricle.

Moreover, even if the echocardiography performed thirty minutes after the intervention did not reveal any pericardial effusion, considering the complicated implant procedure, the patient should have been cautiously monitored in a coronary unit, instead of being transferred to an internistic department. A proper postoperative surveillance would have prevented the fatal outcome with a high degree of probability.

Fatty Infiltration of the Right Ventricle, Delayed Cardiac Rupture, Hemopericardium

G26 Public Death From Orally Ingested Drugs During a One Year Period in Louisiana as Analyzed by a Single Forensic Toxicology Laboratory

Gilbert E. Corrigan, PhD*, 11801 Hidden Lake, Saint Louis, MO 63138

After attending this presentation, attendees will learn about a population-based timed study of death by oral ingestion of drugs.

This presentation will impact the forensic science community by teaching the necessity of scientific precision in all aspects of a forensic study.

Monday, July 28 (HealthDay News) – Researchers have discovered a soaring increase in the number of fatal medication errors that occur in people's homes.

The report incidentally follows the death earlier this year of Heath Ledger, the 28-year-old actor who died from an accidental overdose of prescription drugs in his apartment in New York City.

"[There was] large-scale evidence that the death rate from prescription errors was going up very fast, but I didn't know until this paper that they were going up extremely fast in particular circumstances, namely at home and when alcohol and/or street drugs are involved," said study author David P. Phillips, a professor of sociology at the University of California at San Diego.

"I also didn't know from this paper that the number of years of potential life lost from potential medication errors are greater than the number of years of potential life lost from all accidents combined, including falls and drowning," he said.

According to background information in the paper, published in the July 28 issue of the *Archives of Internal Medicine*, there has recently been a dramatic shift in fatal overdoses away from inpatient settings to outpatient settings. More and more medications are taken outside of the hospital or clinic, with far less oversight from health-care professionals, the researchers said.

At the same time, more medications that once were available only by prescription are now bought over-the-counter, and more people are taking more than one medication.

All of this makes it easier for individuals to combine medications with alcohol and/or street drugs. But despite this shift, few if any studies have looked at drug errors outside clinical settings. Almost 50 million death certificates were filed in the United States between January 1, 1983 and December 31, 2004, with 224,355 of them involving fatal medication errors (FMEs). After examining all of these documents, it was discovered that the overall death rate from fatal medical errors increased by 360.5 percent during that time period.

The surge in FMEs differed by type. FMEs occurring at home and combined with alcohol and/or street drugs increased the most, by 3,196 percent. FMEs not happening at home and not involving alcohol and/or street drugs showed the smallest increase, at 5 percent.

Meanwhile, at-home FMEs not involving alcohol and/or street drugs increased by 564 percent, while at-home FMEs involving alcohol or street drugs increased by 555 percent.

Overall, the increase in FMEs was particularly pronounced among people aged 40 to 59, where the increase was 890.8 percent. "People should no longer just focus on medication errors in clinical settings and caused by clinical staff," Phillips said. "There's a whole new world out there that needs to be investigated, that is to say, fatal medication errors occurring at home and not in clinical settings, and apparently influenced by patients and not by staff."

Another expert agreed.

"Most of the information we have about medication errors and their effect take place within the hospital setting," noted Lisa Killam-Worrall, director of drug information and assistant professor of pharmacy practice at Texas A&M Health Science Center Irma Lerma Rangel College of Pharmacy.

But she said there's a real challenge in finding out exactly what substances people might be taking along with their prescription medications.

"As pharmacists, we always try to counsel people when medications could interact with alcohol or other medications, but there aren't that many studies looking at interactions with street drugs," Killam-Worrall said. "We normally don't ask people, 'Are you using street drugs and which ones are you using?' We normally try to ask people, 'What other medications are you taking, prescription, over-the-counter, herbal supplements?' But usually with illicit drug use, you're not going to garner a lot of information."

The findings also have policy implications in terms of patient care , Phillips added.

"Asking patients to be part of the quality-control team is not something you can just automatically do," he said. "It's true that keeping shorter times in hospitals saves money, but it apparently loses lives, and a way to try to ameliorate that would be to spend more time in educating the patient about the risks of taking these powerful medicines and the risks, particularly, of taking these powerful medicines in conjunction with alcohol and/or street drugs."

Public death as a studied scientific phenomenon provides a unique opportunity for the understanding of the human condition and its attributes. This study of the death during the year 2008 of a small cluster of Louisianians whose death became public as determined by their willful consumption of controlled substances and drugs will provide the reader with a privileged insight into these actions. The study has defined boundaries.

The deaths are in single geopolitical area, under a single authority, had no pre-established descriptors save that the deaths are secondary to drug use investigation, were in a precise timeframe of one year, had a uniform management in all details, and most importantly had professional scientific establishment of the cause and the nature of the death through detailed pathological and toxicological studies. The expenses of the study are secondary to the established budgetary standards of this government. These high standards are dictated by the important and constant use of the data and the conclusions derived therefrom to maintain the order of a complicated modern society.

Public Death, Fatal Oral Ingestion, Population Studies

G27 Complex Suicide: A Case Report

Cristina G. Cordeiro, MD*, and Duarte N.P. Vieira, PhD, Instituto Nacional de Medicina Legal, IP, Largo da Sé Nova, Coimbra, 3000-213, PORTUGAL

After attending this presentation, attendees will appreciate the need of a high index of suspicion for the diagnosis of a complex suicide and the importance of a full and careful autopsy.

This presentation will impact the forensic science community by describing the diagnosis of complex suicides.

In 1974, Marcinkowski had proposed a general division of suicide. In this classification, suicides are first divided into simple versus complex. The term "complex suicide" refers to suicides in which more than one suicide method is applied and usually a distinction is made between planned and unplanned complex suicides. In planned complex suicides, the combination of two or more methods of suicide are previously planned and employed simultaneously in order to make sure that death will occur even if one method fails. On the other hand, in unplanned complex suicides, several other methods of suicide are tried after the first method chosen failed, if death occurs too slowly or when it proves to be too painful.

In planned complex suicides, typically two of the common methods of suicide (e.g., ingestion of hypnotics or other medicaments, hanging, drowning, use of firearms, jumping from a height) are combined. In unplanned complex suicides, injuries by sharp force, especially cutting the wrists, are often found as the primary act of suicide and then an appropriated method of suicide is used, more frequently hanging or jumping from a height.

A case of a complex suicide is presented where the victim shot himself in the head and hanged himself. The death scene investigation associated with the findings at the autopsy was very important to classify this complex suicide as an unplanned one.

The need, in some situations, of a high index of suspicion for the diagnosis of this entity is emphasized. So, a full and careful autopsy, including toxicological analysis, combined with the investigation of the death scene is mandatory in these cases. First, to exclude the possibility of intervention of another person in the death; and second, to allow a distinction between planned and unplanned complex suicide.

Suicide, Complex, Autopsy

G28 Fire Death of Two Lovers: An Immunohistochemical and Toxicological Study

Paolo Fais, MD*, Guido Viel, MD, Massimo Montisci, PhD, Alessandro Nalesso, Silvano Zancaner, MD, and Giovanni Cecchetto, MD, University of Padua, Via Faloppio 50, Padova, 35121, ITALY

After attending this presentation, attendees will understand investigation of deaths due to phosgene intoxication and the importance

of an integrated analysis of histological and toxicological data to determine the manner and the cause of death in such cases.

This presentation will impact the forensic science community by underlining the importance of sampling and analyzing burned materials when phosgene intoxication is suspected. This compound is not detectable in body fluids and tissues due to its rapid conversion to hydrochloric acid.

The rate of annual deaths related to fire is about 13 per million inhabitants in the United States and Canada. These are mostly accidents followed by suicides. Homicides with subsequent burning of the victim or killings by burning are comparatively rare in Europe just as in the United States and Japan and are reported more often from India or South Africa.

The morphological findings in burned bodies may cover a broad spectrum. They can range from minor, local, superficial burns of the skin to calcined skeletal remains without any soft tissue left and total incineration. In most cases the effects of heat on the body continue beyond death, consequently, the changes found are largely of postmortem origin. The forensic investigation of deaths related to fire is important in order to determine the manner and cause of death and the vitality of the findings. The issues of vitality and cause of death are closely linked: the basis of the assessment is a careful evaluation of autopsy findings to distinguish morphological consequences of the effects of heat during life and after death.

A case will be presented where two burned bodies found early in the morning inside a joust (largely made of polyvinyl chloride – PVC and named "Wrestling labyrinth"), that burned in a town square after a festival. The victims were reportedly lovers (the boy 20 and the girl 16-years-old).

At external examination the corpses showed a typical boxer's attitude with general incineration, exposure of body cavities, bone fractures and partial amputation of extremities. To analyze the morphology of the fractures and their location a high-resolution computed tomography (CT) was performed, indicating that all fractures were a result of thermal effect.

Major internal findings consisted of hemorrhagic pulmonary edema and "puppet organs." Foam and soot particle deposits were detected inside the respiratory tract of both victims.

At histological examination of the lungs, ninety-five percent of the alveoli were flooded with edema and erythrocytes. There was no evidence of fibrin and inflammatory infiltrates. Immunohistochemistry, using epithelial (epithelial membrane antigen and cytokeratin) and endothelial (CD-34 and F-VIII) markers, revealed severe alveolar necrosis without endothelial damage of the vessels.

Systematic toxicological analyzes, performed on postmortem blood and urine, excluded alcohol and drugs intoxication. Monoxide-hemoglobin (CO-Hb) and cyanides concentrations were well below lethal values.

The presence of soot deposits and mucus inside the respiratory tract (not occluding the airways) along with a heat damage of the mucosa of the upper respiratory tract (edema, mucosal bleeding and vesicular detachment) suggest that the victims were alive during the fire and breathed fire-fumes.

The combined analysis of histological and immunohistochemical findings led us to identify the origin of the lung damage in the inhalation of an irritative gas. Laboratory tests, performed on burned samples of the joust (collected at death scene) and on samples of a similar undamaged joust, demonstrated an extensive production of phosgene during experimental burning.

Phosgene is a combustion, thermal decomposition or photodecomposition product of certain volatile chlorinated hydrocarbons (for example, trichloroethylene or perchloroethylene). These chlorinated hydrocarbon compounds can evolve phosgene if they come into contact with very hot metal, flame, or ultraviolet light. Phosgene is a colorless, extremely volatile gas which, at low concentrations, smells sweet, like freshly mown hay, whereas at high concentration has a pungent and

objectionable odor. When aspirated, it combines with the water of the mucous membranes being rapidly converted to hydrochloric acid, with subsequent injury to the lungs (hemorrhagic pulmonary edema).

In this cases, even in the presence of extensive direct thermal injuries, the integration of histological and immunohistochemical findings suggests as principal mechanism of death an asphyxia by airway submersion related to the inhalation of phosgene (called "dry land drowning"). Indeed, the detected hemorrhagic pulmonary edema was of such an extension (involving more than ninety five percent of the alveolar space) to be clearly incompatible with life, and capable of causing a rapid death.

In conclusion, the reported cases highlight the following teaching messages:

1. Histological and immunohistochemical investigations may enhance the identification of the real cause and mechanism of death in fire accidents.
2. Sampling and analyzing burned materials may be of valuable importance when dealing with phosgene intoxications. This compound is not detectable in body fluids and tissues due to its rapid conversion to hydrochloric acid.

Phosgene Intoxications, Fire Deaths, Immunohistochemistry

G29 Non-Traumatic Subdural Hematoma in Adults

Carolyn H. Revercomb, MD, and Sarah M. Colvin, MD, Office of the Chief Medical Examiner, District of Columbia, 1910 Massachusetts Avenue Southeast, Washington, DC 20003; and Marie L. Pierre-Louis, MD, 6404 Luzon Avenue, Northwest, Washington, DC 20012*

The goal of this presentation is to provide attendees with knowledge of the range of causes of subdural hematoma in adults and the key clinical and anatomic features that distinguish nontraumatic from traumatic subdural bleeding.

This presentation will impact the forensic science community by enhancing the efficiency and accuracy of investigation and certification of deaths from subdural bleeding.

While head trauma is the commonest cause of subdural hematoma both in hospital and in medicolegal autopsy settings, some patients presenting with subdural hemorrhage have a non-traumatic etiology. Because rapid demise may preclude angiography and other procedures to establish the source of subdural blood, these cases often come to the attention of the medical examiner. Distinguishing such "spontaneous" subdural hemorrhage from the more common traumatic subdural hematoma rapidly and with confidence can be a challenge to the forensic and neuropathologist. Complete radiologic reports often are not available at the time of the report of death, allegations of head impact during collapse may complicate the investigation, and neuropathologic examination of the brain at autopsy is best preceded by fixation of the brain prior to dissection. Certain historical and gross autopsy findings should prompt a heightened index of suspicion of nontraumatic etiology in subdural hemorrhage. The entities most often associated with spontaneous subdural bleeding include subdural extension of intracerebral hemorrhage, cerebral arteriovenous malformations and aneurysms, and metastatic tumors. Impaired coagulation from medications or from natural conditions such as hematologic or hepatic disorders also can result in subdural hemorrhage. In cases of nontraumatic subdural hemorrhage, the face and scalp will lack abrasions or contusions. When the brain is examined grossly on removal, focal, thick subarachnoid hemorrhage, especially if located other than in the parasagittal cerebrum, is suggestive of a source of subdural hemorrhage within the brain rather than from rupture of bridging veins as is usual in trauma. Five cases of non-traumatic subdural hemorrhage in adults are presented with case histories,

radiologic data when available, autopsy findings and a review of the literature. The information presented will enhance the efficiency and accuracy of investigation and certification of deaths from subdural bleeding.

Subdural Hematoma, Death Investigation, Neuropathology

G30 Accidental Carbon Monoxide Poisoning: A Review of Environmental and Cultural Risk Factors of Fatal Cases in King County

Kristinza R. Woodard, MD, University of Washington Pathology and Lab Medicine, 1959 Northeast Pacific Street, PO Box 356100, Seattle, WA 98195; and Richard C. Harruff, MD, PhD, King County Medical Examiner's Office, 325 9th Avenue, Box 359792, Seattle, WA 98104*

After attending the presentation, the attendees will be able to identify certain environmental and cultural factors that may increase accidental death by carbon monoxide inhalation.

This presentation will impact the forensic science community by increasing awareness of environmental and cultural factors that influence the misuse of carbon monoxide producing devices and will suggest ways to decrease the incidence of accidental deaths.

Introduction: Carbon monoxide (CO) is an odorless, colorless gas that forms as a result of incomplete combustion of carbon-containing fuels. While trace levels of CO are found in the atmosphere, fatal levels are found in exhaust from multiple sources including automobiles, generators, propane heaters and charcoal burning grills. Accidental carbon monoxide poisoning is responsible for up to fifty percent of the yearly carbon monoxide related fatalities in King County (five accidental deaths in ten total carbon monoxide deaths in 2007).

Purpose: Risk factors of accidental CO related deaths in King County from 1996 to 2008 were reviewed in an attempt to reveal preventable causes.

Methods and materials: Between 1995 and 2008, 221 cases of carbon monoxide poisoning were identified between 1995 and 2008 within the King County Medical Examiner's information database. Forty-three of which were results of accidental CO poisoning between 1996 and 2008. These cases were analyzed with respect to scene investigation reports and circumstances surrounding fatality.

Findings: CO producing devices were found placed within single family residences in 19 of the 43 accidental deaths. Eleven cases involved CO producing products within vehicles used for residence including trailers, RVs, campers, and vans. Seven of the deceased were found in their cars in their garage, four died from house fires, and the exact location of the source of CO was unclear in two cases (outside versus inside the home). Further review indicated generator exhaust as the most common source of accidental CO poisoning, with 18 of 43 total accidental deaths. Other sources of CO in decreasing incidence included exhaust from vehicles (7), heaters (6), charcoal burning (6), house fires (4), furnaces (2), a hot water heater (1), and an engine from an industrial carpet-cleaning machine. Nine deaths were due to generator exhaust or charcoal burning during power outages, including eight during a windstorm during December 2006. Four incidents included deaths of more than one individual with three paired deaths (6 total deaths) and one Vietnamese family (5 total deaths). 69% (30) of the CO victims during this time were White, 7% (3) were Black, 7% (3) were Hispanic and 16% (7) were Asian/Pacific Islander. The majority of these cases involve people who are unfamiliar with the proper use of generators or charcoal products, either due to inexperience or inability to gain information about certain products in their native language. No carbon monoxide monitors were identified in any scene investigation reports.

Discussion: The most significant environmental and cultural risk factors identified were unfamiliarity with CO producing products and the inability to receive information about these products in various

languages. Preventing accidental deaths in cities with multiple ethnic groups begins with increased availability of educational information in several languages. Many of these products are purchased directly before power outages in a rush to provide heat and power and the proper educational information is not exchanged. The Vietnamese family mentioned earlier, had a receipt for their generator, which was purchased one day prior to death.

After identifying these products in stores, many of the instructions and warning labels are written in English and Spanish, however, warning labels in less frequently spoken languages may help prevent CO poisoning. Ways to educate consumers include increasing awareness via television, the internet through downloadable brochures available in multiple languages and product education including the additional or paired purchase of carbon monoxide monitors, especially prior to anticipated power outages. While the most important time to discuss product education occurs during the purchase of the product, education about CO producing products should occur through multiple methods.

Carbon Monoxide, Poisoning, Accidental Death

G31 Differences in Scene Reenactment of Pediatric Death: Homicide Versus Others

Marianna Sandomirsky, MD, and Jane W. Turner, PhD, MD, St. Louis City Medical Examiner's Office, 1300 Clark Street, St. Louis, MO 63103*

After attending this presentation, attendees will be able to critically apply information gathered from the experience of the City of St. Louis Medical Examiner's office. The main goal is to help differentiate homicide from other manners of death such as accident and undetermined when dealing with pediatric death. Scene reenactment as part of the investigation is an invaluable tool in assessing these difficult cases.

This presentation will impact the forensic science community by discussing key differences observed while investigating pediatric deaths with the aid of scene reenactment.

Pediatric deaths can be complicated cases for the medicolegal system, not to mention the families involved. Determination of cause and manner of death is the driving principle behind the investigation. Key parts of the investigation consist of scene investigation, postmortem studies including autopsy, radiographs, ancillary studies such as toxicology, and if pertinent, microbiology testing. Thorough photographic documentation during the initial visit to the scene as well as at the time of the autopsy is vital to assessing pediatric deaths. Scene investigation is usually performed by medicolegal death investigators who may conduct their inquiry either via telephone or actual visit to the scene.

All pediatric cases (ages 0-5) referred to the St. Louis City Medical Examiner's office during a five-year period, from January 2003 to December 2008 were analyzed. The cases were stratified according to the manner of death of either homicide, accident, or undetermined. The differences in cases that underwent scene reenactments and correlated them with the postmortem studies were compared. Some of the cases were investigated with phone interviews, usually due to traveling or jurisdictional constraints. Telephone interview investigation findings will also be discussed.

One of the most difficult aspects of pediatric deaths for the family is that the event is generally unexpected, unless there is history of natural disease. SIDS (Sudden Infant Death Syndrome) is a diagnosis of exclusion, reserved for cases for which no cause of death is found after a thorough investigation. The scene reenactments conducted in our office frequently demonstrate bed sharing or positional asphyxia as a cause of the child's death. These cases are no longer classified as SIDS as a result of this investigative tool. Additionally, our investigators use a standardized questionnaire published by Missouri Department of

Social Services titled Death Scene Investigative Checklist for Child Fatalities. The form covers minimum necessary information which maybe used later on in the death certification process. It covers key points such as prenatal history, events surrounding death, condition and position of the child, as well as social and environmental conditions.

While natural, accidental and undetermined manner of death is distressing to the family, homicide has its own caveats. The perpetrator is frequently known to the family and is usually not biologically related to the deceased. Most pediatric homicides are crimes of spontaneous impulsive behavior. The killing is not usually premeditated, but rather a reaction to the child's behavior such as loud crying or poor feeding. Most frequently the assailant uses their own body (i.e., hands, feet, torso) to inflict the fatal injuries onto the child. The troubling aspect of pediatric death for medicolegal investigators, law enforcement and forensic pathologists is that homicide within this population does not always exhibit overt trauma. In instances of mechanical asphyxia and unusual poisoning, even a diligent postmortem examination and standard toxicology panel may not reveal the cause and manner of death. Therefore, we must rely on either keen investigative techniques or await perpetrator's confession. While in most sudden infant deaths, the parents or caretakers appear distressed, the stories and reenactments of in cases of homicide frequently shift during the investigation. Investigations in these deaths often reveal an inconsistency or improbability during the scene reenactment.

Scene Reenactment, Pediatric Death Investigation, Manner of Death

G32 Suicide by Multiple Gunshots From Automatic Weapons

Paul Uribe, MD, 7807 Mineral Springs Drive, Gaithersburg, MD 20877*

After attending this presentation, attendees will be able to describe the characteristics of selective fire and "full-auto" weapons and become familiar with the patterns of injury associated with self-inflicted injuries using these types of weapons.

This presentation will impact the forensic science community by providing a case series of a self-inflicted pattern of injury that has rarely been discussed in the forensic literature.

Eight cases of suicide from multiple gunshot wounds by use of automatic weapons will be discussed. Automatic weapons are either solely automatic or have selective fire mechanisms. Selective fire mechanisms include settings for semi-automatic, three round burst, and "full-auto" modes of fire. Weapons with either selective fire settings or that are solely automatic can rapidly discharge multiple rounds in immediate succession when the trigger is pulled. In this case series, there was a strong predilection for wounds of the head (7/8) and only one (1/8) had recovery of the projectile fragments. The recoil produced from firing an automatic weapon can produce considerable distance between entrance wounds. In all of the cases studied, two or more rounds discharged and each had at least two entrance wounds; however, in two cases the number of rounds discharged could not be determined due to the extent of the injuries, co-mingling of trajectory paths, and shared entrance and exit wounds. Thorough scene investigation is essential in these cases to in an effort to determine how many shots were fired, what type weapon was used, and if a selective fire setting was used. Reconstructive computed tomography can also be useful in illustrating wound paths and assisting the determination of how many shots were fired.

Suicide, Gunshots, Automatic

G33 EBV (+) T-Cell Lymphoproliferative Disorder of Childhood Causing Sudden Death: A Case Report

Mark A. Super, MD*, Sacramento County Coroner's Office, 4800 Broadway, Suite 100, Sacramento, CA 95820-1530; and Karimireddy J. Reddy, MD*, University of California, Davis, Department of Pathology, 4400 V Street, Sacramento, CA 95817

After attending this presentation, attendees will become familiar with this unusual disorder that can have a rapid course with high mortality such that medical examiner/coroners (ME/Cs) are involved in the investigation. Attendees will learn the value of special testing in autopsy cases, such as immunohistochemistry, EBER-ISH, and T-cell receptor gene rearrangement studies.

This presentation will impact the forensic science community by stressing the need for access by medical examiner/coroner's offices of good immunohistochemistry testing, in-situ hybridization testing, and gene rearrangement studies. Lack of access to these modern techniques can lead to many death investigations remaining unsolved, or misdiagnosed.

Systemic Epstein-Barr virus (EBV) positive T-cell Lymphoproliferative disorder (LPD) of childhood is a life-threatening illness of children that may be associated with chronic active EBV infection or following a primary acute EBV infection. This entity is most prevalent in Asia and rarely reported in the West. Common sites of involvement include the liver, spleen, lymph nodes, bone marrow, skin and lungs. It has a fulminant clinical course with development of hepatosplenomegaly, liver failure, lymphadenopathy, rapidly progressing to multiorgan failure. Other complications such as hemophagocytic syndrome and sepsis can occur. The prognosis in most cases is dismal with death resulting in days to weeks.

We present a case of a 3½-year-old, previously healthy, Hmong girl who presented with to a hospital ER with nausea and vomiting. Initial CBC revealed leukocytosis with an absolute neutrophilia and lymphocytosis. Over the next twenty-four hours, the decedent developed rapidly progressive hepatic failure, became lethargic and unresponsive. Her hematological parameters were as follows: Fibrinogen=152, PTT=41.8, PT=32.1, INR=3, D-dimers: 1869 (n<250ng/ml). Her liver function tests were markedly elevated AST: 4770, ALT: 5030, Ammonia: 421. Mushroom poisoning was strongly considered. Immunoassays for RSV, Influenza A & B, Adenovirus and Hepatitis A & B were negative. EBV serology showed antibodies to EBV (EBV VCA IgG: 1185 (Normal<100) and EBVNA IgG: 1392 (Normal <100). On day two of admission, a CT scan of the head showed cerebral edema with tonsilar herniation. Due to the extremely poor prognosis of the critically ill patient, care was ultimately withdrawn.

Significant findings at autopsy were cerebral edema with tonsilar herniation, hepatic necrosis, splenomegaly (96.9 grams) and massive mesenteric lymphadenopathy. Multiple matted mesenteric lymph nodes were noted; the largest measuring 3 cm in greatest dimension. Sections revealed homogenous tan-pink cut surfaces.

Microscopic examination of the liver showed moderate portal acute and chronic inflammation with hepatocellular necrosis. Sections of spleen showed atypical lymphoid cell infiltrates. Histological examination of an enlarged mesenteric lymph node revealed complete effacement of nodal architecture by medium to large, atypical lymphocytes with irregular nuclear contours and occasional nucleoli, and abundant mitoses. Immunohistochemical stains performed on the lymph node showed a predominant T-cell population (CD3+/CD5+ cells) with high proliferation index (MIB-1: 70-80%) and a small population of scattered B-cells (CD20+). EBV encoded RNA (EBER) was positive by in-situ hybridization (ISH) in the mesenteric lymph node and spleen. A T-cell receptor gene rearrangement study was performed confirming a clonal population of T-cells.

Neuropathologic examination performed after brain fixation revealed hypoxic encephalopathy with marked swelling and cerebellar tonsillar herniation. Alzheimer type II astrocytes were noted in globus pallidus, neostriatum, thalamus, medulla and cerebellar dentate nucleus consistent with hepatic encephalopathy.

In the work-up of sudden unexpected deaths in children and young adults with similar presentations, especially in Asians, EBV positive T-cell lymphoproliferative disorder should be considered. Since the clinical course is usually rapid and the mortality rate is high, medical examiner/coroners are often involved in investigating the cause of death. Antemortem EBV serology and relevant histological evaluation of liver, spleen, lymph nodes, and bone marrow aid in the initial diagnostic work-up. Immunohistochemistry, EBER-ISH & T-cell receptor gene rearrangement studies that can all be performed on paraffin embedded blocks are additional valuable tools in clinching the diagnosis.

Epstein-Barr Virus, T-cell Lymphoproliferative Disorder, EBER-ISH

G34 Temporal Variation of Ethanol Related Firearm Deaths

Rameen S. Starling-Roney, MD*, Anna Rubio, MD, Donna M. Vincenti, MD, and David R. Fowler, MD, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201

After attending this presentation, attendees will understand the potential risk of ethanol use and subsequent homicidal death by firearms (gunshot and shotgun), and the seasonal temporal variation in homicides in which the decedent was under the influence of ethanol.

This presentation will impact the forensic community by examining the association between ethanol intoxication and firearm related homicides. Previous reports have shown a direct correlation between ethanol intoxication and suicides and accidental deaths (specifically motor-vehicle accidents). However, a definitive association between ethanol intoxication and homicides has not been established.

A review of all homicides in the State of Maryland between 2003 and 2007 was performed for cases in which death was due to firearms and in which heart blood was available and evaluated for toxicology (cases in which complications occurred were omitted). Cases were classified by whether the decedent's heart blood ethanol level was above or below the legal limit of intoxication (0.08 g/dl). Predictors of elevated blood ethanol were examined by logistic regression analysis with multiple independent variables including age, gender, week of the year, day of the week, month, and season. Statistical significance was determined by likelihood ratio tests. The numbers of total homicides were compared for different days of the week and month of the year by Poisson regression analysis, aggregating the five years of the study period.

A total of 1,571 cases were identified using the above criteria. The median age for the cases was 26-years-old, 91.4% of the decedents were male and 86.4% were African-American. Statistically significant temporal variation was noted in the aggregate number of homicides by day of the week (greater on Saturday) and month of the year (greater in July and January). Of all cases, 271 (17.3 percent) had a blood ethanol level of 0.08% g/dl or greater. There was statistically significant temporal variation in ethanol related homicides by day of week (increased on Saturday and Sunday) and month of the year (increased between May and August with peaks in June and July). In addition there was a significant increase in ethanol related homicides in the summer when compared to the remaining seasons. No temporal variation was seen in non-alcohol related homicides. A direct relationship was not seen between increased ethanol related homicides and increased total homicides when compared to month of the year and season, however a trend was seen when compared to the day of the week (increased on Saturday).

In conclusion this study shows temporal variations in overall firearm homicides and ethanol related firearm homicides. However a direct association in terms of increased ethanol consumption was not established.

Ethanol, Firearm, Temporal Variation

G35 Axonal Injury in Pediatric Head Trauma: A Study of the Interpretation of β -Amyloid Precursor Protein (β -APP) Expression in Trauma and Non-Trauma Cases

Michael W. Johnson, MD, PhD, and Anna Rubio, MD, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Juan Troncoso, MD, The Johns Hopkins University, School of Medicine, 558 Ross Building, 720 Rutland Avenue, Department of Neuropathology, Baltimore, MD 21205; and David R. Fowler, MD, and Ling Li, MD, State of Maryland Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will understand that although beta amyloid precursor protein expression (β -APP) can be useful in confirming axonal injury, its presence or absence cannot in and of itself, prove or disprove traumatic injury.

This presentation will impact the forensic community by illustrating the complexities of interpretation of amyloid precursor protein expression as evidence of axonal injury.

The purpose of this presentation is to illustrate the utility of β -APP immunohistochemistry as morphologic evidence of traumatic brain injury. Often special studies are suggested and/or warranted to rule out the possibility of occult trauma in cases of sudden unexpected death of young children. A number of reports, over the past decade, have described various patterns of β -APP expression in axonal injury. Brain material from a group of twenty-seven young children in order to test the application and interpretation of β -APP immunohistochemical staining were examined.

In 1999, the State of Maryland Office of the Chief Medical Examiner (OCME) investigated 153 deaths of subjects three years of age or younger. Of these, 97 deaths were natural [including 56 cases attributed to Sudden Infant Death Syndrome (SIDS)], 24 were accidental, 18 were homicides, and 14 were undetermined. Among the homicides, seven children sustained blunt force injuries to the head. The staining pattern of β -APP in multiple brain regions (frontal, temporal, and parietal cortices, cingulate cortex/corpus callosum, and the cervicomedullary junction) was evaluated. Compared, in a blinded fashion, the β -APP staining of the homicide cases to similar brain regions from seven age matched cases, in which death was due to a non-traumatic disease (other than SIDS), and ten cases with similar ages, from the same calendar year in which death was attributed to SIDS.

Three reviewers achieved consensus regarding the β -APP staining by using a simplified semi-quantitative scoring method based on 1) staining density per high power microscopic field and 2) the presence or absence of multifocal staining within a single microscopic slide from a single brain region. Upon consensus interpretation, the reviewers agreed that significant β -APP axonal expression was present in five of the seven homicides (71%). Subsequent unblinded review of autopsy records demonstrated that in these cases there was gross evidence of intracranial hemorrhage at the time of autopsy. In the other two homicide cases, the reviewers agreed there was not evidence of axonal injury by immunohistochemistry. These two homicide cases had superficial cranial injuries with significant traumatic injury only to the thoracic spinal cord, determined at autopsy. Two (2) of the SIDS cases and one of the non-trauma cases displayed axonal immunostaining with density and pattern similar to that in the traumatic cases, and the reviewers could

not, with certainty, differentiate these cases from the five homicides by immunohistochemical staining alone.

The specifics of the cases to illustrate the complexities involved in interpreting β -APP deposition in cerebral tissues and to make recommendations regarding the use of adjunct immunohistochemical studies in suspicious infantile deaths will be discussed. Perspective of trends, since 1999, in the evaluation of SIDS versus sudden unexplained death of an infant (SUDI)—especially with regards to co-sleeping factors that might result in asphyxia and hypoxic ischemic injury will also be discussed. Data confirms that while β -APP staining can be useful and corroborative, immunohistochemistry cannot be used independently to determine the presence or absence of traumatic injury

Amyloid Precursor Protein, Axonal Injury, Trauma

G36 Association of Retinal Hemorrhages With Fatal Head Injuries in Infant Monkeys

Candace H. Schoppe, MD, and Patrick E. Lantz, MD, Wake Forest University School of Medicine, Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157; Kurt A. Schoppe, MD, and Jonathan Burdette, MD, Wake Forest University School of Medicine, Department of Radiology, Medical Center Boulevard, Winston Salem, NC 27157; Keith G. Mansfield, DVM, Harvard Medical School, New England Primate Research Center, 1 Pine Hill Drive, Southborough, MA; and Constance A. Stanton, MD, Wake Forest University School of Medicine, Department of Pathology, Medical Center Boulevard, Winston Salem, NC 27157*

After attending this presentation, attendees will gain familiarity with the use of animal models for shaking injuries and appreciate the potential for further study of retinal hemorrhages using accidental head injuries in infant monkeys.

This presentation will impact the forensic science community by providing objective scientific data about the natural history of retinal hemorrhages, which will assist forensic pathologists, pediatricians, ophthalmologists, and emergency medicine physicians by offering a better understanding of the pathogenesis of retinal hemorrhages.

Published studies about the specificity of retinal hemorrhages for Abusive Head Trauma (Shaken Baby Syndrome) are controversial. A diagnosis of child abuse based on the presence, number and distribution of retinal hemorrhages has serious consequences, and thus deserves unbiased scientific investigation. Some authors claim that retinal hemorrhages are virtually pathognomonic of a shaking (acceleration-deceleration) injury, but for such a purportedly specific finding, this claim has never been scientifically proven. Many papers have been written on the subject; however, disproportionately few have had significant substantive value. To date, no reasonably scientific, reliable and ethical animal model for retinal hemorrhages has been identified. Consequently, an exhaustive list of situations and conditions in which retinal hemorrhages can be seen has not been established. Based on the experience of this institution, observational data suggests that retinal hemorrhages occur fairly commonly in the absence of shaking or other non-accidental injury. The goal of this study is to help elucidate these situations though the use of a natural animal model for retinal hemorrhages. This study is intended to serve as a pilot study to evaluate the possibility of using baby monkeys that have died as a result of trauma to demonstrate the presence of retinal hemorrhages in the absence of shaking.

Trauma is a well-documented cause of neonatal and infant mortality in certain non-human primate breeding colonies. One mechanism of trauma is related to changes in the carrying behavior of captive dams, including more frequent cradling of the infant monkeys. Cradling of the infants has resulted in an increased number of fatal accidental head

injuries in these monkeys. The injury occurs when the mother's chest touches the ground as she jumps and lands, thus allowing the infant's head to hit the ground with significant force. Previously published necropsy data for infant squirrel monkeys (*Saimiri sciureus*) has revealed both open and closed skull fractures. No non-lethal or incidental skull fractures have been reported in any captive monkey populations. Unfortunately, none of these studies examined the eyes of the infant monkeys for the presence of retinal hemorrhages.

The heads of seventeen infant monkeys (*Callithrix jacchus* or *Saguinus oedipus*) who died from either trauma or natural disease were provided by the New England Primate Center following necropsy and selective histological examination (KGM). Information initially provided to the primary investigators (CHS, PEL, CAS, KAS and JHB) included the species, animal number and necropsy number. All monkey heads received CT scans (KAS, JHB) using the Siemens MicroCT [Resolution: Bin x 4 = .0732 (73 micron)] followed by pathological examination (CHS, PEL, CAS) including external examination, gross dissection and microscopic examination of the brains and eyes. Findings were digitally photographed including all brains and retinas. The examinations demonstrated eleven animals with apparent head injuries. Nine monkeys had skull fractures; five fractures were identified both radiographically and grossly, three fractures were only identified grossly and one fracture was only identified radiographically. Microscopically evident retinal hemorrhages were present in at least one eye in all specimens with skull fractures and were unilaterally present in one specimen without evidence of a head injury. Because of poor preservation, several of the retinas were fragmented, thus hindering interpretation. Following completion of the examinations, the age, date of birth, date of death, dam and sire numbers, type of postmortem examinations originally performed, postmortem interval, and cause of death for each animal was revealed. All animals were born and died in 2002, with a mean and median age of 1.88 and 2 days at death, respectively. The majority of animals (13/17) died or were euthanized (5) as a result of suspected parental neglect and inanition. Of the remainder, two died of infection, one was stillborn and one died of unspecified cause(s). Postmortem interval was less than twelve hours with the exception of the euthanized animals, which were examined with in two hours. Based on the above information, this study demonstrates a possible association between skull fractures and retinal hemorrhages. Although more studies are necessary to identify a causal relationship between accidental head injuries and retinal hemorrhages, these results suggest that this type of animal model may be of use in studying retinal hemorrhages not associated with alleged shaking incidents.

Retinal Hemorrhages, Abusive Head Trauma, Animal Model

G37 Postmortem Pulmonary Findings by Computed Tomography Compared With Conventional Autopsy

Lene W. Boel, PhD*, Institute of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Lars Uhrenholt, PhD, Institute of Forensic Medicine, Department of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; Rita Ullerup, Institute of Forensic Medicine, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; and Anne Grethe Jurik, DSc, Department of Radiology Aarhus University Hospital, Noerrebrogade 44, Aarhus C, 8000, DENMARK

After attending this presentation, attendees will improve their knowledge about interpretation of postmortem CT scanning images of the lungs and to distinguish them from pathological changes developed before death.

The presentation will impact the forensic science community by demonstrating an important contribution to the new practical knowledge that the forensic pathologist should know regarding the role of CT scanning in autopsy (virtopsy) with reference to the new ACCME criteria.

Postmortem CT scanning (PMCT) is becoming an increasingly important supplement to the medicolegal autopsy. It contributes significantly to the description of skeletal lesions, thereby clarifying the mechanisms of trauma. Gas and foreign bodies are readily identified, and it provides insight in the process of decomposition, in case of which visualization of organs such as the brain is also improved. Interpretation of the CT images acquired from dead people is in many ways different as compared to living people. Evidently, the circulation stopped, resulting in reduced blood filling in the arterial system and sedimentation of blood and other body fluids in the soft tissues. Decomposition of the body begins and is clearly visible as air formation in the soft tissues at a very early stage. It can be difficult to discern the various postmortem changes from pathological conditions in the organs and other soft tissues, especially because experience with PMCT is very limited in contrast to the widespread knowledge in clinical CT scanning.

The purpose of this study was to compare the findings in the lungs by PMCT with the findings and diagnosis made by conventional autopsy, and to learn how to identify common postmortem changes in the lungs in PMCT and to distinguish them from pathological changes developed before death. Internal lividity can be present in all organs, but they are easier to recognize in the lungs both at the autopsy table as well as on PMCT images, because the presence of air in the lung tissue acts as a contrast to the denser appearance of blood and tissue. Internal lividity of the lungs is often seen in the posterior parts due to the frequently supine positioning of the body. In many cases, internal lividity is easily recognized as such. However, differential diagnoses should always be considered, e.g. pneumonia, edema, contusion, and infarction.

The material consisted of 100 forensic cases which were autopsied in 2008-2009 at the Institute of Forensic Medicine, preceded by PMCT by using an in-house Siemens Definition 64 slice scanner. Whole-body scanning was performed in all cases. The torso scanning was obtained with 140 kV and 500 mAs; a beam collimation of 1 mm and pitch 0.75. From the PMCT data axial images were made using different algorithms (H20S smooth and H60S sharp) provided by the manufacturer. Evaluation of the axial images was supplemented by secondary multiplanar reconstructions obtained with available software at the workstation. The PMCT images were initially evaluated by an experienced forensic pathologist and in selected cases a senior radiologist with postmortem radiology experience also evaluated the images. Following the initial evaluation all thoracic axial slices obtained in each of the cases were reviewed by the authors in order to complete a detailed description of the lungs with respect to internal lividity and pathological findings, using the standard settings for viewing of the lungs (window width 1200 HU, center -600 HU) and the mediastinum (window width 400 HU, center 40 HU). The results of the PMCT were compared with the macro- and microscopic findings at autopsy.

The results will be presented and discussed.

Postmortem CT Scanning, Virtopsy, Lung Pathology

G38 Forensic Imaging: Yes, We Scan! New Challenges for a Radiographer

Alexandre Dominguez*, Haute Ecole Cantonale Vaudoise de la Santé, Avenue de Beaumont 21, Lausanne, SWITZERLAND; Francesco Doenz, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, Richard Dirnhofer, MD, and Beat Steger, Fumedica AG, Luzernerstrasse 91, Muri, SWITZERLAND; Barbara Sollberger, Department for Cardiovascular Surgery, University Hospital Bern, Hochschulstrasse 4, Bern, SWITZERLAND; Erich Gygax, Department for Cardiovascular Surgery, Hochschulstrasse 4, Bern, SWITZERLAND; Reto Meuli, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, 1011, SWITZERLAND; and Patrice Mangin, MD, PhD, and Silke Grabherr, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND

After attending this presentation, attendees will be able to understand the role of radiographers in forensic imaging regarding CT (computed tomography) angiography and will know the different responsibilities of forensic radiographers such as sample collection for toxicological analyzes (postmortem liquid puncture), sample collection for additional analysis such as histology or bacteriology (postmortem biopsy), and the performance of postmortem angiography including the use of a perfusion machine.

This presentation will impact the forensic science community by displaying the first experiences and future possibilities of this new opportunity. It will also introduce the radiographer and his skills to the medicolegal public.

It is a logical fact, that the implication of a radiographer into a team of forensic radiologist and pathologists can increase the radiological quality of examinations. With the application of postmortem angiography in forensic cases, the importance of such a specialist is again increasing, because this examination is complex and needs experience in handling a CT-scan. Additionally, it brings other needs with it, such as the necessity to perform sample collection for toxicological analysis, before injecting a contrast agent into the corpse. These responsibilities can be fulfilled by the radiographer. His technical knowledge facilitates also the control of the perfusion machine, which is necessary for postmortem angiography.

Sample collection for toxicological analyzes: During the process of postmortem angiography, a contrast agent is injected into the corpse and the blood is rinsed out of the vascular system. Such treatment could eventually alter the findings in toxicological analysis. To avoid this problem, samples of liquids used for these analyzes are collected before angiography. To get samples of vitreous humour, bile, urine, cardiac blood and peripheral blood, punctures are done manually by the radiographer.

Postmortem biopsy: For some additional analyzes such as histology (especially search for fatty embolism) or bacteriology, samples can be collected already before performing angiography in order to avoid contamination of the tissue of interest. For this purpose, postmortem biopsies can be performed by the radiographer.

Performance of postmortem angiography: After sample collection, the radiographer performs the postmortem angiography. He prepares the perfusion machine and the body. The body-preparation includes the correct positioning on the CT-table as well as preparation of the femoral vessels and inserting cannulas into them. After connecting the perfusion machine with those cannulas, the postmortem angiography is performed. Hereby, CT-acquisition and the perfusion machine have to be well synchronized.

For a radiographer, the switch from living patients to dead bodies might be difficult in the beginning. With skills in technology (imaging acquisition, reconstruction of 2D and 3D images, etc.) and anatomical knowledge, (vascular anatomy, positioning of the body, etc.) the radiographer is predisposed to become a member of a forensic team.

The radiographer represents a profession that is necessary to guarantee good quality of radiological examinations and allows a rapid investigation, which is important to implement biopsies and angiography in the daily routine of forensic medicine. This collaboration is well accepted in the forensic team. The interdisciplinary exchange of forensic pathologists, radiologist and radiographers leads to fructuous discussions and successful collaborations between those specialists. Regarding the increase of radiological exams in forensic departments, this new radiographer allows to save much time in the daily routine.

Radiographer, Forensic Imaging, Postmortem Angiography

G39 Benefits and Limitations of Postmortem Multislice Computed Tomography as Adjunct to the Perinatal and Pediatric Autopsy

Kerstin Aschenbroich, MD*, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND; Steffen G. Ross, MD, Institute of Forensic Medicine, Center of Forensic Imaging "Viropsy", Buehlstrasse 20, Bern, 3012, SWITZERLAND; Michael Thali, MD, MBA, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND; and Harald Bonell, MD, Institute of Diagnostic Radiology, Inselspital Bern, Bern, 3010, SWITZERLAND

After attending this presentation, attendees will understand the basics of the radiologic investigation of perinatal and pediatric death by Multislice Computed Tomography (MSCT) as well as the advantages and the limitations of this method.

This presentation will impact the forensic science community by serving as an introduction of postmortem MSCT as a useful noninvasive adjunct to classic autopsy or even as a potential replacement in cases when autopsy is refused by the next of kin.

Perinatal and pediatric autopsy provides essential diagnostic information not only for parents but also for medical audit and clinical trials. The autopsy rate is decreasing throughout the world for numerous reasons. Medical imaging has always been part of the autopsy process, but in the last decade there has been increased interest in imaging as additional to or a replacement for autopsy. A retrospective data analysis of thirty child autopsies will be presented with correlation in all cases with previously performed MSCT. Postmortem whole body six slice CT imaging was performed on average of twenty-three hours after death. Reconstructions in 1.25mm thickness (soft tissue and lung kernel). Radiological diagnosis was carried out by two radiologists, each with three years experience in postmortem/pediatric radiology. The comparison between autopsy and cross sectional imaging showed a high diagnostic accuracy for intracranial hemorrhage, pulmonary pathologies, the visualization of other (partly) gas containing structures like the intestines and bony pathologies like fractures or tumor caused erosions of bony structures. Obvious weaknesses of the unenhanced CT imaging lied in the detection of cardiovascular vascular pathologies and subtle pathologies of the central nervous system. CT imaging does not provide a histological diagnosis, although histopathologic examination contributes often important information regarding the cause of death. This is clearly a crucial issue if CT is to be used to replace autopsy. A possible solution is the application of CT-guided biopsies to gain histological specimens. The emerging field of postmortem CT angiography could help to close the gap in vascular imaging. This study shows that postmortem CT imaging alone is not a sufficient complete replacement of classic autopsy in the perinatal and pediatric death. Despite the drawbacks, we are convinced of the potential of this method as a planning tool and complement to the classical pediatric autopsy and as the method of choice when autopsy is refused by the next of kin.

Postmortem CT, Perinatal Autopsy, Pediatric Autopsy

G40 Multidetector Computed Tomographic (MDCT) Autopsy in Suicide by Gunshot to the Head

Theodore Harcke, MD, Craig T. Mallak, JD, MD, and Terrill Top, MD*, Armed Forces Institute of Pathology, 1413 Research Boulevard, Rockville, MD 21771

After attending this presentation, attendees will be able to discuss the ability of MDCT to identify critical forensic elements in suicide by gunshot to the head. The discussion will include both strengths and limitations of MDCT imaging.

This presentation will impact the forensic science community by showing the potential for postmortem MDCT imaging to simplify cause of death determination in selected cases of suicide.

Postmortem MDCT has been shown to be accurate in the evaluation of gunshot wounds with regard to presence of ballistic fragments, entry and exit wound determination, and determination of wound track. Two-dimensional and three-dimensional CT images from a consecutive series of ten cases (nine male, one female; age range 19-32 years) with history of self-inflicted gunshot wound(s) to the head by small arms were studied retrospectively by a radiologist and forensic pathologist. Neither individual had knowledge of the autopsy findings. Using a computer workstation to view axial images and 2D/3D computer reconstructions, determinations of number of shots, entry and exit wounds, soot/stippling, beveling, and wound direction were ascertained. The results were compared to the autopsy findings. All autopsies were performed by board certified medical examiners with access to 2D radiographic images.

The radiographic conclusion that all cases were single shot perforating wounds (one with residual metal fragments) agreed with autopsy reports. There was agreement in designation of all entry and exit wounds (20); entry wounds were submental (1), glabellar area (3), right temporal region (5) and intraoral (1). Three-dimensional surface rendering of scalp wounds was not as helpful as skull findings in classifying wounds. Presence of soot was not mentioned in any of the radiographic assessments but was described at autopsy in all cases. Stippling was not noted in either the MDCT or autopsy findings. Presence of beveling was agreed upon at 9/18 sites, in 8/18 sites MDCT was positive for beveling but not mentioned or called negative in the autopsy report. At one entry site, the autopsy noted beveling whereas the radiology review did not call it (intraoral and submental entry sites are often not subject to beveling).

There was agreement in 10/10 cases regarding the track direction (anterior vs posterior, left vs right, up vs down) with only a minor variance in one case (horizontal track by MDCT vs downward by autopsy measure from vertex). The internal description of brain injury reflected some differences in terminology. While the MDCT tended to describe direction and distribution of bone fragments and pathway, autopsy was more descriptive of hemorrhage and brain anatomy but overall the pathways were in agreement.

Self inflicted, perforating GSW's of the head were correctly described by MDCT in regard to number of shots, entry and exit wound determination and description of wound direction and track. Significant limitations of MDCT are its inability to assess the external soft tissue findings at entry and exit sites and in particular to determine the presence of soot. This study shows that MDCT adds objective information to the invasive part of the cranial autopsy in cause of death determination for cases of suicide with perforating GSW's; however, it cannot replace external assessment of wounds.

However, the combination of hands-on external/internal autopsy assessments and non-invasive internal evaluation by MDCT are not enough. The knowledge of the circumstances leading up to the death and laboratory tests are required to strengthen the medical examiner's ability

to objectively establish the cause and manner of death in cases involving self inflicted, perforating GSW of the head.

Suicide, MCDT Autopsy, GSW to Head

G41 Classification of Asphyxia: The Need for Standardization

Anny Sauvageau, MD*, Office of the Chief Medical Examiner, 7007, 116 Street, Edmonton, AB T6H 5R8, CANADA

After attending this presentation, attendees will better understand the lack of uniformity in the classification of asphyxia and the need for standardization.

This presentation will impact the forensic science community by proposing a unified system of classification of asphyxia.

Introduction: Asphyxial deaths are common in forensic practice. Unfortunately, the classification of asphyxia and the definition of its subtypes are far from being uniform, varying widely from one textbook to another and from one paper to the next. This presentation will begin by summarizing the definitions that are currently described in the literature and highlighting their discrepancies. An attempt will then be made to draw on the mainstream definitions to create a unified system of classification.

Classification and definition of types of asphyxia in the literature: A comprehensive review of the different classifications of asphyxia found in the literature will be presented as well as a thorough compilation of definitions of each term. From this complete review, the most widely accepted views will be drawn. The following recommendations will be discussed, with their underlying rationale:

a) *Unified classification model:* It is proposed that asphyxia should be classified into four main categories: suffocation, strangulation, mechanical asphyxia, and drowning. Suffocation subdivides into smothering, choking and confined spaces/ entrapment/ vitiated atmosphere. Strangulation includes three separate forms: manual, ligature and hanging. Mechanical asphyxia encompasses positional as well as traumatic asphyxia.

b) *Suffocation:* Some authors confusingly use this term synonymously with smothering. Considering the lack of specificity of this term, its use is strongly discouraged in death certificates and requires replacement with a more precise descriptor.

c) *Smothering and choking:* There is no consensus as to the anatomical landmark serving as a boundary between these entities. The epiglottis is proposed as a standardized anatomical landmark. If confronted with an obstruction extending above as well as below the epiglottis, it is recommended to use the lowest level of airway obstruction in classifying the case.

d) *Mechanical asphyxia:* Mechanical asphyxia has been defined by different authors as either a specific entity characterized by restriction of respiratory movements by external pressure on the chest or abdomen or as a broad term encompassing several types of asphyxia caused by various mechanical means. To avoid confusion, it is recommended to keep the phrase mechanical asphyxia as a specific term to designate asphyxia by restriction of respiratory movements.

e) *Strangulation and hanging:* The classification of hanging is controversial: several authors consider hanging to be a type of strangulation or a subtype of ligature strangulation, whereas other authors consider strangulation and hanging as different entities. It is recommended that hanging should be regarded as a type of strangulation, along with manual and ligature strangulation. Some authors believe that accidental hanging can also occur without a ligature: it is however recommended to restrict the appellation of hanging for cases involving some type of ligature tightened by the weight of the body. Furthermore, it is recommended that all asphyxial deaths caused by external pressure on the neck structures should be labeled strangulation and terms such as

positional asphyxia should be avoided in these circumstances. If a strangulation does not fall into the category of manual, ligature or hanging it should be labeled as strangulation NOS (not otherwise specified).

f) **Drowning:** It is recommended that drowning should be included in the forensic classification of asphyxia. However, this inclusion does not necessarily mean that the entity should be discussed in the chapter of asphyxia in textbooks or formal teaching. A better approach would be to include drowning in the classification of asphyxia but discuss it further in the context of the investigation of bodies recovered in water.

Conclusion: At this point in time, there is so much variation in the classification and definitions of terms that research and practice are inevitably tainted by confusion. Unfortunately, similar research designs can lead to totally different results depending on the definitions used. Closely comparable cases are called differently by equally competent forensic pathologists. The proposed unified model in this study was designed in an effort to standardize the classification of asphyxia in the forensic context.

Forensic Pathology, Asphyxia, Classification

G42 Discrimination of Falls and Blows in Blunt Head Trauma: A Multi-Criteria Approach

Anny Sauvageau, MD*, Office of the Chief Medical Examiner, 7007, 116 Street, Edmonton, AB T6H 5R8, CANADA

After attending this presentation, attendees will have better knowledge of the criteria pointing towards blows or falls in blunt head trauma.

This presentation will impact the forensic science community by providing tools to improve the discrimination between falls and blows.

The distinction between accidental falls and homicidal blows is an important one in forensic pathology as it occurs frequently, but most importantly, because of the legal branching related to a homicide. Indeed, autopsy findings are often used to corroborate or complement investigative information. In the discrimination of falls versus blows, the hat brim line (HBL) rule is mentioned in several textbooks as the most useful single criterion. According to this rule, an injury located at the level where the brim of a hat would lie is more likely the result of a fall, while a blow would generally produce a wound above this line. Recent studies however have found that the HBL rule is only moderately valid and that its use on its own is not recommended. The HBL rule should instead be used in conjunction with other tested criteria, such as the side lateralization and number of lacerations and the length of lacerations. The purpose of this research is first to find additional individually useful criteria in the distinction of falls from blows, and second to construct a decision tree by selecting and combining criteria with the highest predictability rates.

Materials and Methods: This retrospective study used autopsy cases from the Montreal Laboratoire de sciences judiciaires et de médecine légale spanning a six-year period (2000-2005). The selected cases represented falls downstairs, falls from one's own height and homicidal blows to the head by a blunt weapon. Designation of cases as falls or blows was not solely based on head examination but on a thorough case review, including scene investigation, witness testimony, perpetrators confession and other autopsy findings. The cases where a victim was struck while lying on the ground were excluded from the sample. For each case, the following features were compiled: the number of lacerations, the location of lacerations and fractures in relation to the HBL, the side lateralization of lacerations and fractures, scalp laceration length; calvaria fracture type; number of facial abrasions, contusions, and lacerations (including mouth lesions); presence of lacerations on the ear; presence of facial fractures; pattern of post-crani

osseous and visceral trauma; and the quantity of alcohol (mg/100ml) when toxicology reports were available. The HBL definition used in this study is the following: the area located between two lines parallel to a line inspired by the Frankfort horizontal plane (horizontal plane passing through right and left porion points and the left orbitale), the superior margin passing through the glabella (G line) and the inferior margin passing through the center of the external auditory meatus (EAM line).

Results and Conclusion: A total of 113 cases were studied: 29 cases of falls from one's own height, 21 cases of falls downstairs, and 63 cases of homicidal blows. Cases of falls downstairs revealed a male:female ratio of 6:1 with an average age of 50 (\pm 14.3 years ranging from 26 to 79 years), while the ratio for falls from one's own height was 8.7:1 with an average age of 51.5 (\pm 17.5 years ranging from 15 to 85 years). Cases of blunt head trauma to the head showed a male:female ratio of 2.9:1 with an average age of 44 (\pm 19.8 years ranging from 9 to 81 years).

The goal of this study was to improve the discrimination between falls and homicidal blows by a blunt weapon in a forensic pathology setting. The request to give an expert opinion on this distinction is a common and crucial one given the legal consequences. Overall, based on the present study as well as previous ones, the criteria pointing towards blows are:

1. More than three lacerations
2. Laceration length of seven cm or more
3. Comminuted or depressed calvarial fractures
4. Lacerations or fractures located above the HBL
5. A left side lateralization of lacerations or fractures
6. More than four facial contusions or lacerations
7. Presence of ear lacerations
8. Presence of facial fractures
9. Presence of post-crani

Blunt Head Trauma, Falls, Homicide

G43 Glioblastoma – Cause of Sudden Death on an Apparently Healthy Woman

Jerónimo F.S. Silva*, National Institute of Legal Medicine - Portugal, Bairro de Santa Justa, 10, Coimbra, 3000-356, PORTUGAL

After attending this presentation, attendees will learn the importance of performing a complete autopsy in cases of sudden unexpected death, completed with a meticulous neuropathological examination, mainly in the cases where an extracranial cause of death was not found.

This presentation will impact the forensic science community by the report of a very rare case of sudden unexpected death by an undiagnosed glioblastoma.

Sudden unexpected deaths due to primary brain tumors are very rare in forensic pathology practice. Nowadays, most fatal brain tumors are diagnosed before a fatal outcome, based upon neurological manifestations and imaging techniques, such as computed tomography and magnetic resonance imaging. Glioblastomas are the most common primary brain neoplasms and account for more than fifty percent of the malignant gliomas. Usually they cause headaches, seizures and focal neurological deficits according to their anatomic location in the brain.

A case of a 44-year-old woman, who was found dead in her bed, resting naked with her body lying down ventrally. According to relative's statement she was apparently a healthy woman.

The autopsy revealed a vast "froth mushroom" covering her mouth and nostrils, as well as a marked cerebral edema with a cystic yellow lesion on the white matter of the right fronto-parietal lobe, surrounded by hemorrhagic foci. Neuropathological examination established the diagnosis of glioblastoma, grade IV according to WHO (World Health Organization).

The importance of performing a complete autopsy in cases of sudden unexpected death, complemented with a meticulous neuropathological examination, mainly in the cases where an extracranial cause of death wasn't found will be highlighted.

Glioblastoma, Brain Tumor, Sudden Death

G44 Stab Wounds, Incised Wounds, or Blunt Trauma With Single or Multiple Weapons – How to Read Soft Tissue and Bone Injuries

João S. Pinheiro, MS, Rosario L. Silva, MD, and Claudia Marques, MD, Instituto Nacional Medicina Legal, Delegação do Centro, Largo da Sé Nova, Coimbra, 3000, PORTUGAL; José Elísio P.A. de Campos e Sousa, MD, Largo da Sé Nova, Coimbra, 3000-213 COIMBRA, PORTUGAL; and Francisco C. Real, PhD, Instituto Nacional Medicina Legal, Delegação do Centro, Largo da Sé Nova, Coimbra, 3000, PORTUGAL*

The goal of this presentation is to remind attendees of the importance of careful observation in all autopsies performed (either on the skin or internally in soft tissues, organs and even bones), in order to know how to correctly classify injuries, as well as to establish a relationship between both the external and internal injuries and the weapon(s) involved. By combining the knowledge of all these elements, the pathologist will then be able to better read the wounds' language.

This presentation will impact the forensic science community by advocating a return to the basics in the analysis of wounds. Also defended is the need for pathologists to be highly trained in clearly distinguishing incised, blunt and ballistic trauma, and to be prepared to solve difficult cases with mixed and atypical injuries, such as the one presented here. It is argued that the best interpretation of autopsies will come from those who use all these capacities and experience in every case, providing good answers to the questions aroused from the criminal investigation.

A young woman that was found dead in her home, laying on the bed, dressed; the body, clothing, and sheets stained of blood. Profuse blood spatters were visible on the walls and floor. Fragments of cement were found aside of the left hip. The victim presented at autopsy with typical incised wounds in the arms, neck and in the scalp, some of them with a tail. The scalp wounds had an internal translation as bone cut marks. However, these marks had different shapes and particular patterns. Underneath one of the incised scalp wounds there was also a skull fracture of the right zygomatic and frontal bones and cerebral laceration.

The injuries of the head, neck, and arms, suggested at first a knife. However, after examination of the deeper head injuries, it was found that although they appeared incised, the margins were not so clean as usual, and some of the bone cut marks showed one clear cut margin and little splinters on the other margin. Consequently, the knife assumption was discarded and instead, an axe or a similar tool was considered as a hypothesis, reinforced by the blunt trauma seen on the right side of the skull. Nevertheless, one abraded tangential lesion of the skull and the undulated shape of one of the cut marks lead us to look for another weapon that could produce blunt trauma and incised-blunt trauma at the same time – or to consider two different weapons.

This presentation will discuss the possible weapon(s) used to produce the different and complex injuries described, matched to the skin, subcutaneous tissues, organs and bones patterns of wound. The lethal wounds will be identified and possible defense lesions among the multiple injuries observed. Hypothesizing the existence of one or more aggressors and estimating the position versus the victim is also debated.

The solution of this case was found by the police in the main suspect's van (the victim's husband) near other material that as a builder, worked with: a bloody shovel – that fit with all the injuries found.

It was concluded that, facing complex and contradictory lesions such as the ones presented in our case, the pathologist should interpret them all, provide information about the weapon or weapons probably involved, determine those that produced the death, and the position of the aggressor vs. the victim, among other objectives that may appear during the investigation. He/she must be prepared, experienced, and able to read the wound language written in different morphological supports, including skin, soft tissues, and bone.

Cut Marks, Blunt, Shovel

G45 Sudden Infant Death Syndrome and Infant Mortality in Serbia

Djordje M. Alempijevic, PhD, Faculty of Medicine University of Belgrade, Institute of Forensic Medicine, 31a Deligradska Street, Belgrade, 11000, SERBIA AND MONTENEGRO; Ana Milenovic, and Nikola Vukelic, Faculty of Medicine University of Belgrade, 8 Drive Subotica Street, Belgrade, 11000, SERBIA AND MONTENEGRO; and Dragan S. Jecmenica, PhD, Snezana Pavlekic, PhD, Aleksandra V. Nedeljkov, MD, and Branimir V. Aleksandric, PhD, Institute of Forensic Medicine, Faculty of Medicine, University of Belgrade, 31a Deligradska Street, Belgrade, 11000, SERBIA AND MONTENEGRO*

After attending this presentation, attendees will understand possible pitfalls in infant death evaluation, in particular, related to sudden infant death syndrome (SIDS). The attendees should also become familiar with major gaps in data integration between forensic pathology institution and public health system.

This presentation will impact the forensic science community by providing figures on SIDS cases for a ten-year period (1998-2007). Data from two sources, autopsy records from the Institute of Forensic Medicine in Belgrade and the State Office of Statistics are provided, compared, and commented.

A review of 93 cases of SIDS will be presented within a ten years period where 6,980 deaths of children under the age of one year have been recorded. Issues of SIDS autopsy diagnostic and current legislation pertinent to postmortem examination is widely discussed.

Infant Death Evaluation, Sudden Infant Death Syndrome, Public Health

G46 Fatty Versus Fibrofatty Involvement of the Myocardium in Sudden Death and Heart Failure

Lise A.M. Matzke, MSc, and William M. Elliott, PhD, UBC-James Hogg iCAPTURE, University of British Columbia/Providence Health Care, Saint Paul's Hospital Room 166, 1081 Burrard Street, Vancouver, V6H 1P9, CANADA; Crystal Leung, BMLSc, James Hogg iCapture Centre for Cardiovascular and Pulmonary Research, Saint Paul's Hospital, Room 166 1081 Burrard Street, Vancouver, V6Z 1Y6, CANADA; Carol Lee, MD, 2165 Fraserview Drive, Vancouver, V5P 2N2, CANADA; Charles Lee, MD, Vancouver General Hospital, Department of Forensic Pathology, 855 West 12th Avenue, Room 1352, Vancouver, BC V5Z 1M9, CANADA; Bruce M. McManus, PhD, James Hogg iCAPTURE Centre, Saint Paul's Hospital, 1081 Burrard Street, Vancouver, V6H 1P9, CANADA; and Michael Allard, MD, James Hogg iCapture Centre for Cardiovascular and Pulmonary Research, 1081 Burrard Street, Vancouver, BC V6Z 1Y6, CANADA*

After attending this presentation, attendees will recognize the pattern of pathologic and histologic findings as correlated to clinical information from cases within the spectrum of fatty cardiomyopathy including arrhythmogenic right ventricular cardiomyopathy.

* Presenting Author

This presentation will impact the forensic science community by reviewing clinical and pathological data as well as associated histology for sudden cardiac death cases from the spectrum of fatty cardiomyopathy and arrhythmogenic right ventricular cardiomyopathy. Forensic and cardiovascular pathologists, as well as other forensic scientists, may find this information useful for comparison with observations from their home institutions and practices.

Arrhythmogenic right ventricular cardiomyopathy (ARVC) is a genetically determined heart muscle disease characterized by fibrofatty replacement of myocardium in the right ventricle (RV) and to lesser degree in the left ventricle. ARVC is commonly associated with sudden death and heart failure. Isolated infiltration of the RV by fat alone is also believed to be associated with sudden death. However, the ARVC phenotype versus that characterized by isolated fatty infiltration alone have an unclear separation. Such lack of clarity makes pathological evaluation of sudden death in these circumstances very challenging. While genetic testing for mutations in genes known to be associated with ARVC would aid in rendering a diagnosis, that approach is not practical in everyday pathology practice. One other possible strategy in better delineating phenotypic variation might be immunohistochemical staining and quantitative evaluation of proteins related to genetic mutations underlying some ARVC phenotypes.

Purpose and Approach: In this study, heart case materials from autopsy (8) and cardiac transplantation (2) from patients with ARVC and fatty infiltration of the RV are characterized. Each case was accessioned in the iCAPTURE Cardiovascular (CV) Biobank at St. Paul's Hospital/University of British Columbia and each case was referred to a cardiovascular pathologist at the CV Biobank for assessment. Under approved ethics protocols, patient data were obtained from medical records or referring pathologists. The CV Biobank, a research and educational tool, was established in 1982 and includes cardiovascular tissue specimens from surgery and autopsy, along with their accompanying annotations and data held in a secure database.

Methods & Results: The Ten sets of case materials were archived between 1993 and 2008. All hearts were assessed for their macroscopic and microscopic features with confirmation by at least two observers. The specimens were found to fit into one of two patterns. Nearly two-thirds demonstrated **fibrofatty** (6 male, age = 17-36 years) replacement of the RV myocardium, while about a 1/3 showed a pattern of predominantly **fatty** replacement (2 male, 2 female; age = 15-64 years). Within the fatty replacement group, individuals died during non-strenuous activity and at rest. In this group, one individual had a history of fainting and clinical intervention for arrhythmia and one patient had a history of anorexia and bulimia. In the fibrofatty replacement, group patients died following non-strenuous activity, during strenuous activity and at rest. This group of patients included one individual with documented familial ventricular tachycardia for which he received treatment, one patient with dilated cardiomyopathy and mitral valve regurgitation, and one individual with sudden death of a brother due to an unspecified "aneurysm". Quantitative computer-assisted morphometric analysis confirmed two pathological phenotypes, fibrofatty and fatty. Of interest, the distribution and extent of involvement differed substantially between fibrofatty and fatty patterns, with changes being more extreme and widely distributed in the fibrofatty group, while localized to the anterolateral apex and lateral base in the fatty category. None of the hearts studied had a notable cellular inflammatory element. Further, immunohistochemical staining was performed on all heart cases for desmosomal protein plakoglobin, a protein that links adhesion molecules at the intercalated disk to the cytoskeleton and is thought to aid in the evaluation of ARVC.

Summary and Conclusion: Fibrofatty replacement of the RV, characteristic of ARVC, and fatty infiltration of the RV alone are distinctive phenotypes in the setting of sudden cardiac death and heart failure. The distinctly different extent and distribution of involvement between the two morphological patterns supports the concept that they represent different disease processes. Further, preliminary quantitative

analysis of immunohistochemical staining for plakoglobin suggests that such staining may aid in the assessment and distinction of these two conditions.

ARVC/ Fatty Cardiomyopathy, Cardiovascular Pathology, Sudden Cardiac Death

G47 A Homicide Due to an Atypical Asphyxiation Tool: A Rolling Pin

Margherita Neri, PhD, Santina Cantatore, Gabriela Perilli, MD, and Irene Riezzo, MD, Department of Forensic Pathology, University of Foggia, viale degli Aviatori, 1, Foggia, 71100, ITALY*

The goal of this presentation is to present an unusual case of homicide asphyxia due to an atypical compression of the neck by a rolling pin.

This presentation will impact the forensic community by discussing the rarity of the deaths due to rolling pins utilized as an asphyxiation tool, the particular features of macroscopic lesions caused by the tool, and for the importance of a careful autopsy examination with an immunohistochemical study in order to clarify the exact mechanism of the death.

Death by asphyxia can present in various different ways. It is usually determined by typical actions imputable to an asphyxial agent of compression on the neck, usually classified as throttling, strangulation, hanging, and mugging. All these tools can cause an external compression of the neck. Various atypical forms have been described, caused by rods or sticks used to compress the neck anteroposteriorly, by wooden rods with cords or screws attached to their extremities used in garroting, by violent pulling of the neck backwards in a pincer movement between the forearm and arm in mugging, or by compression of the victim's neck by the aggressor's knee or foot. In this case, the tool used to kill was a rolling pin.

On December 1, 2008, at 3:00 p.m., a man called the police and said that he found his wife dead. The police and the forensic pathologist went to the crime scene and found the body of a 74-year-old Caucasian woman inside of the kitchen of her own house. The woman lived in the house with her husband and her only son. The corpse was lying supine on the floor. She was fully and tidily dressed, the head rested on a pillow, the arms were adducted to the trunk, the forearms were on the abdomen, and the legs were extended and slightly spread.

Close to the shoulder of the woman, on the floor, under a metallic feet-stool, was a brown wood rolling pin with a length of 79.5 cm, maximum circumference of 11 cm, diameter of 3.5 cm, and weight of 530 g. The thanatological data recorded by the forensic pathologist called to the scene stated that, at the time of discovery (4:00 p.m.), the corpse did not show rigor mortis, and the hypostasis blanched with finger pressure but was congruous with body position. The rectal temperature was 35 °C and ambient temperature was 24 °C. The prosecutor arranged for an autopsy because the circumstances of the death suggested that it was an homicide, and made inquiries about the son and the husband.

A complete autopsy was performed twenty-four hours after death. The external examination showed a remarkable cyanosis of the face, lips and nails; skin petechial hemorrhages in frontal and periorbital region, and mucosal petechiae on the oral vestibule and conjunctivae. On the neck were two parallel, horizontal, oval shape, mild blue bruise areas, the first on the anterior face of the neck (measuring 2.3 cm x 1.8 cm) and the second on the left mandibular region (measuring 2.8 cm x 2.4 cm). Dissection of the neck revealed thin hemorrhages in the subcutaneous tissues and in both sternohyoid and sternothyroid muscles and right thyrohyoid muscle. The esophagus, larynx, and trachea were unremarkable. Subpericardial and subpleural petechiae were observed. The other organs did not show specific alterations except for an intense vascular congestion. Skin sections for histological examination were removed at the neck in long strips perpendicular to bruises. Sample of

muscle tissue were also taken at the neck (sternohyoid, sternothyroid and thyrohyoid muscle). The histological examination showed mild hemorrhages in the cutaneous and subcutaneous tissues, and in the muscles. The stratum corneum of the epidermidis was detached and the dermis was split from the epidermis. An immunohistochemical study was performed to assess the vitality of the skin injury with antibodies to CD 15, IL15, and tryptase and the microscopical observations showed a strong positivity of tryptase, IL15 and weaker reaction to CD 15. Moreover, histological investigation of other organs showed mild cerebral and pulmonary edema, focal emphysema, and perivascular and intra-alveolar hemorrhages. The toxicological analysis was negative. According to the examination of neck bruises, autopsy findings and histological data, the mechanisms of death was consistent with asphyxia. Death was attributed to an external neck compression, and the tool that caused the death was perfectly compatible with the rolling pin found on the floor near the body. Fingerprints belonging to the son were identified on the rolling pin. Detailed examination of the crime scene and autopsy, along with the investigation of the psychological background of the son produced clear evidence that killer was the son and few days he confessed to the murder.

Rolling Pin, Atypical Asphyxia, Vitality Lesions

G48 Use of Volatile Organic Compounds and Chemometric Procedures to Determine Postmortem Interval

John W. McIlroy, BS, Michigan State University, Chemistry Building, East Lansing, MI 48824; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will be familiar with the use of volatile organic compounds and chemometric procedures for the estimation of postmortem interval (PMI).

This presentation will impact the forensic science community by further developing a chemical method to estimate the postmortem interval, which can be applied to death investigations, when traditional PMI estimations may fail.

An important aspect of any death investigation is to determine time since death, or postmortem interval (PMI). Establishing the PMI is important for identifying and eliminating suspects as well as helping to reconstruct the crime. However, unless eye-witnesses are known, it is difficult to establish when the death occurred. Many of the current methods that are used for PMI estimation involve gross changes to the body and are only useful for the first few days after death. However, after death, chemical changes also occur within a body. This research has focused on the chemical changes that occur in individual viscera to estimate the PMI. The purpose of this initial work was to identify biomarkers that can be useful for the estimation of the PMI.

An initial *in vitro* study was conducted on four viscera (heart, lung, liver, and kidney) harvested from two different pigs. Samples were collected from all viscera and from different areas within each viscus throughout the decomposition process. All samples were homogenized in a tissue grinder, extracted, and derivatized prior to analysis by gas chromatography-mass spectrometry (GC-MS). Total ion chromatograms (TICs) were assessed initially and, through mass spectral interpretation, major volatile organic compounds (VOCs) that are potentially important biomarkers, were identified. Principal components analysis (PCA) was then applied to identify differences in VOCs for samples collected from different areas of the same viscera, as well as differences in VOCs in different viscera. Compounds that showed minimal variation within a viscera and between viscera were selected as biomarkers for PMI estimation. It is important to identify biomarkers that do not have wide variability, in order to allow for accurate PMI estimation. The changes

in abundance of these biomarkers in each viscera, over time, were observed and used to create a model that could be used to estimate the PMI. Samples from each viscera were collected from both pigs over time and analyzed by GC-MS. The abundances of the VOC biomarkers were normalized to an internal standard and plotted as a function of accumulative degree days (ADDs) in order to estimate the PMI. The results of these studies will be presented and discussed along with the implications for PMI determinations using the developed model.

Postmortem Interval, Chemometrics, Volatile Organic Compounds

G49 A Comparison of Drug-Related Deaths in Tarrant County, Texas, With Law Enforcement Seizures of Illicit Substances Over a Similar Time Frame

Lucile B. Tennant, JD, Marc A. Krouse, MD, and Nizam Peerwani, MD, Tarrant County Medical Examiner's Office, 200 Feliks Gwozdz Place, Fort Worth, TX 76104-4919*

After attending this presentation, attendees will have an awareness of the most recent pattern of abuse of illicit substance use in Tarrant County and understand which substances are responsible for the most lethal intoxications in this Texas county.

This presentation will impact the forensic science community by sharing recent information on substance abuse and lethal intoxication in one community. It should also encourage similar studies and the sharing of this information between law enforcement and forensic laboratory personnel.

Hypothesis: There is a change in the pattern of drug-related deaths and substance abuse in Tarrant County.

Methods: Information covering the last twelve months, from three laboratories which do testing for law enforcement agencies in Tarrant County, Texas have been gathered and synthesized. These laboratories perform toxicological analysis on autopsy fluid and tissue, and on evidence seized by law enforcement officers. The results and pattern of substances in fatal intoxications and in drug seizures over a related period of time have been compared.

Results: Tarrant County is a Texas county with a population of approximately 1.7 million which includes its largest two cities, Fort Worth and Arlington which have populations of approximately 650,000 and 650, 000 respectively. The county covers an area of 897 square miles, over thirty incorporated cities and towns and covers urban and rural territory. The demographics of the population include a diverse racial and age makeup and includes more than fifteen different school districts. The Tarrant County Medical Examiner's Office, along with two regional labs serves over 100 county law enforcement agencies. All three labs have cooperated to produce this data.

Although there are differences in the statistics gathered by each laboratory, all have seen a distinct change in the pattern of drug abuse over the last few years. These changes include the emerging popularity of certain prescription drugs as well as illicit drugs, and the appearance of new designer drugs such as "cheese", benzylpiperazine (BZP), 3-trifluoromethylphenylpiperazine (TFMPP) and others. The three laboratories serve different size towns and cities and the drugs seized from these communities follow certain trends, so the laboratories see a different spread of cases in seizures from the small towns than in seizures from the larger communities. In the small towns, law enforcement seizures tend to yield the highest incidence of methamphetamine, ecstasy and pharmaceuticals. The larger towns and cities' cases more frequently involve cocaine and heroin. These findings are consistent with national reports.

Conclusion: The pattern of drug-related deaths and abuse of illicit substances has changed through the years. This study reports some of the changes seen recently. These include the increase in popularity of

certain prescription drugs and the appearance of “new” drugs of abuse and a change in the drugs responsible for acute intoxication and fatal overdose.

Substance Abuse, Lethal Intoxication, Illegal Substances

G50 Nocturnal Oviposition of Blow Flies (Diptera: Calliphoridae) in the Lower Mainland of British Columbia, Canada

Jaime S. Prevolek, BSc*, and Gail S. Anderson, PhD, Simon Fraser University, School of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA

After attending this presentation, attendees will better understand the nocturnal egg-laying behavior of several of the blow fly (Diptera: Calliphoridae) species that commonly inhabit suburban regions of the Lower Mainland of British Columbia, Canada.

This presentation will impact the forensic science community as it will discuss the potential implications of nocturnal oviposition of blow flies (Diptera: Calliphoridae) on postmortem interval (PMI) estimations in human homicide investigations.

The most important and common use of forensic entomology is to estimate the elapsed time since death. Specifically, the postmortem interval (PMI), defined as the minimum time that has elapsed since death, is determined through the analysis and identification of the forensically important insect species present at the crime scene. An accurate PMI estimation has been proven very valuable in homicide investigations as it points the investigators toward the correct time frame.

Nocturnal oviposition of blow flies has not been investigated in Canada; therefore, the potential effect of its presence on the PMI was unknown. If some or all of the blow fly species in British Columbia were found to lay eggs at night, this could have major implications in the Canadian Criminal Justice System, as the presence of nocturnal oviposition could alter the PMI by up to eight to twelve hours. Such an error rate could lead to the appeal of previous cases in which conviction was based on the assumption that nocturnal oviposition does not occur. This may also play a role in unsolved homicides, as suspects would have originally been interrogated based on a time of death that was incorrect.

In this study, six beef liver baited inverted cone traps were put outside in a suburban garden on individual days in July and August in order to monitor the egg-laying behavior of local blow fly species. Individual experimental days were chosen based on an expected nocturnal minimum temperature of greater than 12°C. Oviposition was monitored over twenty-four hour periods in two locations, one with complete darkness nocturnally and one in the presence of artificial light produced from a high pressure sodium street light. The bait was replaced with fresh bait every four hours and the number of eggs was visually estimated. The eggs were then reared to adulthood at the Centre for Forensic Research at Simon Fraser University, for species identification. The use of these traps also allowed for the nocturnal activity levels of blow flies to be assessed as active adults were caught in the plastic bag attached to the top of the trap.

In this experiment, no eggs were ever found after sunset or prior to sunrise on any of the experimental days. The artificial street light was not sufficient to stimulate egg laying at night. The three species that were primarily caught were *Calliphora vicina* (Robineau-Desvoidy), *Lucilia sericata* (Meigen), and *Lucilia illustris* (Meigen). No calliphorid adults were caught after sunset or before sunrise, except on one night, in which three *L. sericata* adults were caught post sunset in two different traps. Based on these results, forensically-important blow fly species in this region do not nocturnally oviposit or remain active at night.

This experiment is the first of its kind to be done in Canada and therefore, these results suggest that the assumption of no nocturnal oviposition that has been used for many years by the Canadian Criminal

Justice System and local forensic entomologists is likely to be accurate. As a result, this research will allow forensic entomologists to estimate time of death in future B.C. homicide investigations with greater accuracy and confidence.

Forensic Entomology, Nocturnal Oviposition, Blow Flies

G51 Blood Aspiration as a Vital Sign Detected by CT Imaging and Postmortem CT Guided Biopsy

Laura Filograna, MD*, and Steffen G. Ross, MD, Institute of Forensic Medicine Center of Forensic Imaging “Virtopsy”, Buehlstrasse 20, Berne, AL 3012, SWITZERLAND; Stephan Bolliger, MD, and Tanja Germerott, MD, University of Berne Institute of Forensic Medicine, Buehlstrasse 20, Bern, AL 3012, SWITZERLAND; Patricia M. Flach, MD, Institute of Forensic Medicine Bern / Virtopsy, Buehlstrasse 20, Bern, SWITZERLAND; and Michael Thali, MD, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND

After attending this presentation, attendees will have learned about the possible contribution of multi-detector computed tomography in forensic investigations on blood aspiration.

This presentation will impact the forensic science community by suggesting that the execution of a CT scanning prior to autopsy in cases suspected for occurrence of blood aspiration may avoid misdiagnoses and provide an easier and immediate visualization of distribution and severity of aspiration.

Based on the proved efficient role of the modern cross-sectional techniques as complementary/additional tool to traditional forensic methods, the aim of this study was to examine the value of postmortem CT imaging in evaluating pulmonary findings related to blood aspiration, compared to traditional forensic pathology techniques.

Identification and correct interpretation of blood aspiration is of substantial importance in forensic cases, as this finding can provide the forensic pathologist with information on whether an injury occurred intravital or postmortem, and give suggestions on the cause of death.

Between January 2005 and December 2008, at the Institute of Forensic Medicine in Bern a total of 359 human corpses underwent MSCT scanning prior to autopsy, within the project. Thirty-seven non-decomposed bodies where blood aspiration was documented with the traditional examinations, or where blood or bloody fluids were found in the airways from larynx to small bronchi were selected. A total of thirty-one cases had demonstration of aspiration in lung parenchyma on autopsy inspection or on histological analysis. The remaining six cases all showed blood or bloody fluids in the airways. Blood aspiration was reported in final autopsy reports as being the primary, assisting or competing cause of death in seven cases. All cases underwent body CT scanning on a six slice scanner. Two- and three-dimensional reconstructions were obtained at a workstation. The images were assessed for presence, entity, density and composition of material in the airways, and for presence, entity and distribution of lung density alterations. The possibility to consider blood aspiration as cause or assisting cause of death was also assessed.

In one exemplary case, biopsy-specimens from abnormal regions of the lungs have been obtained under CT fluoroscopy guidance for histological examination.

The thirty-one cases with traditional demonstration of aspiration in lung parenchyma had ground glass opacities suggestive for blood aspiration on pulmonary CT imaging. In the six remaining cases CT imaging detected pulmonary abnormalities suspected for blood aspiration that was not mentioned in the final autopsy reports. In two cases among these, the route of aspiration was evaluated on the basis of injuries detected by whole body CT images as being anterograde and of

scarce severity, in one case retrograde, and in three combined. The biopsy specimens obtained in the one case confirmed the occurrence of blood aspiration. The concordance between post-mortem CT imaging and traditional techniques in attributing primary, assisting or competing cause of death to blood aspiration was of 71%.

Our results show the superior sensitivity of post-mortem CT imaging in detecting areas suspected for blood aspiration in some particular cases of blood aspiration of scarce severity, or when pulmonary injuries are associated. In these circumstances, the typical macroscopical findings on the lung inspection may be absent or be largely concealed by other alterations. Thus, postmortem CT can be excellently used in these cases to guide the forensic pathologist during lung tissue investigation, and to provide focused specimens for the histological examination.

Moreover, postmortem two and three dimensional CT techniques have been proven by this study to be a great device to better analyze distribution and amount of aspirated blood and to document and conduct hypotheses on the cause of death. With the traditional diagnosis of a fatal blood aspiration (made through the analysis of just few slices of the lung tissues considered representative for the whole pulmonary volume) information about the real extent and distribution of this phenomenon is lost. On the contrary, CT imaging techniques can provide a complete collection and documentation.

The analysis of post-mortem CT images of lungs and airways alone doesn't offer in many cases enough data to distinguish with certainty pulmonary findings due to blood aspiration and lung alterations due to other causes. Nevertheless, it should be considered a fundamental, highly suggested complementary tool to traditional autopsy techniques in cases of blood aspiration to avoid misdiagnoses and to provide complete and exhaustive description of the severity of the phenomenon.

Blood Aspiration, Postmortem CT, Postmortem Needle Biopsy

G52 Brain Tissue Responses After Traumatic Brain Injury in Animal Models

Kazuhiko Kibayashi, MD*, Ken-ichiro Nakao, MS, and Ryo Shimada, PhD, Department of Legal Medicine, School of Medicine, Tokyo Women's Medical University, 8-1 Kawada-cho, Shinjuku-ku, Tokyo, 162-8666, JAPAN

After attending this presentation, attendees will more clearly understand the types of animal models of traumatic brain injury (TBI), the significance of experimental studies of TBI and the mechanisms of brain damage after TBI.

This presentation will impact the forensic science community in aiding the understanding of the mechanisms of brain damage after closed and open head injuries. These studies also show the sequential changes occurring in the brain after TBI: changes that should be useful for estimating the time after trauma in cases of head injury.

TBI can be caused both directly, by immediate mechanical disruption of brain tissue, and indirectly, by delayed injury mechanisms that include intracranial hemorrhage, brain edema, and hypoxic/ischemic damage. Whereas human TBI is a highly complex multifactorial disorder, animal models of TBI are able to focus on various specific factors involved in TBI and so have helped develop a better understanding of pathophysiology after brain injury, including changes in cellular and molecular pathways. The commonly used models that replicate human closed head injuries are fluid percussion, controlled cortical impact, weight drop and freeze injury models. Utilizing these models allows us to produce a controlled range of severity of brain injury.

The magnitude- and time-dependent changes after TBI in a rat fluid percussion model was studied. The focus was on synaptophysin (SYP), a molecular marker of synapse. SYP immunoreactivity increased in both the cortex and subcortical white matter with increasing magnitude of injury and time after trauma. Increased SYP immunoreactivity was

accompanied with neuronal degeneration and glial cell proliferation. The amount of SYP remained unchanged in brains after trauma. These findings indicated that after trauma, SYP accumulates at injured sites of neurons without any change in SYP content. The increased SYP immunoreactivity in the cerebral cortex following traumatic injury reflects an inhibition of synaptic vesicle transportation and synaptic dysfunction, thus providing a histological substrate for brain dysfunction.

In cases of open head injuries, a foreign body may remain in the brain for a period of time after the trauma. A animal model incorporating a foreign body in the brain was developed. The time-dependent brain changes caused by a foreign body was studied. A lead or a glass ball was used as the foreign body and was implanted in the cerebral cortex of rats. Brains were analyzed at various times between twelve hours and four weeks after implantation. Results from brains with a lead ball were compared with those with a glass one. The number of macrophages increased significantly with increasing time after implantation of a lead ball. Multinucleated giant cells appeared at three weeks in brains with a lead ball. The immunoreactivity of metallothionein, a metal binding protein, increased significantly in astrocytes and endothelial cells with increasing time after implantation of a lead ball. Moreover, apoptotic cells were identified at two weeks, but had mostly disappeared at four weeks after implantation of a lead ball. Apoptotic cells were not observed in brains with a glass ball. This study showed that lead leached from a lead ball induces macrophage infiltration, metallothionein expression and apoptosis in the brain.

Forensic Neuropathology, Head Injury, Experimental Model

G53 Determination of Procalcitonin, C-Reactive Protein, Tumor Necrosis Factor-Alpha, Interleukin-6, and Interleukin-8 Levels in Serum, Vitreous Humor, and Cerebrospinal Fluid as Markers of Sepsis

Cristian Palmiere, MD*, Bettina Schrag, Marc D. Bollmann, MD, and Patrice Mangin, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND

The goal of this presentation is to evaluate the potential role of procalcitonin, C-reactive protein, tumor necrosis factor alpha, interleukin-6 and interleukin-8 levels in different biological fluids (serum, vitreous humor and cerebrospinal fluid) as markers of sepsis, to evaluate the stability of these markers at different measurement times after collection, and to evaluate additional benefits of combined analysis of the mentioned markers compared to procalcitonin and C-reactive protein alone.

This presentation will impact the forensic science community by evaluating different markers that can be useful in postmortem diagnosis of sepsis.

In forensic pathology routine, a well-documented medical history is often not available for a deceased person and sepsis as the cause of death remain difficult to diagnose. In fact, postmortem blood cultures are often contaminated by putrefaction processes and macroscopic postmortem findings (such as myocardial ischemia, pulmonary edema and hemorrhages, hypoxic liver damage, mesenteric and gastrointestinal hemorrhages, spleen infarctions and septic spleen alterations, kidney ischemia, and brain edema), as well as routine histological findings, may have an infectious or non-infectious origin and are neither specific nor sensitive for recognizing sepsis-associated fatalities.

The observation by Assicot and coworkers that serum procalcitonin levels increase above normal values in patients with bacterial sepsis, but not in patients with viral infection or without infection, has generated considerable interest in this marker.

A large number of clinical studies have investigated procalcitonin levels and courses of procalcitonin levels under various clinical conditions and they concluded that procalcitonin is valuable as a marker of serious bacterial sepsis and show a good correlation with the severity of the disease. In different groups of patients with sepsis, procalcitonin was compared to C-reactive protein (CRP), tumor necrosis factor alpha (TNF- α), interleukin-6 (IL-6), interleukin-2 (IL-2), interleukin-10 (IL-10) and interleukin-8 (IL-8) as a diagnostic and prognostic parameter. The results commonly showed that procalcitonin exhibits a greater sensitivity and specificity in differentiating patients with systemic inflammatory response syndrome (SIRS) from those with sepsis.

Tsokos and co-workers have investigated procalcitonin, C-reactive protein and interleukin-6 in postmortem serum as a marker of sepsis. Their results show that serum procalcitonin levels can be considered as a valuable postmortem marker to distinguish sepsis-associated fatalities from other non-septic causes of death. Compared to other potential biochemical postmortem markers of sepsis, procalcitonin has several advantages: in contrast to tumor necrosis factor alpha and interleukin-6, procalcitonin has a long half-life (25 to 30 hours); in comparison to cytokines, procalcitonin is a very stable protein, even at room temperature; procalcitonin concentrations do not differ in arterial and venous blood samples from living persons; repeated freezing and unfreezing of the blood samples does not significantly influence procalcitonin concentration.

Levels of C-reactive protein and interleukin-6 may increase very rapidly in response to inflammation of infectious origin; however, significantly elevated C-reactive protein and interleukin-6 levels can also be demonstrated in a large number of life-threatening clinical conditions, such as major trauma, extensive surgical procedures or burn injury, as a result of the systemic inflammatory response syndrome, irrespective whether the patient develops a sepsis or not.

Statement of the Method: Postmortem blood, vitreous humour and cerebrospinal fluid samples were collected at autopsy. Two study groups were formed according to whether there was an underlying septic condition as the cause of death based on the subject medical records as well as autopsy findings. Marker levels were measured at different times after collection. In the sepsis group, cause of death was multiple organ failure. In the non-sepsis group, cardiopulmonary resuscitation was not attempted in any case. Autopsy findings did not give any cause to suspect an underlying infectious disease.

Results will be presented and compared with published results in the literature.

Postmortem Chemistry, Sepsis, Diagnostics

G54 Sudden Death Due to Mesothelioma of the Atrio-Ventricular Node

Géraldine Maulean, MD, Alain Tabib, PhD, Daniel Malicier, and Laurent Fanton, PhD, Institut of Legal Medicine, 12 Avenue Rockefeller, Lyon, 69008, FRANCE*

After attending this presentation, attendees will gain much knowledge on sudden cardiac deaths, and understand that sudden cardiac deaths constitute a major health problem as one of the central topics in forensic literature. Although most cases are still attributed to complications of cardiomyopathies or coronary artery diseases, functional dysregulations are nowadays reported with an increasing frequency, due to the development of molecular autopsy. The role played by primitive cardiac tumors in sudden deaths is smaller as their prevalence is estimated to 0.05% of autopsies. Despite its rareness, mesothelioma of the atrioventricular node should be considered in the differential diagnosis of heart block in children or young adults.

This presentation will impact the forensic science community by informing attendees that the clinical presentation of a mesothelioma of the atrio-ventricular node is non-specific and may considerably vary

from sudden death to an asymptomatic patient. This presentation is the third case of sudden death in patients with pace makers. The role played by primitive cardiac tumors in sudden deaths is small as their prevalence is estimated to 0.05% of autopsies. Among such lesions, mesothelioma of the atrio-ventricular node is rare and has only been reported about seventy-five times since its first description in 1911.

Case: A 35-year-old man was found dead in the early morning by one of his friends, while he was lying on his sofa, after having lived it up with some friends. The emergency physician could only certify death. Six years previously, the man had a syncopal episode while coming out from his truck. Electrocardiography showed a type I second degree atrioventricular block. Echocardiography was normal and no curable etiology could be found. He finally had a dual-chamber pacemaker fitted a few weeks later, which had been reliably effective and well tolerated up to his sudden death. Considering the young age of the man and the sudden character of his death, a medicolegal autopsy was ordered to determine the cause of death.

On external examination, the body was that of a young Caucasian man, 164 cm in height and 80 kg in weight. Nonspecific abrasions were detected on both the right and left frontal scalp. Toxicological investigations, including alcohol, were negative. At autopsy, the only gross abnormality was a left atrophic kidney, which was 24 g in weight. The heart weighted 420 g; there was no abnormality in the epicardium or in the valves. The coronary arteries only showed a few lipidic striae. One endocavitory pacemaker lead was found located in the atrial cavity, and was involved by noninfectious vegetations. The other pacemaker lead, which was observed in the right ventricular cavity, was also affected by some fibrosis. The myocardium showed fibrosis blocks and recent left subendocardic ischemia. Left and right ventricular walls were respectively 18 and 8 mm thick. Histopathological examination revealed an extensive infiltration of the atrioventricular node and of the his bundle trunk, corresponding to a benign tumor called a mesothelioma. This tumor consisted in tubular adenoid micronodules of various sizes, lined by mesothelial cells. In the lumens, pseudo colloid eosinophilic material was found. Some areas of the tumor also showed a moderate degree of fibrosis.

On the basis of these findings, arrhythmia-related death was diagnosed, directly caused by a mesothelioma of the atrioventricular node, despite the presence of a pace maker.

Discussion: The clinical presentation of a mesothelioma of the atrioventricular node is nonspecific and may considerably vary from sudden death to asymptomatic patient, including syncopal episodes related to severe atrioventricular block, with a possible familial occurrence discussed by Travers. No correlation was found in the literature between the size of the tumor and the symptomatology observed.

This explains that the precise incidence of such a disease is quite difficult to estimate, as much as diagnosis is most often done after death when an autopsy is ordered, only nine cases having been successfully treated antemortem.

Conclusion: This report is the third case of sudden death in patients with pace maker. Despite its rareness, mesothelioma of the atrioventricular node should be considered in the differential diagnosis of heart block in children or young adults.

Sudden Death, Mesothelioma, Atrio-Ventricular Node

G55 Accidental Drowning Deaths in a Coastal Region of South India – A Ten Year Study

Tanuj Kanchan, MD*, Kasturba Medical College, Department of Forensic Medicine, Light House Hill Road, Mangalore, 575 001, INDIA

After attending this presentation, attendees will identify with the pattern and trend of drowning deaths in a coastal region of South India. This presentation will impact the forensic science community by developing an understanding of the burden of accidental drowning in the coastal region and to develop preventive strategies so that precious human lives are saved.

Accidental drowning constitutes a significant public health problem that is often neglected in our country. This study will describe the epidemiology and pattern of accidental drowning deaths in Manipal, a coastal region in South India. This study is a registry based descriptive research spanning over a period of ten years from January 1998 to December 2007. All medicolegal autopsy case records were retrospectively reviewed and the cases of death due to drowning were studied. The information obtained from autopsy reports, police investigations and toxicological analysis was registered in a database and analyzed. All deaths where the manner was recorded as suicidal or homicidal were excluded from the study.

During the study period forty cases of drowning deaths were reported. Males accounted for 82.5% of cases, male-female ratio being 4.7:1. Majority of the victims were in 2nd and 3rd decades, together accounting for 55% of drowning deaths followed by children in the first decade (15%). Fresh water drowning was reported in 70% cases. Rivers constituted the most common sites of drowning (35%) followed by sea (27.5%). Wells, canals, lakes, ponds, and water tanks were the other sites of drowning. Most (87.5%) victims of drowning were found dead. The remaining five cases died in hospitals later on. The maximum period of stay in hospital before a fatal outcome was three and a half days. Most of the accidental drownings (45%) were reported in the post monsoon period. Nearly one-third (30%) of the total drowning deaths were reported in the years 2006 and 2007.

Drowning is a major global public health problem which is amenable to prevention. The study highlights the pattern of accidental drowning deaths in Manipal, a coastal region of South India. Morbidity and mortality due to drowning can be prevented by understanding its epidemiology, common patterns and educating people about prevention. This is especially when hindsight often shows that many deaths from drowning are preventable.

Drowning, Accidents, South India

G56 Sudden Death From Atypical Pneumonia in a Healthy Adolescent

Sabina Di Donato, MD*, Ospedale San Carlo - U.O. Medicina Legale, Via Potito Petrone, s.n.c., Potenza, 85100, ITALY; Margherita Neri, PhD, Department Forensic Pathology, University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY; and Rocco A. Maglietta, MD, C.R.O.B. - Rionero in Vulture (Pz), via Padre Pio, 1, Rionero in Vulture (Pz), 85100, ITALY

After attending this presentation, attendees will become familiar with the possibility that a completely asymptomatic atypical pneumonia may induce sudden death, even in a previously healthy adolescent, with absence of histological signs of diffuse alveolar damage.

This presentation will impact the forensic science community by making attendees aware of the insidious development of atypical pneumonia in immunocompetent subjects, focusing the possible responsible mechanisms of sudden death in such cases, in the absence of ARDS and histological signs of diffuse alveolar damage.

The most common causes of atypical pneumonia are *Mycoplasma pneumoniae*, *Chlamydophila pneumoniae* and *Legionella pneumophila* which cause fifteen percent to as much as fifty percent of cases of community-acquired pneumonia. Other organisms include viruses; few cases are due to zoonotic agents like *Chlamydophila psittaci*, *Coxiella burnetii* and *Francisella tularensis*. Clinical and pathological patterns range from mild upper respiratory infection to severe lower respiratory tract disease. Atypical pneumonia generally is benign, with systemic complaints often more prominent than respiratory ones; fever, headache and myalgia are common. Although the clinical course is often self-limited, these pathogens can cause severe community-acquired pneumonia. The inflammatory reaction is localized in the alveolar septa that appear thickened, edematous, with infiltrates of leukocytes. In severe cases, fibrinous thrombi inside alveolar capillaries and haemorrhagic necrosis of alveolar walls are visible. Alveoli may contain scant exudate. Fibrin and hyaline membranes line the denuded alveolar walls, due to diffuse alveolar damage. Superimposed bacterial infection is common.

Case Report: A 16-year-old boy who spent all the day with his family, went to sleep after dinner. His brother checked on him after one hour and found him agonizing in an anomalous prone position, with the legs out of bed. Immediately he turned the body supine, called the ambulance, and tried to resuscitate him. When the doctor arrived, after the attempting with reanimation maneuvers, pronounced the adolescent dead. The boy had a negative history (except for a mild headache) and a negative family history for sudden death. He was a basketball player on the school team and was not known as a drug abuser. Death scene investigation was unremarkable. External examination was insignificant except for the presence of a little superficial wound on the right frontal scalp. The internal examination revealed polyvisceral congestion, cerebral and pulmonary edema, free fluid in the pleural cavities, and release of foamy material on sectioning of both lungs. The left ventricle showed a concentric hypertrophy (anterior wall 2 cm, lateral 2.4 cm, posterior 2 cm, septal 2.2 cm). The histological examination showed a pattern of massive diffuse interstitial pneumonia with markedly thickened alveolar septa with extreme congestion of capillaries, the presence of abundant eosinophilic material, and infiltrates of leukocytes. In the adjacent fields there were some amorphous eosinophilic material and erythrocytes inside the alveoli. The immunohistochemical stains revealed that the pulmonary infiltrates consisted of lymphocytes, histiocytes and plasma cells. There were some foci of leukocytes within the epicardium, and focal areas of patchy myocardial fibrosis and perivasculär fibrosis were visible, with a mild degree of myocardial hypertrophy. The encephalon showed leukocytic meningitis with subarachnoid infiltrates of lymphocytes and mild perivascular edema. The immunohistochemical analysis (RSV, HSV1, HSV2, VZV, CMV, HHV A and B, Parainfluenza Virus 1, 2 and 3, Adenovirus, Aspergillus spp., P. carinii, T. gondii) gave negative results. Additional tests were carried out to identify possible pathogenic agents through microbiological studies. Toxicological screening was negative. Molecular genetic analysis was conducted and excluded underlying heritable diseases. The decedent's parents indicated that the boy did not have the scalp injury before going to sleep, so it's possible that the boy suddenly fell to the bed, striking the bedside table and arresting in the anomalous position described by his brother. To explain the occurrence of sudden death in this case, two possible mechanisms of acute respiratory failure are hypothesized: (1) the underlying respiratory acidosis (well tolerated by a young active boy, by means of an induced tachypnoea) and hypoxemia may have conducted to tachycardia and deteriorating hemodynamics. This instability may have elicited a lethal ventricular arrhythmia supported by a mechanism of re-entry, considering that the boy's heart showed diffuse areas of patchy fibrosis; and (2) the irritation of the adjacent cerebral cortex by inflamed meninges may have caused epileptic seizures. Seizure activity can disrupt normal physiological regulation and control of respiratory and cardiac activity (similar to mechanisms operating in cases of sudden

death in epilepsy), precipitating the unstable equilibrium present at lung level (reduction in gas exchange due to massive interstitial pneumonia), causing an acute respiratory insufficiency.

Sudden Death, Atypical Pneumonia, Meningitis

G57 Virtopsy Project - Postmortem Needle Biopsy of the Lungs: A Feasible Tool for the Study of Fat Embolism as Vital Reaction

Laura Filigrana, MD, Institute of Forensic Medicine, Centre of Forensic Imaging and Virtopsy, Buehlstrasse, 20, Berne, SWITZERLAND; Stephan Bolliger, MD, University of Berne Institute of Forensic Medicine, Buehlstrasse 20, Bern, AL 3012, SWITZERLAND; Danny Spendlove, MD, Institute of Forensic Medicine, Centre of Forensic Imaging and Virtopsy, Buehlstrasse, 20, Berne, AL 3012, SWITZERLAND; and Ulrich Preiss, MD, and Michael Thali, MD, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND*

After attending this presentation, attendees will learn how to overcome the diagnostic gap of postmortem cross-sectional imaging in detecting the occurrence of fat embolism as vital reaction, by using percutaneous needle biopsy techniques.

This presentation will impact the forensic science community by demonstrating how percutaneous needle biopsy technique can improve the diagnostic accuracy of postmortem imaging investigations on pulmonary fat embolism as vital reaction within the concept of a minimally invasive virtual autopsy.

Pulmonary fat embolism, usually, and pulmonary embolism of bone marrow, always, can be considered indicative for antemortem violence. In fact, it is a vital phenomenon after trauma, depending on the pumping action of the heart and an intact circulation. The postmortem diagnosis of pulmonary fat embolism is traditionally based on the histological demonstration and analysis of fat droplets within the lung microcirculation.

The study population consisted of twenty-six randomly selected autopsy cases examined from September 2008 to November 2008, delivered to the Institute of Forensic Medicine of the University of Berne.

In each case, probes from both lungs were obtained using two different sampling methods. Prior to the autopsy, multiple postmortem biopsies from both lungs were executed using clinically approved and postmortem tested ACN-III biopsy core needles (14 gauge -160 mm) with an automatic pistol device. Then, during the traditional autopsy of the same cases, other thin slices of lung tissue from both lungs were taken, using a double-edge knife technique. The double-edge knife consists of a blade sharpened on one or both slides to which a second blade, similar in size and shape, is added on the side, folded out by means of a joint. A knurled nut regulates the distance between the blades, and thus the slice thickness.

All the samples were subjected to water storage and Sudan III staining. The microscopical examination was then performed by six board certified forensic pathologists, and scores were assigned according to the grading scale by Falzi et al. A comparison was made between the results of the histological examinations on both lung specimens from the twenty-six death cases, obtained with postmortem needle biopsy and double edge knife techniques respectively. A statistical analysis of the results was performed.

The statistical analysis conducted separately for each sampling technique showed no significant differences in the grading score for the samples from both lungs obtained with the two techniques. Moreover, it was demonstrated that the six forensic pathologists evaluated homogeneously the slides obtained by both lungs. Absence of pulmonary fat embolism was detected in the same cases investigated by

both techniques. With respect to the assigned grading score, a statistically relevant discrepancy between the results of the histological examination conducted on samples by the needle biopsy and double edge knife techniques was found in six cases. Nevertheless, the discrepancy was not systematic, because in three cases the analysis conducted with needle biopsy gave results bigger than that with double edge knife, and in the other three smaller.

In conclusion, this study demonstrates that postmortem pulmonary biopsy, if compared with double edge knife technique, can represent a feasible method of specimen collection for detecting and analyzing pulmonary fat embolism as vital reaction.

Although further studies are needed, the application of post-mortem percutaneous needle biopsy methods to forensic investigations on fat embolism as vital reaction could be able to improve the diagnostic accuracy of postmortem imaging examinations, and even more, the possibility of a minimally invasive virtual autopsy can be envisaged for select cases.

Pulmonary Fat Embolism, Percutaneous Needle Biopsy, Postmortem Imaging

G58 Cerebral Artery Thrombosis After Penetrating Oral Trauma: An Exceptional Autopsy Case

Renaud Clement, MD, 1 Rue Gaston Veil, Nantes, 44093, FRANCE*

After attending this presentation, attendees will understand the mechanisms of interruption of intracranial cerebral circulation by thrombosis arising in the anterior cerebral artery as a result of penetrating oral trauma.

This presentation will impact the forensic science community by presenting the forensic examination supported by the histological findings. Microscopic examination made it possible to establish the exact causes and vascular consequences of the impalement; they explain perfectly the clinical symptomatology, as well as its neurologic evolution.

A young man fell onto a metal rod at a construction site. The accident resulted in perforation of the oropharynx. After several hours, right hemiplegia developed.

Complementary examinations revealed left middle cerebral artery thrombosis. Forensic autopsy performed after the death of the patient revealed left sylvian artery thrombosis extending into the left intracranial carotid sulcus, into the left internal carotid artery and into the left anterior cerebral artery. Skull base exploration demonstrated a fracture of the left internal tip of the petrous bone. There was a breach of the intima in the anterior communicating artery and extensive thrombosis extending to the anterior, middle and internal cerebral arteries, and to the internal carotid arteries. As the adventitia was spared, this indicated indirect injury to the anterior communicating cerebral artery. This is the first description of cerebral artery thrombosis caused by indirect traumatic injury to this artery. Although the case is clinically similar to internal carotid arterial thrombosis by perforating trauma of the palate in young children, the initial clinical symptoms and signs were different, with hypoesthesia in the territories of the V2 and V3 branches of the fifth cranial nerve. These clinical findings indicated traumatic injury to the base of the skull.

Anterior Communicating Cerebral Artery, Thrombotic Process, Penetrating Trauma

G59 Does Embalming Impact Vitreous Glucose Levels?

Stephany Fiore, MD, County of Sacramento, Coroner's Office, 4800 Broadway, Suite 100, Sacramento, CA 95820-1530; and Charlotte A. Wacker, MS*, University of California, Davis Body Donation Program, 4800 Broadway, Suite 100, Sacramento, CA 95820*

After attending this presentation, attendees will understand how embalming may impact the level of glucose found in vitreous fluid obtained during autopsy.

This presentation will impact the forensic science community by educating the viewer on the utility of analyzing vitreous glucose in embalmed decedents and by informing people of the valuable resource of human body donors and how they can be used to further forensic science.

This case involves an 80-year-old female who was known to be a brittle diabetic. Because of a presumed natural cause of death, the body was originally released to the funeral home. Adult Protective Services requested the coroner perform an investigation into the death due to allegations of elder abuse/neglect by a home care provider. The decedent was embalmed six days prior to autopsy using Ultra 27 (Pierce Chemicals/Royal Bond, Inc) as the arterial preservative and Restorative (The Dodge Company); both fluids are rich tissue hydrators. Most mortuary chemicals use glycerol as the main humectant. The vitreous glucose was analyzed at University of California Davis Medical Center using a GLUCm reagent on a Beckman Coulter Synchron System. The concentration of glucose is determined by measuring the rate of oxygen consumption based on the following chemical reaction:

Vitreous fluid collected at autopsy had an elevated level of glucose (544 mg/dL). The cause of death was determined to be from hyperglycemia due to diabetes mellitus with hypertensive cardiovascular disease listed as a contributing condition. The caregiver, a registered nurse, is facing criminal charges of elder abuse/neglect for failing to provide medical care.

It is not uncommon for the forensic pathologist to perform an autopsy on an individual who has already been embalmed. The interpretation of tests performed on the blood is clearly limited due to the dilution effects of the embalming process, but what about the vitreous fluid within the eyes? Is this fluid protected from the embalming process and can it be used to aid in postmortem examination? Can the value of an elevated glucose level in a post-embalmed individual be trusted or is the result falsely elevated due to contamination by an embalming fluid with high glycerol content? Was the analytical method used to measure the glucose specific for this analyte or was it unable to distinguish glycerol from glucose?

An experiment was designed to test the vitreous glucose levels on a body donor before and after embalming. The body donor was a 78-year-old female, average height and weight that died from respiratory failure and interstitial lung disease. Standard anatomical embalming was performed. The donor remains were arterially injected, and the preservation was supplemented by hypodermic injection to poorly preserved areas. The total amount of fluid injected was 951oz., much more than the funeral home had injected. The embalming solution used consists of various preservatives, disinfectants, water correctives, and humectants. A total of three samples of vitreous were obtained; the first an unadulterated sample from the un-embalmed donor, the second, also from the un-embalmed donor, was "spiked" with embalming solution by adding a drop to the test tube, and the final sample was obtained post-embalming. All samples were sent for glucose testing by the same service that tested the autopsy sample.

Results: There was a very slight increase in the post-embalming glucose level compared to the pre-embalming samples (15 mg/dL vs. 7 mg/dL), but not enough to be clinically significant. Both pre-embalming samples (neat and spiked) had the exact same result (7 mg/dL).

Conclusion: Embalming does not interfere with the analysis of glucose in the vitreous fluid when using the Beckman Coulter Synchron System with the GLUCm reagent. This study supports what has been previously published in the literature.

Autopsy, Embalm, Glucose

G60 Analysis of an Unusual Misfire of a Common Handgun

Janaki Warushahennadi, MD, King County Medical Examiner's Office, 325 9th Avenue, HMC Box 359792, Seattle, WA 98104; Brian J. Smelser, BS, Washington State Patrol Crime Laboratory, Washington State Patrol, 2203 Airport Way South, Building A Suite 250, Seattle, WA 98134; Richard T. Wyant, MS, Washington State Patrol CLD, 2203 Airport Way, South, Suite 250, Seattle, WA 98134; and Timothy L. Williams, MD, King County Medical Examiner's Office, 325 - 9th Avenue, Box 359792, Seattle, WA 98104-2499*

After attending this presentation, attendees will be informed of an unusual mechanism accounting for the misfire of a common handgun.

This presentation will impact the forensic science community by illustrating the utility of cooperation between experts from different disciplines in reconstructing incidents.

There are many circumstances in which an apparent live cartridge may misfire even though the firing pin has struck the primer. Factors that contribute to those circumstances include design, manufacture, and condition of the ammunition and firearm as well as the actions of the individuals involved in the case.

In this report, a case will be illustrated in which two unusual misfired cartridges were found at the scene of the suicide of a 53-year-old woman by means of gunshot using a Glock 9 millimeter handgun.

Expert examination of the firearm and ammunition involved determined that the main factors contributing to the misfiring of the cartridges were likely the design of the firearm in conjunction with the actions of the decedent. The examination supported the conclusion that the misfires were caused by the decedent pressing the firearm slightly against her head in such a way that a safety mechanism was activated.

Questions outside of particular investigators' areas of expertise can arise during any investigation. In such cases, cooperation between experts from different disciplines is essential to understand the complexities of reconstructing incidents.

Misfire, Handgun, Glock

G61 Fatal Cardiac Perforation During Percutaneous Treatment in Iliac Artery Occlusion

Alessandro Bonsignore, MD, Massimo Gallo, MD, Francesco Ventura, PhD, and Francesco De Stefano, MD, Department of Legal and Forensic Medicine, University of Genova, Via De Toni 12, Genova, 16132, ITALY*

After attending this presentation, attendees will have learned of an extremely rare complication of percutaneous transluminal angioplasty (PTA) and stenting for iliac artery occlusive disease; attendees will also understand the cause of the error and verify the professional liability profiles derived from this case.

This presentation will impact the forensic science community by reminding researchers of this rare complication and the opportunity to avoid this event.

Only a complete forensic approach by means of autopsy and microscopy examination led to the conclusion for cardiac tamponade due to left ventricular wall rupture.

Aortoiliac occlusive disease (AIOD) is a common manifestation of atherosclerosis that may lead to lower limb ischemia. In this case the Trans Atlantic Inter-Society Consensus (TASC) offers guidelines for the treatment of such disease. In particular total unilateral iliac occlusions should be treated by primary stenting, reducing the risk of embolisation in iliac stenoses, and moreover the periprocedural morbidity and mortality rates. In addition, primary stenting is indicated in the presence of specific risk factors as ulcer/gangrene, smoking history, and chronic renal failure with hemodialysis. Following these directives the use of endovascular interventions for arterial occlusive lesions continues to increase consequently causing the detriment of open surgical revascularization. A careful evaluation of the various restraining parameters should precede the choice of surgical approach, to ensure the selection of the most suitable technique in each individual patient on the grounds of clinical presentation of the disease. For example, TASC lesions type A or B are best treated with angioplasty and stenting, while TASC lesions type C and D show better results with surgical treatment.

Technically PTA provides for an ipsilateral, or less frequently contralateral, common femoral artery access, crossing the lesion with a guide wire, dilating the vessel with an angioplasty balloon catheter and placing a self-expandable stent. Sometimes a brachial approach is preferred, especially when many lower limb vessels are impaired. In this kind of approach it is important to pay attention at some neurological complications (i.e., hematoma that compresses the brachial plexus leading to a sensory-motor deficit) and vascular ones (i.e., pseudoaneurysm, local thrombosis or distal embolism) which have a low incidence, estimated between 2 and 13,4% (Tsetis et al, 2008).

A 68-year-old male smoker presented to the hospital with a history of bilateral and severe lower limb arterial disease. He was suffering a left common iliac arterial occlusive lesion as showed by the arteriographic examination. The patient was treated with PTA and stenting through the left brachial artery, instead of contralateral femoral approach, due to the presence of small lesions in the right leg vessels. During the procedure, the radiologist used videoscopic to help to see the part of the iliac artery concerned the occlusion without following the entire route taken by the guide wire. By doing this he did not notice that he had taken a wrong direction, passing through the ascending aorta and then going into the cardiac chambers; in a second attempt he finally was able to enter the descending aorta and reach the left common iliac artery where the stent was successfully located.

Two hours after PTA the patient suddenly died. An autopsy was arranged for investigating any professional liability profiles. A complete postmortem examination was performed three days after death.

External examination was insignificant. The internal examination revealed a cardiac tamponade without identifying the breaking point, but with evidence of hemorrhagic infiltration area in the epicardium and throughout the thickness of the myocardium at the distal part of the left ventricle. At the aortic cone level a small area of hemorrhagic infiltration, in contact with the fibrous pericardium, was found. The presence of a correctly positioned stent in the left common iliac artery was observed. Other findings concerned polyvisceral congestion, cerebral, and pulmonary edema.

The histological heart examination, performed with routine hematoxylin-eosin, revealed hemorrhagic dissection of myocardial tissue at left ventricle level consistent with a rupture of the heart, excluding natural causes of death as myocardial infarction.

In conclusion, the cause of death was attributed to a cardiac tamponade due to traumatic left ventricular rupture during PTA procedure.

This case, which has attracted medicolegal interest because of medical liability profiles that were assumed as the doctors' fault, shows a fatal PTA complication particularly uncommon, as reported by

literature. The complications rate for angioplasty selective stenting, indeed, is generally very low both for perioperative deaths (0,03-0,06% - Aburahma et al, 2007) and immediate total complications (0,7% - Kudo et al, 2005).

Iliac Artery Occlusion, Percutaneous Transluminal Angioplasty, Fatal Left Ventricular Rupture

G62 Swiss Virtobot (Virtual Autopsy) Documentation and Analysis: Work Flow and Procedure

Steffen G. Ross, MD, Institute of Forensic Medicine Center of forensic imaging "Virtopsy", Buehlstrasse 20, Bern, AE 3012, SWITZERLAND; Lars Ebert, University Bern, IRM, Buehlstrasse 20, Bern, AE 3012, SWITZERLAND; Silvio Näther, Institute of Forensic Medicine, Centre of Forensic Imaging, Bühelstrasse 20, Bern, 3012, SWITZERLAND; and Stephan Bolliger, MD, and Michael Thali, MD, University of Bern, Institute of Forensic Medicine, Buehlstrasse 20, Bern, 3012, SWITZERLAND*

The goal of this presentation is to discuss the 2009 report concerning "Medical Examiners and Coroners Systems: Current and Future Needs" of the "National Academy of Sciences", it is written, that modern imaging technologies (Virtual autopsy, Virtopsy, www.virtopsy.com) has a great potential to detect forensic relevant findings. In the lecture, based on the experiences obtained up until now, the possibilities and realization of a process-optimized forensic examination procedure, including the subsequent analysis process, are illustrated.

This presentation will impact the forensic science community by presenting an overview of the techniques of forensic imaging and virtual autopsy and the effect to forensics in future and in correlation with the 2009 National Academy of Sciences report concerning, "Medical Examiners and Coroners Systems: Current and Future Needs".

Over ten years ago, the Virtopsy Project with its systematic integration of various technologies and modalities, such as photogrammetric 3D surface scanning, computer tomography and magnetic resonance scanning as well as in the area of clinical and postmortem forensic medicine as well as postmortem biopsy and angiography and synthetic somatic modeling development, was perceived by professional circles as being revolutionary.

After a decade, these technologies at the University Forensic Institute Bern have been integrated as an evolutionary process development in daily forensic practice.

The almost completed documentation procedure in the postmortem area has also influenced future image-based documentation and analysis processes in clinical forensic medicine.

Forensic Imaging, Virtual Autopsy, Virtopsy

G63 Mortuary Management in the Aftermath of the 2009 Australian Bush Fires

Jodie J. Leditzschke, PhD, Victorian Institute of Forensic Medicine, 57-83 Kavanagh Street, Southbank, Melbourne, 3006, AUSTRALIA*

After attending this presentation, attendees will have a greater understanding of the principles and logistics behind mortuary management following a mass fatality incident.

This presentation will impact the forensic science community by serving as a reference for improving the management of the dead and encouraging greater emergency preparedness within communities.

The Victorian Institute of Forensic Medicine (VIFM) is a statutory body with the responsibility to provide forensic pathological, clinical forensic medical, and related services to the State of Victoria, Australia. This includes the conduct of postmortem examinations and the provision of a range of forensic scientific investigations in cases referred by the coroner.

One of the roles of the VIFM is to provide scientific services in the event of multiple fatalities within the State of Victoria and extending to around Australia where necessary. Some of these past incidents include the 1996 Port Arthur Massacre, 2003 Bali Bombing, 2004 Tsunami and the Australian Embassy bombing in Jakarta.

On February 8, 2009 now known as Black Saturday, the State of Victoria, Australia suffered the deadliest bushfires recorded in its history. There were 173 fatalities and over 2,200 homes were destroyed. Over the following days 298 suspected human remains were admitted to VIFM.

On the day of the fires VIFM activated its emergency plan. Within 48-hours, a temporary mortuary was constructed adjacent to the existing mortuary facility. This temporary mortuary had the capacity to store up to 300 deceased persons. It was linked to the main building by a series of marquee walkways, was completely undercover and surrounded by security fencing. Additional catering and office spaces were also constructed.

Pathologists, anthropologists, odontologists, police, and mortuary assistants responded from all around Australia, New Zealand and Indonesia. The mortuary facility and staff were divided into two areas: DVI (Disaster Victim Identification) and “normal operations.”

A high priority for the mortuary was to ensure all “normal” admissions of deceased persons (those cases which were not related to the bushfires) were handled concurrently and in a timely manner. The VIFM examines approximately 3,000 deceased persons per year and in 2005 a multi-slice CT scanner was installed. This scanner has become integral to the day to day operations of the VIFM and played a major role in the identification of the victims.

On admission, each bush fire victim was given both a unique DVI and a coroner’s case number. The case was CT scanned, examined by a pathology team, an anthropologist, an odontologist, and in some instances a fingerprint expert. Where possible a DNA sample was taken. All processes, samples, labels, and paperwork underwent a quality assurance check prior to the case completion. Regular audits were conducted. The majority of postmortem examinations were completed within twenty days of admission.

Occupational health and safety issues of the staff were paramount; this included correct manual handling, infection control, and psychological debriefings. During the operation it was found that some remains were contaminated with asbestos. Procedures were set in place to manage these cases individually and each was isolated to reduce the exposure to staff.

On May 1, 2009 the identifications of all missing persons was complete. Of the 164 missing persons, 163 were found, identified, and the remains returned to the families. Nine deceased persons died in hospital or related circumstances and did not undergo the formal DVI process.

This operation identified a number of significant challenges, in particular the management of multiple parts of human remains for one individual. A new procedure was developed to ensure all human remains, where possible, were reconciled with deceased persons prior to the release to the funeral director.

Finally, no mass disaster operation can function successfully without a close working relationship between police, mortuary, medical examiners, and coronial staff. This operation highlighted the value of cultivating this relationship during the “quiet” times to ensure efficient

activation of an emergency response, timely identifications, and ultimately some degree of closure for the victim’s families.

Mortuary, Disaster, Bush Fires

G64 A Uniform Protocol to Address the Rapidly Accumulating Unidentified Human Remains and Missing Persons in the United States — A Nation’s Silent Mass Disaster

Marzena H. Mulawka, MFS, Forensic Sciences Program, National University, 11255 North Torrey Pines Road, La Jolla, CA 92037-1011; Ismail M. Sebetan, MD, PhD, 12752 Via Nieve, San Diego, CA 92130; and Paul Stein, PhD, 25757 Bellemore Drive, Ramona, CA 92065*

After attending this presentation, attendees will understand the problems involved with the investigation of unidentified human remains (UHR). The strengths and limitations of current technologies and resources available for investigating UHR cases will be discussed as well as presenting for the first time, a uniform protocol and procedures for the identification of UHR.

The presentation of this protocol will impact the forensic science community by serving as a guideline as it can expedite and augment UHR identification efforts by presenting the resources available in an organized and consistent format. As a direct result, utilization of this protocol may help identify the tens of thousands of UHR that are currently being held within medical examiner/coroner’s (ME/C) offices throughout the United States. More importantly, families of these deceased individuals will no longer wonder what happened to their loved ones and struggle with the agony of possibly never having the ability of laying their loved ones to rest.

Statistical data from UHR cases at the San Diego County Medical Examiner’s Office (SDMEO) from 1997-2007 will impact the forensic science community by demonstrating the effectiveness of this new protocol.

No uniform protocol or procedure exists describing every avenue currently available to facilitate the identification of UHR. Therefore, many jurisdictions lack consistent guidelines for pursuing the identification of UHR and continue to be unaware of the most current resources available to aid in their investigations. This study was conducted to determine whether a uniform protocol could be developed to aid in streamlining the process of identification. Many avenues currently available to aid in the identification of UHR were examined and combined to create a comprehensive and universal procedure that can be followed by any agency or organization in the forensic science community tasked with the identification of unidentified persons.

During a brief time period from January 2007 to January 2008, when components of the uniform protocol were used for the investigation of specific UHR cases at the San Diego County Medical Examiner’s Office (SDMEO), there were seventeen “cold” UHR cases from the 1997-2007 time period that were identified. Furthermore, there were only four UHR cases recorded in 2007, a significant decrease from the average number of fourteen UHR cases per year. An obvious decline in the number of unidentified persons was yielded, which correlated to the utilization of components of the uniform protocol.

A uniform protocol as will be presented can be created to assist in the identification of current and “cold case” UHR and linking them to missing person cases, which can further assist law enforcement in any related criminal investigations.

Collaboration and organized, consistent protocols among local, state, and federal agencies tasked with the identification of missing and unidentified persons will expedite the collection and distribution of information crucial to these investigations. Thus, a consistency of

incoming information will be established, allowing the searching and correlating of case information and as a result, increasing the probability of UHR cases being linked to missing person cases. This will likely result saving millions of dollars and countless hours of time that could be used more efficiently by the agencies involved with the identification of UHR.

Specific resources and supporting data for the application of the uniform protocol in ME/C offices in the United States will be presented. It is recommended that ME/C offices and agencies tasked with the identification of UHR become familiar with the various UHR identification avenues available that the protocol will exhibit.

Unidentified Human Remains, Missing Persons, Investigation

G65 Request for Uniform Autopsy Protocols on Certain Drowning Victims

Gerald N. Nance, BA, National Center for Missing and Exploited Children (NCMEC), 699 Prince Street, Alexandria, VA 22314*

The attendees will learn indicators that may determine whether drowning victims may require additional forensic examination to assess whether the drowning is in fact a homicide staged to look like an accident. Attendees can anticipate implementing autopsy protocols that help identify the need to conduct examinations that assist law enforcement in investigating suspicious or inadequately corroborated deaths while proactively addressing potential threats to vulnerable populations of abuse/neglect.

This presentation will impact the forensic science community by providing key indicators to identify drowning cases of interest, improving their understanding of a certain class of victim (victims of unobserved and inadequately corroborated drowning) resulting in improved forensic evidence collection, enhancing the accuracy and utility of the autopsy on these victims, and increasing the ability for law enforcement to respond and investigate viable/scientifically-driven time sensitive leads.

Use of Indicators for Positive Impact: A plan of action to improve forensic evidence collection related to victims of unobserved or inadequately corroborated drowning will enhance the utility of the autopsy, and positively impact the medical examiner (M.E.)/forensic scientist community, law enforcement (L.E.) partners, victims' families and the safety of both children and adults. Oftentimes, the M.E./forensic scientist community is best situated to provide investigators tools to recognize a homicide staged to look like an accident; excluding natural, traumatic, and toxicological factors in the medical cause of death (COD) are critically important.

Preservation of Forensic Evidence: Frequently, forensic evidence indicating criminal conduct is destroyed or washed away in victims of unobserved or suspicious drowning. While the accurate assessment of autopsy findings requires thorough examination of circumstances preceding death and circumstances of recovery – without advance evidence of foul play, when victims are recovered from the water, the circumstances, manner of death (MOD), and water entry point often lack thorough examination. NCMEC request consistent initial drowning examinations to complement L.E. efforts nationwide – as timely information on MOD can lead L.E. to water entry point analysis and other investigative leads prior to the disappearance of critical evidence.

Methodology Changes: NCMEC request the AAFS support the establishment of uniform nationwide protocols for the examination of unobserved drowning victims and for victims recovered in the water under suspicious or inadequately corroborated circumstances. Treating these investigations as homicides from initiation is vital to judicious evidence recovery and adoption of certain examinations (including testing for sexual assault, subcutaneous bruising, predatory drugs, etc.)

under a defined set of circumstances can provide vital forensic clues regarding the MOD, and potential prevent serial or repeat murders.

Drowning, Protocols, Homicide

G66 MAPS: How a Statewide Pharmaceutical Database Improves Death Investigation

Shawn A. Silver, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909; Joyce L. deJong, DO, Sparrow Health Systems, Forensic Pathology, 1322 East Michigan Avenue, Suite 118, Lansing, MI 48909; and Philip R. Croft, MD, Michael A. Markey, MD, and Michelle P. Elieff, MD, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909*

After attending this presentation, the attendee will have a better understanding of the benefits of using a controlled substance pharmaceutical database such as the Michigan Automated Prescription System (MAPS) when obtaining a decedent's medical history. Attendees will be presented with several case studies illustrating how the MAPS system can provide missing information and potentially change the cause and/or manner of death.

This presentation will impact the forensic science community by raising awareness among all parties involved in death investigation, specifically medical examiners, by describing the Michigan Automated Prescription System (MAPS) and its use in aiding in the investigation of deaths reported to medical examiners.

Accurate patient medical history is essential to the success of every death investigation. However, gaps in patient histories and medical records can sometimes lead to incorrect interpretation of data and may compromise the opinion rendered by the medical examiner. Obtaining accurate information regarding a decedent is critical to a high quality investigation and the interpretation of postmortem toxicology. The Michigan Automated Prescription System allows the medical examiner to gather information regarding controlled substances prescribed to the decedent for months before the death.

MAPS grants physicians with a DEA number the ability to access pharmaceutical dispensing data statewide to determine all controlled substances dispensed to a particular patient. The MAPS requires pharmacists, veterinarians, and dispensing physicians to report electronically (or by mail) all controlled substances dispensed in Schedules 2-5. Michigan launched the service in its current form in January 2003, and any previously existing prescription, patient, and healthcare provider data were entered into the new system. With over 1.2 million prescriptions reported each month, the MAPS system was built for ease of use, fast report generation (average turnaround time for individual reports is less than ten minutes), and prescription trend watching.

In cases of suspected drug overdose due to a controlled substance with "positive" toxicology, the medical examiner makes an inquiry into the database using the name and date-of-birth of the decedent. The report generated may indicate no information is available for an individual with the particular information. More commonly, the report generates a list of the controlled substance(s) prescribed, the quantity dispensed, the date dispensed, the prescribing physician(s), and the dispensing pharmacy(s).

The use of information provided by MAPS led to the prospective review of seventeen deaths since February 2009. Of the seventeen deaths, the MAPS report in three deaths did not change the opinion or assist the medical examiner in the investigation, the report in ten confirmed or supported the medical examiner's opinion, and in four cases, a change of the cause and/or manner of death occurred based on information contained in the MAPS report.

Example cases will be presented in detail to demonstrate how the information available in a database of controlled substances dispensed to

patients contributes to the investigation of deaths of individuals with postmortem drug screens “positive” for prescription medications in which drug intoxication may have caused or contributed to the death.

Death investigators should be aware of this advantageous tool. With a better understanding of the patient’s history, investigators can paint a more accurate picture of the life of the decedent, which, in turn, gives the medical examiner better tools to properly evaluate the situation and return a more confident ruling regarding cause and manner of death.

Toxicology, Death Investigation, Drug Related Fatalities

G67 Death Investigation and Organ and Tissue Donation in Clark County, Nevada

Alane Olson, MD, Clark County Coroner’s Office, 1704 Pinto Lane, Las Vegas, NV 89106*

After attending this presentation, attendees will be acquainted with alternatives and compromises which have been adopted between a medicolegal death investigation agency and the local organ procurement organization in an effort to optimize medicolegal death investigations and organ and tissue procurement.

The presentation will impact the forensic science community by providing knowledge of some successful alternatives in meeting the needs of coroner/medical examiner offices and organ procurement organizations.

During its 2007 session, the Nevada Legislature considered model legislation to modify the Uniform Anatomical Gift Act. At the same time, the Clark County Office of the Coroner/Medical Examiner and the Nevada Donor Network initiated discussions aimed at tailoring the model legislation to better accommodate specific needs and existing relationships. As a result of these activities, the legislation finally enacted contains provisions which, among other things, allow the coroner’s office to refuse organ and tissue donation if it will interfere with the death investigation, attend the procurement if necessary, be reimbursed for attending the procurement, and obtain video and photographic documentation before, during, and after the procurement. In order to accommodate the anticipated need for photo documentation, the coroner’s office formed the Forensic Investigative Rapid Support Team (FIRST), which is composed of experienced autopsy technicians who are on-call and available to respond to hospitals in conjunction with the coroner investigator for the purpose of photographing prospective donors. When the coroner’s office is notified of a request for donation, on-call medical examiner is responsible for deciding if the procurement can take place, and the FIRST team is activated at his/her discretion. The coroner’s office and organ procurement organization consider this a reasonable compromise between optimizing recovery of organs and tissues, and the requirements for conducting thorough medicolegal death investigations.

Death Investigation, Organ Procurement, Legislation

G68 Fatal Sexual Violence Database for Postmortem Genital Examinations With Colposcopy

Sharon R. Crowley, MN, FCNS, 122 Emeline Avenue, Santa Cruz, CA 95060*

The goals of this presentation are to provide a systematic method of data collection and storage that will enable us to better understand the nature and appearance of the anogenital tissues at various postmortem intervals; to integrate a taxonomy that is consistent with conventional

terminology, e.g., terms used in forensic pathology and forensic odontology; and to study the reliability of previously-presented methodology for postmortem genital examinations, with colposcopy.

This presentation will impact the forensic science community by improving the diagnostic acumen of the forensic examiner and serve as a format for quality improvement; providing a framework for the evaluation of fatal sexual violence against women; and increasing the reliability and validity of both taxonomy and techniques (methodology) used to examine victims of fatal sexual violence.

This paper describes ongoing clinical research of postmortem genital anatomy and a methodology to capture data gleaned both from baseline studies and presenting cases of fatal sexual violence.

The nature of these crimes, coupled with a lack of a detailed history from the victim, predicates adoption of the most accurate methodology and technology available; these victims are not available for follow-up examinations.

A fatal sexual violence database provides a relational system in which to record, analyze, and compare data from both baseline studies of normal anogenital anatomy and cases of sexual homicide. While it is helpful for the forensic examiner to be cognizant of previous classification systems used to describe findings in living subjects (Fraser: WHO, 1999), a taxonomy germane to the postmortem arena should incorporate salient terms that will be consistent and universally applicable and acceptable within the forensic community (Crowley & Peterson: AAFS, 2004). Inclusion of these findings into a relational database will permit aggregate summaries of individual and population-based summaries.

Materials and Methods: Initial case documentation for the baseline clinical study conducted at the Donated Body Program of University of California Davis, Sacramento, is via the *Postmortem Genital Examination Case Worksheet*. A hardcopy of this form is completed in the morgue. It contains all data fields, with essential elements of the case, methods of examination, and summary of findings.

For these cases of normative controls, some fields in the database will not be populated; other variables are common to both sexual homicide and control groups. Because the strictest efforts are enacted by the Donated Body Program to protect identifying data and personal information of the donors, some information is simply not available, e.g., date of birth (only age is used), address, disposition of the body, time body found, position of the body, social history and lifestyle, gynecological history, clothing, and other personal items on the body at the time of death. Conversely, for cases of sexual violence, the aforementioned variables, plus date of birth, elements of the crime scene, restraints and bindings, body positioning, nongenital trauma, including bitemarks and other patterned injuries, genital trauma, and all biological and forensic specimens for the Sexual Assault Evidence Kit are germane to the case composite. Some techniques for examination would be relevant to medical-legal cases, but might not routinely be available for normative studies, e.g., Wood’s Lamp, alternate light source, or reflective light imaging.

Some variables common to both normative and sexual homicide cases include age and reproductive status, (pre-pubertal, reproductive age, peri-menopausal, and post-menopausal) and genital examination techniques (gross visualization, colposcopy, single lens reflex (SLR) camera photography, speculum and anoscopic examination, and the use of balloon-tipped swabs). Also, the same twelve anatomic sites are visualized, inspected, and photographed: *labia majora, peri-clitoral area, peri-urethral area, labia minora, hymen, vagina, cervix, perineum, fossa navicularis, posterior fourchette, anus, and rectum*.

Other common variables include the unique case identifier, date and time of the examination, interval from death to arrival in forensic science morgue (< 24 hrs., 24-48 hrs., 48-72 hrs., 72-96 hrs., ³ 5 days); general condition of body; race and ethnicity (per CDC definitions); cause of death, and contributory and/or concomitant medical and gynecological conditions, especially those presenting lesions.

Postmortem artifact, such as mucosal autolysis and skin slip that is visualized in the anogenital tissues is documented for each anatomic site where it is noted.

Initially, a spreadsheet was utilized for its capability to easily record, sort, and organize the various data elements. A relational database, e.g., ACCESS®, permits data to be divided into many subject fields and represented only once. Divided information can be resynthesized via common, related subject-based tables. This will remove data redundancy and help ensure accurate information. The rows and columns in the tables are expanded data collections of the postmortem examination worksheets for documentation of data during the course of the clinical examination. Data can eventually be exported into other data systems, e.g., SPSS®, for more advanced statistical analysis.

Discussion: In addition to the multiple variables present during any female genital examination, the postmortem arena superimposes a unique set of factors onto the scene. Many of these were not previously been studied or sufficiently documented in the literature. A fatal sexual violence database serves as an efficient repository of data accumulated during the Donated Body Program baseline study, in addition to any concomitant, presenting sexual homicide cases.

Missing data may also be significant e.g., the fact that a body of a Jane Doe found without any identifying information, e.g., driver's license, passport, could be a potential link to human trafficking (Crowley: AAFS, 2009). Records of actual fatal sexual violence cases will have many variables that are not germane to the baseline controls. Thus, a relational database is an ideal method to simplify and quantify data for interpretation, analysis, and linkage to other cases.

Storage and evaluation of data will help avoid ambiguity in the interpretation of findings for this target population. Analysis and interpretation of data will increase the diagnostic acumen of the forensic examiner. It will also facilitate effective and reliable communication within the forensic and legal community, via a more descriptive taxonomy. An effective database will allow eventual comparison of the genital findings in fatal sexual homicide victims to a control group of individuals who died of other causes, i.e., natural, accidental, suicide, and non-sexual homicide.

Finally, the ultimate goal of this research is to improve our understanding of what is normal, and what is not, for the anogenital anatomy during the postmortem interval. To this end, data gleaned from a fatal sexual violence database can be used to expand and enhance our knowledge. The forensic examiner is presented with the challenge to "capture" in hardcopy and electronic systems, a myriad of variables and conditions presented by each body in the morgue. Until recent years, a paucity of information existed on the appearance of the anogenital tissues during the postmortem interval. Comparisons to either living sexual assault victims or postmortem cases of non-sexual etiology were extremely difficult. Thus, it is paramount that the examiner always be cognizant of the need to perform these examinations with optimal levels of expertise and to permanently chronicle vital information. In this manner, our capacity and understanding of fatal sexual violence against women will continue to grow.

Fatal Sexual Violence, Colposcopy, Forensic Clinical Nurse Specialist

G69 Grant Solicitations: New Opportunities for Medical Examiners and Coroners – Tips on the Process

Marcella F. Fierro, MD*, Fierro Forensics, 8702 Berwickshire Drive, Henrico, VA 23229-7833

After attending this presentation, attendees will be able to avoid pitfalls in the process of preparing grant solicitations.

The availability of Federal grants for medical examiners and coroners has been limited. In contrast to academics, medical examiners

and coroners do not have much experience in preparing grant solicitations. With new funding available, this presentation will impact the forensic science community by demonstrating how medical examiners could benefit from some tips on pitfalls in the process.

Grant funding for medical examiners and coroners has previously been limited. New federal funding sources are now available with more expected in the future. Preparing a grant solicitation may appear to be a daunting task. This presentation will offer some simple tips to make a grant solicitation more appealing to reviewers and some pitfalls to avoid.

Grant Solicitations, Grant Pitfalls, Grant Tips

G70 Development of Standard Operating Procedures for Conducting Arthropod Succession Studies: Improving Postmortem Estimates Through Ecology

Jeffery K. Tomberlin, PhD*, Department of Entomology, TAMU 2475, College Station, TX 77843-2475; and Jason H. Byrd, PhD*, Maples Center for Forensic Medicine, University of Florida, 4800 Southwest 35th Drive, Gainesville, FL 32608

The goal of this presentation is to provide attendees with a better understanding of experimental design as it relates to arthropod-based decomposition studies.

This presentation will impact the forensic science community by demonstrating the development of standard operating procedures for conducting arthropod succession studies in the field.

The period of insect activity (PIA) encompasses the time from discovery of human remains to when the remains were actually colonized. Therefore, the PIA in most cases represents the minimum postmortem interval (minimum-PMI). The amount of the PMI encompassed by the PIA can vary depending on a number of variables such as wind, rain, temperature, or if arthropods are excluded from the remains due to a physical barrier (i.e. wrapping, enclosed in a car or home). Consequently, understanding the variability the actual time of colonization as it relates to the actual time of death is of great importance.

Arthropod succession studies are conducted for a number of reasons. The majority of these studies are done to determine the species composition for a given location during a particular time of year to provide data that can be used to determine the "postmortem interval" of a decedent discovered in the same vicinity of the study site, and to determine the variation in time of initial colonization of remains.

A review of the forensic entomology literature indicates that a standard operating procedure is needed to in order to glean as much information from these decomposition studies as possible. Such information could lead to a better understanding of the succession and decomposition variability in different geographic regions and greater explanation of variables delaying arthropod colonization patterns on human remains. Furthermore, developing consistent practices could lead to data sets that can be combined in meta-analyses.

The following variables are suggested for inclusion in a SOP for arthropod succession studies:

1. Actual time of death of the remains used in the study
2. Storage of remains prior to use (i.e., frozen)
3. Method used for euthanasia
4. Actual time of initial colonization
5. Identification of species initiating colonization
6. Environmental conditions at the time of colonization (temperature, rain, shade, etc)
7. GPS coordinates of study site

Forensic Entomology, Ecology, Period of Insect Activity

G71 Using Biolog EcoPlates™ as an Economical Approach to Determining Postmortem Body Dump Sites Through Microbial Community Level Physiological Profiling

M. Eric Benbow, PhD, University of Dayton, Department of Biology, 300 College Park, Dayton, OH 45469-2320; Jeffery K. Tomberlin, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475; Tawni L. Crippen, PhD, Southern Plains Agricultural Research Center, Agricultural Research Service, U.S. Department of Agriculture, College Station, TX 77845; Andrew Lewis, BS, University of Dayton, Department of Biology, 300 College Park, Dayton, OH 45469-2320; and Jennifer Pechal, MS, TAMU 2475, Texas A&M University, College Station, TX 77843-2475*

After attending this presentation attendees will have a better understanding of the role microbial communities play in the rate and ecological dynamics of decomposing remains, and how this information can be used to better understand the timing and postmortem placement of human remains in the environment. Attendees will learn how changes in microbial community level physiological profiles (MCLPPs), during community succession on a body and in the soil beneath, can be utilized to predict the location and duration of decomposing remains.

This novel approach will impact the forensic sciences community by providing a more in-depth understanding of the ecological principles governing microbial community succession. Its cost-effective framework makes it ideal for use in crime scene investigations. On a broader scope this technique will provide insight into the influence of the microbial composition and metabolic products on insect colonization of decomposing remains (i.e., forensic entomology), thus improving the science behind estimates of the period of insect activity (PIA), and hence, that of the postmortem interval (PMI).

Microbial communities are a substantial component of the decomposition ecology and processing of organic material, such as carrion and human remains. Studies in both aquatic and terrestrial systems have shown that microbial communities follow a pattern of succession by metabolizing and modifying resources in a way that makes them usable or undesirable to other organisms, such as insects. While there have been studies describing the succession and diversity of microbial communities involved in carrion decomposition, none have evaluated their potential use for determining the postmortem spatial and temporal placement of decomposing remains in the natural environment. Further, most forensic entomology studies of insect succession suggest that volatile metabolic by-products of this community cue initial blow fly attraction and colonization. Postmortem structural and functional changes in these microbial communities may thus affect the PIA on decomposing remains, having applied importance to estimates of the PMI.

One established and economical method for understanding changes in environmental microbial communities is the use of Biolog EcoPlates™. EcoPlates™ have 31 different carbon sources represented in triplicate on each plate, and were designed for describing entire microbial communities from environmental samples such as soil. The pattern, or signature, of carbon resource utilization by the microbial communities provides MCLPPs. The MCLPPs, calibrated with temperature and genomic sequencing, has the potential to provide ecological data that can predict how long a body has been decomposing, and for how long at a particular location (e.g., on soil).

The objectives of this study were to describe microbial community changes over time (i.e., succession), in a variety of environmental settings and throughout multiple seasons, using Biolog EcoPlates™ in conjunction with pyrosequencing of the microbial genome. MCLPPs from communities on decomposing remains and the soil beneath were

hypothesized to change as a function of succession, and identified stages of succession could be used to determine the stage of decomposition and the spatial and temporal positioning of remains on a rural forest floor. Further, we hypothesized that microbial successional dynamics (community structure rate and sequence of change) would impact initial species-specific blow fly oviposition and colonization. We predicted that MCLPPs could be matched and calibrated with genomic-based methods of describing microbial communities, providing a more economical approach for use in crime scene investigations.

For this study, microbial samples were taken from carrion (swine) ($N = 3-9$) and the soil underneath (treatment soil) and at two distances lateral (0.25 and 1.0 m) of each carcass (control soil). To understand microbial community structure differences on the carcass, swabs of the buccal, urogenital and shoulder skin were evaluated, and all samples were described using Biolog EcoPlates™. This study was done in two seasons and two geographic locations to understand variability and generality of these techniques. In one location, matched samples of each individual sample, or composite sample, were taken and evaluated using the Roche 454 FLX pyrosequencing platform. Each of the samples were analyzed using the bacterial tagged encoded FLX amplicon pyrosequencing (bTEFAP) method to identify patterns of organisms occurring on the decomposing tissue during the longitudinal study and calibrated to MCLPPs from the EcoPlates™.

Preliminary results found substantial change in microbial communities both on the carcass and in the soil beneath the carcass, with little change in the control soil communities over time. Variation of MCLPPs among body regions was minimal and could be combined to provide an average body MCLPP signature. During the decay stage of decomposition, MCLPPs were significantly different in soil beneath compared to soil lateral of the body; this supported the hypothesis that MCLPP have the potential to differentiate soil communities where decomposition has been occurring, and possibly predict the time since placement. Further, there was substantial MCLPP variation among interreplicate body communities, indicating different volatile signatures which could be important to initial blow fly attraction and oviposition location; creating “founder” conditions that could influence subsequent intra- and inter-specific competition, the duration of PIA and, thus, estimates of PMI. Calibration of MCLPPs with metagenomic sequencing is on-going. We will continue to evaluate these communities during multiple seasons and habitats, providing new data important for a better understanding of the ecology of decomposition, and its relevant application to forensic science.

Biolog EcoPlates™, Forensic Entomology, Microbial Communities

G72 Microbes Associated With Decomposing Remains Regulate Insect Colonization

Jeffery K. Tomberlin, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475; M. Eric Benbow, PhD*, University of Dayton, Department of Biology, 300 College Park, Dayton, OH 45469-2320; Tawni Crippen, PhD, 2881 F&B Road, College Station, TX 77843; Charity Owings, BS, 2475 TAMU, College Station, TX 77845; Francisco I. Ortiz, BS, 1818 South 2nd Street, Apartment 62, Waco, TX 76706; and Jill C. Ross, BS, 110 Hillview Avenue, Millersville, PA 17551*

The goal of this presentation is to give attendees a better understanding of the role microbes play in regulating colonization of decomposing remains by blow flies (Diptera: Calliphoridae).

This presentation will impact the forensic sciences community by providing a more in depth understanding of the ecological principles governing insect succession of human remains.

Explaining why insects delay their colonization of human remains in some instances while colonizing immediately in others is a fundamental question in forensic entomology. Two of the authors of this

presentation, Tomberlin and Benbow, along with others have developed and proposed a new framework for studying human decomposition. They point out that a majority of past research focuses on the post-colonization interval (post-CI) which extends backwards in time from the discovery of the insect infested remains to the point that the insects initially colonized the remains. The time of colonization estimation is viewed as the period of insect activity (PIA) and is often considered the minimum postmortem interval (minimum PMI). The time frame prior to colonization has been termed the pre-colonization interval (pre-CI). Speculations as to why insects delay colonization have been suggested and small advancements explaining this ecological unknown have been made. Known abiotic factors, such as temperature, wind, and rain play a role in regulating colonization of human remains. It is hypothesized that microbial populations associated with human remains represent a major biotic factor regulating insect colonization.

Human remains represent nutrient rich resources for many organisms ranging from microbes to vertebrate scavengers. Microbes were initially thought of only as nutrient recyclers. However, recently other hypotheses have been suggested. Some researchers speculated that microbes were resource competitors with other consumers, including insects. Microbes may alter food resources and produce toxins that affect the “appeal” of the resources, and themselves, to other consumers. It is hypothesized that volatiles emitted by microbes associated with carrion, regulate the attraction to and diversity of colonization of the remains by insects. It is further hypothesized that volatiles emitted by microbes associated with and physiological by-products produced by blow fly larvae feeding on the remains influence the attraction and colonization of the resource by future blow fly species. It has been demonstrated that many saprophagous insects feed directly on microbes associated with decomposing material as part of their diet. In addition, microbes can have a mutualistic relationship with these arthropods. It is hypothesized that specific bacterial species which survive digestion and pupation with one fly species, may not with another fly species. Therefore, bacterial proliferation and dispersal is mitigated by colonization patterns of fly species. Such an association could, however, prove detrimental to both microbe and associated fly if the volatiles emitted also attract predators. Basically, it would be a two-way ecological chess match where the pawns are the insects and the players are the associated microbes. But, these roles can be reversed depending on those involved. This model examines if the volatiles emitted by the native species, *Cochliomyia macellaria*, larvae (the prey) and associated bacteria attract the introduced predatory blow fly, *Chrysomya rufifacies*.

A series of laboratory experiments were conducted examining the interactions between microbes associated with carrion (beef liver) and the attraction of *C. rufifacies* and *C. macellaria* adults. Furthermore, two field experiments were conducted examining the interaction of microbes on carrion with the attraction of blow flies as well as the role of excretions/secretions of blow flies on the attraction of Diptera. These results will be provided in this presentation and will hopefully shed light on biotic factors governing the time span of the pre-CI.

Forensic Entomology, Microbes, Trophic Interactions

G73 Lower Temperature Threshold for Black Soldier Fly (Diptera: Stratiomyidae) Egg and Adult Eclosion

*Leslie A. Holmes, BS**, and *Sherah L. Van Laerhoven, PhD, University of Windsor, Department of Biology, 401 Sunset Avenue, Room 119 Bio, Windsor, ON N9B 3P4, CANADA; and Jeffery K. Tomberlin, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475*

After attending this presentation, attendees will learn the lower developmental threshold dynamics of temperature that either facilitate or impede black soldier fly egg and adult eclosion.

* Presenting Author

This presentation will impact the forensic science community by providing valuable insight into variation in developmental thresholds with respect to insect development and its application in calculating the minimum time to colonization.

Black soldier flies, *Hermetia illucens* (L.) (Diptera: Stratiomyidae) are of particular interest for their applications in forensic entomology. Initially thought to be a late colonizer (20-30 d postmortem) of carrion, recent evidence indicates they will colonize a corpse within the first week after death. Black soldier flies are native to warmer environments, including North and South America, and therefore studies on black soldier fly development have primarily focused on determining the higher temperature thresholds and optimal temperatures for development. This study determined the lower temperature thresholds for egg and adult eclosion. Preliminary studies indicate temperatures facilitating successful egg eclosion do not necessarily result in larval development and adult eclosion. For that reason, the black soldier fly has two different lower developmental thresholds; one supporting egg hatch, and one supporting egg hatch and larval development to the adult stage. In relation to the postmortem interval, not differentiating these two temperature thresholds could result in errors in calculating larval age and retrospectively, time of colonization. Black soldier fly eggs were collected in corrugated cardboard clutches from an established colony outdoors, at the Texas A&M University's F.L.I.E.S. facility in College Station, Texas and placed in three growth chambers, each maintaining a 70% RH, 14:10 [L:D] photoperiod respectively. Each growth chamber was set at 12°C, 15°C or 18°C. Egg clutches were randomly assigned to each treatment. Percent hatch and survivorship to the adult stage were recorded. Larvae were provided bovine liver *ad libitum* and allowed to develop without disturbance. Egg eclosion, length of development, and adult eclosion was recorded daily.

Black Soldier Fly, Lower Developmental Threshold, Forensic Entomology

G74 Colonization Behavior of Forensically Important Blow Fly Species: Implications for Postmortem Interval Estimations

Jennifer Y. Rosati, BSc, and Sherah L. Van Laerhoven, PhD, University of Windsor, Department of Biology, 401 Sunset Avenue, Room 119 Bio, Windsor, ON N9B 3P4, CANADA*

After attending this presentation, attendees will have a better understanding of ecological interactions between various forensically important blow fly species and how this relates to PMI estimation.

This presentation will impact the forensic community by providing insight into the importance of understanding species interactions and individual colonization events and how these behaviors can impact one's estimation of the MTC. This presentation will highlight the importance of rigorous scientific testing in order to validate current assumptions in the field with respect to delays in colonization prior to their incorporation into estimations of colonization events and, ultimately, PMI estimations.

Blow fly species are known to be among the primary colonizers of remains and as a result, blow fly species composition, colonization events and successional patterns are important aspects to consider in the determination of the postmortem interval (PMI) and minimum time of colonization (MTC). Previous research and case studies have indicated that certain blow fly species may experience a delay in colonization (i.e., *Phormia regina* (Meigen) and *Chrysomya rufifacies* (Macquart)). These findings have led to a debate within the field of forensic entomology as to whether or not these delays should or should not be incorporated into MTC and PMI estimations.

It was hypothesized that the colonization behaviour of blow flies (i.e., *P. regina* and *C. rufifacies*) would be altered based upon the presence or absence of an additional blow fly species (i.e. *Lucilia sericata* (Meigen)). The colonization behaviour of three forensically

important blow fly species were examined: *L. sericata*, *P. regina* and *C. rufifacies*. Specifically, gravid adult females of *L. sericata* and *P. regina* and *L. sericata* and *C. rufifacies* were allowed to colonize fetal pig carcasses, *Sus scrofa* (Linnaeus), however, their arrival order varied according to one of five different treatment conditions. Species were allowed to colonize either on their own, in the presence of an additional species, and prior to and subsequent to an additional species. colonization events and behaviour were recorded from the time of arrival to forty hours postmortem. Upon removal of the carcasses, egg masses were examined and depth measurements were recorded. The eggs masses were then photographed and volumetric measurements were obtained using the Image J software program. A linear regression was carried out (using SPSS) with volume (mm³) versus total number of eggs in known egg masses in order to predict the number of eggs based upon the volumetric measurements recorded.

It was determined that the colonization behaviour varied with respect to time of first colonization, location of colonization, and total number of eggs laid on an individual species basis. In particular, *P. regina* experienced a significant decrease in time to first colonization and laid more eggs in the presence of *L. sericata*, which indicates that the presence of an additional blow fly species could act to facilitate the colonization of *P. regina*. Thus, the colonization behavior of blow flies should be examined on an individual basis. Furthermore, ecological interactions between other blow fly species could play an important role in altering a species colonization behavior, specifically with respect to the time and location of colonization, as well as the amount of eggs laid.

Blow Fly, Postmortem Interval, Minimum Time of Colonization

G75 Petechiae in Hanging: A Retrospective Study of Contributing Variables

Renaud Clement, MD*, 1 Rue Gaston Veil, Nantes, 44093, FRANCE, and Anny Sauvageau, MD, Office of the Chief Medical Examiner, 7007 116 Street, Edmonton, AB T6H 5R8, CANADA

After attending this presentation, attendees will better understand the variables contributing to the development of petechiae in hanging.

This presentation will impact the forensic science community by providing evidence-based data on the contributing variables to the development of petechiae in hanging.

Introduction: It is often stated in the literature that petechiae are more frequently observed in cases of hanging where part of the body is supporting the victim's weight, i.e., cases of incomplete hanging, because it is believed that the jugular veins become occluded while the deeper and less compressible carotid and vertebral arteries remain patent. The present study is intended to evaluate the relationship between petechiae and the type of hanging (complete vs. incomplete) as well as several other variables: victim's age, height, weight, the body mass index (BMI), type of ligature and cardiopulmonary resuscitation.

Material and Methods: A total of 309 suicidal hanging deaths were autopsied in the province of Quebec (Canada) over an 8.5-year period. Of these, one case was excluded since it was not a typical hanging but a hanging from height, with dislocation of neck vertebrae (hanging after jumping from a bridge). Additionally, fifty cases were excluded from the analysis because postmortem changes interfered with the evaluation of petechiae (significant decomposition, skeletal and charred bodies). Finally, fifty two cases were also excluded because the type of hanging was not specified in the autopsy files, thus making their analysis not applicable to the present study. Overall, a total of 206 cases were analyzed for the presence of conjunctival, palpebral, gingival and facial petechiae. For each case, the following information was also compiled: gender and age, height and weight, the type of hanging (complete or incomplete), the type of ligature used (rope, wire, clothes, sheet or lace) and the presence of alcohol or drugs. A note was also

added about whether or not the victim had received cardiopulmonary resuscitative maneuvers.

Results: *Incidence of petechiae in relation to cardiopulmonary resuscitation maneuvers:* Of the 206 hanging victims, thirty-six underwent attempts at cardiopulmonary resuscitation (CPR). No significant difference existed between the two groups ($\chi^2 = .34$, df = 1, N=206, p=.56).

Incidence of petechiae in relation to the type of hanging: Of the 170 victims without reanimation manoeuvres, 128 died of an incomplete hanging and 42 of complete suspension. The incidence of petechiae in incomplete hanging (50%) was significantly higher than in complete hanging (29%) ($\chi^2 = 5.87$, df = 1, N=170, p=.02). The age and sex distribution was similar between both groups.

Incidence of petechiae in relation to the type of ligature: The type of ligature was known in all 170 cases of hanging victims without reanimation manoeuvres: 72 ropes, 28 electrical cords, 27 pieces of clothing, 30 bed sheets, and 13 shoe strings. These types of ligatures were regrouped into two broad categories: narrow and wide. The incidence of petechiae was similar ($\chi^2 = .66$, df = 1, N=170, p=.42) for wide and narrow ligatures (47% and 40% respectively).

Incidence of petechiae in relation to age: The incidence of petechiae decreased slightly with age, from 61% in teens to 40% in adults over forty years of age. However, the differences between the three age groups was not statistically significant ($\chi^2 = 2.41$, df = 2, N=170, p=.30), and neither was the statistical comparison of victims older to younger than 40-years-old ($\chi^2 = .66$, df = 1, N=170, p=.42).

Incidence of petechiae in relation to the BMI: In the studied population, only two hangings occurred in underweight individuals. For the remaining 204 there was no statistically significant difference between the incidence of petechiae in normal weight individuals and overweight individuals ($\chi^2 = .13$, df = 1, N=204, p=.71). The comparison between the three groups (normal weight, overweight and obese) was not statistically significant either ($\chi^2 = .82$, df = 2, N=204, p=.67).

Incidence of petechiae in relation to height: The incidence of petechiae varied inversely with the height of the victims: 77% in victims of less than 1.60 m, 44% in victims between 1.60 and 1.79 m and 35% in victims of 1.80 m or more ($\chi^2 = 5.36$, df = 2, N=204, p=.07). This is not merely attributable to a difference in the proportion of complete vs. incomplete hangings in the different height groups. Among incomplete hanging victims, a similar inverse relationship with height was noted ($\chi^2 = 4.64$, df = 2, N=155, p=.10).

Asphyxia, Hanging, Petechiae

G76 Fractures of the Neck Structures in Suicidal Hangings: A Retrospective Study on Contributing Variables

Anny Sauvageau, MD*, Office of the Chief Medical Examiner, 7007, 116 Street, Edmonton, AB T6H 5R8, CANADA; and Renaud Clement, MD, 1 Rue Gaston Veil, Nantes, 44093, FRANCE

After attending this presentation, attendees will better understand the variables contributing to the development of neck structures fractures in hanging.

This presentation will impact the forensic science community by contributing to a better understanding of important factors to the development of fractures of the thyroid cartilage and hyoid bone in hangings.

Introduction: Fractures of the neck structures figure among the classic autopsy findings in suicidal hangings. Several factors may play a role in the development of fractures of the neck structures in hanging. It has been repetitively demonstrated that the incidence of fractures increases with age. The role of gender is less clear: some authors found

G77 Precision of Autopsy Body Length Measurements

William Oliver, MD, MPA*, Leone Lisa, MA, and Colleen Tetterton, PA, Brody School of Medicine at East Carolina University, Division of Forensic Pathology, Department of Pathology and Laboratory Medicine, 7S-10 Brody Medical Sciences Building, Greenville, NC 27858

After attending this session, attendees will learn the precision of body length measurements at autopsy and its importance in medicolegal death investigation. In addition they will learn how this compares to height determination precision in antemortem clinical practice.

This presentation will impact the forensic science community by introducing quantitative measures of error in an important determination made at autopsy.

In many cases, the height of a decedent is important in the investigation of his or her death. For instance, prosecutors may wish to posit hypotheticals and ask if it is physically possible for a person of a given height to commit suicide with a particular weapon, such as a long gun. In these cases, autopsy body length measurements are sometimes used as ground truth for antemortem height. This study attempts to provide a bounds on the precision of autopsy body length measurements in one facility.

Methods/Data collection: For a period of approximately two and one-half months (83 days) as cases were sequentially brought into the morgue facility, all staff members on duty and available in the autopsy area were asked to independently measure the length of each body. Measurement was done with a standard metal tape measure (Metric/English, 8m/26'). This particular facility is an academic facility with permanent staff members, student workers, resident physicians in training, and attending physicians. In most cases, only one or two staff members were available, but for those cases in which three or more were available, the body length measures were recorded. Each observer was blinded to the measurement results of other observers. The measurement by the assistant assigned to the case was recorded as the nominal "correct" body length measurement for the autopsy report. The bodies were weighed on a calibrated scale, and body mass index (BMI) was calculated using the official length recorded in the autopsy report. Visual evaluation was done to estimate the degree of body deformation due to rigor or pugilistic pose in charred remains, and recorded on a subjective scale of one (straight) to five (full fetal or pugilistic pose) by the second author, blinded to the measurements.

Study Population: A total of 74 cases had three or more measurements. Of these, 73 were adult cases. A total of eight observers were involved, including two certified Pathology Assistants, two full-time staff members, two student workers and two resident physicians. Twenty-six cases had three measurements, 33 cases had four measurements, 12 cases had five measurements, two cases had six measurements, and one case had seven measurements.

Results: The average range of measurements was 1.86 inches (4.72 cm) with a standard deviation of 1.2 inches (2.99 cm). The range varied from 0 to 5.5 inches (0-13.97 cm, Figure 1). No individual observer displayed significant systematic error (Table 1). The average range did not vary significantly with the number of measurements(Chi-square p=0.54), body length (Pearson's r = 0.08), or body deformation (Spearman's r= 0.15, two-tailed p= 0.2). There was a moderate correlation with BMI (Pearson's r = 0.27, two-tailed p=0.019).

Discussion: Autopsy body length measurements are prone to numerous errors. There are issues of posture, with some bodies being straight and other being held in flexion by rigor, heat effect, or other constraints. Obese bodies may have an artificially increased body length if the tape is laid over the panniculus. Charred and fragmented bodies may not have all body parts. The position of the feet may cause the heel to rise or fall. Hair may cause observers to incorrectly estimate the exact

a male predominance of fractures, whereas other observed a female predominance or no significant difference between genders. Similarly, studies on the role of several other factors have shown opposite results for the type of hanging (incomplete or complete suspension), the type of ligature, the location of the knot, the highest suspension point and the suspension time. However, most of these studies evaluated these factors independently of the age of the victims. Considering that age is probably the most important factor in the development of neck structures fractures, all other contributing factors should be studied in relation to age. The goal of the study is to evaluate the role of contributing factors to the development of neck structures fractures, taking age categories into account.

Material and Methods: Overall, a total of 206 suicidal hangings were analyzed for the presence and localization of fracture of the neck structures. For each case, the following information was also compiled: gender and age, height and weight, type of hanging (complete or incomplete), type of ligature used (rope, wire, clothes, sheet or lace) and localization of the knot (anterior, right, left or posterior).

Results: *Incidence of fracture in relation to age and gender:* The incidence of neck structures fractures increased with age ($\chi^2=21.851$; p=.000). Victims of less than forty years of age presented an incidence of fracture of 18% whereas this incidence increased significantly to 49% in victims of forty years or more. The average age of victims without fractures of the neck structures was 31.7 compared to 42.6 for victims presenting fractures (t=5.66; p<.001; D=.88). As for gender, the incidence rate of fracture is significantly higher in male victims (31.4%) compared to female ones (11.8%) ($\chi^2=5.408$; p=.020).

Incidence of fracture in relation to the height, weight and BMI: The incidence of fractures varied significantly with the height (t=2.19; p=.031; D=.33), weight (t=4.38; p<.001; D=.89) and BMI (t=3.84; p<.001; D=.60) (Table 3). The average height of hanging victims with fractures of the neck structures was of 1.74 m compared to 1.71 m for victims without fractures. As for the average weight and BMI of victims with fractures, it was of 78.2 kg and 25.6 respectively, compared to 68.6 kg and 23.2 in victims without fractures.

Incidence of fracture in relation to the type of hanging and the type of ligature: The incidence of fractures did not vary significantly with the type of hanging ($\chi^2=.05$; p=.828; Phi=.015) and the type of ligature ($\chi^2=3.12$; p=.077; Phi=.077). However, when taking the age of the victims into account, a different picture was revealed: in individuals aged forty years or more, victims with complete suspension of the body presented with a significantly higher incidence of petechiae (63.2%) compared to victims with incomplete suspension (31.0%) ($\chi^2=6.79$; p=.009; Phi=.318). This difference was not present in individuals of less than forty years of age ($\chi^2=.52$; p=.471; Phi=.061). As for the type of ligature, no significant difference was found in individuals of less than forty years of age ($\chi^2=.11$; p=.737; Phi=.028) as well as in older victims ($\chi^2=.01$; p=.936; Phi=.010)

Incidence of fracture in relation to the localisation of the knot: The incidence of fractures did not vary significantly with the localisation of the knot ($\chi^2=4.11$; p=.250; Phi=.141). The side lateralization of fracture in relation to the position of the knot will also be presented.

Conclusion: Apart from age, several other factors seem to play an important role in the development of fractures of the neck structures: height, weight and BMI. The type of hanging is also an important factor in victims of more than forty years of age.

Hanging, Thyroid Cartilage, Fracture

position of the top of the head. Different observers may measure with different care.

This study attempted to evaluate the precision of body length measurement within one facility. This was specifically not an attempt to estimate accuracy, not merely because the nominal antemortem height was generally not known, but also because antemortem height measurements are themselves variable. The concept of "ground truth" in body length measurements may be inappropriate.

Studies on antemortem height measurement show significant variation for measurements of a single individual. Antemortem height can vary over time. It can vary significantly with posture. Further, antemortem height measurements are themselves fraught with error. Studies of the measurement of height routinely show that observer variation provides enough error to make them uninterpretable for some purposes.

Precision, Error, Autopsy

G78 "Goodness Gracious Great Balls of Fire": Genital Thermal Injuries From Airbag Exhaust

William S. Smock, MD, University of Louisville Hospital, Department of Emergency Medicine, 530 South Jackson Street, Louisville, KY 40202*

After attending this presentation, attendees will understand the potential for thermal injuries from airbag exhaust.

This presentation will impact the forensic community by expanding the investigators knowledge of airbag induced injuries, in particular second and third degree burns.

Burns, thermal and chemical, from the hot gases and chemical by-products of deploying airbags account for approximately 7-8% of all airbag-induced injuries. Three mechanisms for thermal injuries have been described: (1) the direct skin exposure to hot gases expelled from the airbag vents; (2) the melting of fibers or burning of clothing from exposure to the hot gases; and, (3) direct contact with a hot airbag.

A 25-year-old restrained driver was transferred to an urban trauma center from a suburban emergency department for evaluation of thermal injuries to his penis, scrotum, thighs and arm. The patient reported that he was involved in a single-vehicle collision on his way work after a deer ran into his path. He stated he turned his steering wheel 180-degrees to the right when the front of his vehicle impacted the rear of a parked vehicle at approximately 20 mph. Moments later he noticed two areas of flames coming from his pants, one in the area of his upper left thigh and the other over his groin. The driver quickly removed his seat belt and attempted to smother the flames with his hands and arms. He exited the driver's door, dropped to the ground and rolled to smother the remaining flames. He stated he was not wearing any underwear.

Examination of the patient's skin revealed first and second degree thermal injuries to the following areas: left forearm, left thigh, left inguinal area, scrotum and penis. Blisters were noted on the glans, scrotum and medial aspect of the left thigh. Arm and pubic hair were also burned to the skin level in some areas. The patient's pants demonstrated two areas with melted and charred fibers over the groin and left anterior thigh.

The vehicle, a 2009 Dodge Charger was examined within hours of the event. The airbag vents are located at the 1 and 11 o'clock position when the steering wheel is in a straight ahead position and in the 5 and 7 o'clock position when the wheel is turned 180-degrees. Examination of the airbag vents revealed melted nylon airbag fibers around both vent openings and charred material, presumed to be fibers from the pants, around one vent.

Hot gas is generated within an airbag from an exothermic reaction that occurs when sensors within the vehicle are activated during a sudden deceleration. The gas, principally nitrogen that is a byproduct from the

rapid burning of sodium azide, is exhausted from inside the airbag through vent holes in the airbag. The temperature of the exhaust gases has been measured to be between 200 and 500 °C.

The 180-degree rotation of the steering wheel at the time of impact resulted in the vents and the associated hot exhaust gases being discharged directly toward the driver's pants in the area of his groin and left thigh. The synthetic composition of the pants, 75% polyester and 25% rayon, melted and produced a flame based upon the patient's history and confirmed from inspection of the clothing. The melting point of Rayon is 120 to 170 °C and 225 °C for polyester.

The extremely hot gases associated with airbag deployment pose a risk of burns to vehicle occupants. Thermal injuries to the male genitals and inguinal area from the exhaust gases have not been reported in the medical literature. Consideration of modifying the direction of hot vented gases from the airbag by the automotive industry and airbag manufacturers maybe warranted in light of the severity of injuries sustained in this patient.

Airbag, Thermal Injury, Airbag Exhaust

G79 Histologic Diagnosis of Amniotic Fluid Embolism: Providing Context Through Immunohistochemistry

Philip R. Croft, MD, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909-7980; Michael A. Markey, MD, Sparrow Forensic Services, Sparrow Hospital, 1215 East Michigan Avenue, Lansing, MI 48912; Joyce L. deJong, DO, Sparrow Health Systems, Forensic Pathology, 1322 East Michigan Avenue, Suite 118, Lansing, MI 48909; and Michelle P. Elieff, MD, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909*

After attending this presentation, attendees will understand that a substantial amount of cytokeratin-positive cellular material is consistently present in the vasculature of lung sections obtained at autopsy from non-gravid women, complicating the utility of keratin immunohistochemistry in the evaluation of cases of suspected amniotic fluid embolism. This cytokeratin-positive material is likely an autopsy artifact, as corroborated by the presence of TTF-1-positive cells within vascular spaces in the same lung sections. The caliber of vessel in which cytokeratin-positive material is found may help to identify true circulating keratin.

This presentation will impact the forensic science community by using immunohistochemistry to characterize the intravascular cellular material in postmortem lung specimens from non-gravid women in order to provide the appropriate context in which to assess the same immunohistochemical stains when they are employed in the evaluation of suspected cases of amniotic fluid embolism.

Amniotic fluid embolism (AFE) is among the most common natural causes of maternal death in the United States, yet AFE remains an enigmatic condition that is difficult to diagnose, the identification or confirmation of which often rests on the autopsy pathologist. The microscopic examination of multiple lung sections is essential when evaluating for AFE, with the identification of squamous cells, keratin debris, mucus, and other presumably fetal cellular debris, usually in the lungs, widely considered diagnostic in the appropriate clinical setting. Identifying these cellular elements, in particular circulating squamous cells or keratin, can be challenging despite extensive tissue sampling and thorough microscopic examination.

The difficulty in finding circulating keratinocytes is compounded by other cellular debris that may mimic their appearance, such as sloughed endothelial cells and pneumocytes. Immunohistochemistry, in particular cytokeratin AE1/AE3, has been advocated as a means to identify circulating keratinocytes. However, cytokeratin immunostains are not specific for fetal keratinocytes, and the immunohistochemical

profile of intra-vascular cellular material in autopsy lung specimens from women who are not pregnant has not been formally described. To this end, three immunohistochemical stains—cytokeratin AE1/AE3, Thyroid Transcription Factor-1 (TTF-1) and CD34—were used to characterize the intravascular cellular debris in postmortem lung sections from non-gravid women in order to provide the appropriate context in which to interpret such stains in the evaluation of suspected cases of AFE.

Fourteen cases of women who died without penetrating injuries or identifiable peri-mortem needle punctures, who were not pregnant, and who were not decomposed at the time of autopsy were selected. Lung tissue was fixed in formalin and embedded in paraffin as part of the routine histologic sampling of each autopsy. Hematoxylin and eosin (H&E), TTF-1, cytokeratin AE1/AE3 and CD34 stains were performed on sections of each block of lung tissue. For purpose of comparison, H&E stains and the same three immunohistochemical stains were also performed on blocks of lung tissue from a known case of unequivocal amniotic fluid embolism and a case of a deceased neonate with abundant intra-alveolar amniotic fluid. The H&E sections were evaluated for the presence of intra-vascular material consistent with or resembling squamous cells or keratin debris. The immunostains were evaluated for the presence or absence of positive-staining intra-vascular cellular material.

All fourteen lung sections from non-gravid women contained elongate cellular material and debris by H&E staining, most of which appeared to be sloughed endothelial cells and only superficially resembled epidermal squamous cells and keratin when compared to the known AFE case and the neonatal lung. Rarely, fragments of bronchial epithelium were located in intra-vascular spaces. In both the known AFE and the neonatal lung sections, keratin characterized by distinct basophilic, “glassy” flakes of material, often in aggregates, was easily identifiable by H&E staining. No such material was identified in the lungs of the non-gravid women. All fourteen lung sections also contained intra-vascular keratin-positive cellular material, usually in great abundance. This material consisted of round cells and debris, some of which was reminiscent of keratin. However, the keratin-positive material in these lung sections was present only in larger caliber vascular spaces and not in capillaries and arterioles. By contrast, the keratin-positive material in the known AFE case was present in both large and small caliber vessels, including capillaries and arterioles. Eleven of fourteen cases had TTF-1 positive cellular material in intra-vascular spaces, although always a small amount and consisting only of round cells. All fourteen cases had abundant intra-vascular CD-34 positive material, consisting of elongate cells and debris.

Most intra-vascular cellular material that even superficially resembled circulating squamous cells and keratin in the lung sections from fourteen non-gravid women was sloughed endothelium as confirmed by CD34 immunostaining. The cytokeratin-positive intra-vascular cellular material in the lungs of the non-gravid women most likely represented respiratory elements trans-located into the vascular spaces as an autopsy artifact, an etiology corroborated by the presence of TTF-1-positive cells within vascular spaces. The consistent abundance of intra-vascular cytokeratin-positive cellular material emphasizes the need for caution interpreting cytokeratin stains when evaluating autopsy lung sections for amniotic fluid emboli. The caliber of vessel which contains cytokeratin-positive material may help to differentiate true circulating keratin from an autopsy artifact, as only the known AFE case had keratin in capillaries and arterioles.

Amniotic Fluid, Immunohistochemistry, Maternal Mortality

G80 Utility of Large Bowel Examination in Medicolegal Death Investigation

Michael R. Condron, MD, and Mary L. Anzalone, MD, Harris County Medical Examiner, 1885 Old Spanish Trail, Houston, Texas 77054; and Dwayne A. Wolf, MD, PhD, Harris County Medical Examiner, JAJ Forensic Center, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will understand the contribution to medicolegal death investigation of examination of the lumen and mucosal surface of large bowels.

This presentation will impact the forensic science community by showing what additional information can be contributed to medicolegal autopsies by examination of the large bowel.

The mucosal surface of the large intestine is not always directly examined in cases where findings in the bowels are not suspected to be a cause or contributing cause of death. Some pathologists opt to examine the serosal surfaces and palpate the colon while others routinely open all colons during the course of the autopsy. Numerous disease processes such as ischemia, ulceration, colitis or diverticulitis, which may have contributed to death, may be overlooked if the colon is not thoroughly examined. Additionally, the autopsy provides an opportunity for surveillance for colon carcinoma or precancerous lesions. Routine thorough examination of the colon can potentially provide valuable information to the family members of the decedent if a hereditary natural disease is found, and can also provide general epidemiological data on the prevalence of early precancerous lesions in the population younger than the age currently recommended for screening by colonoscopy. To study the utility of opening colons in medicolegal autopsies, we present a series of over 200 colons examined from sets of sequential autopsies performed at our institution. Colons were opened, rinsed of their contents, and examined along their entire length internally and externally. Correlation of findings with decedent's age, sex, and cause and manner of death are presented. The most common pathological finding is diverticulosis, and after examination of over 100 colons in this ongoing study, no carcinomas have been identified.

Colon, Examination, Large Bowel

G81 Detection of KCNQ1 Genetic Variations by High Resolution Melting Analysis for the Diagnosis of Channelopathies in Postmortem Investigations

Audrey Farrugia, MD, Christine Keyser, PhD, and Bertrand Ludes, MD, PhD, Institut de Médecine Légale, 11 rue Humann, Strasbourg Cedex, 67085, FRANCE*

After attending this presentation, attendees will be informed of the great interest of the high resolution melting method used for genetic variations screening in cardiac ion channel genes in postmortem investigations.

This presentation will impact the forensic science community by demonstrating the application of a recently developed molecular technique, high resolution melting (HRM), for the detection of genetic variant on genes implicated in channelopathies in postmortem investigations.

In developed countries, sudden cardiac death (SCD) is one of the most common causes of death. One of the largest epidemiological studies of unexpected deaths in young people showed that more than half of the deaths were of cardiac origin and in 29% no recognizable cause was identified at postmortem (Tester et al., 2007).¹

Potentially lethal ion channel disorders (channelopathies) such as long QT syndromes, catecholaminergic polymorphic ventricular

tachycardia (CPTV) and the Brugada Syndrome may be responsible for a portion of such cases of sudden death in young persons.

Postmortem genetic testing for sequence variations in cardiac ion channel genes has become an important tool for elucidating the cause of sudden cardiac death (Ackerman et al, 2001; Kauferstein et al., 2009).² Formalin-fixed and paraffin-embedded tissue (FF-PET) as well as frozen tissue could be used as source of DNA in postmortem investigations. If frozen tissue is undoubtedly the greatest source of intact DNA, in some cases FF-PET is the unique source of genetic material.

In this context, the purpose of our study was first to validate a successful DNA extraction and purification method corresponding to the association of phenol-chloroform extraction and silica-based purification protocols. This protocol was previously reported in ancient DNA studies on archaeological bones but had not been used for DNA extraction from FF-PET. The second step consisted of genetic investigations on frozen and FF-PE tissues in each case of sudden death involving adult younger than thirty-five years with no significant morphological anomalies particularly with no cardiac structural disease and with negatives toxicological investigations. The samples studied were collected from autopsy cases performed at the Institute of legal Medicine from Strasbourg (France). The autopsy practice and modalities of sampling were realized according to the recommendations of the "European Cardiovascular pathology Association" (Basso et al. 2008).³ The KCNQ1 gene was chosen in a first approach.

Since, according to the literature, mutations on this gene are randomly distributed, genetic screening was performed for each studied case, with the HRM method on the LightCycler 480 (Roche). The HRM is a technique that can detect sequence changes in amplicon through monitoring of the fluorescence of a double DNA binding dye which dissociates from DNA as it denatures with increasing temperature. If sequence changes are present within the amplicon, they cause a difference in the melting profile compared with wild-type. The principle of this methodology will be more developed in the presentation.

The comparison of results obtained with frozen and FF-PE samples showed that the two types of samples have a great interest in the genetic investigations. The advantages and limits of each type of samples will be discussed in details. From this study, it appeared that the HRM is a rapid, cost-effective and specific method allowing identification of KCNQ1 genetic variations and avoids systematic sequencing of the entire coding region of gene of interest in postmortem investigation of sudden cardiac death.

High Resolution Melting, KCNQ1, Formalin-Fixed and Paraffin-Embedded Tissue

G82 Cardioinhibitory Reflex Cardiac Arrest – Myth or Reality?: A Systematic Review From Cases

Bettina Schrag*, Rue du Bugnon 21, Lausanne, SWITZERLAND

After attending this presentation, attendees will be presented a systematic review of literature concerning reported cases of death by

cardioinhibitory reflex cardiac arrest due to short neck trauma and a proposal on how to diagnose it.

This presentation will impact the forensic science community by presenting constructive evidence based guidelines to diagnose death caused by death from a cardioinhibitory reflex due to short neck trauma will be proposed.

Background: Forensic physicians often evoke baroreflex cardiac arrest following short neck trauma as a cause of death. No clear evidence is available to support this hypothesis.

Objective: Construct evidence based guidelines to diagnose death caused by death from a cardioinhibitory reflex due to a short neck trauma.

Methods: A systematic review of the literature extracting case studies or reports from cases using [Medline, ISI Web of Knowledge, and Embase.] Two independent reviewers selected and extracted data. From the available data, the four authors then discussed the most probable cause of death for each case. A narrative approach was finally used to define conditions and procedures to be followed to evoke cardioinhibitory death.

Results: From the forty two cases (thirteen are anecdotes) which mention cardioinhibitory reflex as a possible cause of death, twenty two are most likely due to other causes (mechanical asphyxia, excited delirium and drug abuse). The twenty remaining cases were mainly men (15/20) and were from all ages (5 yrs to 74 yrs). From the fifteen who were autopsied, ten had local lesions at carotid bifurcation, seven had reported heart disease, and six were under the influence of alcohol.

Conclusion: Death should only be attributed to cardioinhibitory reflex when sequence of events are known, duration of trauma is certain, macroscopic and microscopic findings reveals important subsequent trauma lesions of the carotid bifurcation, and all other possible causes of death are excluded, including excited delirium, and cerebral hypoxia due to substance abuse. Such cases are apparently extremely rare.

Neck Trauma, Baroreflex, Death

G83 Differentiation of Bullet Type Based on Analysis of Gunshot Residue Using Inductively Coupled Plasma Mass Spectrometry

Ruth N. Udey, BS*, Michigan State University, 209 Biochemistry, East Lansing, MI 48824; Brian C. Hunter, MD, 630 South Saginaw Street, Flint, MI 48502; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 506 Baker Hall, East Lansing, MI 48824

The goal of this presentation is to demonstrate a chemical means to differentiate gunshot residue (GSR) deposited by two different bullet types throughout decomposition. Porcine tissue samples shot with full-jacketed and non-jacketed bullets and analyzed using inductively coupled plasma mass spectrometry (ICP-MS) displayed differences in chemical composition of the resulting GSR, allowing differentiation between the two bullet types. Decomposing porcine tissue samples were also analyzed to identify the most persistent elements to be used for differentiation between the two bullet types at all stages of decomposition.

These research findings will impact the forensic science community by increasing the confidence of gunshot wound identification, aiding pathologists and medical examiners in cause of death determination even in corpses presented in an advanced state of decomposition. Identifying wounds as gunshot wounds also aids law enforcement agencies in their search for the perpetrator, and knowing the bullet type may provide a link between a suspect and a crime.

In decomposing corpses, the presence of GSR can be difficult to visualize due to the decomposition process and larval activity, making

chemical means of GSR identification necessary. Solution ICP-MS has been used for the determination of antimony (Sb), barium (Ba), and lead (Pb), elements characteristic of GSR, from cotton swabs spiked with these elements, from shooters' hands, and from shot cotton tissue. Preliminary studies conducted in our laboratory have demonstrated the utility of ICP-MS for the determination of Sb, Ba, and Pb in decomposing GSR-containing porcine tissue samples through all stages of decomposition. However, in order to increase confidence in GSR determination in advanced stages of decomposition, the identification of additional elements, characteristic of the bullet or the interior of the barrel, is necessary. The goals of this research were to differentiate two different bullet types based on element profiles and to investigate the persistence of GSR in decomposing tissue as a function of bullet type.

In order to study the elemental composition of GSR deposited by different bullet types, three pigs were euthanized and control (unshot) samples of skin removed from one. The other two pigs were then shot using a .357 Smith & Wesson Magnum revolver. One pig was shot with ammunition cartridges containing full-jacketed bullets, and the other with non-jacketed bullets. The fresh wounds were excised, and sections of each wound were microwave digested for ICP-MS analysis. Sections of each wound type were also removed for histology analysis, and results confirmed the presence of GSR in both wound types. The digests were initially analyzed in full mass scan mode to identify all elements present at significant levels in the GSR-containing tissue but not present in the control tissue. A selected ion monitoring (SIM) method was then developed to detect only the suite of characteristic elements from both bullet types with greater sensitivity. The significance of variation in element concentrations among full-jacketed bullet wounds, among non-jacketed bullet wounds, and between full-jacketed and non-jacketed bullet wounds were assessed statistically. Differences in element concentrations between the wound tissue (both full-jacketed and non-jacketed) and the control tissue were then assessed statistically. In this way, the two bullet types were differentiated based on differences not only terms of elements present but also based on differences in concentration of common elements.

For this research to have any impact on the forensic science community, the effect of decomposition on GSR persistence was investigated. Three euthanized pigs were obtained and wounded. One was shot with full-jacketed bullets, one was shot with non-jacketed bullets, and one was stabbed to generate open wounds to serve as control (unshot) tissue. Wounds and control tissue samples were collected throughout the decomposition process, and then digested for ICP-MS analysis. Histology was also used to detect GSR throughout decomposition, and results were compared with those from ICP-MS analysis. The tissue digests were analyzed using the SIM method developed previously for ICP-MS analysis of the characteristic suite of elements that differentiate the two bullet types. The most persistent elements throughout decomposition were identified, as they are the most useful for discrimination of bullet type.

Gunshot Residue, ICP-MS, Firearms

G84 Vehicular Emissions Systems and Their Effects on Suicides and Attempted Suicides by Carbon Monoxide

Mark E. Goodson, PE, 1500 Spencer Road, Denton, TX 76205-5105*

After attending this presentation, attendees will understand the workings of vehicular emissions systems and their ability (and inability) to generate CO (Carbon Monoxide). As cars run cleaner, CO suicides in a closed space (garage) are more difficult to accomplish. The cleaner car allows for more time for a "victim" to alter his intentions. The attendee will understand these timing issues, as well as the possibility that death is brought on not by CO intoxication, but by hyperthermia.

This presentation will impact the forensic science community by showing how to properly investigate deaths associated with vehicles left running in confined spaces.

Concerns about automotive emissions, greenhouse gasses, and fuel economy have led car manufacturers to decrease CO emissions from vehicles. Over the last thirty years, CO emissions levels from tailpipes have dropped substantially. Corresponding with this drop in CO, the presenter has seen a substantial drop in his caseload of deaths brought about by acute CO intoxication (usually suicide) brought about by running cars in enclosed garages.

The modern automotive engine (gasoline) makes use of an oxygen sensor to determine how close the engine is running at ideal stoichiometry: - 14.75 parts air to one part fuel. The engine has one (or several) O₂ sensors placed in the exhaust stream to measure free oxygen. In an open air atmosphere, the oxygen sensor and ECU (Engine Control Unit) work together to insure that CO emissions are kept low.

For a person attempting suicide, the effects of the emissions system can have three outcomes:

1. Non event – no fatal levels reached
2. Suicide – fatal COHb levels reached
3. Suicide – minor to moderate COHb levels reached, but death caused by hyperthermia

The non-event is perhaps the hardest for a medical examiner system to analyze, as there is neither a death or case report.

Empirically, testing of vehicles has shown that in some instances, a garage has enough "leakage" and infiltration (air changes per hour) that there is sufficient oxygen to keep the engine running clean and for CO levels to stay at a minimum. This "non-event" can manifest itself in one of three ways:

1. The emissions system 'slowed' down CO production so much that the would-be suicide candidate changed his/her mind.
2. A fatal COHb level was never achieved because the vehicle ran out of fuel, thwarting the suicide.
3. The vehicle had enough free O₂ (leaky building) that under no circumstances would a fatal COHb level ever be achieved.

The fatal CO event is the easiest case to analyze. Grossly, the cherry red lividity is the telltale sign, along with supporting COHb levels at autopsy. But the fatal level raises the question: with modern cars running so clean, how does one ever achieve fatal results. Testing carried out shows the function of the O₂ sensor in the exhaust stream. This sensor is a ratiometric device, comparing free O₂ in the exhaust stream to free O₂ in the atmosphere. The vehicle's ECU will keep CO production to remarkably low levels for some time, but there reaches a point (in a well sealed garage) that the design assumptions (IE, 20% free O₂ in the atmosphere) are invalid and the vehicle become very dirty. Note that this fatal outcome is just an extension of one, above – CO production was slowed down, but the candidate's ardor was not inhibited; the death just took longer to achieve. Using empirical data, the presenter has been able to model the CO production/accumulation as a first order differential equation.

The fatal outcome with low CO is at first the most complex to analyze. The body presents with CO levels more associated with high levels of cigarette smoke: 5 to 10%, possibly higher, but never at levels associated with death. Testing done at our lab shows that temperatures can be reached in garages (closed spaces) that are untenable. The indicator that first led us to this area of inquiry was the existence of spray cans (paint, insecticides) that had bulged at their seams. It was known at what internal pressures the cans would expand, as well as the nature of the propellant gas inside. This data shows the increase in temperature over time within various garages, and the factors that work for and against this type of hyperthermic event are presented. In these cases the manner of death is still suicide, but causation has changed from acute CO intoxication to hyperthermia.

Suicide, Carbon Monoxide, Hyperthermia

G85 Pseudostrangulation

Thomas W. Young, MD*, Heartland Forensic Pathology, LLC, 12717 Oakmont Drive, Kansas City, MO 64145

After attending this presentation, attendees will recognize autopsy findings that can be misinterpreted as due to homicidal strangulation. Attendees will also learn how to avoid making false positive determinations of strangulation in cases where the body is found dead at the scene.

This presentation will impact the forensic science community by instructing forensic pathologists how to avoid concluding falsely in any case that strangulation is the cause of death. Successful application of these concepts by forensic pathologists will prevent injustices that come from false accusations made by police officers and prosecutors – accusations that may lead to false convictions and imprisonments.

The investigation of the death of a person found unexpectedly dead is critically important. Prosecuting attorneys and police officers rely on the knowledge and expertise of the forensic pathologist to determine the cause and manner of such deaths. Unfortunately, the unwary forensic pathologist may misinterpret findings in the head and neck areas of the dead person at autopsy and falsely conclude that strangulation is the cause of death and that the manner of death is homicide. Incorrect determinations such as these all too often lead to the arrests of innocent people on false charges, to confusion in the courtroom with the presentation of misinterpreted evidence, and to false imprisonments. Even in cases truly involving foul play, a falsely positive determination of strangulation may lead to a misunderstanding of the chain of events that led to the violent death.

The classic and typical autopsy findings for manual or ligature strangulation are well documented in the literature and in forensic pathology textbooks, but simply relying on autopsy findings alone to reach a proper conclusion will lead to mistakes. Without knowledge of the witness evidence and other physical evidence in a case, a pathologist at the autopsy table may misinterpret certain head and neck findings, falsely concluding that they indicate homicidal strangulation. On the other hand, knowledge of the witness evidence and other physical evidence and the proper interpretation of this evidence will prevent the pathologist from being misled at the autopsy table.

Five general sources of confusion at autopsy will be presented. These include: (1) confusion of ligature marks with band-like discolorations from decomposition; (2) confusion of asphyxial findings with artifacts from postmortem hypostasis; (3) confusion of strap muscle hemorrhages caused by blunt or sharp force with strangulation; (4) misinterpretation of blood extravasations posteriorly placed within the neck; and, (5) misinterpretation of laryngeal petechiae.

The forensic pathologist may make an erroneous determination of strangulation when he or she attempts to surmise the past events that led to the physical findings disclosed by autopsy without regard to the statements of the witness or witnesses, particularly if the witness is the defendant. In this presentation, why that approach leads to mistakes will be demonstrated. The Also demonstrated is how to correctly test witness accounts with the physical evidence in order to determine if the witness accounts are truthful.

The cases and illustrations used in this presentation come from the author's forensic pathology consultation practice. The forensic pathologists who originally performed the autopsies concluded in each case that strangulation caused each of the findings.

Strangulation, Homicide, False Positive

G86 Investigation and Autopsy Procedures in Cases Involving Conducted Energy Devices (CEDs) in the State of Maryland

Mary G. Ripple, MD*, David R. Fowler, MD, and Ling Li, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201

After attending this presentation, attendees will understand the investigation and autopsy procedures necessary in cases involving the use of CED's and the demographics of their use.

This presentation will impact the forensic community by reporting investigative and autopsy findings in a group of conducted energy device cases.

Controversy exists over the possible contribution of CED use to sudden death. CEDs are primarily used as a restraint method by law enforcement personnel on aggressive individuals. The typical scene involves an acute onset of agitated and delusional behavior in a person with mental health issues and/or who is on drugs. An attempt is made to control the uncooperative individual leading to a struggle at which some point the person becomes unresponsive. Experience at the OCME has emphasized the necessity of complete investigation and autopsy in these complex cases.

From 2004 until January 2009, the OCME autopsied 12 cases involving CEDs. The most commonly used CED in Maryland is the X26 TASER®. The TASER® was used in drive stun mode only in 2/12 (16%) cases, probe deployment only in 6/12 (50%) cases, and combination of both in 4/12 (33%) cases. In 75% of the cases, the TASER® was used more than once. The average age of the individuals was 35 years old, 92% were male, 67% were black, and 33% were white. Manner of death was ruled undetermined in 58% of the cases, homicide in 25% of the cases, and accident and suicide in 8% each of the cases. In two of the homicides, gunshot wounds were the cause of death when the X26 TASER® was ineffective. Excluding these two homicides, the accident and the suicide, the TASER® probes were deployed in seven of the eight remaining cases. The time elapsed between deployment of the TASER® and the time the individual went unresponsive was several minutes in four cases and in three cases it could not be determined with certainty. In the eight remaining cases, the cause of death was generally considered to be a combination of police restraint methods, the agitated/excited delirium state of the individual, the presence of drugs or alcohol, and heart disease when these were identified. In no case was the TASER® considered the sole cause of death. Of these cases, 75% were considered to be in an agitated/excited delirium (ED) state and 87.5% had ethanol or illicit drugs including cocaine, heroin, or phencyclidine in their systems. Of the ED cases, all were obese and most had heart disease. The non-ED cases included two thin individuals who struggled with police and both cases had either ethanol or illicit drugs in their system. The temperature was not recorded in the majority of cases. The initial cardiac rhythms recorded were also evaluated.

In June of 2008, in their interim report studying deaths following electromuscular disruption, the National Institute of Justice (NIJ) published considerations in the performance of investigation and autopsy in CED cases. The OCME has adopted these considerations and added to them. Investigation should develop a timeline of events with emphasis on when the subject went unresponsive. A complete review of past medical records and incident EMS, hospital, and police records, TASER® dataport download, types of restraint used, witness reports, and any videos or photos must be performed. Autopsy procedures should include: documentation of all injuries with both black and white and color photographs, measurement of the distance between the injuries and soft tissue injury, separate anterior and posterior neck dissections, cut downs of the body, microscopic sections of organs and injury, cardiovascular and neuropathology consultations, and a full toxicology screen.

Recommendations in this report are based on the experience at the OCME and follow those put forth by the NIJ in their interim report. These complex cases should each be evaluated on an individual basis, as the correlation of the investigation and autopsy findings is critical in order for the medical examiner to come to a determination of the cause and manner of death.

Conducted Energy Device, Investigation, Autopsy

G87 Postmortem CT-Angiography Using Angiofil®

*Silke Grabherr**, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1011, SWITZERLAND; *Francesco Doenz*, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, , SWITZERLAND; *Alexandre Dominguez*, Haute Ecole Cantonale Vaudoise de la Santé, Filière Technique en Radiologie Médicale, Avenue du Beaumont 21, Lausanne, , SWITZERLAND; *Richard Dirnhofer*, and *Beat Steger*, Fumedica AG, Luzernerstrasse 91, Muri, 5630, SWITZERLAND; *Barbara Sollberger*, and *Erich Gygax*, Department for Cardiovascular Surgery, University Hospital Bern, Hochschulstrasse 4, Bern, 3012, SWITZERLAND; *Reto Meuli*, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, 1011, SWITZERLAND; and *Patrice Mangin*, MD, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND

After attending this presentation, attendees will know how to perform a postmortem CT-Angiography using Angiofil®, will understand the differences between this technique and other techniques of postmortem angiography, and will understand the advantages and limitations of postmortem angiography.

This presentation will impact the forensic science community by presenting a new technique of postmortem angiography which has the potential to be largely used for postmortem radiological examinations. The perfusion machine and other technical materials developed for the method as well as a standardized protocol makes it easy applicable and therefore interesting for postmortem examiners.

Postmortem CT-angiography using Angiofil® is a minimally-invasive technique that allows to map the vascular system of a decedent in detail and therefore to perform vascular diagnosis similar to clinical CT-angiography.

Synopsis of Contents: *Preparation of the corpse:* To perform the postmortem CT-angiography, the body is placed on the CT-table. There, a small incision is made in the inguinal region to prepare the femoral vessels. Cannulas are inserted into the vascular lumina, and connected with the tubes of a special perfusion machine.

Perfusion Machine: In the University Center of Legal Medicine Lausanne and Geneva, a special perfusion machine has been developed that is easy to handle. Its special software gives further information about the pressure measured in different regions of the vascular system and these parameters provide some information about the conditions of the investigated vessels.

Contrast Agent: Angiofil® is a mixture of paraffin oil and iodized linseed oil. Thanks to the hydrophobic abilities of this oily contrast agent, no extravasation through the intact vascular wall is observed. Therefore, infiltration of the surrounding tissue is avoided. This is important to increase the quality of the procedure and to avoid deformation of the investigated body as it happens when using aqueous contrast agents, especially when important quantities of aqueous contrast agent are injected.

Technique of the Angiography: To start the angiographic examination, the cannulas are inserted into the femoral vessels and connected with the tubes of the perfusion machine. The examination consists of different phases. As a first step, the arterial phase of

angiography is performed. The perfusion machine is started and Angiofil® is introduced into the vascular system, entering by the femoral artery. To demonstrate the venous part, the contrast agent is injected by the femoral cannula and a further CT-acquisition is started.

As a third step, one or more further CT-acquisitions can be performed after establishing a “postmortem circulation”. Hereby the contrast agent is flowing from the arterial into the venous system and quits the vascular system by the femoral vein.

Conventional autopsy: In the University Center of Legal Medicine Lausanne and Geneva the radiological findings are compared with those obtained by conventional autopsy. This procedure is important to verify the angiographic diagnoses and to define advantages and limitations of the angiographic examination.

Results: By performing a dynamic postmortem CT-angiography, the vascular system can be visualized in detail. Vascular pathologies such as ruptures of vessels, aortic dissection and cardiac tamponade can be diagnosed. By comparing the different phases of angiography, information about the rapidity of extravasation and therefore about the quantity of blood loss can be gained.

However, problems persist in the diagnosis of thrombosis and embolism, since postmortem clots have the same appearance on CT-images.

Conclusion: Postmortem dynamic CT-angiography is of great interest in forensic pathology, because the detailed mapping of the entire vascular system is almost impossible with conventional autopsy tools. The presented method and the use of the recently developed perfusion machine allow postmortem angiography in an easy and standardized way. The new method using Angiofil® as a contrast agent allows to investigate blood vessels under pressure similar to real life conditions without creating artifacts due to extravasations and therefore without deforming the corpse. By performing different phases of angiography, information about the relation between the quantity of blood loss and time can be gained.

Postmortem Angiography, Forensic Radiology, Postmortem CT

G88 Radiological Interpretation of Postmortem CT-Angiography

*Francesco Doenz**, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, SWITZERLAND; *Alexendre Dominguez*, Haute Ecole Cantonale Vaudoise de la Santé, Avenue de Beaumont 21, Lausanne, SWITZERLAND; *Richard Dirnhofer*, and *Beat Steger*, Fumedica AG, Luzernerstrasse 91, Muri, SWITZERLAND; *Erich Gygax*, and *Barbara Sollberger*, Department for Cardiovascular Surgery, University Hospital Bern, Hochschulstrasse 4, Bern, SWITZERLAND; *Reto Meuli*, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, 1011, SWITZERLAND; and *Patrice Mangin*, PhD, and *Silke Grabherr*, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1011, SWITZERLAND

After attending this presentation, attendees will have the knowledge to distinguish normal from abnormal findings on postmortem CT-angiography, to recognize the traumatic and non-traumatic pathologies, to understand the differences between clinical and postmortem CT-angiography, and to know the limitation of diagnosis in postmortem CT-angiography.

This presentation will impact the forensic science community by demonstrating the key findings of traumatic and non-traumatic vascular lesions allowing for an accurate diagnosis of the cause of death.

Postmortem CT-angiography is a minimally invasive technique which enables the diagnosis of traumatic and non-traumatic vascular lesions with confidence. However, interpretation of postmortem CT-

angiography varies from clinical CT-angiography and demands special knowledge from the interpreting radiologist.

This presentation will introduce the attendees to the general principles of postmortem CT-angiographic interpretation describing the normal and pathological presentation of the venous and arterial vascular circulation. After a short introduction on the technique of opacification we will first present the normal appearance of the organs during arterial opacification, followed by the normal appearance during the venous opacification and in the end during systemic continuous circulation with the help of a perfusion pump. The description of the pathologic findings will distinguish the traumatic and non-traumatic pathologies with special care, describing the false positive findings and how to distinguish them. The most common pathologies responsible for death and visible in CT-angiography are traumatic rupture of vessels, mostly aortic ruptures followed by aortic dissection and aneurismal ruptures. Traumatic organ lacerations are also a common finding, splenic lacerations being the most frequent, followed by renal and hepatic lacerations. These organic lacerations are by themselves most of the time not the cause of death, but accompany more vital lesions, such as aortic, cerebral and cardiopulmonary ones. On the venous side the most common pathology responsible for death are also ruptures due to trauma, followed by massive pulmonary embolism. This pathology is picturing the limitation of postmortem angiography because it is the origin of most of the diagnostic errors. The reason therefore is the presence of postmortem blood clots which are often situated in the pulmonary vessels and the heart chambers. While small exemplars of these clots can be rinsed out by an ongoing perfusion, large ones can not be removed and imitates the radiological image of thrombosis or embolism. The importance of imaging during active circulation will be discussed to distinguish embolism from postmortem thrombi, in the arterial as well venous circulation.

Conclusion: The advent of postmortem CT-angiography allows visualization of traumatic and non traumatic lesions of the arteries and veins. Clear advantages of postmortem angiography over conventional autopsy are observed in detecting sources of bleeding. By the use of our method, which includes acquisition of data during a dynamic circulation, it is even possible to quantify blood loss. This is important to confirm if a lesion may have been the cause of death and if the injury may have led to an immediate or a delayed death. The main limitation of the technique is the inherent difficulty in differentiating pre and postmortem thrombi and emboli. Another difficulty, due to the same mechanism, is to distinguish aortic dissection from sedimented postmortem blood clots, mainly in the descending thoracic aorta. Because of all these challenges in vascular diagnosis, the help of an experienced angiographer has proven useful to us.

Postmortem Angiography, Postmortem CT, Forensic Radiology

G89 Perfusion Technique for Postmortem CT-Angiography

Erich Gygax*, and Barbara Sollberger, Department for Cardiovascular Surgery, University Hospital Bern, Hochschulstrasse 4, Bern, SWITZERLAND; Alexandre Dominguz, Haute Ecole Cantonale Vaudoise de la Santé, Avenue de Beaumont 21, Lausanne, SWITZERLAND; Richard Dirnhofer, and Beat Steger, Fimedica AG, Luzernerstrasse 91, Muri, SWITZERLAND; Francesco Doenz, and Reto Meuli, Service de Radiodiagnostic et de Radiologie Interventionnelle, Rue du Bugnon 46, Lausanne, 1011, SWITZERLAND; and Patrice Mangin, PhD, and Silke Grabherr, Centre Universitaire Romand de Médecine Légale, Rue du Bugnon 21, Lausanne, 1011, SWITZERLAND

After attending this presentation, attendees will understand the interpretation of different pressure variations and gradients, understand the concept of a specialized perfusion machine with integrated controller

and software for most-mortem CT-angiography, and know the concept of an ideal ante- or retrograde perfusion.

This presentation will impact the forensic science community by explaining the background and the development of a new technique and new equipment for postmortem CT-angiography, which is easily applicable and therefore interesting for everyone performing postmortem analysis.

By the use of special perfusion techniques and equipment, important information about the status of the vascular system can be gained, even without performing radiological imaging. The combination of such adequate perfusion and imaging by CT-angiography provides images and physical data that allow diagnoses of the vascular system.

In the University Center of Legal Medicine, Geneva – Lausanne, a research group has been created with the goal to develop a standardized protocol and special equipment for postmortem CT-angiography. Therefore, a specialized perfusion machine that should ease the use of the technique and that includes software giving information about the vascular status of the investigated body should be developed. With the knowledge of two European-board certified perfusionists, pressure values obtained during the perfusion for postmortem angiography are used for this development.

In general, the postmortem perfusion can be obtained by a femoro-femoral access. Therefore, the femoral artery and vein of one side are cannulated. Once the cannulas are connected to the tubes of the perfusion machine, the perfusion is started using the oily contrast agent Angiofil®. The arterial and the venous tubes are connected to the pressure monitor to register the pressure variations and pressure gradients.

In the first phase of the perfusion, the arterial system is filled antegrade under pressure control. In general, 1200 ml of contrast agent are introduced during ninety seconds. Increasing pressure values measured in the venous tube are signaling the integrity of the arterial system. Once the defined quantity of contrast agent is injected, the arterial and venous tubes are clamped to keep the pressure inside of the vascular system steady and the perfusion machine is stopped. Under those “static conditions” (stopped perfusion), a first acquisition of CT-images can be performed to visualize the arterial phase of angiography.

The same technique is repeated with the venous system, with the only difference that the veins are perfused retrograde. This second phase of the perfusion is made to visualize the venous phase of angiography.

During the first to phases of postmortem angiography, the most important perfusion value is the “delta p” which is indicating the pressure gradient form the arterial to the venous system. A low delta p, during an arterial perfusion is a sign for an intact arterial system, during a venous perfusion it indicates the integrity of the venous system. If this value increases, a leak of the arterial (during the arterial perfusion) or the venous system (during the venous perfusion) has to be suspected.

As a third phase in postmortem angiography a dynamical perfusion can be performed, that means that further contrast agent is injected and CT-data are obtained during the ongoing perfusion. Depending on the case, one or more acquisitions of images can be made. During the perfusion, pressure gradients are measured under a volume-controlled pump speed. This dynamic phase is especially useful if leaks of the vascular system are identified. In those cases, it can allow to quantify blood loss in cases of hemorrhages.

Conclusion: By performing a standardized perfusion technique with adequate perfusion equipment, changes of perfusion values can indicate leaks and show whether they are situated in the arterial or in the venous part. By using a contrast agent as perfusate, the perfusion can be used to perform postmortem angiography. The developed perfusion technique and special perfusion pump with integrated controller and software allows the performance of postmortem CT-angiography and the interpretation of the perfusion values, so that the technique becomes applicable in the routine of postmortem investigation.

Postmortem Angiography, Forensic Radiology, Postmortem Perfusion

G90 The Role of Microscopic Postmortem Study in Explaining Traffic-Crash Related Neck Injury: A Case Review

Lars Uhrenholt, PhD*, Institute of Forensic Medicine, Department of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK; and Michael Freeman, PhD, 205 Liberty Street, Northeast, Suite B, Salem, OR 97301

After attending this presentation, attendees can expect to understand the state of the literature regarding the microscopic investigation of histopathology of traffic crash-related neck injuries.

This presentation will impact the forensic science community by discussing how the histopathologic study of traffic crash related cervical spine injuries indicate that imaging occult injury must be considered as a possible source of symptoms in patients with apparently negative plain x-ray, CT or MRI studies. The relatively high false negative rate of conventional imaging for injury to the cervical spine following traffic crash must be taken into account when a forensic medical review of such injury is conducted.

Introduction: Approximately fifty percent of occupants involved in a road traffic crash sustain a painful neck injury, ranging in severity from short lived mild discomfort to long lasting pain syndromes. Approximately ten percent of all injured patients are impaired to the point that they are disabled from their work duties. In the majority of patients objectively identifiable injury using medical imaging modalities such as x-ray, CT, and MRI are the exception rather than the norm. Since the late 1980s it has been suggested by some authors that there are crash-related spine injuries that cannot be visualized with conventional medical imaging because they are too small. Subsequent postmortem studies describing microscopic investigations of cervical spine tissue in decedents with a history of neck injury have demonstrated that such imaging occult injuries do exist. The purpose of the current review is to present a review of the literature describing histopathologic studies of the post-traumatic cervical spine.

Methods: A MEDLINE search was conducted using the Mesh terms/keywords; "Accident, Traffic", "Spine", "Autopsy", "Whiplash Injuries", and keywords; forensic imaging, imaging occult lesions, postmortem, and cervical spine. Articles describing examination of the cervical spine after fatal road traffic trauma using microscopic procedures of stained histological sections were included and retrieved articles were further crosschecked for relevant references. The included references were reviewed with regard to microscopical procedures used, microscopical findings, and diagnostic imaging procedures, to be described in a table format.

Table 1

Reference	Number subjects (N) and type of trauma	Microscopical procedure	Microscopical findings	Diagnostic imaging procedures
Schonstrom et al. 1993 ¹	41 trauma cases (unknown number of motor vehicle trauma) and 10 controls	Evaluation of 2-mm thick slices using a dissecting microscope	Extra-capsular bruising, bruising of the synovial folds, tearing of joint capsules, haemarthrosis, facet fracture, haemarthrosis	None
Taylor et al. 1992 ²	16 cases (15 motor vehicle accident and 1 hanging) and 16 controls	Photographic evaluation of 2-mm thick slices and microscopy of 100-μm slices	Haemarthrosis, damage of the articular cartilage, IVD injury	All were negative on conventional radiology evaluation
Taylor et al. 1993 ³	109 trauma cases (72 motor vehicle trauma)	Evaluation of 2.5-mm thick slices using a dissecting microscope	Haemarthrosis, synovial fold injury, damage of the articular cartilage, intervertebral disc injury, ligamentous injury	Conventional radiology
Taylor et al. 1998 ⁴	108 trauma victims (unknown number of motor vehicle trauma)	Evaluation of 2.5-mm thick slices using a dissecting microscope, and histological examination in selected cases	Dorsal root ganglion injury, ventral root injury, and nerve root avulsion	None
Stäbler et al. 2001 ⁵	10 trauma victims (unknown number of motor vehicle trauma)	Microscopy of 3-μm thick stained histological section	Muscular bleeding, haemarthrosis, capsular injury, intervertebral disc injury, spinal cord injury, ligament injury, fracture of vertebral body and lamina	Conventional radiology, microfocus radiography, and magnetic resonance imaging

Yen et al. 2005 ⁶	5 trauma cases (4 motor vehicle trauma)	Histological examination not further defined	Medulla, spinal cord bleeding, upper cervical fracture	Computed tomography and magnetic resonance imaging
Uhrenholt et al. 2008 ⁷	19 traffic crash fatalities and 21 controls	Microscopy of 10-μm thick stained sections at 3-mm intervals	Injuries to the articular cartilage (horizontal splitting) and disruption of the synovial folds	None
Uhrenholt et al. 2009 ⁸	19 traffic crash fatalities and 21 controls	Microscopy of 10-μm thick stained sections at 3-mm intervals	Fractures of the facet joints, haemarthrosis, disruption of and bleeding in the synovial folds	Conventional radiology, computed tomography, and magnetic resonance imaging
Uhrenholt et al. 2009 ⁹	19 traffic crash fatalities and 21 controls	Stereomicroscopy of 3-mm thick slices and microscopy of 10-μm thick stained sections at 3-mm intervals	Fractures of the facet joints, haemarthrosis, disruption of and bleeding in the synovial folds	None

* References arise from one large-scaled study

Results: Nine references were retrieved for review (Table 1). The number of subjects suffering from road traffic crash related deaths was not defined clearly in all studies. The microscopic procedures included the evaluation of 2 to 2.5-mm thick slices using a dissecting microscope, and stereomicroscopy of 3-mm thick slices to microscopy of 3 to 100-μm thick stained sections. The microscopic findings were defined in all studies and included injuries to the osseous cervical spine (vertebral body, lamina and articular facets), surrounding soft tissues (muscles, ligaments, joint capsules, and synovial folds), articular cartilage, bleeding in the joints, dorsal root ganglion injury, ventral root injury, nerve root avulsion, and injury to the intervertebral disc. Diagnostic imaging procedures were performed in five studies, including one or more of the following procedures; conventional radiology, microfocus radiography, computed tomography (CT) and magnetic resonance imaging (MRI).

Discussion: The current review of publication describing an investigation of microscopic injuries to the cervical spine of occupants subjected road traffic crashes identified nine studies for review. Discrete non-fatal injuries to the cervical spine were described in all nine studies. Injuries to the facet joints (synovial folds, articular cartilage, joint capsule, and haemarthrosis) as well as the nerve roots were particularly common. The majority of injuries could not be identified using conventional plain x-rays nor could they be found using advanced diagnostic imaging procedures such as CT and MRI. Although the research described herein did not investigate whiplash injuries *per se*, the injuries identified in these postmortem studies were non-fatal in severity and potentially painful. The presence of similar injuries in survivors from road traffic crashes of different severities seems likely. Three studies were not included in the current review, as they did not utilize microscopical procedures but relied on macroscopic examination and evaluation of photographs.¹⁰⁻¹² Even though these studies were not included, they identified very similar findings of discrete injuries to cervical spine structures and supported the finding of these being imaging occult.

Conclusions: The present review demonstrates the important role that microscopic postmortem investigation can have in elucidating traumatic pathology that is not apparent with conventional medical imaging.

Forensic Pathology, Microscopic Lesions, Imaging Occult

G91 Lethal Consequences Arising From the Rupture of an Undetected Large Ductus Arteriosus Aneurysm During a T-12 Kyphoplasty Procedure

William J. Bonner, BA, 1100 South Broad Street, Unit 402B, Philadelphia, PA 19146; and Fredric N. Hellman, MD, Office of the Medical Examiner, Fair Acres, Route 352, Lima, PA 19037*

After attending this presentation, attendees will appreciate the complications encountered with a patent ductus arteriosus, the necessity for repair of the ductus, and a rare case of rupture of an undetected patent ductus arteriosus aneurysm.

This presentation will impact the forensic science community by addressing the importance of diligent diagnostic assessment of all patients. The decedent had undergone numerous prior imaging studies with failed recognition of a large ductus arteriosus aneurysm, and failure to detect such lesions can have disastrous consequences. Additionally, this case illustrates the importance of a thorough autopsy examination with toxicologic assessment to clarify the circumstances of in-hospital/intraoperative deaths, recognizing the potential civil litigative pitfalls should such an approach not be pursued.

The case of an 80-year-old white female who suffered hypertensive crisis and cardiovascular collapse during T-12 kyphoplasty is reported. The decedent had been admitted to the hospital for kyphoplasty to repair a T-12 compression fracture. She had a history of prior cerebrovascular accident, hypertension, hyperlipidemia, and osteoporosis. During the procedure, the decedent experienced a spike in blood pressure to approximately 200/100 mmHg, with sudden cardiovascular collapse. Resuscitative efforts were unsuccessful. Autopsy examination revealed rupture of a large ductus arteriosus aneurysm producing a large left hemothorax. The aorta and its main branches showed marked arteriosclerotic change with Monckeberg calcific sclerosis, and the heart was enlarged, with biventricular hypertrophy. Additionally, examination revealed arterionephrosclerosis and adrenal cortical hypertrophy. The cause of death was listed as massive left hemothorax due to rupture of a large ductus arteriosus aneurysm associated with marked aortic arteriosclerotic change, with calcific sclerosis during kyphoplasty of T-12, associated with intraoperative hypertensive crisis.

The ductus arteriosus connects the aorta to the pulmonary artery and functions in the fetus to bypass the unexpanded lungs. Ordinarily, this connection closes shortly after birth, but in some infants the ductus arteriosus remains patent. A patent ductus arteriosus creates a left-to-right shunt and can lead to complications like congestive heart failure, infective endocarditis, and aneurysm with subsequent rupture. However, not all individuals with a patent ductus arteriosus become symptomatically evident, and some people can live normal lives never knowing they have this congenital abnormality. In the rare case of a patent ductus arteriosus aneurysm, the ductus must be repaired to prevent rupture of the aneurysm. Rupture of a ductus arteriosus aneurysm is a devastating event and often leads to a swift death.

Detection of a large ductus arteriosus aneurysm can often be accomplished through the acquisition of a chest x-ray, though arteriography is the definitive technique if such an anomaly is suspected. While multiple imaging studies of her chest had been conducted in the past, the decedent's large ductus arteriosus aneurysm was nonetheless not identified. It is unclear what event prompted the sudden, lethal hypertensive event which led to aneurysm rupture, though an adverse event arising from administered anaesthetic agents must be considered as a potential etiology. The tragic consequences arising from this sad sequence of events is a sobering lesson that uncommon and unsuspected diagnoses are far too commonly lethal.

Ductus Arteriosus, Aneurysm, Rupture

G92 Exploring the Potential for Nocturnal Colonization of Fresh Cadavers by Carrion Flies in the Central United States

Timothy E. Huntington, PhD, Concordia University Nebraska, 800 North Columbia Avenue, Seward, NE 68434; and Leon G. Higley, PhD, University of Nebraska, 706 Hardin Hall, Lincoln, NE 68583-0987*

After attending this presentation, attendees will understand the unlikelihood of nocturnal colonization of bodies by blow flies and how this affects estimates of the postmortem interval.

This presentation will impact the forensic science community by demonstrating that while nocturnal colonization of human bodies by carrion flies is conceivable, it remains highly improbable and nocturnal colonization of carrion by flies appears to be the exception rather than the rule.

Forensic (or medicocriminal) entomology, the use of arthropods in legal investigations, is most frequently employed to estimate the postmortem interval (PMI) of victims of violent crimes or suspicious deaths. The most commonly used method of PMI estimation employs temperature-dependent developmental rates of blow fly larvae (Diptera: Calliphoridae). Retrospective scene temperatures, those temperatures which the insects experienced during development, are used in combination with known developmental rates of the species involved to estimate the age of the insects.

Because forensically important flies are known to colonize cadavers very shortly after death (often within minutes), the age of their developing offspring found on a body often corresponds closely with the time of death. One exception to this standard has traditionally been death occurring at night, when flies are not presumed to be actively searching for host carrion, and colonization is often assumed to be delayed. Recent studies both confirm and refute this assumption. However, none of the previous studies have actually examined whole carrion that has been freshly killed after dark. Previous work has been limited to butchered meats, thawed carcasses, or aged meats, all of which do not adequately replicate the conditions often encountered during medicocriminal investigations of human death; death occurring during the hours of darkness.

Live pigs (*Sus scrofa*), ranging from 23-32 kg each, were euthanized at the study site via captive-penetrating bolt device to the brain. Euthanization took place after astronomical twilight had passed, ensuring that conditions were as dark as possible. Each night of the study, three pigs were placed at a site illuminated by a mercury vapor lamp and three pigs were placed at a separate site that was kept dark. Periodic observations of the dark site were made using 3rd generation night vision equipment to observe any insect activity. Exposure of the cadavers continued until either astronomical twilight began or ambient air temperatures went below 5°C, whichever came first, with a minimum period of exposure of four hours. Following exposure of the cadavers, the body surface and orifices of each pig were closely examined under a bright light for the presence of fly eggs, maggots, or fly artifacts (spots caused by regurgitation or defecation).

After eighteen studies in both brightly lit and completely dark field settings with dense populations of necrophilous insects, no colonization of the cadavers was observed at night. It is our opinion that estimates of PMI based on insect development should continue to exclude nighttime as potential times for colonization. The data at hand from multiple studies indicates nocturnal colonization of human bodies by carrion flies is highly improbable and appears to be the exception rather than the rule. When applied to medicocriminal investigations, the data do not support nocturnal colonization as a plausible scenario.

Forensic Entomology, Postmortem Interval, Nocturnal Colonization

G93 Suicide by Extraordinarily Numerous Blade Wounds

Dollett T. White, MD*, and Leszek Chrostowski, MD, Hillsborough County Medical Examiner Department, 11025 North 46th Street, Tampa, FL 33617

After attending this presentation, attendees will understand the importance of correlating terminal events, scene investigations, and autopsy findings in determining the manner of death in a multiple stab wound suicide.

This presentation will impact the forensic science community by outlining the findings of a case of uncommon method of suicide by multiple stab wounds.

In the absence of any circumstantial information, the autopsy finding of multiple stab wounds ordinarily creates the rebuttable presumption of homicide. Classification of the manner of death always requires integration of the terminal circumstances, scene investigation and autopsy findings. This case illustrates the importance of all three in assigning manner of death.

The decedent was a 42-year-old man with a history of depression, suicidal ideations and an involuntary admission to a behavioral health institution. On the day of his death, neighbors did not see or hear any suspicious activity. He was found dead by his girlfriend on the garage floor of his undisturbed single family home, when she returned from work. The body was lying at the edge of a very large stain of smeared blood on the floor. A large, blood-stained, non-serrated, kitchen knife was on the floor. The wall opposite the bay door had smeared hand marks. The floor below had drops of blood with a pattern of vertical impact. Several bloody footprints were on the floor, and matched the decedent's shoes. The body was in a flexed position, face down on the floor, leaning to the right; numerous stab wounds to the neck, chest and forearms were visible at the scene. The death was deemed of suspicious circumstances by the police.

The autopsy revealed more than fifty four incised and stab wounds. These included Twenty three stab wounds to the right side of the neck, three stab wounds on the anterior aspect of the neck, eight stab wounds on the left side of the neck, nineteen stab wounds on the anterior aspect of the thorax, and one stab wound to the abdomen. The wounds

penetrated the pharynx, pericardium, heart, left lung, and the blood vessels of the neck. The left wrist had multiple horizontally oriented superficial cuts. The configuration of wounds, i.e., shape, depth, location, etc., in correlation with the scene findings and circumstances of death indicated that the manner of death was suicide, despite the unusually high number of the injuries, and impressively complex blood stain pattern at the scene.

Multiple stab wounds are possible but not common with suicides. This case demonstrates the importance of correlating terminal events, scene investigations and autopsy findings in determining the manner of death in a multiple stab wound case.

Multiple, Stab Wound, Suicide

G94 A DNA Database for Species Identification of Forensically Important Flesh Flies (Diptera: Sarcophagidae) in the Continental United States

Trevor I. Stamper, PhD*, 3516 State Route 222, Batavia, OH 45103-9708; Alice E. Timm, PhD, Department of Biological Sciences, University of Cincinnati, Cincinnati, OH 45221-006; Gregory A. Dahlem, PhD, Department of Biological Sciences, Northern Kentucky University, Highland Heights, KY 41099; and Ronald W. DeBry, PhD, Department of Biological Sciences, University of Cincinnati, Cincinnati, OH 45221-0006

The goal of this presentation is to inform attendees of the basic content for a newly developed DNA database for the identification of carrion flies in the continental United States. In particular, emphasis is placed upon the flesh flies (Diptera: Sarcophagidae), a hitherto largely unusable resource due to the lack of expertise in species identification for either adults or immature (larval or pupal) stages.

This presentation will impact the forensic science community because with this tool, species identification of sarcophagid flies is possible in a fast, precise method. This will then allow flesh flies, species commonly encountered at carrion, to be used by forensic entomologists in postmortem interval (PMI) estimation.

Species were collected from as far across their United States geographic range as possible. Geographic patterns of the mtDNA locus as well as the utility of subdivisions of the locus for species identification will be discussed.

Additionally, data is also provided for other sarcophagid species that are believed to be closely related to forensically important species, or might be confused for forensically important species from morphological examination. In total, we report on twenty three individual species, for a total of over 200 specimens. All specimens are vouchered in a collection that will be publicly available, allowing for future comparison of the original specimens if necessary.

This sarcophagid data joins the 300 plus specimens already sequenced from the families Calliphoridae and Muscidae to provide the most comprehensive database to date for the sole purpose of species identification of these flies and allows for the first time a rapid, independent verification of almost every major species found actively involved in the decomposition process.

Forensic Entomology, PMI, Diptera

G95 NMR and Bioinformatic Studies on the Metabolic Effects of Acetaminophen in Rat's and Human's in Urine: A Metabonomic Approach

Joshua R. McMillen, BS, 4715 Garden Ranch Drive, Apartment 308, Colorado Springs, CO 80918*

After attending this presentation, attendees will have learned how acetaminophen affects the body differently, depending on the individual, and how to identify biomarkers that are unique to that individual's response to acetaminophen.

This presentation will impact the forensic science community by discussing how once unique biomarkers are identified and correlated, and how further study can be done to help determine which individual's will have adverse side effects to certain medications.

Acetaminophen is one of the most widely used analgesic drugs in the United States today due to its therapeutic effects and high toxicity threshold. This research aims to measure the effects of various acetaminophen doses on rats and humans using ¹H-NMR spectroscopy. Previous work has been done to establish the therapeutic and toxic levels of acetaminophen and found them to be 10-15mg/kg and 150mg/kg respectively. The purpose of this research is to study the effects of acetaminophen on rats to determine if metabolic biomarkers can be identified and then compare those biomarkers to those found in a human study. This research will show that the unique metabolic biomarkers found are due to the specific responses of exposure to the acetaminophen. This particular experiment will involve three groups of five rats (control, low, and high dose) and two groups of five humans (control and low dose). Urine will be collected over the course of seven days post-dose. A pre-dose urine sample will also be collected and this will act as another control. Once samples have been prepared and analyzed using a water suppression method, data analysis will begin. The spectra will be analyzed using various bioinformatics methods to see if changes occurred metabolically and what those changes were. These results will then be compared to those found in the human study to see if any correlations can be established. The biomarkers identified will determine whether or not the subject in question is genetically predisposed in their metabolism of acetaminophen. This can then be expanded to other medications, including those still undergoing clinical trials, to help establish what biomarkers are indicative of certain adverse side effects of a medication. This will assist in prescribing medications to individuals who will not exhibit the adverse side effects.

Metabonomics, Acetaminophen, Biomarkers

G96 A Cold Case: A Forensic Review Nine Years After the Crime

Luigi Saravo, PhD, Reparto Carabinieri Investigazioni Scientifiche, Viale Tor di Quinto 151, Roma, 00190, ITALY; Gennaro Aprea, PhD, Università degli Studi di Napoli "Federico II", Complesso Monte Sant'Angelo, Via Cinthia, Napoli, 80126, ITALY; and Paola A. Magni, MS, F.E.LAB ASL TO1, c/o Civico Obitorio di Torino, Via Bertani 112/A, Torino, 10137, ITALY*

The goal of this presentation is to provide information about potential capabilities and limits of forensic entomology analyses on an old case in order to determine time of death.

This presentation will impact the forensic science community by underlining how our current understanding of the forensic sciences can help solve old cases and how important it is to have a DNA database of forensically important insects.

Three days after the disappearance of a teenage girl from a small city in the South of Italy the corpse of a girl was found in a wood not far from that city.

Immediately it was clear that the girl was murdered and moreover the crime scene appeared to be an execution. She was still clothed, but her hands and feet were tied with wire, her head was covered with a supermarket plastic bag and her eyes were hidden by a plastic tape. The murdered girl was recognized as the girl who disappeared.

The autopsy noted that she was not sexually abused, but there were many contradictory observations about the cause of death. The head of the girl sustained a bloody wound and the plastic bag over her head was not sealed properly, so there was a large mass of fly larvae on the head wound and in the eyes. The entomological evidence was poorly sampled and not used at the time, instead the level of humidity of the girl's clothes was used to determine a contradictory time of death. Many medicolegal professionals were consulted and each one wrote a different conclusion.

Two years later, the investigation led to a male suspect who was found with a note written by the girl. However, after two years of imprisonment he was exonerated.

The case was reopened six years later and the prosecutors who were handling the case decided to use another team of investigators and they also decided that a forensic entomology analysis might be useful to determine the time of death.

All entomological samples collected during the autopsy were destroyed some years before, so the work was performed with the collaboration of old and new investigators and based only on reports, pictures, crime scene and autopsy video, the girl's clothes and meteorological data from the area nearest to the crime scene.

Desiccated insect material was collected after eight years from the girl's clothes and because of the state of this evidence a morphological examination was not possible. Instead using mtDNA analyzes (COI) the insect material was determined to be *Lucilia sericata* (determined by a taxonomist).

To identify the instar of the desiccated larvae a lab experiment was designed in order to identify the original length of maggots before the dehydration process. This experiment revealed that the larvae from the body of the girl were 2nd instars of *Lucilia sericata*.

This information together with the environmental parameters and the ecological data helped to determine when the eggs were deposited and therefore the most probable time of death. The investigation is still in progress.

Investigation, Entomology, mtDNA

G97 Dead Men in Wells: How Forensic Science Was Used to Solve a Crime in an Aquatic Environment

Paola A. Magni, MS, F.E.LAB ASL TO1, c/o Civico Obitorio di Torino, Via Bertani 112/A, Torino, 10137, ITALY; and Mario A. Apostol, PhD, SC Medicina Legale ASL TO4, Via C. Beretti 10A, Torre Canavese (TO), 10100, ITALY*

The goal of this presentation is to provide information on how three allied sciences (pathology, anthropology, and entomology) working together can produce important information on a complex crime scene in an obscure location. Furthermore, some understanding of the technical difficulties of removing a corpse from an aquatic environment while still retaining corpse integrity.

This presentation will impact the forensic science community by underlining the importance of collaboration and dialogue between forensic specialists. Moreover, this case demonstrates how important protocols are in crime scene recovery so fundamental information is not lost.

A corpse in an advanced stage of decomposition was found in late February at the bottom of a well. The well was a small hole in the ground covered by a large and heavy stone and it was situated in an open roofed dwelling of an abandoned farmhouse not far from a lake in northern Piedmont (Turin, Italy).

The extraction of the corpse was very difficult because the very small opening of the well (about 50 cm of diameter). The size was just sufficient for the entry of one man with his equipment and the air tank. The well was deep, a little more than 6 m and the corpse was floating in about 3 m of water.

The corpse was clothed but no documents were found. Because of the high decay of both tissue and bone the identity of the corpse was performed by anthropological and anthropometrical examination. It was recorded that the man disappeared in May the year before.

Further pathological, histological, and SEM EDX examination of the bone marrow was performed to determine the presence of diatoms, causes of death were identified.

Forensic entomology was used in order to calculate time of death (colonization interval) and to investigate with a possible time frame in mind as to whether following his murder he was dumped in the lake. This led to the lake being scoured for months by many civil defense and firemen volunteers.

Entomological material was sampled both from the corpse and from the water in the well which was pumped into large plastic tanks. Numerous species of flies were identified including *Calliphora vicina*, *Fannia* sp., *Muscidae*, *Trichoceridae*, *Sphaeroceridae* and *Psychodidae*.

Data on seasonal presence of Calliphoridae in the Piedmont region of Italy and stage of corpse decomposition (saponification) helped to confirm that the time when the man first disappeared coincided with the beginning of insect colonization. Moreover, it was possible to demonstrate that the corpse was never in the lake environment, thanks to information gathered from the literature about the biology of the insects found on the corpse. This fact was supported by the absence of diatoms within the marrow of long bones, and by the presence in the internal organs of the same silicates found in the water.

This case underlines the importance of collaboration and communication at crime scenes. In particular, when there are several experts such as firemen, policemen, medical examiners and other different forensic scientists (entomologists, botanists, anthropologists) present team work is essential. When a crime scene is conducted properly, relevant evidence is conserved and subsequently a complete analysis of the association of the human remains and the place of recovery can be documented.

Moreover, this case highlighted the importance of evidence recovery from water bodies and the scant information available on this topic, in particular the lack of literature on protocols and equipment.

Aquatic Environment, Anthropology, Entomology

G98 Fatal Rescue Burns

*Tamuj Kanchan, MD**, Manipal University, Department of Forensic Medicine, Kasturba Medical College, Light House Hill Road, Mangalore, 575001, INDIA

After attending this presentation, attendees will identify with the significance of identification of a rescuer in a case of burns to ascertain if burns are sustained in an effort to save the victim, or trying to commit the crime.

This presentation will impact the forensic science community by understanding the need to prevent rescuers from becoming a victim of burn injuries, and the need to identify rescuers for medicolegal implications.

Dowry deaths in India are an investigative challenge and identification of a rescuer can have serious medicolegal implications. A

case of fatal rescue burns where a six month pregnant female committed suicide by pouring kerosene and igniting herself will be reported. The father-in-law of the deceased, in trying to rescue her, got entrapped in fire and sustained fatal rescue burns. As per the preliminary investigations into the incident and eyewitnesses account, a young six month pregnant female poured kerosene and set herself ablaze following an argument with the mother-in-law. The father-in-law, in an attempt to rescue her, also sustained burn injuries. Subsequently both were rushed to the district hospital. The female aborted on the 4th day of the incident. The victim (female) and the rescuer (father-in-law) expired later. The pattern of burn injuries in the rescuer and the victim will be presented and the case details of the victims along with body involvement in burns will be discussed.

Self-immolation is a preferred method of suicide in Indian women. The death of married females due to thermal burns that is commonly reported in India is usually associated with the social evil of dowry. A fatal thermal injury in married women in India hence is a major concern for the investigating and law-enforcing authorities. It is a challenging task for the medicolegal experts to discriminate homicidal and suicidal burns in married women and comment on the manner of sustaining injuries in cases relating to dowry disputes. Pattern of distribution of burns in different circumstances have been studied and a difference has been noted in between assault and self-immolation groups as well as between males and females. The issue becomes critical in case of thermal injuries sustained to the relatives and associates of the victim (a young married woman) during such an incident. It is vital to ascertain if burns are sustained in an effort to save the victim or trying to commit the crime.

An unprofessional rescuer of a burn victim is one who tries to save the victim, in spite of the consequences of putting out the fire without any safety precautions. Menezes et al introduced the term "rescue burns" for such thermal injuries as an option to allow easy tracking and identification of such cases. They opined that difference between rescue burns, accidental burns, and suicidal burns can have profound ramifications to the family of the injured or deceased rescuer, or the insurance company concerned in the case, as well as the judiciary. In India, dowry is a tradition; bride burning a social problem, hence cases of thermal burns in newly married females is an investigative challenge and identification of a rescuer can have serious medicolegal implications.

Rescuers, under the influence of emotional distress and with great courage, try to save the victim. Efforts should be made so that a rescuer does not become the next victim. To prevent the rescue burns general public should be educated about precautions to be taken before trying to prevent a victim especially during their early years of life. Identification of the rescuer is vital since it has profound medicolegal implications.

Dowry Deaths, Rescuer, Rescue Burns

G99 Sports Tool as a Weapon of Assault: A Case Report

*B. Suresh K. Shetty, MD**, Kasturba Medical College, Light House Hill Road, Mangalore, 575001, INDIA

After attending this presentation, attendees will understand the injuries produced by a rarely reported sports tool as a weapon of assault.

This presentation will impact the forensic science community by helping the officials responsible for the maintenance of law and order to administer the justice.

Trauma to different regions of the body using different types of weapons is commonly seen in literature, but there is a dearth of cases reported about sports equipment as a weapon of assault. Here a case of a moderately built male who had a homicidal attack with a hockey stick thus producing multiple injuries in head, abdomen, and genitals.

A case report will be presented of a sports tool as a weapon of assault, a rare event. It is recommended that medicolegal death investigators become familiar with such injuries in a detailed autopsy, which may ultimately prove or disprove the case, and may be of significant value to the investigating authority.

Sports Tool, Hockey Stick, Multiple Injuries

G100 Unusual Case of Blunt Chest Trauma Without Rib Fractures Leading to a Major Pulmonary Laceration

Javier Serrano, MD*, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921; and Carlos F. Chavez-Arias, MD, Puerto Rico Institute of Forensic Sciences, PO Box 11878, Caparra Heights Station, San Juan, PR 00922-1878

The goal of this presentation is to describe and discuss a case of a major pulmonary laceration after a blunt chest trauma without rib fractures in an infant involved in a car accident as a passenger.

This presentation will impact the forensic science community by demonstrating an infrequently discussed mechanism of lung laceration due to a blunt chest trauma.

Pulmonary laceration is a common result of penetrating trauma but may also be caused by blunt trauma; broken ribs may perforate the lung, or the tissue may be torn due to shearing forces that result from different rates of acceleration or deceleration of different tissues of the lung.

This case involved a 6-year-old, Hispanic healthy female infant who was a partially restricted backseat passenger in a compact vehicle that was traveling along a local highway. She was lying across the back seat when the driver suddenly fell asleep and collided with the back of a large truck. As a result of the impact her body was thrown against the back of the passenger's front seat and died instantaneously.

At autopsy the body corresponded to a well-developed and well nourished female infant. She was forty inches tall and weighed thirty two pounds. External examination of the anterior torso disclosed the presence of a horizontal linear abrasion over the superior aspect of the left hemithorax. Also a small elliptical contusion was over the superomedial aspect of the right hemithorax. Other small abrasions were present in the lateral aspects of the right upper and lower quadrants of the abdomen and posterior aspect of the right arm. The body had no other external signs of trauma. Upon reflection of the skin of the anterior thorax, no hemorrhagic infiltrates were present. There were no rib fractures. The left pleural space had 420 mL of liquid blood. The right pleural space and pericardium had no hemorrhages. The left lung had an extensive oblique laceration that practically transected the upper lobe, from the apex to the inferior medial aspect of the base. In addition multiple contusions were present over the anterior and posterior aspects of both lungs. The rest of the thoracic and abdominal organs had no lesions. Toxicological evaluation was negative for alcohol, cocaine, opioids and cannabinoids.

Major laceration of the lung is a rare and not a well recognized complication of blunt chest trauma. Pulmonary laceration caused by blunt high-energy trauma results from a mechanical shear or puncture that disrupts the parenchyma, creating a cleavage plane within the lung. The mechanism of development of pulmonary laceration after blunt chest trauma is usually thought to be the result of direct impact leading to rib fractures and thereafter, the broken ends of the ribs directly tearing the lung. However, the absence of rib fractures in this infant makes this mechanism unlikely. In 1988 a group led by R.B. Wagner divided pulmonary lacerations into four types based on the manner in which the person was injured. In type 1 the laceration results from sudden compression of the thorax causing rupture of the lung. They usually

occur in a central location of the lung and tend to be large as in this case. Type 2 laceration results from severe compression of the pliable lower thorax of younger patients. Sudden herniation of the lower lobe in front of the vertebral bodies causes a paravertebral shear injury with laceration. Type 3 lacerations result from direct puncture of the lung by a displaced rib fracture. Type 4 results from lung shearing at sites of pleural adhesions.

This case represents a particular mechanism involved in a blunt chest trauma in which a high-energy non-penetrating injury was applied to one hemithorax leading to a major unilateral pulmonary laceration without other organ involvement

Pulmonary Laceration, Chest Trauma, Car Accident

G101 Postmortem Analysis of Vitamin D Using Liquid Chromatography Tandem Mass Spectroscopy

Geza Bodor, PhD, Denver VA Medical Center, 1055 Clermont Street, Denver, CO 80220; John Carver, JD, City and County of Denver, 660 Bannock Street, Denver, CO 80204; and Amy Martin, MD, and Michael A. Burson, PhD*, City and County of Denver, Office of the Medical Examiner, 660 Bannock Street, Denver, CO 80204

The goal of this presentation is to review physiology of vitamin D, review current methodologies for measuring vitamin D, and understand the utility of measuring vitamin D in postmortem blood samples.

This presentation will impact the forensic science community by providing the framework to understand the utility of measuring vitamin D in postmortem blood samples. With the recent debate regarding vitamin D deficiency, bone fractures, and questions of child abuse it seems imperative to be able to address these issues as thoroughly as possible. Often is the case in forensic cases that antemortem blood samples are not available or specific questions have not been asked by a decedent's physician prior to death. Thus, there is no way to know if a vitamin D deficient state was present prior to death. The results study will allow the forensic community to know whether or not a postmortem blood sample can or cannot be analyzed appropriately for vitamin D nutritional status.

Objective: To measure vitamin D in postmortem blood samples using our recently developed liquid chromatography-tandem mass spectrometric (LCMSMS) method. Briefly, our current method provides for measurement of the 25-hydroxy derivatives of vitamin D, specifically 25(OH)-D₂/D₃, (OHD₂, OHD₃) in human serum. Increasingly, current clinical practice is to measure OHD₂ and OHD₃ to assess vitamin D nutritional status. To our knowledge, methods have not been evaluated for measuring these analytes in postmortem samples. The most common assay platform used today is an immunobased assay, which relies on antibodies which are known to cross-react with many vitamin D metabolites. Such immunobased assays are particularly sensitive to sample integrity and it is likely that a postmortem blood sample may not be appropriate due to hemolysis and other postmortem artifacts.

Hypothesis: Postmortem vitamin D concentration, measured with a sensitive and specific assay such as LC-MSMS, will correlate well with antemortem concentrations. Such analysis will be helpful in those cases where antemortem vitamin D levels have not been previously measured in the primary care setting. Furthermore, with the recent debate over vitamin D deficiency (Rickets) and suspicious non-accidental bone fractures, such an assay will, without doubt be of interest in cases questioning abuse.

Materials and Methods: In preliminary studies, three recent cases of natural disease were selected. In each case, peripheral blood (iliac vein) was sampled within 24 hours of the time of pronouncement. Approximately 8 ml of peripheral blood was drawn into a red-top tube

under gentle pressure to minimize hemolysis. Each sample was allowed to clot at room temperature for one hour and then centrifuged for twenty five minutes. The serum was then transferred to a clean red-top tube and frozen at -10 C until assayed. Hexa-deuterated OHD2 and OHD3 (OHD2d6 and OHD3d6, Medical Isotopes, Inc.) were used as internal standards (IS). Calibrators were prepared in acetonitrile (ACN) at 5, 10, 20, 50, 100 and 150 ng/ml for each analyte (OHD2 and OHD3). Samples and calibrators (500 ul) were spiked with 75 ng IS, extracted in 1 ml ACN and centrifuged. Thirty ul of supernatant was injected into a Shimadzu HPLC at 70% H₂O:30% ACN at 350 ul/min flow. Analytes were separated on a C18 column (100 mm x 2.1 mm x 3 um, RESTEK) and then introduced into a triple quadrupole mass spectrometer (ABI 3200 Q-trap) via an APCI source in the positive ion mode. The analytes were eluted at 100% ACN over a 13 minute run.

Results: Preliminary studies addressed whether or not vitamin D analytes are stable in postmortem blood and if so whether they can be measured with our LC-MSMS method. In each of the samples tested to date, successful and reproducible total vitamin D in levels ranging from 6.43 ng/ml to 95.3 ng/ml have been detected and quantitated. We are confident in these results because the level of quantitation (LOQ) has previously established of these assay at 5 ng/ml.

Summary: It can be shown that postmortem blood contains measurable vitamin D and can be accurately measured on our LC-MSMS platform. Immediate planned studies on adult and pediatric cases include: (1) a direct comparison of hospital admission antemortem blood with our 24 hr postmortem blood samples; (2) a direct comparison of plasma and serum samples; and, (3) a postmortem stability assay to characterize how the postmortem interval affects our ability to accurately measure vitamin D.

Vitamin D, Postmortem Analysis, LC-MSMS

G102 An Unusual Case of Homicide by Knife, Screwdriver, and a Kitchen Fork

Sabina Di Donato, MD, Ospedale San Carlo - U.O. Medicina Legale, Via Potito Petrone, s.n.c., Potenza, 85100, ITALY; Aldo Di Fazio, Section of legal medicine - Matera Hospital, via Montescaglioso n.5, Matera, 75100, ITALY; and Rocco Maglietta, CROB Rionero in Vulture (Potenza), via Padre Pio n. 1, Rionero in Vulture (Pz), 85028, ITALY*

After attending this presentation, attendees will be familiar with wound patterns inflicted by multiple unusual means. Only a few cases of homicide by screwdriver, knife, and kitchen fork are reported in forensic literature. Sometimes it may be difficult for the forensic pathologist to identify the penetrating weapon missing from the crime scene. The importance of a thorough forensic investigation, including crime scene evaluation, analysis of circumstantial data, autopsy findings, toxicological analysis, histological, and immunohistochemical studies is emphasized.

This presentation will impact the forensic science community by presenting a homicide where the murderer assaulted the victim with a screwdriver, a knife, and a kitchen fork. The unusual injuring tools and the relevant injuries were studied and analyzed to approach the case. The confocal microscope was utilized to verify the three dimensional appearance of the cutaneous lesions.

Injuries caused by sharp or pointed objects are common. They rarely cause fatal injuries; however, and the fatality rate is estimated to be 3% at most. Most fatalities caused by sharp force are homicides. The ratio of homicide to suicide is estimated at 6:1 to 5:2. When investigating deaths owing to sharp force, the forensic pathologist is expected to give an opinion on the following points: the type of injuries; the number and anatomical distribution of injuries; the shape, size, length, and depth of injuries; the object (weapon) used; the amount of force needed to inflict the injuries; the extent of internal injuries; the cause of death; and the victim's capability to act. These points are of

decisive importance for the reconstruction of the sequence of events. Most homicides by sharp force are committed by males, often under the influence of alcohol. The most common tool used is a knife, but other pointed objects, such as scissors, ice picks, forks, or broken glass, may also be used. The victims are usually family members or acquaintances. The death scene is most frequently the victim's home. Fatal stabs are usually located in the precordial or cervical region. The number of stabs does not allow the drawing of conclusions as to the mode of death, the motive, or sex of the perpetrator. When the number of stabs is higher than necessary to kill the victim, this is referred to as "overkill," and may point to a strong emotional conflict between the perpetrator and the victim.

Case Report: The lifeless body of a 18-year-old girl was found in a mansard by the owner. He was giving hospitality to a friend since three months. The girl was the former girlfriend of his guest. The body laid face down in a large pool of blood. Immediately he tried to help her and called the ambulance, but she was pronounced dead. There was a great confusion in the room, on the floor beneath the body a large pool of blood was evident, with extensive blood spatter on the surface of the wall on the right, of the cupboard on the left and of the bed, in the center of the room. The head of the decedent lied near a chest of drawers which surface was full of stripes of blood made by the girl's fingers in an attempt to getting up from the floor. The postmortem examination showed the face devastated by very numerous cross lesion of the cutis, 0.4 cm in length, ending in deep incision on the bone surface underneath. The same wounds were also on the thorax and on the dorsal face of the hands. These wound appeared similar to the shape of a phillips screwdriver tip. On the left side of the face and neck there were many linear wound that appeared always paired and of the same length, suggesting the use of a sharp and pointed object like scissors, kitchen fork, etc. There were also numerous deep linear cutaneous wound on the anterior surface of the neck, slightly oblique, with clear-cut divergent margins, exposing the underlying structures, also sectioned, and ending in linear superficial incisions at different vertebral bodies of the cervical spine. Other deep linear cutaneous wounds were localized on the right emithorax; beneath these lesions the costal cartilage was sharply sectioned at many levels, with soft tissue bleeding underneath. No pulmonary lesions were found. On the hands and the forearm the girl showed many defense lesions made by the sharp and pointed object, and by a cross-tipped mean. Immunohistochemical studies were performed on the cutaneous specimens for the determination of the vitality. The evaluation of skin samples with confocal microscope allowed researchers to observe the three-dimensional model of the different wounds. Toxicological analyzes were negative. On the basis of the autopsy results, the pathologists gave indications to policemen about possible responsible weapons. A thorough investigation of the crime scene allowed the finding of a phillips screwdriver dried with blood and a kitchen fork in a drawer; no other weapons were found. The day after the body finding, the boyfriend, who was sought by police, crashed with his car while he was escaping along the highway. Inside his car police discovered a knife, stained with blood, and locks of hair.

Knife, Screwdriver, Fork

G103 Love and a Bullet: Autoerotic Accident or Intentional Suicide?

Kelly L. Rose, MD, and Kim A. Collins, MD, Fulton County Medical Examiner's Office, 430 Pryor Street Southwest, Atlanta, GA 30312*

The goal of this presentation is to highlight the potential for confusion regarding manner of death by using an interesting example.

This presentation will impact the forensic science community by highlighting the gray area of manner of death.

Autoerotic deaths have traditionally been caused by asphyxia due to hanging. To a lesser degree, trauma secondary to electrocution and

insertion of objects have resulted in death. Based on scene investigations and the autopsy findings in these more traditional autoerotic cases, manner of death is best classified as accident. However, there does arise within the forensic spectrum cases involving autoerotism where the manner of death is more equivocal. It is in these fringe cases where excellent investigation of the scene and the victim's past medical history, is paramount. We present here an unusual case of autoerotic death in which the autoerotism involved a gun.

The decedent, a 29-year-old man killed his father when he was thirteen-years-old. Using a handgun, he shot his father because he was repeatedly abused by him. His mother encouraged the murder. As a young man, the decedent found titillation from a toy handgun. As he grew older, he felt the need for a more powerful arsenal in order to achieve sexual arousal. During his last years, the decedent not only considered his silver .38 caliber Rossi handgun to be "sexy," but he smelled, fondled, and caressed it. The 38 Rossi was kept in a velvet bag in his bedroom, retrieved easily to be used as a sexual and masturbatory aid. His sexual routine with his beloved Rossi escalated from dry firing the empty gun, to leaving one bullet in the cylinder of the revolver while pulling the trigger. Eventually, this repeated practice resulted in his death due to a self-inflicted contact range gunshot wound to his head. A further complication in this case is the decedents past psychiatric history. He had mild depression and suffered from bouts of insomnia. So this case serves as a great illustration and topic for discussion regarding aspects of autoerotism, cause of death, manner of death, and the less clear distinction between suicide and accident.

Gunshot Wounds, Autoerotic, Manner of Death

G104 Laryngeal and Hyoid Bone Trauma Resulting From Forces Other Than Compression of the Neck

Carlos F. Chavez-Arias, MD, Puerto Rico Institute of Forensic Sciences, PO Box 11878, Caparra Heights Station, San Juan, PR 00922-1878; Dario Sanabria, MD, Puerto Rico Institute of Forensic Sciences, Department of Pathology, PO Box 11878, Caparra Heights Station, San Juan, PR 00922-1878; and Javier Serrano, MD, Puerto Rico Institute of Forensic Sciences, Calle Maga Esquina Casia #9, Urb. Reparto Metropol, San Juan, PR 00921*

The goal of this presentation is to describe and discuss ten cases associated with laryngeal and hyoid bone blunt trauma.

This presentation will impact the forensic science community by demonstrating the pathological features of this infrequently discussed entity in the non-homicidal setting.

Hyoid bone fractures are usually the result of direct trauma to the neck through manual strangulation or hanging. These fractures secondary to blunt trauma other than strangulation are rarely reported and discussed. This report discusses ten cases with hyoid bone or laryngeal fractures associated to blunt trauma.

Ten head and neck trauma cases in which the autopsy disclosed the presence of hyoid bone or laryngeal fractures were reviewed. These cases occurred within the period 2008-2009 and examined at the Puerto Rico Institute of Forensic Sciences. Cases with a diagnosis of strangulation or hanging were excluded.

The ten cases are summarized in Table 1.

Eight of ten cases were male and two were women. All cases corresponded to adults between 24 to 80 years. Half of the cases were older than 50 years. Eight out of ten cases corresponded to motor vehicle accidents; one case was a small plane crash accident and one case was a homicidal blunt trauma to the head with a concrete block. The motor vehicle accident cases included three motorcyclists, three pedestrians and two car drivers.

Common autopsy findings for all cases included the presence of hyoid bone and/or laryngeal fractures associated with craniomandibular trauma with maxilla and mandible fractures.

The most common fractured site was the joint between the left greater cornu with the left side of the body of the hyoid bone. Five cases had only one fracture at the left side and two cases had bilateral fractures. One case had a unilateral fracture at the right side. Fractures of the hyoid body were found in two cases, including one case with multiple fractures of the hyoid bone. Cases with thyroid cartilage fractures included one left superior cornu fracture and two cases with fractures of the right and left laminae. The cause of death for each of the ten cases was Blunt Force Injuries and the manner of death for nine of the cases was accident and one case was homicide.

Hyoid bone fractures secondary to trauma due to strangulation or hanging are rare. In the forensic literature, little information of laryngohyoid trauma in victims other than compression of the neck is available. Forensic pathologists look for a fractured hyoid bone as evidence of strangulation. There are several reasons contributing to the rarity of this fracture. The first is that the hyoid bone is well protected by the mandible. Most trauma to the face results in fracture of the mandible without hyoid bone fracture. The second is that hyoid bone is protected by its mobility in all directions, so the pressure may be cushioned. The third is that it is not completely ossified in younger patients allowing for more flexibility and decreased rigidity.

In laryngohyoid fractures, three mechanisms could be involved. The first involves a direct impact of the neck structures. The second involves an indirect muscle strain on the hyoid bone or thyroid cartilage resulting from hyperextension or hyperflexion of the neck or secondary to associated local trauma such as mandible fractures. The third is a combination of direct and indirect mechanisms.

These cases could represent similar mechanisms involved during a blunt trauma in which hyoid bone and laryngeal fractures are the result of high energy forces applied to the mandible strong enough to be transmitted by its anatomical contiguity. Strong muscle strains on the mylohyoid muscle could lead to hyoid bone lesions in case of mandible fracture where this muscle is inserted. This could explain the common association of hyoid bone fractures with mandible fractures in this report.

Table 1: Ten Laryngeal and Hyoid Bone Trauma Cases

Case #	Sex	Age(years)	Circumstances	Hyoid/thyroid trauma	Cartilage	Facial fractures	Cause/Manner of death
1	M	80	Hit on head with a concrete block	Midpoint of Hyoid body	Maxilla Mandible		BFI/Homicide
2	M	38	MVA: Motorcyclist	Left joint (body and greater cornu). Left lamina of thyroid	Mandible		BFI/Accident
3	M	69	MVA: Driver	Left joint (body and greater cornu)	Maxilla Mandible		BFI/Accident
4	M	27	MVA: Pedestrian	Hyoid Body - Right and Left joints (body and greater cornua)	Maxilla(L) Mandible		BFI/Accident
5	M	65	MVA: Pedestrian	Right joint (body and greater cornu). Right lamina of thyroid	Maxilla (R&L) Mandible		BFI/Accident
6	M	30	MVA: Motorcyclist	Left joint (body and greater cornu)	Maxilla(R) Mandible		BFI/Accident
7	F	72	MVA: Pedestrian	Left superior cornu of thyroid	Mandible		BFI/Accident
8	F	45	MVA: Driver	Left joint (body and greater cornu)	Mandible		BFI/Accident
9	M	24	MVA: Motorcyclist	Right and Left joints (body and greater cornua)	Mandible		BFI/Accident
10	M	52	Small Plane crash Pilot	Left joint (body and greater cornu)	Maxilla (R&L) Mandible		BFI/Accident

Hyoid Bone Fracture, Laryngeal Fracture, Mandible Fracture

G105 The Evolving Distribution of Cause and Manner of Death in HIV Positive Medical Legal Cases: Links Between ART and Traditional Categories of Chronic Disease

Sharon M. Derrick, PhD*, Harris County Medical Examiner's Office, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054

The goal of this presentation to describe and evaluate the impact of HIV infection, obesity, and two linked diseases, diabetes mellitus (diabetes), and cardiovascular disease (CVD), on the forensic practice and public health roles of medical examiner/coroners. Attendees will receive an epidemiological analysis of these diseases in medicolegal (ML) cases presenting to a large urban-based medical examiner office. Specific emphasis will be placed on the interrelationships between HIV infection and traditional categories of chronic disease and on the implications of the study results for other medical examiner offices nationally.

This presentation will impact the forensic science community by illustrating the evolving status of HIV infection as a chronic disease and the effects of increased longevity of the HIV positive patient on the composition of medicolegal caseloads. The role of medical examiner offices as guardians of the public health and the practical aspects of public health reporting will be discussed.

In 2009 the Centers for Disease Control and Prevention (CDC) released the results of HIV/AIDS surveillance data collected from thirty four reporting states. An estimated 552,000 adults and adolescents were living with HIV/AIDS in these states in 2007, an increase of 16% over 2004.¹ The increase in persons living with HIV infection is well-documented in the literature and it is associated with the implementation of ART treatment (combined antiretroviral therapy and highly active antiretroviral therapy), prolonging the time interval from HIV infection to development of AIDS, and with increased HIV screening at point of care, which can lead to earlier treatment. HIV positive patients are living longer through better disease management. However, ART produces side effects that increase the HIV positive patient's susceptibility to obesity, (especially visceral fat around the waist), diabetes, hyperlipidemia and CVD.

The population sample for this retrospective study consists of ML cases investigated by the Harris County Medical Examiner's Office (HCMEO), Houston, Texas in 2008-2009 that fall within these parameters: 15+ years old, 60+ inches tall, and weight of 70+ pounds. Size limits are set to exclude young children and decedents in advanced decomposition. The incidence of CVD and diabetes is obtained from the primary and contributing causes of death, and HIV incidence from medical history and HCMEO serology results reported to the local health authority. The data presented here reflect 5794 ML cases received from January 1, 2008 through July 22, 2009. The balance of the 2009 cases and the biostatistics results will be included in the final analysis and presentation.

The population of Harris County, Texas is an ethnically diverse 3.9 million residents, of which 29% are obese (BMI >30) and the average BMI is 27-30. Approximately 8.3% of Harris County residents have been diagnosed with CVD, 7% with diabetes, and 0.5% with HIV.² In concordance with these data, 29% of the ML decedents have a BMI >30, with a range of 10-98 and an average BMI of 27, and in 7% of cases diabetes is the cause or contributing cause of death. Due to the nature of ML cases and the efficacy of autopsy diagnosis, the percentages of CVD and HIV in the sample are higher at 31% and 0.9%, respectively, even though these conditions may be under-reported in a forensic sample.

Among the fifty five HIV positive decedents, 13% (7) have a BMI >30. The average BMI is 24 and the range is 15-55. Examination photographs reveal that 42% (23) have a concentration of visceral fat in

the belly area. Review of the medical records is underway to determine the number of these decedents in ART at death. The racial/ethnic composition is 44% black, 42% white, 13% Hispanic, and 2% Asian. The age range is 18-81 years, with a median age of 47, a relatively middle-aged distribution. The leading causes of natural death are complications of AIDS (11) and CVD (11).

As these preliminary results show, improved treatment of HIV infection may lead to a higher number of deaths from CVD, fewer AIDS-related causes of death, and fewer infectious findings at autopsy that result in a request for an HIV serology by the forensic pathologist. Medical examiner/coroners can prevent a negative impact on public health surveillance of HIV infection in forensic cases through awareness of the changing epidemiology of HIV.

HIV, Medical Examiner, Epidemiology

G106 Death in a Wine Vat

Romano La Harpe, MD*, Sandra E. Burkhardt, MD, and Kebede Shiferaw, MD, Institut de Medecine Legale, 9 Av de Champel (CMU), Geneva, 1206, SWITZERLAND

After attending this presentation, attendees will understand the necessity of good collaboration between the different institutions that work on an undetermined death crime scene and will become familiar with the autopsy presentation of death by inhalation of carbon dioxide (CO₂).

This presentation will impact the forensic science community by increasing understanding the need for collaboration between the different institutions (e.g., police, casualty department, national toxicology department, local eco-toxicology department, regional wine institute) to get the cause of death in a unclear case.

A 42-year-old man was found unresponsive by his father with the head and the left limb in a wine vat. The father could not remove the body, so he immediately called for a help. The emergency responders found him in asystole and pronounced him dead after twenty minutes of a resuscitation attempt.

The vat of 1,750 liters (455 gallons) was fuelled at 80% with grapes the day before. To give a better aroma and flavoring to the wine, 40 kg (88 pounds) of dry ice were added into the grapes. The worker had to then check the evolution of the must. For that, he had to regularly take samples to look at the color, to smell and to taste the must, especially during the period of fermentation of alcohol (about 15 days).

Autopsy showed cyanosis of the face and the neck, conjunctival petechiae, cerebral edema, and signs of acute anoxia into the brain. Toxicological analysis was negative. The National Toxicology Department suggested that it could be an intoxication by carbon dioxide, but could not prove it, because of the evaporation of the gas (CO₂).

The day after, the scene was visited with the police to try to understand the events. The Local Eco-Toxicology Department was asked to perform the analysis of the air on the top of the vat. They found 100% of CO₂. The Regional Wine Institute speculated that the addition of dry ice produce immediately a lot of CO₂ and not progressively as in a normal fermentation. In this case, if someone breaths inside the vat, loss of consciousness can come in a few seconds and then the death in a few minutes. Finally, as a result of the police investigations, a pair of glasses were found inside the vat when it was emptied after three months. It was concluded that the worker had lost his glasses into the vat and he tried to recover them.

The medical literature contain only a few cases of intoxications by carbon dioxide, occurring in ship holds, in the brewing industry, in silos,

tunnels, sewer shafts, and poultry plants that use dry ice, but rarely in wine industry.

The cause of death was not determined on the basis of the autopsy. But the information received from the different institutions allow the determination the cause of death as an acute intoxication by carbon dioxide and the manner of death as a accident, due to the loss of glasses in the vat.

Death, Wine Vat, Carbon Dioxide

G107 Nailing the Diagnosis: Features of Fatal Injury Inflicted By Unusual Projectiles and Firearms

Hilary S. McElligott, MD, Cook County Office of the Medical Examiner, 2121 West Harrison Street, Chicago, IL 60612-3705*

After attending this presentation, attendees will recognize the distinguishing features and potential diagnostic pitfalls of injuries inflicted by uncommon projectiles and firearms.

This presentation will impact the forensic science community by discussing the pertinent characteristics of a variety of wounds inflicted by atypical ammunition or firearms. A ten-year retrospective review of case files at the Cook County Office of the Medical Examiner and a regional collar county yielded seven cases of suicide committed with atypical projectiles or firearms. These include four cases of nail gun suicide and a case of an antique firearm loaded with Phillips head screws used to commit a double homicide-suicide. Additionally, two cases of accidental death involving aerial fireworks mortars were identified which are similar in many ways to two cases of suicidal fireworks injuries that have been previously reported in the literature.

The use of a nail gun to commit suicide is extremely rare, with fewer than ten cases detailed in the literature. It has been previously reported that nails recovered from individuals who have committed suicide remain straight upon entering the body. This is in contrast to reports of accidental nail gun injury where recovered steel nails have been observed to be curved or bent most commonly as a result of ricochet. It has been suggested that one may infer a given injury is accidental if the nails are bent and suicidal if the nails are straight. A case of nail gun suicide is reported with recovery of both bent and straight nails.

The external evidence of injury inflicted by nail guns may be subtle and easily overlooked, especially if the nail is not visible externally. Blood may be minimal or absent both on the body and at the scene. Not until the autopsy examination may the devastating extent of the injuries be appreciated. In three cases of nail gun suicide involving the head and one involving the chest, the injuries were small entrance wounds typically measuring 0.1 inch or less in diameter. The individual with self-inflicted chest wounds was dead at the scene and the three remaining cases had variable survival times.

In contrast to the injuries produced by nail guns, the cases involving the use of an antique firearm produced injuries deceptively similar to close-range or contact shotgun wounds. Radiographic examination identified the atypical nature of the projectiles, short Phillips head screws. Because the load was noncommercial, the number of projectiles (screws) varied between the cases. Additionally, from two cases, paper used as patching to contain the projectiles was recovered from within the wound track.

Atypical projectiles can, of course, produce atypical patterns of injury. Two cases of accidental death involving aerial fireworks mortars show that patterns of injury and soot deposition can be distinctive and, in the absence of additional information, may help identify the use of less common incendiary powders. Although no cases of suicide involving fireworks were found, two cases of accidental death involving fireworks were identified. Both occurred outdoors and had massive craniocerebral

injuries with complete or partial avulsion of the brain as well as thermal injury of the surrounding scalp and skin. The injuries were limited to the head. This pattern of injury is consistent with that seen in suicidal fireworks injuries as described in the literature and highlights the importance of a scene investigation when investigating these deaths.

Perhaps due to the ready availability of more conventional weaponry, suicide using atypical projectiles and firearms remains rare. Despite their infrequency, it is important to recognize the pertinent features of such cases. In nail gun suicide cases involving the head, both bent and straight nails were identified. Many of the wounds in these cases were very subtle and could easily be overlooked. In cases of firearms loaded with atypical ammunition, the external appearance may be that of a close-range or contact shotgun wound. Finally, cases of accidental fireworks deaths demonstrated injuries similar to those described in suicidal fireworks deaths. All of these cases emphasize the importance of obtaining a detailed history, radiographic studies, and performing a thorough scene investigation.

Nail Gun, Fireworks, Atypical Injury

G108 Please, Don't Get Angry! Two Fatal Cases of Emotional Stress-Related Death in Left Ventricular Apical Ballooning Syndrome (Tako Tsubo Cardiomyopathy)

Stefano D. Errico, MD, Benedetta Di Battista, MD, Carmela Fiore, MD, and Cristoforo Pomara, MD, PhD, Department of Forensic Pathology, University of Foggia, Viale degli Aviatori 1, Foggia, 71100, ITALY*

The goal of this presentation is to present two cases of death due to Tako Tsubo cardiomyopathy. The growing interest of the scientific community in understanding physiopathology, still far from a complete definition and the amazing of videos presented, makes the presentation absolutely peculiar.

This presentation will impact the forensic science community by highlighting characteristics of syndrome and the importance of a complete postmortem examination in rare fatal cases. This presentation demonstrates the typical histological signs of catecholamine toxicity (CBN), but further studies are still needed for further in-depth knowledge of TTC and stress-related cardiac physiopathology. In particular structural alteration of the contractile and cytoskeletal proteins could also be investigated.

Tako-tsubo cardiomyopathy (TTC) is also known as stress-induced cardiomyopathy (SICMP) or left ventricular apical ballooning syndrome (LVABS), broken heart syndrome, and ampulla cardiomyopathy. It was first described in the early 1990s in Japan in which patients (generally postmenopausal women) complained of chest pain and dyspnea, mimicking a coronary arterial disease. The name of "tako-tsubo" cardiomyopathy is derived from a pot with a short neck and a round bottom used for octopus fishing in the Japanese sea, as this resembles the left ventriculogram during the acute phase of the disease. It is characterized by a transient akinesia of the apex and compensatory basal hyperkinesis, triggered by marked psychological or physiological stress in the absence of significant epicardial coronary artery disease. TTC has been recently classified as primary, acquired cardiomyopathy and diagnostic criteria have been proposed: reversible akinesis or dyskinesis of the left ventricular apical and midventricular segments, with apical ballooning extending beyond a single epicardial vascular territory, new ECG ST-segment or T-wave abnormalities mimicking AMI, absence of exclusion criteria, including obstructive coronary disease or angiographic evidence of acute coronary plaque rupture, recent significant head trauma, etc. Although precipitating stress is not always identifiable, the stressful trigger could be emotional or physical. Multivessel epicardial spasm, myocardial dysfunction triggered by

excess of catecholamine levels, microvascular coronary spasm or dysfunction and neurologically mediated myocardial stunning have been proposed to explain TTC. Generally the prognosis is good but complications including death have been reported with an extremely low mortality rates. Deaths in these cases generally occur as a consequence of fatal ventricular arrhythmia (VF) or cardiogenic shock due to stress-related sudden severe ventricular dysfunction. Two fatal cases of TTC will be presented.

Case 1: A 52-year-old woman complained of thoracic pain and dyspnea after a quarrel with colleagues at the workplace. She had complained of the same symptoms a few months prior. Clinical examination on ED showed moderate high BP (160/90); pulse (90 bpm) and oxygen saturation (96%) were normal. A 12 lead ECG registration was immediately performed showing ST segment reduction mimicking myocardial infarction. Cardiac markers were elevated on lab test (CK 220, troponin 5.173). A severe ventricular failure was observed on echocardiography (EF < 30%). Cardiac catheterization was unremarkable for coronary obstruction. TTC was suspected, and confirmed at ventriculogram, where a typical systolic dysfunction involving left ventricular apex was recorded. Beta-blocker therapy was introduced but few hours after charge on cardiology department, death suddenly occurred in spite of resuscitation maneuvers.

Case 2: A young 30-year-old suddenly collapsed after a violent altercation with colleagues at the workplace and immediately presented to the emergency department of the local hospital. ECG was performed, showing ventricular fibrillation. The patient died few minutes after presentation. One week before, the young man complained thoracic pain and a 12 lead ECG was performed, showing ST segment reduction mimicking myocardial infarction. A complete postmortem examination was performed few days after death, in both cases. External examination was unremarkable. Internal examination showed mild cerebral edema and heavy lungs presenting white foam on the main bronchi, in both cases. Hearts were fixed in formalin. Cardiac sizes were normal, with conical shape. Macroscopic study (cut in cross-section 3 mm intervals) of coronary arteries were unremarkable, in both cases. Histological examination revealed polyvisceral stasis, mild cerebral edema; massive pulmonary edema was also detected. The pathological myocardial picture included multiple foci of contraction band necrosis; a few areas of patch interstitial fibrosis were also detected. Cardiac microscopic study was completed by means of immunohistochemistry by means of beta2 adrenergic receptor antibodies, showing expression on myocyte membranes in both cases. Confocal laser 3D scans of myocytes was also performed. No signs of cell death (apoptosis) was detected (TUNEL). Dosage of catecholamines and their metabolites on a blood and urine samples was performed, showing high levels of catecholamines, metanephrine and vanillyl-mandelic acid. Toxicological examination was negative. Clinical data, autopsy findings, data collected from immunoistochemical and CLSM study of myocytes and laboratory analysis, led us to conclude that cardiogenic shock after intense emotional stress complicated by malignant arrhythmia (VF) in Tako-tsubo cardiomyopathy was the main cause of death in both cases.

This research demonstrates typical histological signs of catecholamine toxicity (CBN) but further studies are still needed for further in-depth knowledge of TTC and stress-related cardiac physiopathology. In particular, structural alteration of the contractile and cytoskeletal proteins could be also be investigated.

Tako Tsubo Cardiomyopathy, Emotional Stress-Related Death, Cathecolamine Toxicity

G109 A Case of Anaphylactoid Syndrome of Pregnancy

Jennifer L. Shuttlesworth, MD, Ana E. Lopez, MD, and Luis A. Sanchez, MD, Harris County Medical Examiner's Office, 1885 Old Spanish Trail, Houston, TX 77054*

The goal of this presentation is to explain the use of the term anaphylactoid syndrome of pregnancy and the difficulties one can encounter in making a diagnosis of amniotic fluid embolus.

This presentation will impact the forensic science community by illustrating a case of anaphylactoid syndrome of pregnancy and will include a discussion of the autopsy procedures necessary for intrapartum deaths.

A 19-year-old G2P1 Hispanic female presented to the emergency room with spontaneous rupture of membranes at 33-6/7 weeks gestation. She had no prior medical history and had undergone routine prenatal care. Upon admission, fetal heart rate monitoring showed evidence of fetal distress, and a decision was made to deliver the fetus via Cesarean section (the decedent had undergone a Cesarean section for a prior delivery). During the C-section delivery with an epidural anesthetic, the patient suddenly became bradycardic and hypoxic at the point of fascial closure, following delivery of the fetus and placenta. Cardiopulmonary resuscitation efforts were unsuccessful, and she died in the operating room. The male fetus survived and had no complications.

At autopsy, she had an intact surgical site with no evidence of cardiac disease or pulmonary embolus related to deep venous thromboses. Microscopically, there were platelet and fibrin thrombi with admixed neutrophils filling the small pulmonary vasculature. Thorough sampling and special stains of the lungs failed to reveal squamous cells in the pulmonary vasculature, necessary for the diagnosis of amniotic fluid embolus. Examination of the placenta showed acute chorioamnionitis.

Even though the clinical features in this case pointed towards an amniotic fluid embolus (i.e., sudden intrapartum bradycardia and cardiopulmonary arrest), the diagnosis could not be made because squamous cells were not identified in the pulmonary vasculature. A review of the decedent's medical records indicates that intraoperatively her hemoglobin decreased from 9.0 to 5.2 to 4.5 gm/L. No source of hemorrhage was identified at autopsy; therefore, the decrease in hemoglobin and the pulmonary platelet and fibrin thrombi were likely related to disseminated intravascular coagulopathy (DIC). Instead of classifying the cause of death as "amniotic fluid embolism", the cause of death was classified as "intrapartum maternal demise with diffuse pulmonary fibrin and platelet thrombi complicating Cesarean section for fetal distress, with acute chorioamnionitis."

The clinical and hemodynamic manifestations of amniotic fluid embolism have been noted to be similar to those that are manifested in anaphylaxis and septic shock. The signs and symptoms include hypotension, fetal distress, cardiopulmonary arrest, coagulopathy, cyanosis, dyspnea, and seizures. The pathophysiological mechanism for the development of the amniotic fluid embolism begins with maternal intravascular exposure to fetal elements, when there is a breach in the barrier between amniotic fluid and maternal circulation. This in turn initiates an endogenous mediator response similar to an allergic reaction, with mast cell degranulation and activation of the complement pathway.

The diagnosis of amniotic fluid embolism has been traditionally made by identifying squamous cells in the pulmonary vasculature; however, fetal tissue or amniotic fluid components are not always found in the women who present with the clinical signs and symptoms of amniotic fluid embolism, as was the case in our autopsy. In light of the apparent pathophysiological mechanisms involved and because squamous cells may not always be identified in the pulmonary vasculature, the term "anaphylactoid syndrome of pregnancy" has been used to describe the syndrome of acute peripartum hypoxia,

hemodynamic collapse, and coagulopathy, which we believe this case represents.

The postmortem diagnosis of amniotic fluid embolism can be challenging to forensic pathologists. The gross findings are usually nonspecific and can include pulmonary edema and atelectasis, evidence of DIC, and pulmonary hyperinflation. Autopsy findings include fetal squamous cells in the pulmonary vasculature and masses of neutrophils and fibrin thrombi in the small pulmonary vessels. Special stains such as cytokeratin and mucin may be helpful. The autopsy should include a thorough sampling of the lungs, a proper evaluation of the uterine body looking for the possibility of wall tears as well as examination of the placenta. Thorough toxicology testing and a tryptase level are also important procedures in the evaluation of intrapartum deaths when an amniotic fluid embolism is suspected because the diagnosis is essentially one of exclusion, based on clinical presentation.

Amniotic Fluid Embolism, Anaphylactoid Syndrome of Pregnancy, Intrapartum Death

G110 Pheochromocytoma Causing Unexpected Death – Two Unusual Presentations

Jacqueline L. Parai, MD, Ontario Forensic Pathology Services, Division of Anatomical Pathology, The Ottawa Hospital, 501 Smyth Road, Box 117 4th Floor, Ottawa, ON K1H 8L6, CANADA; and Iris Teo, MD, Itrat Ahmed, MD, and Christopher M. Milroy, MD, The Ottawa Hospital, 501 Smyth Road, Box 117 4th Floor, Ottawa, ON K1H 8L6, CANADA*

After attending this presentation, attendees will be able to appreciate the postmortem pathology of pheochromocytomas and sudden death.

This presentation will impact the forensic science community by presenting the medicolegal significance and varied clinical presentation of adrenal and extraadrenal pheochromocytomas including sudden death, their histological features and the possible genetic implications of their diagnosis.

Pheochromocytomas are rare tumors of paraganglionic tissue. Paraganglionic tissue is distributed throughout the body and tumors may occur in multiple sites. Patients may present with severe headaches, nausea, excessive sweating, palpitations due to tachycardia and anxiety, tremors, pain in the lower chest and upper abdomen, and weight loss. These symptoms are due to the fact these tumors produce, store and secrete catecholamines (epinephrine, norepinephrine). Patients typically have hypertension, which may be intermittent. Clinical diagnosis is made by urinary and plasma catecholamine measurement, along with imaging. The tumors may present in the adrenal medulla and extra-adrenal sites. They may rarely be associated with sudden death, and catecholamine induced damage to the myocardium may be present, as the so called catecholamine cardiomyopathy.

Two cases of sudden death due to pheochromocytomas are presented. Both patients were 34-year-old males. In the first case, the male presented with abdominal pain. An ECG showed left bundle branch block and changes of an inferior myocardial infarction. He was variably hypertensive and hypotensive. He went into cardiac arrest while undergoing radiological investigation. At autopsy there was a suprarenal mass measuring 8.5 x 7.5 x 4.5 cm, with 700 mL of blood in the peritoneal cavity along with retroperitoneal hemorrhage. On histology, the tumor had the characteristic appearance of a pheochromocytoma. There were typical Zellballen. The tumor cells stained positively with neuroendocrine markers including chromogranin and synaptophysin. The supporting sustentacular cells showed some S100 positivity.

In the second case, the male had a witnessed collapse and died unexpectedly. He had been diagnosed as a non-insulin dependent diabetic five days previously. On the day of his death, he was described as well and his glucose level had been measured within the normal range.

At autopsy a mass was found adjacent to the kidney but below the adrenal gland 3.5 cm in diameter. Histology showed the characteristic appearance of a pheochromocytoma.

Pheochromocytomas secrete catecholamines which cause hypertension. They also modify glucose metabolism, which accounts for the hyperglycemia seen in the second case. Diagnosis depends on histology and the characteristic immunohistochemical appearance. Malignancy cannot be reliably diagnosed by morphological features. These tumors may also be associated with genetic syndromes – such as multiple endocrine neoplasia (MEN) syndromes. Although traditionally known as the 10% tumor because 10 % are extraadrenal and 10% malignant, a higher proportion of the cases, of the order of 25%, are malignant when associated with familial syndromes.

In the two cases, their clinical presentations alone may have resulted in their deaths being erroneously attributed to more common causes of sudden death, such as hypertensive or atherosclerotic cardiovascular disease. An appreciation of the clinical and pathological features of pheochromocytomas however properly diagnoses these cases. As such, surviving relatives can be informed and screened.

Pheochromocytoma, Sudden Death, Adrenal

G111 Digital UV/IR Photography for Tattoo Evaluation in Mummified Remains

William Oliver, MD, MPA, and Leone Lisa, MA, Brody School of Medicine at East Carolina University, Department of Pathology and Laboratory Medicine, Division of Forensic Pathology, 7S-10 Brody Medical Sciences Building, Greenville, NC 27858*

After attending this presentation, attendees will recognize an additional value of UV/IR imaging in the evaluation of mummified remains.

This presentation will impact the forensic community by providing an additional tool for postmortem identification.

The presence and location of tattoos can be an important component in the identification of remains in the extended postmortem period when remnants of skin persist. However, when there is significant mummification, elucidation of tattoos can be technically difficult due to skin discoloration and dehydration. Many methods have been proposed to increase the visibility of tattoos in the extended postmortem interval, including rehydration, hydrogen peroxide, and exposing subdural tissue. All have some, but limited applicability.

The use of ultraviolet and infrared photography has been of significant interest in forensic science in general and of cyclical published interest in forensic pathology and odontology. A large number of articles were published in the 1990s investigating the use of so-called “alternate light” methods, including narrow band illumination, fluorescence, and UV/IR photography for the evaluation of bite marks and trauma. There has been limited publication in the use of such methods for tattoo evaluation in the extended postmortem interval. One study found utility in evaluating fluorescence of ink using narrow band illumination. This study noted that infrared photographic evaluation, while slightly more useful than hydrogen peroxide, has traditionally been of limited utility because it “required photographic skills and was difficult and time consuming.” Others have noted that the use of ultraviolet photography was difficult because it is impossible to see what is being photographed. With the use of film photography, the opportunity for quick feedback and fine-tuning of photographic parameters was not available. The photographs were, literally, taken blind.

In recent years, relatively inexpensive cameras sensitive to infrared and ultraviolet light have been marketed for forensic use. Many low-cost consumer digital cameras are sensitive to the infrared or ultraviolet spectrum, and incorporate blocking filters for standard use. An aftermarket has developed to market these cameras with the filters

removed. The availability of these relatively inexpensive cameras has spawned an active hobby market in artistic infrared and ultraviolet photography.

In this report, a commercial forensic camera sensitive in the UV/IR range was used to visualize a tattoo that was not perceptible in the visible spectrum.

The nude body of an adult female was found prone unburied in the woods. A missing person's report had been filed in a nearby city approximately two months earlier and police investigators suspected these were the missing person's remains. At autopsy, the body was largely skeletonized, with mummification of the skin of the back and upper extremities. Anthropological evaluation was consistent with the age, sex, and race of the missing person. Dental evaluation was consistent with the missing person, but was limited to do postmortem loss of teeth, which defied efforts at recovery. By history, the decedent was known to have a small tattoo of a heart on the back of her left hand, though the exact location was uncertain.

Examination of the left hand revealed marked mummification, but the skin of the dorsal surface of the hand was intact. Visual examination of the hand did not reveal any evidence of a tattoo. Attempts to increase visualization by rehydration and washing were unsuccessful. Hydrogen peroxide was not applied.

Under both UV and IR photography, a small heart-shaped tattoo was noted between the metacarpals of the thumb and index finger. The detail of the tattoo was visually similar in both spectra, though the UV provided a more subjectively "realistic" appearance of the texture of the skin.

This case demonstrates that at least with some inks, tattoos are clearly discernible using UV and IR photography. The almost immediate feedback provided by digital photography allowed evaluation of each image as taken to provide the optimum exposure.

The development of relatively inexpensive commercial digital UV/IR cameras allows the immediate evaluation and optimization of UV/IR photographs of postmortem tattoos. This, in turn, may make a previously rather esoteric method practical.

Ultraviolet, Infrared, Tattoo

G112 Undiagnosed, Untreated Acute Promyelocytic Leukemia Presenting as Suspicious Sudden Death

Pauline Saint-Martin, MD, and Patrick O Byrne, MD, Service de Medecine Legale, CHRU Tours, Tours, 37000, FRANCE; Jean Michel Gaulier, PhD, Service de Pharmacologie et Toxicologie, CHRU Dupuytren, 2 avenue Martin Luther King, Limoges, 87042, FRANCE; and Sophie Martin Dupont, MD, Agnès Peyclit, MD, and François Paraf, PhD, Service de Medecine Legale, CHRU Dupuytren, 2 Avenue Martin Luther King, LIMOGES, 87042, FRANCE*

Leukemia as a cause of sudden death is rare, because symptoms are usually present and treatment is initiated prior to death. After attending this presentation, attendees can expect to learn about a rare differential diagnosis of criminal death.

This presentation will impact the forensic science community by presenting a differential diagnosis of criminal death and reveals an aspect of the French medicolegal system which can be unknown to the American audience and in competence as it enlightens the importance of bone marrow removal during the autopsy.

Introduction: An autopsy case with acute promyelocytic leukemia is reported in which foul play had been initially suspected.

Case Report: A 40-year-old male who was found dead in his bedroom will be presented. He was working for the Brazilian Army and was in France for a training period. He had a two-month history of lower

back pain. A complete blood count was normal one month before his death. At scene, the police noticed multiple bruises of markedly different colors on the body. A forensic autopsy was requested by the Chief Prosecutor because foul play was suspected. The external examination revealed multiple subcutaneous hemorrhages of different ages covering the whole body. The autopsy showed subarachnoid hemorrhage without any skull fracture. There was no other significant finding. Toxicology was negative. Histology revealed right-sided subarachnoid hemorrhage and a cerebellar hematoma. As foul play was initially suspected, the hyoid bone was removed. Histologic examination of the bone marrow showed no normal hematopoietic cells. Myeloperoxidase staining revealed the diagnosis of acute promyelocytic leukemia (APL). Death was attributed to acute intracranial hemorrhage due to APL. The manner of death was ruled natural.

Discussion: According to the literature, the most common tumors causing sudden unexpected death in adults include bronchogenic carcinoma, acute leukemia, gastric adenocarcinoma and adenocarcinoma of the urinary bladder. Death is usually attributed to a variety of mechanisms, including hemorrhage, thromboembolism and widespread dissemination. APL is characterized by the proliferation of abnormal promyelocytes and is classified as type M3 in the French-American-British (FAB) leukemia system. APL comprises approximately ten percent of the acute myeloblastic leukemias in adults. Because of the complicating disseminated intravascular coagulation and the likelihood of threatening hemorrhage, APL is usually regarded as a medical emergency. This disease leads to a high rate of mortality, primarily from intracranial hemorrhage. There could be a tendency to overlook the diagnosis of this disease when a deceased presents multiple bruises that seem consistent with injuries. However, the French medicolegal system is different from the American system. In France, the decision to perform toxicology or histology after the autopsy is made by the office of the prosecutor and not by the pathologist. Due to financial considerations, it is quite frequent that no complimentary analyzes are made, even if the pathologist thinks it is necessary to determine the cause of death. In our case, the circumstances of death and external examination at the autopsy did not raise the diagnosis of a malignant neoplasm in the hemopoietic system. This type of case points out the importance of a thorough autopsy, including microscopic examination to protect innocent people from unwarranted prosecution. It is also important to retain bone marrow to enable the testing to be done and to confirm the diagnosis if required.

Forensic Pathology, Sudden Death, Acute Promyelocytic Leukemia

G113 Death of a Bodybuilder: A Case Report of Mixed Drug Overdose With Lethal Gamma-Hydroxybutyrate Level

Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046*

After attending this presentation, attendees will learn an approach to evaluation of a multi-drug overdose primarily due to gamma-hydroxybutyrate (GHB) with complex history and presentation; and, be able to recognize the symptoms and signs of GHB poisoning when combined with lower levels of multiple other drugs. Consideration of the changes in drug levels possible with decomposition; and be able to evaluate the role of confounding causes of death such as the possibility of heat-related death in an enclosed car in a parking lot in the sun.

This presentation will impact the forensic science community by assisting attendees to be able to recognize the signs and symptoms of gamma-hydroxybutyrate use, abuse, and overdose, particularly when exacerbated by the presence of multiple other drugs; compare to other

drug signs and symptoms when assessing a multi-drug overdose; and evaluate the confounding effect of perimortem heat exposure with onset of decomposition.

A 29-year-old male bodybuilder with a history of utilizing gamma-hydroxybutyrate (GHB or GBH) for its anabolic effect, was found dead in the passenger seat of a car in an airport short-term parking lot, at 2:00 p.m. during the month of May. The windows of the car were closed. Although it had been slightly more than seven hours since he was last seen alive, the decedent was in the early stages of decomposition.

The decedent had mentioned use of GHB to his employer as an event that occurred in the past. His father was also aware of his GHB abuse, but believed it to have ended. In April, a drug screening had not found any drugs in his system. He was known to have an intermittent problem with alcohol abuse and had recently signed up for rehab. He had sustained a significant fall not long before his death, for which he was treated and released; he had multiple healing injuries. He was also on regularly prescribed medications for a recent problem with sleep. These medications included zolpidem, alprazolam, and mixed amphetamine salts.

The week before his death, he hosted a friend from out of state, who was a physician. The night before death, which was also the last night of his friend's stay, the two of them went to a party which lasted for most of the night. In the early morning hours, they had an argument. The victim called another friend asking for intervention; this friend noted that he seemed somewhat groggy on the phone. The other friend was not able to provide intervention. A neighbor saw the victim's car depart in the early morning with two men in it, but could not identify them through the windows. It is possible that the friend who needed to go to the airport was driving the car, with the victim in the passenger's seat, where he was found dead more than seven hours later.

At autopsy, he was well developed and very muscular (5'8", 236 lbs; BMI = 35.9). The BMI classification into "obese" is likely incorrect as the body fat percentage was probably low, based on body habitus. The body showed evidence of early decomposition, with rigor passed, livor fixed in a pattern consistent with his position slumped forward in his seat, and extensive skin slip along the upper back. Small amounts of decomposition fluid in the body cavities were found on internal examination, and tissues were moderately autolyzed on histologic examination.

The only autopsy findings besides decomposition were healing injuries of the face, hands, toes, heels, and left flank, which were nonsignificant in death; and minor heart hypertrophy, which was probably physiologic (exercise-related), as he was known to do extensive exercising, and there were no hypertensive changes to the myocardium on histology. Of note, the gastric mucosa was free of small hemorrhages.

Toxicology provided the answer. There was present in his system more than enough GHB to be lethal. There were also small amounts of four other drugs, amphetamine (likely due to Adderall), citalopram (prescribed for depression), diphenhydramine (over-the-counter antihistamine, sometimes used as a sleep aid), and trazodone (another antidepressant). These four drugs likely contributed to death and likely contributed by making him sleepy, so that he did not exit the car nor telephone to seek help. Amphetamine likely made him more vulnerable to a cardiac arrhythmia in the setting of a lethal dose of GHB causing respiratory depression. Of note, no alcohol was present. The role of perimortem heat in accelerating his death could not be definitively determined by autopsy; this was a point of considerable significance to the family, who were of the opinion that the physician friend was culpable for allowing the groggy victim to remain in the car with the windows rolled up when it was time for him to catch his plane.

The time sequence of GHB intoxication, its effects in use, abuse, and overdose, and the likely mitigating or exacerbating effects of the other drugs present, are considered in relation to the findings in this case

of fatal GHB overdose in a setting of multidrug use in a decedent who was otherwise probably healthier than the average person.

Gamma-Hydroxybutyrate, Perimortem Heat Exposure, Multi-Drug Overdose

G114 Hara-Kiri or Homicide?

Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, 830 Southampton Avenue, Suite 100, Norfolk, VA 23510-1046*

After attending this presentation, attendees will be able to recognize factors from scene investigation, history, and autopsy which may help in differentiating stab wound suicides from homicides.

This presentation will impact the forensic science community by reviewing an in-depth case presentation some of the factors that assist in differentiation of stab wound suicide from homicide.

The body of a 49-year-old white male was found collapsed face down on the carpet of his bedroom during the afternoon of a Saturday in April, about twenty hours after he had last been seen alive.

The front door was secure, but the back door to the residence was unlocked and propped ajar. The decedent had been seen mowing his back yard on the evening prior to death, and all his mowing equipment was still out in the back yard. He was found clad in gray shorts without shirt or shoes, appropriate for mowing. He was known to drink heavily when he mowed.

He was last seen alive by his girlfriend, with whom he had made arrangements to grill steaks on Saturday. She came to his house at the prearranged time, found the front door locked, knocked and called out for some time, but was unable to reach him; she did not think to check the back door. She left the scene, but continued to feel concern, and at last contacted police for a welfare check. Police found the body at shortly after 1600h; emergency medical services pronounced him dead on the scene at 1643h.

On initial examination, officers found a small fluctuant discolored mass protruding from the left lower side of his abdomen, and guessed that it might be a tumor eroding through the skin. There was a small amount of brown fluid on the carpet near the mass, but no blood. Based on this information and on history that the decedent carried the diagnosis of an unspecified aneurysm, while his twin had died prematurely at age thirty four of a myocardial infarct, the decedent's doctor initially agreed to sign the death certificate. It was not until a senior officer recognized the fluctuant mass as a loop of bowel protruding through a stab wound that patrol officers realized they should contact homicide detectives.

The house was immaculate. The decedent was a martial artist, and the first floor of the house contained a room dedicated to multiple displays of numerous Eastern swords and daggers. As far as police could ascertain, no swords were missing. There was no obvious blood staining or spatter, but there were too many swords in the room to ascertain on the day of death whether any had blood smears, or had been wiped.

There had been no 911 call nor was there any sign of a struggle. A beagle dog in the house seemed to be in no distress, and had not been heard barking. Cash and expensive watches were in place where they had been laid out with care equidistant and parallel on top of a dresser in the bedroom. The only item out of place was a box cutter, with a possible bloodstain on the blade, which was lying on the counter in the upstairs bathroom about eight feet from where the decedent was found collapsed. In the bedroom, about the same distance from him there was a tray table at the foot of the bed, on which was a tray with three sheathed knives laid out carefully equidistant and parallel. Investigation showed wiped blood smear on one of the sheathed blades.

At autopsy, the decedent was muscular and slightly obese at 65" and 183 lbs. There were no defense injuries on his arms or hands. The fingernails were very cyanotic, but short and even, without chips or tears. There were scabbed healing superficial abrasions on the backs of the 2nd and 3rd fingers, by the proximal interphalangeal joints. A number of linear scars were identified on the arms and hands. Scars on the backs of the hands appeared consistent with martial arts practice, but three transverse superficial linear scars across the wrist suggested self-incision, and there were overlapping linear scars on the anterior left upper arm which also suggested self-cutting. A 3½" linear scar on the outer aspect of the left upper arm was initially attributed to an assault he told family he sustained many years prior.

The only sign of injury was a complex stab wound overlain by incised wounds in the left lower quadrant. The abdominal wall showed internal characteristics of perforation by more than one blade. The wound, which was 1" long and about 6" deep, and therefore not consistent with the box cutter in the bathroom, perforated the abdominal aorta and ended its course in the anterior ligament of the lumbar spine; it caused death by internal bleeding. There was an extensive and bulging retroperitoneal hematoma, as well as 1400 cc of liquid blood and clots forming casts of the right and left colonic gutters. The blade passed very close but without injury to the loop of bowel which eviscerated through the stab wound. Evisceration had blocked the exit of blood through the wound and was responsible for the lack of blood on the carpet at the scene. Toxicology showed an ethanol level of 0.19% by weight by volume in blood, 0.23% in vitreous humor. Of note, no aneurysm of the cerebral, coronary, or aortic circulation was identified.

In the trash can in the bedroom was a letter to his girlfriend in his handwriting. The letter was not a suicide note. It appeared to be an angry letter of accusation. However, it had been crumpled and discarded without signing.

The decedent's complex history, involving decades of training in martial arts, samurai stories and films, alcoholism, divorce, current plans for remarriage, and the absence of support for his remote story of assault, caused a scenario to develop suggesting that he had attempted to commit hara-kiri as an honorable way out of an intolerable emotional situation. The story unraveled at last when the family reported on reading years of his journals, at which time a manner of death could be pronounced.

This complex history is presented in light of the autopsy findings and scene investigation to illustrate why this case of attempted hara-kiri was adjudged to be suicide rather than homicide.

Hara-Kiri, Stab Wound, Manner of Death

G115 Two Cases of Novel Influenza A (H1N1) Virus (“Swine Flu”) Infection: Clinical Presentations, Autopsy Protocol With Findings, and Review of Literature

Abraham T. Philip, MD, Onondaga County Medical Examiner's Office, 100 Elizabeth Blackwell Street, Syracuse, NY 13210; Kerry Whiting, BS, and Sanjay Mukhopadhyay, MD, State University of New York - Upstate Medical University, 766 Irving Avenue, Syracuse, NY 13210; and Robert Stoppacher, MD, Onondaga County Medical Examiner's Office, 100 Elizabeth Blackwell Street, Syracuse, NY 13210*

After attending this presentation attendees will be familiar about the origins, spread, autopsy procedures, and findings in seven cases of H1N1 virus infection, that is currently designated a global pandemic.

This presentation will impact the forensic science community by organizing its preparation for a mass disaster situation involving a biological agent. The lessons learned from the way the nation and the world has responded will also be reviewed.

This novel infection, which has undergone a series of nomenclature changes (including new influenza virus, swine-like influenza virus,

swine-origin influenza virus, and known colloquially as “swine flu”) is now labeled a novel form of influenza. A virus resulting from a combination of genes derived from two types of swine influenza, one of which was in turn a “reassortment” of human, avian, and swine influenza A strains.

The initial spike of cases started in La Gloria, Mexico, generally regarded as the ground zero of this epidemic. The United States of America soon after became the epicenter of this rapidly spreading epidemic with a distinct pattern of disease incidence in relation to the usually seasonal variety of Influenza. On June 11, 2009, the WHO proclaimed the H1N1 infection as a global pandemic, based on its spread in several continents, especially in the southern hemisphere. Now in early November, North America has become the epicenter of the disease. As of the of November 1, 2009, there have been more than 480 thousand laboratory confirmed cases of pandemic influenza worldwide and over six thousand deaths reported to the World Health Organization. The week of October 25 to 31 saw spike of at least eighteen flu related pediatric deaths, of which fifteen death were confirmed 2009 H1N1 and three were not sub-typed.

Described in this presentation is the experience with cases evaluated in two counties in Central New York. The clinical history, hospital course and autopsy precautions and protocol followed, and diagnostic testing in cases seen by us are summarized in this Table # 1.

Table # 1.

#	Age	Sex	Major risk factor(s)	Clinical progression	Autopsy	Diagnosis	Major pathological findings	Other pathological findings	Major non-pathological findings
				Onset to Admit to death					
1	36	Male	Morbid Obesity BMI 46.3	05/22/09 – 3 days - 9	Yes	RT-PCR	Diffuse Alveolar Damage	Patchy alveolar hemorrhage	Congestive heart failure
2	46	Female	Chronic Ethanol abuse	05/31/09 – 0 days - 5	Yes	RT-PCR	Diffuse Alveolar Damage	Acute bronchopneumonia	Steatohepatitis remote brain injury
3	13	Female	Asthma, Spina Bifida	06/26/09 – 5 days - 7	No	RT-PCR	Diffuse lung disease	Pneumo-mediastinum	
4	44	Female	Morbid Obesity BMI 52.2	06/30/09 – 7 days - 0	Yes	RT-PCR	Intravascular hemorrhage	Aleactasis	Passive venous congestion liver
5	22	Female	Pregnancy	08/23/09 – 6 days - 4	Yes	RT-PCR	Diffuse Alveolar Damage	Pregnancy changes to liver	Uterus early involucral change
6	20	Male	Asthma, Spina Bifida	09/04/09 – 1 day - 7	Yes	RT-PCR	Diffuse Alveolar Damage	Consolidation	Sub emphysema, Pleural effusion
7	47	Female	Developmental delay, Asthma	10/18/09 – 4 days - 3	Yes	Surrogate	Consolidation		

Besides the variation in risk factors, the H1N1 infection itself has raised many changes in business (loss of earning by the pig industry), changes in social mores, religious rituals and public behavior. It has also raised questions, including how one defines epidemic and pandemic, and to what extent preventive strategies should be allowed to disrupt normal life and economic activity. In New York State the Public Health Department had promulgated laws mandating all health care workers to receive the Seasonal and Novel Influenza vaccinations. Onondaga County expanded the requirement to include all medical examiner Personnel as well. These were later rescinded, and shortages of the vaccines became the dominant theme for conversation. Meanwhile there are reports that the virus has mutated and developed resistance to commonly used anti retroviral medications.

This presentation will also review the most recent publications, monitor and update the latest information about the spread of the infection as well as evaluate the public health response and lessons learned from the epidemic/pandemic. The main focus of this presentation will be to review the role of medical examiners/forensic pathologists monitoring sentinel events which adversely influencing public health.

Swine Flu, Bronchopneumonia, H1N1 Virus

G116 An Unusual Case of “Piggyback” Sandwiched Projectiles Caused by a Round-Nose Bullet Shot Through a Door

Geoffrey P. Smith, MD, Kelly L. Rose, MD*, and Randy L. Hanzlick, MD, Fulton County Medical Exam Center, 430 Pryor Street, Southwest, Atlanta, GA 30312

The goal of this presentation is to reinforce with an unusual example, the concept of intermediate targets and secondary projectiles as they relate to gunshot injuries and in addition, to highlight the importance of correlating scene investigation with autopsy findings.

This presentation will impact the forensic science community by reinforcing the concept of secondary projectiles and highlighting the importance of correlating scene investigation with autopsy findings.

The concept of an intermediate target and secondary projectiles causing bodily injuries has been well documented in relation to gunshot wounds. An unusual case is presented in which a round-nose, copper jacketed .40 caliber projectile perforated a foam-filled metal door and carried two disc-like pieces of metal from the inner and outer lining of the door to the victim's body. Autopsy showed a distant type gunshot entry wound to the left front shoulder area and an adjacent superficial laceration, as well as a second small laceration of the left flank. The overlying clothing had corresponding defects from the bullet and fragments. On the adjacent skin and under the clothing, two metallic, essentially circular, concave pieces of thin metal were found. A round-nose, copper jacketed .40 caliber bullet had perforated the spinal cord and was retrieved from the spine. The nose of the bullet was slightly flattened. The two disc-like pieces of metal were very close in diameter to the bullet's diameter and fit nicely on top of each other on the flattened nose of the bullet, having the same, slightly out-of-round shape as the underlying bullet nose. The fragments also had a similar thickness as the metal surfaces on the door. Scene investigation and findings suggested that the man was shot through the door and the bullet carried the two metal discs “piggyback” on its flattened nose toward the victim, then the fragments perforated the clothing causing the small lacerations. Wounds caused by materials from intermediate targets have been well described, but we have found no case reports of piggyback sandwiched fragments carried on a round nose bullet such as we have described. By thoroughly analyzing the scene and the bullet, we were able to determine that the door fragments piggybacked on the bullet's nose to the decedent. Therefore, this case highlights the importance of correlating scene investigation with autopsy findings and shows the benefit of maintaining persistence when trying to explain discovered peculiarities.

Bullet Wounds, Intermediate Targets, Projectiles

G117 Newborn Kidnapping by Crude Cesarean Section

Todd M. Luckasevic, DO*, Laine L. Frazier, BS, Abdulrezak M. Shakir, MD, Baiyang Xu, MD, and Karl E. Williams, MD, MPH, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222

The goal of this presentation is to illustrate an unusual case of fetal abduction via crude cesarean section.

This presentation will impact the forensic science community by illustrating the need for close collaboration between the forensic pathologist and the forensic laboratory when dealing with cases that involve kidnapping, drugging and restraining.

Introduction: The number of missing children reported each year in the United States remains astronomical. Between the years 1983 and 2008, 256 infant abductions occurred in the United States. The first documented case of a newborn kidnapping by cesarean section occurred

in 1987. Currently, there are a total of eleven reported cases in which the fetus was abducted by a prenatal fetal snatcher between the years 1987 and 2008.

Materials and Methods: This case involves an 18-year-old African-American female who was 38 weeks pregnant. The victim became acquainted with the abductor, a 38 year old African-American female, while visiting their respective male partners at the jail. On July 15, 2008, the women saw each other again at the jail and engaged in conversation. The victim never returned to her home that evening. On the next day, the abductor presented to a local hospital claiming that she just gave birth in her apartment to a healthy baby boy.

Results: The scene of the crime is a third floor apartment in Wilkinsburg, PA. There was a foul order coming from the apartment. There were numerous flies around the windows. The decedent's body was located in an alcove off of the bedroom hidden by a mattress and head board. The body was that of a decomposing black female who was wrapped in a comforter. Upon inspection, it was noted that the hands were bound behind the back with duct tape and the ankles were bound together also with duct tape. The head was completely wrapped in duct tape with a plastic bag and duct tape totally occluding the airway. There was an incised wound of the abdominal area with clearly exposed intestine and uterus. The placenta was clearly visible.

Further inspection of the apartment revealed a roll of duct tape with a bloody fingerprint and a roll of plastic wrap. Loose pills were found on a shelf. All the above evidence was collected and submitted to the forensic laboratory.

The autopsy revealed a well developed, well nourished African-American female in a state of moderate decomposition. The body was identified via fingerprint comparison. The postmortem examination revealed a crude jagged edged incision of the lower pelvis and abdomen. There was exposure of a gravid uterus with a vertical incision over its anterior aspect. Loops of small intestine were exposed. A placenta was recovered from the comforter that covered the body. The distal edge of the umbilical cord revealed a dog-eared cut surface. Inspection of the cervix revealed that it was not dilated.

There were no other pathologic abnormalities or trauma identified during the autopsy.

Conclusions: The pills that were recovered from the scene were identified as Gabapentin. The decedent's blood along with a sample of the newborn baby's urine was found to contain elevated levels of Gabapentin. The abductor's fingerprints were recovered from the rolls of duct tape and plastic wrap. Investigation revealed that the abductor recently had a miscarriage and had recently faked another pregnancy going so far as to have a baby shower weeks before the abduction. The cause of death was certified as asphyxiation due to smothering by plastic bag and duct tape with contributing conditions of exsanguination due to partial evisceration of abdominal and pelvic contents and the presence of Gabapentin in the victim's blood.

Pregnancy, Kidnapping, Cesarean Section

G118 An Unusual Case of Accidental Poisoning: Fatal Methadone Inhalation

Cristian Palmiere, MD*, Christophe Brunel, MD, Frank Sporkert, MD, and Patrice Mangin, MD, PhD, Centre Universitaire, Romand de Medecine Legale, Rue du Bugnon 21, Lausanne, CH-1011, SWITZERLAND

After attending this presentation attendees will gain insight on a case of unusual accidental poisoning with methadone, occurring in a 38-year-old man who inhaled a white powder bought on the black market.

This presentation will impact the forensic science community by presenting the dangers from using “home-made” drug preparations. To date and to our knowledge, no case of accidental death following

methadone inhalation has been previously described up to the case herein presented.

Methadone hydrochloride (3-heptanone, 6-(dimethylamino)-4, 4-diphenyl-, hydrochloride) is a white, essentially odorless, bitter-tasting crystalline powder. It is very soluble in water.

It is a synthetic, long-lasting opioid with pharmacologic actions qualitatively similar to morphine and is active by oral and parenteral routes of administration. It is primarily used for relief of moderate to severe pain. It is also used in the detoxification and maintenance of patients who are dependent on opiates, particularly heroin. Recreationally, it is abused for its sedative and analgesic effects.

Methadone was synthesized by Ehrhart and Schaumann in Germany in 1941 in the Hoechst Laboratories and came into clinical use after the war. The use of methadone as a maintenance drug in heroin addicts began only in 1964, when Dr Vincent Dole and Dr. Marie Nyswander pioneered the use of a particular form of synthetic opiate for narcotic maintenance.

It is primarily a μ -receptor agonist and may mimic endogenous opioids and affect the release of other neurotransmitters (acetylcholine, norepinephrine, substance P and dopamine). This accounts for its analgesic and antitussive properties, respiratory depression, sedation, decrease in bowel motility, increase in biliary tone, hormone regulation and increase of prolactin and growth hormone release, miotic pupils, nausea, and hypotension.

As well as being an opioid receptor agonist, methadone acts as an antagonist at the N-methyl-D-aspartate (NMDA) receptor. The NMDA receptor system is a major excitatory central nervous system pathway involved in the neurobiology of pain. Methadone's ability to antagonize the NMDA receptor system may explain its superior analgesic behavior and why it can have effects in morphine resistant pain.

Unlike other opiates, methadone is primarily administered orally because of its good gastrointestinal absorption. It has high oral bioavailability and minimally lower rectal bioavailability. It is commercially available in liquid form. Most pharmacies, however, manufacture solutions, capsules or suppositories from less costly methadone powder.

Methadone hydrochloride powder is for oral administration only and is used in the preparation of a liquid by dissolving the powder in an appropriate vehicle. This preparation must not be injected.

The first fatality from methadone was recorded by Bieter and Hirsch (1948) in a 54-year-old man, who was given hypodermic injections of methadone (50 mg) in three doses over eight hours and who developed cyanosis and hypotension. They also recorded severe respiration depression in a 15-year-old boy who was given, by mistake, a 25 mg methadone hypodermic injection.

After inhaling methadone powder, he developed a cardiopulmonary arrest. Cardiac activity was restored only after prolonged resuscitative efforts. He was admitted to the local hospital and died after twenty-four hours of intensive care due to cardiac arrest.

An autopsy was performed at the University Center of Legal Medicine in Lausanne. At external examination there were only signs of medical treatment. Internal examination showed congestion of internal organs and cerebral and pulmonary edema. Histological examination showed moderate generalized congestion and hepatic steatosis.

Toxicological tests included blood ethanol levels and screening for common drugs and illegal substances by gas chromatography and mass spectrometry. This presentation will impact the forensic science community by showing the dangers of using "home-made" drug preparations. To date, case presentations of accidental death following methadone inhalation have not been previously described.

Conclusion: The cause of death was determined to be methadone intoxication, whose effects have been enhanced by the presence of ethanol.

Substance Abuse, Methadone, Intoxication

G119 Fatalities Occurring With Ingestion of Ibogaine

James R. Gill, MD, Office of Chief Medical Examiner, 520 First Avenue, New York, NY 10016; and Kenneth R. Alper, MD, New York University School of Medicine, 403 East 34th street, 4th Floor EPC, New York, NY 10016*

After attending this presentation, attendees will understand ibogaine, its uses, and issues that may arise with the investigation of these deaths.

This presentation will impact the forensic pathology and toxicology communities by increasing knowledge of ibogaine's use, detection, and risk of death.

The psychoactive indole alkaloid ibogaine is the focus of an alternative medical subculture in which it is used most often for opioid detoxification, as well for individuals seeking psychotherapeutic insight or religious experience. Eighteen fatalities were reviewed that are reported to have occurred since 1990 in individuals within seventy six hours of taking ibogaine. These deaths occurred in numerous countries and we reviewed all available autopsy, toxicologic, and investigative reports.

There were fourteen males and four females with a mean age of 39 years (range 24-54) years. Fourteen individuals took ibogaine for the indication of acute opioid withdrawal and 3 individuals were non-addicts who used it for spiritual/psychological reasons. The circumstances were unknown in one decedent. Ibogaine was given as the HCl form in nine instances at doses ranging from 4.5 to 29 mg/kg, and as an alkaloid extract in four. The concentrations determined in ten decedents ranged from 0.24 to 6.6 mg/L. The time interval from the most recent ingestion of ibogaine until death ranged from 1.5 to 76 hours. In addition, commonly abused drugs (including benzodiazepines, cocaine, opiates, and methadone) were detected in eight of eleven decedents. Seven of the decedents had co-morbidities including: cirrhosis, hypertensive and atherosclerotic cardiovascular disease, and obesity. Among the two decedents in which no other drugs of abuse were detected in postmortem toxicology analysis, one had advanced heart disease and another had cirrhosis of the liver. Full toxicology and autopsy results were not available in seven and three decedents, respectively. Among these 18 decedents, the involved countries included the United States (5), Mexico (4), France (4), the Netherlands (2), Germany (1), the United Kingdom (1), and South Africa (1).

The uncontrolled settings in which ibogaine is given make the causes of these deaths difficult to evaluate, and little is known regarding toxic concentrations of ibogaine in humans. Contributing causes of some of these deaths appear to have involved drug use during treatment and preexisting cardiovascular disease. There appeared to be no clinical or postmortem evidence suggestive of a characteristic syndrome of neurotoxicity. Cardiac monitoring may be a more important safety issue in view of published observations of bradycardia in animals and a recent case report of QT prolongation in an alcohol dependent woman following the ingestion of alkaloid extract, as well the common use of pretreatment EKGs and cardiac exclusion criteria, and in some medical settings, implementation of cardiac monitoring during ibogaine treatment.

Ibogaine, Intoxication, Substance Abuse

G120 Acetaminophen Induced Death of a Fetus With Maternal Survival: An Unusual Case of a Suicide Attempt Resulting in Fetal Death

Jeffrey K. Racette, MD, Todd M. Luckasevic, DO, Baiyang Xu, MD, Abdulrezak M. Shakir, MD, and Karl E. Williams, MD, MPH, Allegheny County Medical Examiner's Office, 1520 Penn Avenue, Pittsburgh, PA 15222*

After attending this presentation attendees will learn about an unusual case of a suicide attempt with unexpected complications to an unborn child.

This presentation will impact the forensic community by illustrating the risks of acetaminophen overdose on fetal survival.

Introduction: Suicide represents one of the most common causes of death in young women. Acetaminophen overdose represents one of the most common methods used to attempt suicide. Suicide rates among pregnant women are fortunately rare by comparison. However, poisoning deaths, both suicidal and unintentional are rising.

Material and Methods: The subject of this case is a 32-year-old caucasian woman who was pregnant with a healthy 35 week, 5 day gestation fetus. The subject has a history of depression and is prescribed Zoloft, although she was not compliant with her medications. She has no prior suicide attempts or ideations. She had a fight with her husband and exhibited increasing depressive symptoms. She stated to her husband that she had taken 'all her medicine', but she refused medical attention for approximately thirty six hours. Upon admission to the hospital, she was found to be in liver failure. She was treated with n-acetylcysteine. The next day, she started having uterine contractions. She was not able to clot her blood due to acetaminophen toxicity and liver failure, precluding a Cesarean section. Attempts to delay the delivery were unsuccessful. The fetus became increasingly bradycardic with labor progression and died shortly before spontaneous vaginal delivery (approximately four and one half days after the initial overdose event).

Results: The external and internal examination of the fetus was consistent with a gestational age of 36 weeks. There were no gross malformations, anomalies or evidence of external trauma to either the fetus or to the placenta. Likewise, metabolic screening was negative and postmortem tissue cultures were not helpful. Histologic sections of the fetal tissue were unremarkable with no signs of placental abnormalities or liver necrosis. Neuropathology of the brain revealed findings consistent with fetal distress and hypoxia. Postmortem toxicology on the fetal blood revealed an acetaminophen level of 8.55 mcg/ml.

Conclusion: The cause of death in the previously healthy fetus is attributed directly to the high levels of maternal acetaminophen. In an adult, an intake of 7000 mg or more is associated with death via liver failure in the absence of treatment. The maternal intake in this case is estimated to include 60 tablets of 500 mg each. Acetaminophen readily crosses the placental barrier to alter the function of the immature fetal liver which has only minimal abilities to safely metabolize the drug. The fetus is thus placed at greater comparative risk by acetaminophen than is the maternal source in cases of an acetaminophen overdose.

The mother ultimately survived, although she was placed on full liver support for coagulopathy. She is currently on the liver transplantation list. The fetus, despite survival to within minutes of delivery, died in utero secondary to fetal distress complicated by maternal acetaminophen toxicity.

Suicide, Acetaminophen Overdose, Fetal Complications

PATHOLOGY/BIOLOGY

G1 Exertional Collapse in a Youth With Hemoglobin SE

Elise F. Arbefeville, MD, and Vernard I. Adams, MD, Hillsborough County Medical Examiner Department, 401 South Morgan Street, Tampa, FL 33602*

After attending this presentation, attendees will understand one of the potentially lethal sequelae of hemoglobinopathy SE.

This presentation will impact the forensic community by helping forensic pathologists recognize occurrences of exertional death in compound heterozygous SE hemoglobinopathy.

Hemoglobin S is the most common abnormal hemoglobin. It occurs in 10% of North Americans of West African descent. Hemoglobin E is the second most frequent abnormal hemoglobin and is found in persons of Southeast Asian ancestry. Because of the wide geographic separation of the original epicenters for these genotypes, the double heterozygous and manifesting as hemoglobinopathy SE is uncommon with less than 30 cases reported. Hemoglobinopathy SE is typically asymptomatic. A twelve-year-old American boy was participating in football practice in the sun in summer when he collapsed ill on the ground. When the paramedics arrived, he was alert, hypotensive and in sinus tachycardia. His temperature was 97.3 degrees Fahrenheit. During transportation to the hospital his heart was unstable and several sternal rubs were performed. He initially responded to the treatment but his heart rate dropped suddenly. He became unresponsive with pulseless electrical activity followed by asystole. Resuscitation efforts started by the paramedics and continued in the Emergency Room were unsuccessful. On gross examination the spleen, lungs, brain, liver, and heart were unremarkable. Microscopically the cerebellum, heart, and kidney had sickled erythrocytes. Hemoglobin electrophoresis revealed 0.9% hemoglobin F, 57.4% hemoglobin S, 34.2% hemoglobin E, and 7.5% other. Follow-up investigation determined that the decedent's father was of West African ancestry and his mother had Thai ancestry. This is an example of exertional collapse in a person with hemoglobinopathy SE with a clinical presentation similar to that sometimes observed in persons with sickle cell trait. The pathophysiology of sickling in persons heterozygous for hemoglobin S is discussed with particular reference to the mitigating and aggravating effects of other abnormal hemoglobin haplotypes.

Hemoglobinopathy SE, Exertional Collapse, Sudden Death

G2 Machinery-Related Occupational Death: The Relevance of Workplace Investigation and Antemortem Radiological Data in Forensic Reconstruction

Giovanni Cecchetto, MD, Via Faloppio 50, Padova, 35121, ITALY; Guido Viel, MD, and Federica De Lotto, MD, University of Padua, Via Faloppio 50, Padova, 35121, ITALY; Renzo Manara, MD, Istituto di Neuroradiologia, Padova, 35121, ITALY; Massimo Montisci, PhD, Via Faloppio 50, Padova, 35121, ITALY; and Silvano Zancaner, MD, Sede di Medicina Legale - Università degli Studi di Padova, Via Faloppio 50, Padova, 35121, ITALY*

After attending this presentation, attendees will have a clear example of the utility of radiological data and workplace investigations in reconstructing work-related deaths.

This presentation will impact the forensic community by demonstrating the importance of taking into consideration radiological data (x-rays, computed tomography or nuclear magnetic resonance) obtained at hospital admission and of performing a detailed work-place investigation when a work-related incident must be investigated.

A "work-related death" is defined as "A person who was fatally injured as a result of, or who died of a fatal condition caused by, exposure to their own or others' activity or work factors; or who was fatally injured whilst travelling to or from work."

In 2002, 1,478 Italian workers died from work-related injuries. In the same year 5,475 United States workers died due to traumatic injuries related to their work.

There are many potential contributing factors to any work-related incidents, including aspects or characteristics of the working systems, the equipment and material used, the environment, and the worker. For these reasons it is very important to verify if any malfunctioning equipments or any lack in safety measures have played a role in the occupational injuries.

In many cases reconstructing the event can be difficult because of the lack of detailed information about the circumstances of the incident and the design description of the machinery. Furthermore, the victim may not die at the workplace, but is admitted to the hospital and undergoes neurosurgery. In such cases neurosurgeons, removing skull fragments and generating new fracture lines, can complicate forensic examination and sometimes prevent a clear identification of the etiology of the lesions.

A case of a 40-year-old man who was involved in an injury while performing his job in a manufacturing industry will be presented. The victim, found unconscious by a colleague, was immediately transported to the general hospital. In the emergency room he presented with severe cranial trauma with bilateral skull fractures, a subarachnoid hemorrhage, and multiple cortical and intraparenchymal contusions. Despite urgent craniotomy and neurosurgical treatment the man died due to increased intracranial pressure.

Forensic autopsy revealed:

- the laceration of the right ear;
- a curved surgical sutured incision at the left side of the head;
- a lack of part of the left parietal bone due to the craniectomy;
- a linear fracture of the right parietal bone;
- massive subarachnoid and fourth ventricular hemorrhage;
- hemorrhagic necrosis of the pons and medulla oblongata.

There were no witnesses watching the accident and the pictures of the work place did not help the reconstruction. Moreover, the findings

collected at autopsy did not allow investigators to establish whether the skull had been struck by a blunt object or had hit the ground violently, preventing a clear identification of the etiology of the cranial fractures.

To analyze the morphology of the fractures and their location a three-dimensional (3D) reconstruction (surface shaded display, SSD) based on CT scans performed at admission to the emergency room was employed. The analysis revealed a depressed skull fracture involving the left sphenoid and temporal bones with penetration of bone fragments in the left temporal lobe.

With the new information gained from the 3D-CT reconstruction of the skull, a second work-area investigation was performed. The fit-matching analysis between the components of the machinery and the depressed skull fracture permitted to identify a metal parallelepiped as the cause of the cranial staving and to reconstruct the event.

This case underlines the importance of taking into consideration radiological data (x-rays, computed tomography, or nuclear magnetic resonance) obtained during hospital admission and of performing a detailed work-place investigation when a work-related incident must be investigated and reconstructed.

Machinery-Related Occupational Death, Forensic Radiology, Work-Place Investigation

G3 Impetigo Contagiosa Simulating Non-Accidental Injuries in a Pregnant Woman Using Intravenous Drug

Fleres Pierangela*, Institute of Legal Medicine, Via del Vespro, n. 127, Palermo, 90100, ITALY; Farina Graziana, MD, Institute of Legal Medicine of Palermo, Via del Vespro, n. 129, Palermo, 90100, ITALY; Antonina Argo, via Narbone n. 13, Palermo, , ITALY; Paola Pugnetti, Department of Biotechnology and Legal Medicine, Section of Legal Medicine, Via del Vespro, n. 129, Palermo, 90127, ITALY; Paolo Procaccianti, Palermo University, Via del Vespro, n. 127, Palermo, 90100, ITALY; and Emiliano Maresi, Via del Vespro, n. 127, Palermo, 90100, ITALY

After attending this presentation, attendees will understand the possibility of pitfalls when distinguishing between pathological and traumatic injuries.

This case presentation will impact the forensic science community by emphasizing the possibility of these pitfalls when distinguishing between pathological and inflicted injuries.

This case confirms that for subjects using intravenous drugs, a fulminating course of endocarditis by *Staphylococcus aureus* that involves the left cardiac valves in association with systemic embolism of cutaneous vessels may cause dermal lesions simulating non-accidental injuries.

Even though it is well known how the use of intravenous drug increases the risk of endocarditis, available data about the clinical aspects related to the involved site and bacteriological characterization seem to be controversial. *Staphylococcus aureus* represents the most frequently implicated microorganism (i.e., 76% of cases) that significantly impacts the tricuspid valve. Different from the other etiologic forms, the endocarditis by *S. aureus* generally starts with symptoms of sepsis and pulmonary embolism linked to a past use of intravenous drug which defines the so-called "diagnostic triad" of the tricuspid valve endocarditis. Cardiac insufficiency and neurological signs are not usual symptoms. In endocarditis cases resulting from *S. aureus*, a fulminating course has been observed only if the left cardiac valves were involved, with systemic embolism and/or cardiac decompensation. The course is favorable in the remaining cases.

Case: A young woman, at the 32.2 week of amenorrhea was assisted by first aid and admitted to the hospital with a diagnosis of

"labor of preterm fetus." At the clinical exam, the woman was in a very bad general condition and not awake. She had widespread signs of acupuncture, ecchymoses and bruises in the forearms, bruises and scrubs on both the thighs and the vulva. The fetus was in cephalic presentation and the membranes were broken and very bad smelling. The woman was assisted during labor. However, the fetus, a male weighing 1,530g, was terminal. Immediately after the labor, the woman exhibited cyanosis, marked hypocapnia, hypotension, and hypothermia. She was transferred to the intensive care unit where she arrived unconscious with tachypnea, tachycardia, hypotension, metabolic acidosis, hyperkalemia, and hypercreatinemia. Despite intubation, a sudden bradycardia arose evolving into asystole after about four hours. Resuscitation was attempted but the patient died by electro-mechanical cardiac dissociation. The external exam of the decedent showed extended bruises and abrasive injuries on the thighs and on the vulva, resulting in the hypothesis that the woman could have been a victim of violence. The judicial authority, considering the clinical evolution of the patient and the hypothesis of personal violence, ordered the autopsy of the woman and fetus.

The autopsy and histological examinations revealed tricuspid valve acute vegetating endocarditis by *S. aureus*, multiple septic pulmonary, renal, encephalic, cardiac and cutaneous emboli, impetigo contagiosa causing apparent cutaneous abrasions, ecchymoses, and consumption coagulopathy. Similarly, the fetal autopsy showed that the cause of death was a sepsis by *S. aureus*.

This case emphasizes the possibility of pitfalls in distinguishing between pathological and traumatic injuries.

Impetigo Contagiosa, Non-Accidental Injuries, Cutaneous Emboli

G4 HPLC Analysis of Benzocaine in "Green Products"

Harminder S. Bhawara, PhD*, fsl, S/O Shri A.S. Bhawara, Shanti Nagar, Near Ram Mandir, Raipur (C.G), INDIA

After attending this presentation, attendees will understand some principles of analyzing condoms that contains benzocaine as a desensitizer. Such a condom is commonly known as a "Benzocaine condom." Benzocaine is a compound that is prepared from 4-aminobenzoic acid and ethanol. It is also the active ingredient in many over-the-counter anesthetic ointments and is indicated for general use as a lubricant and topical anesthetic on intratracheal catheters, pharyngeal and nasal airways, sigmoidoscopes and vaginal specula.

A benzocaine condom is a completely unique condom in itself. These condoms have a small amount of benzocaine lubricant cream in the tip. This cream helps to disperse the heat of the body. The main role of benzocaine is to desensitize the tip of the penis and prolongs the act of lovemaking between couples. Benzocaine binds to sodium channel and reversibly stabilizes the neuronal membrane which decreases its permeability to sodium ions. Depolarization of the neuronal membrane is inhibited thereby blocking the initiation and conduction of nerve impulses, thus making the sexual encounter last longer.

The condom is a widely used mechanical barrier contraceptive. It is one of the oldest methods of birth control. They are available over the counter as a non-prescription product and are procured very easily by sexual offenders. Sexual offenders often use condoms in the commission of sexual assaults in order to prevent identification through deposited biological material. Even the detection of DNA is inhibited in cases of sexual assault involving condom use. In such circumstances trace evidence, including condom lubricant residues viz. PEG, PDMS, benzocaine, etc. provides the crucial associative evidence. The seminal fluid residue containing sperm, proteins, blood grouping factors, and DNA helps in identification of sexual assault offenders. However, perpetrators of sex crimes using condoms during the commission of sexual assaults prevent identification through deposited biological

material. However, when assailants use condoms, they leave behind other valuable evidence.

Benzocaine, HPLC, Condom

G5 Child Deaths Due to Television Falls With Injury Patterns That Mimic Child Abuse

Evan Matshes, MD, c/o Dr. Amy Gruszecki, Southwestern Institute, of Forensic Sciences, 5230 Medical Center Drive, Dallas, TX 75235; Reade A. Quinton, MD, University of Texas Southwestern, Department of Pathology, 5323 Harry Hines Boulevard, Dallas, TX 75390; and Amy C. Gruszecki, DO, and Jeremy Deisch, MD*, Southwestern Institute, of Forensic Sciences, 5230 Medical Center Drive, Dallas, TX

After attending this presentation, attendees will have learned about two cases illustrating the types of injuries sustained when televisions fall on small children and their similarity to inflicted child abuse trauma.

This presentation will impact the forensic community by explaining how blunt trauma secondary to falling televisions is occasionally reported in the clinical literature; however, descriptive reports of the patterns of such injuries are limited and such cases may mimic those considered “typical” of inflicted trauma.

Data from the CDC indicate that accidents and inflicted trauma account for 33 percent and 5-8 percent of childhood deaths, respectively. Blunt trauma secondary to falling televisions is occasionally reported in the clinical literature, however, descriptive reports of the patterns of such injuries at autopsy is limited. Data from the clinical literature indicate that under such circumstances, blunt head trauma is far more common than blunt chest or abdominal trauma. The severity and patterns of injury identified in such cases may mimic those considered ‘typical’ of inflicted trauma. As such, careful integration of data collected from the death scene (including witness statements), from hospital records, and all components of the autopsy is necessary to ensure accurate and defensible determination of cause and manner of death. Two cases will be presented to illustrate the types of injuries sustained when televisions fall on small children.

Case #1: A 13-month-old male was at his aunt’s house, playing with other children. A family member heard a loud crash, after which he observed a 21-inch cathode ray tube-type television lying on the child’s head. Emergency Medical Services (EMS) was summoned, and the child was transported to the nearest Emergency Department (ED). After initial evaluation, he was admitted to the Intensive Care Unit (ICU). A computed tomography (CT) scan revealed left-side calvarial skull fractures, left orbital skull fracture with slight proptosis, laceration of the left transverse dural venous sinus, and expansile intracerebellar hematoma, for which he underwent suboccipital craniotomy. Despite supportive measures, he expired 15 days after hospital admission. Pertinent autopsy findings included posterior scalp abrasions; frontotemporoparietal and occipital scalp and subgaleal hemorrhages; simple linear, minimally displaced fractures of the left lateral aspect of the frontal bone and orbital shelf; complex comminuted fractures of the left sphenoid and temporal bones; extensive comminuted fractures of the squamous portion of the occipital bone; subdural and subarachnoid hemorrhages; cerebral edema; cerebellar sequelae of neurosurgical evacuation of intraparenchymal hematoma; bilateral optic nerve sheath hemorrhages; no retinal hemorrhages. Evaluation of 3-dimensional reconstructions of the admission head CT scan demonstrated that many of the fractures identified at autopsy were altered (and thus appeared worse) by brain swelling, and sutural diastasis along a Mendosal suture. The cause and manner of death were certified as *blunt head trauma and accident*, respectively.

Case #2: A 32-month-old female was at home with her father and four other children; she was unsupervised while watching television.

The father heard a crash, after which he entered the room and found the child face-up on the floor with a 27-inch cathode ray tube-type television on the floor next to the child. EMS were summoned, the child was transported to a local ED, and admitted to the ICU. An admission CT scan demonstrated complex comminuted multifocal left-side skull base fractures, epi- and subdural hemorrhages, massive cerebral edema with midline shift, and brainstem hemorrhage. Despite supportive measures, her neurologic condition rapidly declined, and a determination of brain death was supported by clinical evaluation. She died two days after hospital admission. Pertinent autopsy findings included bilateral bulbar and palpebral conjunctival ecchymoses; left frontal scalp contusion; frontal and occipital subgaleal hemorrhages; large right epidural hematoma; cerebral edema with bilateral uncal herniation; fragmentation of the cerebellar folia; multifocal cerebral and brainstem hemorrhages; left periorbital soft tissue hemorrhage; scant right perioptic nerve sheath hemorrhage; no retinal hemorrhages. The cause and manner of death were certified as *blunt force injuries to the head and accident*, respectively.

Child Abuse, Accident, Television

G6 Application of Forensic Engineering for the Reconstruction of Manner of Death: A Nautical Accident

Daniele Gibelli, MD*, Istituto di Medicina Legale e delle Assicurazioni di Milano, V. Mangiagalli, 37, Milan, ITALY; Angela Cantatore, BE, and Remo Sala, BE, Politecnico di Milano, Pzza Leonardo da Vinci, Milan, ITALY; and Salvatore Andreola, MD, and Cristina Cattaneo, PhD, Istituto di Medicina Legale e delle Assicurazioni di Milano, V. Mangiagalli, 37, Milan, ITALY

Attendees of this presentation will be presented with a case where the application of forensic engineering helped in reconstructing manner of death and mode of lesion production in a nautical accident.

This presentation will impact the forensic community by showing how the application of forensic engineering to cases may result in obtaining more precise data concerning the reconstruction of events.

In forensic pathology it is sometimes necessary to reconstruct the manner in which a victim fell or was hit, stabbed, or shot in order to verify the compatibility between the pattern of distribution of lesions and the dynamics of the lethal event. Reconstruction aids in acquiring information which may help in determining homicide, accident, or suicide. More and more in these cases, forensic engineering assists the forensic pathologist. This case shows the importance of forensic engineering in the reconstruction of events. The case concerns an unmarried couple on a boating trip. One morning the man woke up to find his partner overboard in the water tied at the waist by a security rope. He later reported that she must have fallen in the water during the night, when it had been her turn to steer and check on the boat. The woman underwent postmortem examination, which showed typical signs of drowning, such as foam in the airways, overinflated lungs, and water in the stomach. Authorities initially classified the death as accidental. The woman’s family remained suspicious that the partner was responsible for the death since he had recently been made the sole beneficiary of her will. Their accusations led to the exhumation of the corpse and a new autopsy was performed, which highlighted typical signs of blunt trauma, such as bruises distributed to the head, right thorax, right hand and shoulder, back, and linear abrasions on the abdomen.

Microscopic analysis of the lungs showed signs of drowning, such as oedema and expansion of the alveoli. Unfortunately no diatoms could be found (only fragmentary). The cause of death was identified as mechanical asphyxia by drowning. Although the cutaneous signs of blunt trauma observed during the postmortem examination could not

justify death by a traumatic cause, they could have been the signs of an aggression which may have caused the fall of the victim into the water. The main question was: could a simple fall from that boat explain the pattern of lesions (anterior and posterior), or did they indicate an aggression? Initial experiments were performed with a dummy and a boat of the same model. Different manners of precipitation in different positions were then simulated, which provided the first general data concerning the mechanisms of the fall. A more precise analysis was then conducted with computer-simulation software in order to obtain more reliable data concerning the physical characteristics of the boat and dummy model as well as the mutual interactions between the two. After recording every physical characteristic which may have had importance in the reference system and the virtual reconstruction of the environment, different simulations of the fall were reconstructed. The position of skin lesions were considered as points of contact between the body and boat during the fall. Three hypotheses of falling were then considered and simulated. In the first case, the victim was facing the sea, in the second she had the sea to her right, and in the third she had the sea behind her. In the first case, the simulation was concordant with all the lesions described but for the bruise on her back. In the second case the fall could explain only the lesion on her right hand. The third type of fall explained all lesions.

Results showed therefore that the pattern of lesions could be consistent with an accidental fall and may not have necessarily been caused by an aggression. This experience strengthens the importance of forensic engineering in the reconstruction of events.

Forensic Pathology, Forensic Engineering, Nautical Accident

G7 Homicide, Suicide, and the Missing Mother: The Mysterious and Tragic Deaths of a Latino Family

William C. Rodriguez III, PhD, Armed Forces Medical Examiner, 1413 Research Boulevard, Building 102, Rockville, MD 20850; and Carroll Allen, Donna Vicente, and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will have a better appreciation of the importance of joint investigation of complicated cases involving skeletonized and decomposed remains by forensic pathologists and anthropologists. In addition, the importance of proper recovery techniques at a burial site to insure complete recovery of all skeletal remains and associated evidence will be discussed. Strong emphasis will be placed on the importance of DNA maternal and fraternal posterior testing when known antemortem DNA comparative samples of a deceased parent are unavailable.

This presentation will impact the forensic community by enforcing among forensic scientist to utilize a group approach when dealing with complicated homicides involving decomposed and skeletonized remains. Utilizing of individuals representing various forensic specialties can greatly increase the rate of success in an investigation. Use of anthropological skeletal markers such as parturitional pitting of the pelvic bones can be very useful in possibly determining the status of a female as one who has given birth to children vs. a woman who has not given birth to a child. Such information can be extremely useful to law enforcement when trying to identify a female victim.

In late March of 2007 a gruesome discovery was made by police in Frederick, MD as they entered a local residence. Discovered in the house was the body of an adult Latino male who was suspended by a noose ligature along the stairwell leading up the upstairs level of the residence. A continued search of the residence led to the discovery of four children, ages one, three, four and nine. All four of the children were found deceased and in an advanced state of decomposition. One pair of the children was discovered in a single bed covered by blankets,

and the other pair in a single bed in a separate bedroom covered by blankets. Placed above the bodies of the deceased children in each room were religious pictures. An extensive search of the residence by police failed to locate the mother of the children. Autopsy and forensic examination of the adult male who was identified as the father of the children determined the cause of death to be asphyxiation and the manner of death suicide by means of hanging. Autopsy results for three of the children found death to have resulted from suffocation and the fourth child to have died as the result of blunt force trauma. All four deaths of the children were determined to be homicides at the hands of their father. Initially it was thought that the reasoning behind the murder and suicide by the father was that he was despondent over his wife being kidnapped, or possibly leaving him for another man.

As these seemingly senseless killings shocked the community, police were baffled as to the whereabouts of the missing mother. Various speculations surfaced in the news media concerning the disappearance of the mother. Some individuals suspected she abandoned her family and ran off with another man, others claimed that she had been abducted by a Latino gang as retribution for not paying them for illegal assistance she may have received in entering the US. Reports had even been received from her sister who lived in the same community that she had returned to her native El Salvador. The case of the missing mother and the tragic deaths of the father and children received so much media attention that the FBI was called in to assist in the investigation. Law enforcement officials were contacted in El Salvador who later reported possible sightings of the mother in their country as well as bordering Honduras. The plausible leads and high profile nature of the case prompted the FBI to send agents to El Salvador to investigate the sightings. Based on the primary evidence gathered by law enforcement it was believed that the mother had been kidnapped. An intensive national media blitz was conducted to provide leads to police and the FBI in order to locate the mother.

Human skeletal remains were discovered at a clandestine burial site located in the same county in which the deceased family had resided almost a year after the horrific discovery of the murdered children and their father's suicide. The grave was located by a local real estate agent who was conducting a survey of a four acre parcel of land located along the edge of a major highway. While walking the property the real estate agent discovered a skull and partial lower limbs exposed within the grave. Also discovered lying directly next to the grave was a snow shovel and a large digging pick. The Office of the Chief Medical Examiner was immediately called to the scene where the remains were carefully recovered.

During the initial recovery of the remains anthropological analysis determined that the remains represented a Mongoloid / Hispanic female who was in her early twenties at the time of death. Examination of the bones of the pelvis at the scene also determined that the deceased had given birth vaginally to multiple children as indicated by the presence of deep and extended parturitional pitting along the ventral surfaces of the pubic bones of the inomites. Several jewelry items were located with the remains which included a gold religious symbol common to Central American coastal countries. Examination of the gravesite revealed it to be an incomplete burial, as the body was never fully covered possibly due to its close proximity and visibility from the highway, and the non-retrieval of the digging tools.

Anthropological examination of the skeletal remains found them consistent with the biological profile for the missing mother. Due to the lack of antemortem dental or radiographic records, DNA analysis was conducted on the skeleton. Positive identification of the remains was established by comparing the postmortem DNA profiles obtained from the children and the husband to that obtained from the bones of the deceased in question. No skeletal injuries were noted on the remains therefore cause of death was undetermined but manner signed out as homicide. Continued investigation of the case revealed that the woman and her husband had been having marital problems which arose from the wife seeing other men. As a result of the martial unrest it is believed that

the husband murdered his wife and buried her body along the interstate. Possibly despondent over his actions the father, knowing he would be imprisoned and the deleterious affect it would have on his children, he chose to kill the children and then commit suicide.

Asphyxia, Buried Remains, Parturitional Pitting

G8 Sudden Death in Epilepsy: A Review of 51 Consecutive Cases

Rudy J. Castellani, MD, University of Maryland, Department of Pathology, 22 South Greene Street Baltimore, MD 21201; Heather F. Grothous, BS, Michigan State University College of Osteopathic Medicine, A306 East Fee Hall, East Lansing, MI 48824; Philip R. Croft, MD, 1215 East Michigan Avenue, Lansing, MI 48909-7980; Michael A. Markey, MD, Sparrow Forensic Services, Sparrow Hospital, 1215 East Michigan Ave, Lansing, MI 48909-7980; and Joyce L. de Jong, DO, Sparrow Forensic Pathology, 1215 East Michigan Avenue, Lansing, MI 48909*

After attending this presentation, attendees will be able to list the risk factors for sudden death in epilepsy, discuss pathophysiological mechanisms for sudden death in epilepsy, and address the role neuropathological examination in epilepsy cases.

The presentation will impact the forensic community by providing a broader understanding of the role of seizures in sudden death as well as the role of detailed neuropathological examination in characterizing such cases. The presentation will also identify two additional subgroups of epilepsy patients and provide attendees of an enhanced understanding of causes of death in epilepsy patients in general.

Sudden unexpected death in epilepsy (SUDEP) is a well-known but poorly understood phenomenon. While certain risk factors are consistently associated with SUDEP, the pathophysiological mechanism for sudden death remains speculative. Autopsy data from 51 consecutive cases with a history of "seizures" and who underwent complete autopsy, including toxicology and neuropathological examination were reviewed. A board-certified neuropathologist completed the neuropathological examination in 50 of the 51 cases. Of 51 cases, 24 (47%) met criteria for SUDEP (history of epilepsy, sudden unexpected death, no other cause of death, no status epilepticus). Of the cases meeting criteria for SUDEP, 15 (63%) were male and nine (37%) were female, with a mean age of 32.4. Fourteen were found in bed, none were found outside, and eight were lying prone. Seven (29%) had evidence of tongue biting. Fourteen were treated with a single antiepileptic drug. Two were receiving polytherapy. General autopsy revealed pulmonary edema in 17 (71 %) cases. Twelve of 19 cases had childhood onset of epilepsy. Neuropathological examination revealed significant abnormalities in 67%. Among these were remote contusions, vascular malformations, hamartomas, mesial temporal sclerosis, and migration disturbances. Of cases excluded from the SUDEP category, two groups were apparent: one with complex neurological disorders in children complicated by seizures (CND-S), and the second with atherosclerotic cardiovascular disease in older decedents complicated by seizures (ASCVD-S). No acute cause of death was apparent in a number of these cases, raising the possibility that seizures could have played a role. In conclusion: 1) cases discussed indicate general SUDEP risk factors consistent with the published literature; 2) the percentage of cases with significant neuropathological findings is higher than indicated in other studies, emphasizing the need for detailed neuropathological examination (formalin fixation and examination by a neuropathologist); and 3) two additional subgroups, ASCVD-S and CND-S, are in need of further study regarding the role of seizures in sudden death.

Epilepsy, Sudden Death, Seizures

G9 Spontaneous Coronary Artery Dissection – An Isolated Eosinophilic Vasculitis?: Report of Two Sudden Death Cases

Dario Sanabria, MD, Puerto Rico Institute of Forensic Sciences, Department of Pathology, PO Box 11878, Caparra Heights Station, San Juan, 00922-1878; Carlos F. Chavez-Arias, MD, Puerto Rico Institute of Forensic Sciences, PO Box 11878, Caparra Heights Station, San Juan, 00922-1878; Lee M. Tormos, MD, Instituto de Ciencias Forenses, PO Box 11878, Caparra Heights Station, San Juan, 00926; and Jose Rodriguez-Orengo, PhD, Puerto Rico Institute of Forensic Sciences, PO Box 11878, San Juan, 00922-1878*

After attending this presentation, attendees will understand two cases of spontaneous coronary artery dissection, recognize them as a cause of sudden death, and discuss the role of an adequate gross recognition and histological examination with emphasis on the presence and significance of the eosinophilic infiltrate that is frequently associated to this disorder.

This presentation will impact the forensic community by increasing the awareness of the existence of this rare natural disorder and demonstrating its pathological characteristics emphasizing in the gross recognition and histological presentation.

Spontaneous dissection of the coronary artery is a rare entity. It has an increased prevalence in women, especially in the peripartum state. It is defined as hemorrhagic separation of the media of the coronary artery with creation of a false lumen, in the absence of chest trauma, extension of aortic dissection or iatrogenic trauma.

The first case involved a 55-year-old woman with no personal or family history of heart disease. History was also negative for systemic disease, recent trauma, or drug abuse. She was last seen in her usual state of good health a few hours before her death. She was found unresponsive by family members at her apartment where she was pronounced dead after unsuccessful resuscitative measures.

At autopsy the decedent was 167 cm tall and weighed 72 kg. Externally there were no signs of natural disease or trauma. The heart weighed 370 g without ventricular hypertrophy or gross ischemia. The coronary arteries were free of atherosclerosis and had a normal distribution. The left anterior descending coronary artery (LAD) had a focal dissection within the media with a hematoma surrounding and compressing the wall causing total occlusion of the lumen. The total length of the dissection was 2 cm, and it started 3 cm from the origin of the LAD.

The second case involved a 43-year-old woman whose medical history was relevant for back pain, occasional episodes of tachycardia and shortness of breath. She had no history of recent trauma or drug abuse. She was in her usual state of health when she complained of increased back pain and shortness of breath. She was taken to the emergency room by family members but was pronounced dead on arrival. At autopsy the decedent was 165 cm tall and weighed 67 kg. Externally there were no signs of natural disease or trauma. The heart weighed 310 g without ventricular hypertrophy or gross ischemia. The coronary arteries had a normal distribution with minimal atherosclerosis. The LAD showed a focal dissection within the media with a hematoma compressing and occluding the lumen of the artery. The total length of the dissection was 1.5 cm at the distal third of the LAD.

A common histological finding for both cases was a dense focal infiltration of the adventitia and the outer media of the dissected coronary artery by inflammatory cells of predominantly eosinophilic granulocytes with a few lymphocytes and mononuclear histiocytes. Polymorphonuclear granulocytes were infrequent. The inflammation did not involve the inner media or intima. The non-dissected portions of the LAD, the rest of the coronary arteries and the myocardium were free of inflammatory infiltrates in both cases. No myocyte hypertrophy, myocardial scarring, or small vessel disease was present.

Spontaneous Coronary Artery Dissection is a rare entity whose precise incidence, etiology and pathogenesis have not been clearly established. Periadventitial and medial wall eosinophilic inflammation have been commonly observed, generating the hypothesis of an underlying localized inflammatory or vasculitic process that predisposes to this condition. This primary process could cause weakening of the arterial wall and subsequent dissection. However it has also been proposed that such inflammation could be a consequence of dissection, rather than its cause.

These two cases illustrate that a detailed examination of not only the affected coronary artery but also the rest of the vasculature and myocardial tissue is essential to identify and understand this process. In order to clarify the pathogenesis of this entity, it is necessary to perform future studies including cases of non-spontaneous dissection of the coronary artery. These cases are presented and discussed with a review of the literature available to date.

Spontaneous Coronary Artery Dissection, Sudden Death, Eosinophilic Inflammation

G10 Fibromuscular Dysplasia of Pulmonary Arteries: Report of Two Cases

Stefania Zerbo, MD, and Rosa Liotta, MD, Institute of Legal Medicine, Via del Vespro, 127, Palermo, 90100, ITALY; Antonina Argo, PhD, Via Narbone n.13, Palermo, ITALY; Cettina Sortino, Via del Vespro, 129, Palermo, ITALY; Antonino Bonifacio, MD, Institute of Legal Medicine, Via del Vespro, n. 127, Palermo, 90100, ITALY; Eugenia Di Stefano, Via Raffaello n.9, Palermo, ITALY; and Emiliano Maresi, PhD, Via del Vespro, 127, Palermo, 90100, ITALY*

After attending this presentation, attendees will learn of a case showing complications of fibromuscular dysplasia (FMD) (aneurysmatic dissection, arterial obstruction) most likely triggered by chest trauma and by possible cardiotoxicity due to association local/general anesthesia.

FMD is a non-atherosclerotic and non-inflammatory vascular disease, with a familiarity of 10% (inheritance dominante autosomica), and is characterized by fibrous or muscular or both types proliferation subverting normal architecture of the arterial wall. Etiology of FMD is unknown although various hormonal and mechanical factors have been suggested. Fibromuscular dysplasia generally affects women (94%) in their fertile age; it is frequently associated with pregnancy or hyperestrinism, but FMD can occur in any age, infancy included.

Clinical manifestations of FMD depend on involved arterial segment, histological type, and complications (obstructions, aneurysm rupture; embolism; sudden death). FMD commonly affects renal and carotid arteries, and less frequently it's observed in other small and medium arteries; pulmonary localization is rare. Prevalence of symptomatic renal FMD is about 4/1000 cases, twice as to that observed in carotid arteries. Histologically, FMD has been classified into three distinct types: intimal fibroplasia; fibromuscular medial dysplasia (medial hyperplasia, perimedial fibroplasia), and periarterial (adventitial) fibroplasia. Angiographic classification includes multifocal type, related with histological variant "medial fibromuscular dysplasia"; tubular and focal types, both no related with specific histological type.

In this study, two cases of unknown FDM involving pulmonary arteries are described. Clinical manifestation occurred in one case following a road accident related trauma and, in another case, following an anaesthetic induction and local anesthesia before surgical procedure.

Case 1: A 52-year-old obese man while driving a car got into an accident and suffered severe multiple trauma. He was taken to the Emergency Room where he presented coherent and breathing (SpO₂ 92%), with SBP/DBP 150/90 and CF 92b/m.

Chest x-ray showed several rib fractures on the right side, associated with bilateral hydrothorax, upper pneumomediastinum; mild

right pneumothorax. After the first day the patient refused hospital care and discharged himself but a few hours later, he went to another hospital due to persistent pain. When he arrived was mildly dyspnoic and had bilateral basal pleural effusion. During his second hospitalization, he received antibiotics, anti-thromboembolic, anti-hypertensive, and gastroprotective therapies, and had progressive improvement of his clinical conditions. Six days after release, the patient suffered cardio-respiratory arrest and was not responsive to rescue procedures. Autoptic histological finding were mainly in the lungs that showed conspicuous bilateral pulmonary hemorrhage associated with perimedial fibroplasia variant of FDM, with aneurysmatic and dissectant patterns, in lack of pulmonary embolism.

Case 2: A 31-year-old female patient was scheduled for rhinoplasty. Presurgical hematochemical and cardiovascular examinations were normal and anesthesiological risk class was ASA1. Twelve minutes after general anaesthesia induction and immediately after infiltration of nasal mucosa with mepivacaina and adrenalina, a rapid decrease of both oxygen saturation and cardiac frequency occurred until there was irreversible cardiocirculatory arrest, and no response to rescue procedures. Autoptic histological finding were mainly in the lungs that showed vascular congestion and acute focally hemorrhagic edema, associated with FDM, perimedial fibroplasia type. Chemical-toxicological analysis for research of Mepivacaina levels showed non-toxic concentration.

Conclusions: In both described cases death was referable to complications of FMD (aneurysmatic dissection, arterial obstruction) most likely triggered by chest trauma in the first case and by possible cardiotoxicity due to association local/general anesthesia.

Fibromuscular Dysplasia, Pulmonary Arteries, Histopathology

G11 Sudden Death From Arteritis Involving a Surgically Repaired Coronary Artery - Right Atrium Fistula

Marc A. Krouse, MD, Tarrant County Medical Examiner, 200 Feliks Gwozdz Place, Fort Worth, TX 76104-4919*

After attending this presentation, attendees will be informed of the possibility of late complication of a repaired congenital coronary artery anomaly by an independent pathologic process.

This presentation will impact the forensic science community by revealing an unusual complication of surgically treated congenital cardiac malformation, specifically coronary artery - right atrium fistula.

After attending this presentation attendees will appreciate that an anomalous coronary artery (coronary artery - right atrium fistula), successfully repaired many years prior, may be involved by independently occurring disease processes such as pan-arteritis and may prove a cause of morbidity or mortality despite successful earlier treatment.

The subject of this presentation was an 11-year-old male who had a diagnosis of coronary artery - right atrium fistula some eight years prior. The anomalous vessel was ligated at the distal (right atrium) end and he was followed, without complication, for a period of some two years. He was well and active until the day prior to his collapse and demise with no complaints that could be related to cardiac disease. In early morning hours his family members responded to sounds of distress, he collapsed and began dry vomiting before becoming unresponsive. Resuscitation efforts, including ACLS protocol and emergency department treatment, were unsuccessful and he was declared dead less than two hours after onset. His history of previous surgery was initially reported (incorrectly) as repair of an abnormal right coronary artery.

At necropsy examination the body was normally developed. There were diffuse pericardial adhesions over the anterior and left side of the heart. Serial sectioning of the left coronary artery circulation revealed a

slightly large (4-5 mm) left main coronary artery with a similar size anomalous branch passing posterior to the aortic root between the atria. In this area the vessel was markedly dilated (up to 2 cm) and filled with layered, clotted blood. The firmer clot had propagated retrograde and gelatinous, acute clot was found throughout the proximal part of the anomalous artery, into and occluding the left main coronary artery. The left coronary artery ostium was also large, some 1 cm. Microscopic sections of the coronary arteries and coronary artery fistula were notable for active pan-arteritis and healed arteritis in the dilated area of the fistula as well as layered blood clot without notable organization. There was no gross or microscopic evidence of ischemic myocardial injury.

The gross appearance of the artery fistula was reminiscent of Kawasaki disease and the pan-arteritis points to a similar pathogenesis of the vascular injury, aneurismal dilation and eventual thrombosis of the injured vessel. His recent medical history included only an episode of acute sinusitis with a four day course of an unknown prescribed medication, but in interviews with family a previous episode of a viral illness some four months prior was elicited.

This case study is presented to inform forensic and/or pediatric pathologists of the possibility of a late complication of a successfully repaired anomalous coronary artery, presumably by an immune-mediated vascular injury indistinguishable from typical Kawasaki disease.

Coronary Artery Fistula, Arteritis, Sudden Death

G12 Ephemeral Petechial-Like Spots in a Victim of a House Fire

Russell T. Alexander, MD, and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will be familiar with a case of short-lived petechial-like spots on a woman who died due to inhalation of soot and smoke in a house fire.

This presentation will impact the forensic community by discussing the occurrence of transient petechial-like spots in fire related deaths.

A 33-year-old black female was found deceased within her apartment after a house fire. Per report, she had been drinking alcohol that evening with a girlfriend. At approximately 3:25 a.m., her daughter heard the fire detector within their apartment go off. She opened her bedroom door, saw thick black smoke, and then exited the apartment through her bedroom window. The fire department responded and was informed by the daughter that no one else was in the apartment because she thought her mother was still out drinking. The fire department extinguished a "small" fire in a loveseat located on the east end of the living room. Extensive soot was deposited throughout the residence except for the daughter's bedroom. The decedent was found "hiding" behind a chair in the northwest corner of the living room. Her keys were found underneath the burned loveseat. An ashtray with four cigarette butts was on an end table within the living room. An investigation of the fire revealed no evidence of foul play.

At autopsy, soot was densely deposited on the face, within the nares and on the tongue. Less dense soot was deposited over much of the body. Partial thickness burns involved approximately a third of the body surface area. Internally, dense soot was deposited in the airways. No thermal fixation was noted to the airways. The level of carboxyhemoglobin in iliac blood was 62.2%. The iliac blood alcohol content was 0.14 mg/dl. No other drugs were detected on a comprehensive drug screen.

Washing of the body revealed a petechial-like rash on the eyelids, face, shoulders, and back in areas where the epidermis was wiped away during cleaning. The spots appeared to have a follicular or peri-adnexal distribution. A similar though quite subtle pattern of spots was on adjacent areas where the epidermis was intact. Reexamination of the body two hours later revealed that the petechial-like rash had often faded

to a blotchy red-purple area of drying skin, though some faint spots remained. When intact epidermis along the edges of denuded skin was wiped away at this time, a new crop of petechial-like spots emerged. Two hours later, the second set of spots had faded similar to the first. Wiping away more epidermis made a third round of spots apparent. A histologic section of skin showed congested dermal blood vessels, particularly adjacent to hair follicles.

Conjunctival and facial petechiae are thought to be due to increased cephalic venous pressure resulting in rupture of small blood vessels and extravasation of blood; morphologically similar "Tardieu Spots" are formed in areas of livor mortis when engorged blood vessels in dependent portions of the body rupture (Ely and Hirsch, 1999). A literature review found only a single reference to petechiae in a fire victim (Rao and Wetli, 1988). The petechial-like spots in the present case are not related to lividity since they were equally prominent along the anterior and posterior surfaces of the body. The fading of the spots demonstrates that they are due to a congestive process and not vasculature rupture; a finding confirmed by histologic examination. It is possible that rubbing the skin created physical traction that drew blood into the vasculature further accentuating the pattern. Blood flow out of intact vessels into surrounding tissues caused the spots to fade.

This case demonstrates that inhalation of soot and smoke in a house fire can be associated with congestion of peri-follicular and adnexal blood vessels resulting in a subtle petechial-like rash that will be accentuated by wiping away of the epidermis. Furthermore, rupture of capillaries and venules with extravasation of blood is not necessary for the formation of petechial-like spots.

Fire, Petechiae, Autopsy

G13 Forensic Identification of Microbial Mixtures Via ESI-TOF Mass Spectrometry

Joshua K. Stone, BS, and Raleigh W. Parrott, MS, Federal Bureau of Investigation, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135; Jason D. Bannan, PhD, and Bruce Budowle, PhD, Federal Bureau of Investigation Laboratory, 2501 Investigation Parkway, Quantico, VA; and James M. Robertson, PhD, and Brian A. Eckenrode, PhD, Federal Bureau of Investigation, CFSRU, Federal Bureau of Investigation Academy, Building 12, Quantico, VA 22135*

After attending this presentation, attendees will learn the basics of ESI MS, the basic problems with current identification methods of unknown microbes, and how ESI-TOF can correctly identify microbes based on DNA base composition.

This presentation will impact the forensic community by explaining a novel method of identifying unknown microbes in a complex sample.

The growing threat of bioterror events is a significant problem for the security of individuals worldwide. When an unknown biological agent is released, identification can be delayed due to complexity and number of samples required. Whole genome sequencing (WGS) is a possible solution; however this can be costly for complex mixtures. Targeted methodologies search for specific bacterial agents and can be limited by the requirement to determine if the agent of interest is present within the sample. An alternative to WGS and targeted methodologies was developed by Ibis BioSciences using mass spectrometry (MS). This new MS-based method allows an analyst to determine initially which species are present in the sample, rather than asking if a certain species of bacteria is present. Further delineation is then possible by fine-tuning the assay. The DNA base composition can be determined by mass measurements using high resolution MS, which can detect differences in DNA and allow strains of bacteria to be identified. A primary goal of this research is to determine the level of strain delineation possible amidst other strains of a select microbe using this MS-based method.

Broadly conserved genes in bacteria were selected for amplification with specifically designed forward and reverse primers to *Bacillus*

subtilis. Genomic DNA was extracted from *B. subtilis* and amplified using PCR. These selected amplicons were analyzed via Electrospray Ionization Time of Flight (ESI-TOF) MS. Using an integrated fluidics system, DNA samples could be introduced to the ESI source at a high flow rate but then electrosprayed at a slower flow rate to improve resolution. After deconvoluting the information from the mass spectrometer, the organism can be identified by comparison to a library using abundance estimation, joint maximum likelihood, and base composition analysis. The molecular weights from multiple strands, when combined, provide a unique molecular fingerprint which allows an organism to be identified down to the species and strain-level.

A binary set of strains from *B. subtilis* were mixed at various concentration levels to evaluate this MS-based approach in terms of speed and accuracy. An internal mass standard sequence of DNA was used to allow the concentrations of microbial DNA to be calculated after amplification. When using single-stranded oligonucleotides, more than 1200 base compositions could be reported. However, using the complement strand at low concentrations has shown to reduce complexity and error in the data, improving the accuracy of the result.

An expansion and variation of the number of bacterial species and strains tested will occur as time permits for this presentation. As a bioterror event could result in thousands of organisms present in a sample, there will continue to be a need for methods which can select the correct organism, especially in the case of a novel strain for forensic studies.

ESI-TOF, Unknown Microbes, Base Composition

G14 Environmental Scanning Electron Microscopy and Other Techniques in Cutting Crime Investigation: Case Report and Review of the Literature

Paolo Fais, MD, and Giovanni Cecchetto, MD, Via Faloppio 50, Padova, ITALY; Guido Viel, MD, University of Padua, Via Faloppio 50, PADOVA, 0 35121, ITALY; Attilio Cecchetto, PhD, Istituto Anatomia Patologica, Via Gabelli 61, Padova, 35121, ITALY; Claudio Furlan, MD, Via Faloppio, Padova, ITALY; and Massimo Montisci, PhD, Via Faloppio 50, Padova, ITALY*

After attending this presentation, attendees will understand some principles of investigation of a dismembered body concerning the cause of death and the identification of the tools used to separate arms and legs from the trunk.

This presentation will impact the forensic community by suggesting a novel approach for the analysis of cutting crimes in general and dismembering in particular.

Herein investigators present the case of a 40-year-old female killed by throat cutting and consequently dismembered. She was found cut into 30 pieces inside three plastic bags in a garage.

Dismemberment is the act of cutting, tearing, pulling, wrenching, or otherwise removing the limbs from the trunk of a living or deceased object. It may be practiced upon human beings as a form of capital punishment, a result of a traumatic accident, or in connection with murder, suicide, or cannibalism. After killing the victim, the murderer uses a very sharp cutting weapon (a saw, knife, axe, etc.) to sever the limbs and cut the body into pieces. The operation is generally carried out immediately after the crime, although more rarely a long time may pass between the two events. There are two types of dismemberment that are commonly seen: localized, such as the removal of the head or hands in an attempt to hinder identification of the victim, or generalized at multiple sites (commonly bisection of limbs or disarticulation of the joints) to aid in the disposal of the body. In these cases a new pattern of investigation must support classical techniques to solve the following forensic issues:

- The evaluation of the time since death and of the time since dismemberment. Indeed, exsanguinations and dismemberment of the body prevent an accurate evaluation of lividities and rigidity.
- The identification of the tools used to cut the body. Careful, thorough investigation is a key point to ensure that potential physical evidence is not tainted or destroyed. In particular it is essential to identify any potential sharp cutting weapons at the crime scene. Moreover, when saws are used to cut the body, characteristic tool marks are left on the bone. The nature of the marks depends on the size, shape, width of the saw, and on the sawing action of the user.

Environmental Scanning Electron Microscopy (ESEM) may help in identifying the specific saw that has been used in the act of dismemberment. ESEM can detect and measure different types of striations, paint traces (such as rust inhibitor paints) or metal residues remaining on the bone after the cutting.

In the case presented, the determination of potassium levels in the vitreous humour and their time changes showed that the victim had been killed 20 – 25 hours before the death scene investigation.

The absence of lividities combined to histological and immunohistochemical investigation of the skin let investigators classify the dismembering injuries as non-vital wounds and to estimate the time interval between the death and the dismembering.

However, the most interesting finding was the identification of the tools used to cut the soft tissues and the bones of the victim. Morphological and morphometrical analysis of the skin lesions pointed out that the arms and the legs were cut with a sharp knife, whereas the head was removed from the trunk by a woodworker saw. ESEM analysis determined that the bone injuries were produced by a particular type of saw covered by rust-inhibitor paint.

Cutting Crime, ESEM, Dismembering

G15 Exploration of Non-Cardiogenic Pulmonary Edema With Chronic Opiate Use: Case Studies and Scientific Review

Marrah E. Lachowicz, MFS, University of California Davis, One Shields Avenue, UCDSOM, Tupper Hall 4112, Davis, CA 95616-8643*

After attending this presentation, attendees will learn how to characterize non-cardiogenic pulmonary edema during autopsy caused by opiate use. Additionally, attendees will learn about alternative opiate sources which may lead to cases of non-cardiogenic pulmonary edema. Such cases may present during autopsy and potentially lead to classification of a secondary cause of death or change in the classification of manner of death.

This presentation will impact the forensic community by providing potential answers to cases in which underlying chronic opiate use potentiates mortality. Chronic opiate use may synergistically lead to fatal pathology not readily recognized when secondary to diseased states in the lung. The presentation focuses on the reliability of diagnosing cause and manner of death during autopsy with the goal of increasing the validity of techniques, processes, and methods used in forensic medicine.

Use of opiate variants, including pain management medications such as morphine and street drugs such as heroin, have all been implicated in causing acute respiratory distress marked by non-cardiogenic pulmonary edema (NCPE). Despite efforts to treat patients who develop NCPE through chronic use or acute over-dose; presentation of NCPE stills has a mortality rate of 30-50%. With significant mortality and the rise in cases, development of NCPE is increasingly significant to the forensic community. The molecular and cellular mechanisms by which opiates induce non-cardiogenic pulmonary edema (NCPE) remain elusive. NCPE is a clinical hallmark of opiate use in long-term drug

users as well as patients treated with narcotics for chronic pain. Sporadic cases of NCPE were recently reported with use of other medications: primarily drugs used to treat other forms of edema, regulate blood volume, or blood pressure.

Although the pathogenesis of NCPE is largely unknown it thought to be dose related—thus maybe a presentation of an abhorrent cardiorespiratory response. Acute or chronic opiate use causes acute respiratory distress syndrome (ARDS) marked with pulmonary capillary leak and exudation leading to NCPE. Data shows us of opiates, primarily heroin, is the primary cause of NCPE in patients under 40. As many as 50% of these patients are clinically defined as an overdose with as much as 20% of these cases will be fatal. Previous animal models and marginal human studies identified three active opioid receptors ($\delta\mu\kappa$) varying in distribution throughout the respiratory tract. The lung is a very complicated microenvironment. Several hypotheses regarding the pathogenesis of NCPE indicate involvement of various cell and tissue types throughout the respiratory tract. Local changes may cause alterations to the alveolar epithelium direct or have effects on the pulmonary capillary bed resulting in NCPE. The lung parenchyma co-exists with the alveolar terminal air space where gas exchange occurs. Studies indicate there are two distinct H³-morphine binding sites—with the most abundant binding localized within alveolar walls. Therefore, this is the site implicated as responsible for fluid clearance in the lungs. The exact mechanism by which activation of opiate receptors in this region leads to fluid influx is largely unknown. It is possible alveolar tissue plays a role in the release of soluble mediators or recruitment of inflammatory cells leading to a cascade of events contributing to the pathogenesis of NCPE. Dysregulation of solute and fluid clearance by the alveolar epithelium itself may be altered by opiate receptor activation. Finally, long-term or acute activation of opiate receptors with may lead to significant alterations in the epithelial surface that are the basis local changes conducive to the onset of NCPE.

With underlying disease in the lungs or other chronic conditions which require use of opiates, these changes may not be easily recognizable during autopsy. The goal of this poster is to demonstrate how opiate toxicology may induce local effects in the respiratory tract which ultimately results in direct changes to the pulmonary alveolar epithelium contributing to underlying disease. Secondary pathology may contribute to cause and manner of death in forensic cases. Understanding how opiates contribute to altered pathology will enhance the methods by which forensic pathologists diagnose NCPE postmortem.

Autopsy, Forensic Pathology, Pulmonary Toxicology

G16 Is Toxicological Analysis Necessary in Postmortem External Examinations?

D. Kimberley Molina, MD, Bexar County, Medical Examiner's Office, 7337 Louis Pasteur Drive, San Antonio, TX 78229; and Meredith A. Lann, MD*, UCDHSC, AIP - Department of Pathology, 12605 East 16th Avenue, Room 3026, Aurora, CO 80045*

After attending the presentation, the attendee will understand the decision process of performing an external examination versus a complete or partial autopsy in medicolegal cases and the potential ramifications of not ordering a full toxicologic panel on cases where a postmortem external examination was performed.

The presentation will impact the forensic community by serving as a critical part in the decision making process of medical examiners in deciding how to analyze medicolegal cases and will serve to augment the literature used to establish the standard of practice for the performance of external examinations.

In many jurisdictions, external examinations are performed rather than complete autopsy examinations in certain types of medicolegal cases. Deaths in elderly patients or deaths after a fall are just a couple examples which may be included in such cases. In many of these cases,

the cause of death appears to be readily apparent from the medical records and/ or circumstances of death and toxicology is not performed.

A retrospective review of all external examinations performed at the Bexar County Medical Examiner's Office during a five year period (2003 - 2007) was undertaken comparing cases in which: toxicology was not performed; toxicology was performed but did not alter the cause and manner of death; and toxicology was performed and altered the cause and manner of death.

It was found that in cases where toxicology was performed, the toxicology results altered the cause and/ or manner of death in an average of 1.8% of cases. If toxicology had been routinely ordered on all external examinations at the BCMEO, it would have theoretically altered approximately 21 additional cases during the five- year period.

Toxicology, External Examination, Cause and Manner of Death

G17 TASER® Wound Progression in Two Deployment Modes

Donald M. Dawes, MD, Lompoc Valley Medical Center, 518 East Hickory Avenue, Lompoc, CA 93436; and Jeffrey D. Ho, MD, Hennepin County Medical Center, 701 Park Avenue South, Department of Emergency Medicine, Minneapolis, MN 55415*

After attending this presentation, attendees will have a better understanding of the wounds created by the TASER® X26 device.

This presentation will impact the forensic community by assisting in the identification of characteristic wound patterns created by the TASER® X26, the most commonly used conducted electrical weapon.

Introduction: Conducted electrical weapons are used by law enforcement to control violently resistive subjects. The TASER® X26 is the most commonly used conducted electrical weapon. It can be used in the probe-deployment mode in which probes are fired from the device at the subject, or it can be used in the drive-stun deployment mode in which the device is physically touched to the subject. The two deployment strategies can create different signature wound marks. To date, there is no study that has attempted to catalogue and describe these marks.

Methods: Subjects were recruited from police training classes for the study. The subjects were to receive an exposure from a TASER X26 as part of their training class. Subjects were allowed to choose between the two deployment modes depending on the rules of their class. Subjects completed a screening questionnaire that included the Fitzpatrick scale. The exposures were five seconds or less. Subjects had photographs of the wounds taken after the exposure immediately, and at 24, 48, and 72 hours, as well as at one month.

Results: The two deployment strategies left differing marks. The probe deployment mode generally created circular superficial partial thickness burns. The drive-stun mode created variable marks depending on the movement of the subject which included irregular superficial partial thickness burns that may be paired at about 40 mm (the distance between the metal contact points on the device), but not necessarily so. This mode also created abrasions and contusions. Some subjects had persistent hyperpigmented marks at one month.

Conclusions: The two probe deployment modes left different marks. It may be important for forensic examiners to be able to distinguish these marks from other minor skin trauma. Studies such as these will help in this.

TASER®, Wound, Burns

G18 Rat Bite Fever: A Fatal Case of *Streptobacillus moniliformis* Infection in a 14-Month-Old Boy

Priya Banerjee, MD*, The Johns Hopkins Hospital Department of Pathology, 600 North Wolfe Street, Carnegie/Pathology 401, Baltimore, MD 21287; and David R. Fowler, MD, and Zabiullah Ali, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201

After attending this presentation, attendees will understand the features of *Streptobacillus moniliformis*, are, under recognized infection as they apply to a forensic setting through an autopsy case presentation.

This presentation will impact the forensic sciences community by highlighting the key features of *S. moniliformis* infection including the clinical presentation, postmortem diagnosis of *S. moniliformis* infection, and risk factors as they relate to a particular forensic autopsy case.

After viewing this presentation attendees will understand the features of *S. moniliformis*, a rare, under recognized infection as they apply to a forensic setting through an autopsy case presentation.

Rat Bite Fever, caused by *S. moniliformis* infection, is an acute syndrome of fever, rash, and migratory polyarthritis. In the United States, primarily children under the age of 12 years are infected with a total of less than 200 cases reported. Common vectors include rats and mice, which are natural reservoirs. Transmission is predominantly from a bite or scratch, but contact with or ingestion of food contaminated with feces or saliva has also been reported.

A previously healthy 14-month-boy died after a rapid decline after onset of fever and a diffuse rash over his face, trunk, and extremities. Crime scene investigation revealed a disheveled, cluttered bedroom where the child's crib was located. Several markedly soiled animal cages were adjacent to the crib containing rabbits and ferrets. The room was also infested with roaches, flies, and ticks over the floor, walls, ceilings, and all of the bedding. A complete autopsy, including laboratory testing, revealed a well-developed and well-nourished white male infant with normal age-adjusted height and weight. A red-pink macular and mostly confluent rash covered almost the entire body surface with prominence on the head including the scalp, neck, anterior and posterior torso, anogenital region, and portions of the thighs without mucosal involvement. There was sparing of the bilateral legs, soles, palms and portions of the forearms, nose and mouth, except the left lateral corner of the mouth. The rash did not involve the buccal mucosa or gums. The right knee had a donut-shaped bite rash suspicious for a bite mark. Internal examination revealed a mildly enlarged, congested liver and enlarged mesenteric lymph nodes. Microscopic examination of the lungs showed interstitial pneumonitis with rare neutrophils and edema. There were focal areas of gastric aspiration without associated vital reaction. The kidneys had fibrin micro-thrombi with focal fibrinoid necrosis of the tubules, consistent with Disseminated Intravascular Coagulopathy. Microbiologic culture of cerebrospinal fluid was positive for *S. moniliformis* while routine blood cultures were negative. Viral cultures were also negative. Routine toxicologic analysis of heart blood and liver revealed diphenhydramine administered during resuscitation.

In the United States, 55% of cases of Rat Bite Fever occur in children less than 12 years of age. The demographics of the victims have broadened to include children, pet store workers, and laboratory technicians, because the rats have become popular pets and study animals. The infection is associated with a mortality rate of 7-13%, if untreated. The actual rate of infection may be much higher, because it is not a reportable disease. Although easily treatable with antibiotics, the diagnosis and treatment can be delayed due to a broad differential diagnosis which includes meningococcemia, *Staphylococcus aureus* or *Streptococcus pyogenes* septicemia, Rocky Mountain Spotted Fever, or other Rickettsial diseases, enterovirus infection, disseminated gonorrhea, Lyme disease, ehrlichiosis, brucellosis, leptospirosis, and secondary syphilis. Given this differential of more common entities, laboratory

identification is essential to proper diagnosis. This paper shows the importance of considering *S. moniliformis* as an etiology

In all suspected cases, a complete autopsy should be performed and the microbiology lab should be contacted for guidance in submitting blood, cerebrospinal fluid, and probably synovial fluid in appropriate media supplemented with 20% blood serum or ascitic fluid to prevent growth inhibition of *S. moniliformis*.

Rat Bite Fever, Streptobacillus moniliformis, Actinobacillus muris

G19 Contributions From Forensic Imaging to the Investigation of Fatal Upper Cervical Fractures

Lars Uhrenholt, PhD, and Lene W. Boel, PhD*, University of Aarhus, Institute of Forensic Medicine, Brendstrupgaardsvej 100, Aarhus N, 8200, DENMARK

After attending this presentation, attendees will understand the value of advanced diagnostic imaging procedures in forensic medical investigations of upper cervical spine fractures following trauma.

This presentation will impact the forensic community by showing how upper cervical spine fractures are frequently seen in relation to fatal trauma to the head and neck, and where this anatomical region may be difficult to evaluate during medicolegal autopsy, the contributions from advanced diagnostic imaging procedures may be of great importance to the investigation.

The purpose of this presentation is to present the value of advanced diagnostic imaging procedures in the forensic medical investigations of upper cervical spine fractures following trauma.

Upper cervical spine fractures are frequently seen in relation to fatal trauma to the head and neck and, where this anatomical region may be difficult to evaluate during medicolegal autopsy, the contributions from advanced diagnostic imaging procedures may be of great importance to the investigation.

The upper cervical spine is clinically a very important anatomical region, where the high degree of mobility is obtained on the expense of poor stability. Several types of fractures are possible at the atlas (C1) and axis (C2) vertebrae. Five cases have been retrieved where different types of trauma, (e.g., road traffic crash collisions, fall, blow to the head from moving objects), had occurred causing fractures to the upper cervical vertebrae. Each of the deceased was examined using advanced computed tomography, an in-house Siemens Definition 64 slice dual-energy scanner facility, as adjunct to the medicolegal autopsy. The upper cervical spine was reconstructed using sub-millimeter slice thicknesses and all images were examined in three planes (horizontal, coronal, and axial) as well as using 3-dimensional reconstructions. The findings from the CT-scanning were correlated with the findings from the medicolegal autopsy and the contributions from the forensic imaging procedures to the medicolegal investigations were evaluated.

The review of five unique cases with upper cervical spine fractures showed that forensic imaging procedures in combination with medicolegal autopsy allow very detailed evaluation and categorization of fractures. Although fractures of the odontoid process were readily identified during autopsy, the exact classification according to the system by Anderson and D'Alonzo was made possible by examination of the CT-images. The fractures of the atlas were more difficult to visualize during the medicolegal autopsy, particularly at the posterior arch, whereas the diagnostic imaging procedures allowed clear identification as well as classification of the fractures according to the system proposed by Jefferson.

This presentation of five trauma cases showed that advanced diagnostic imaging procedures contributes significantly to the forensic medical investigations of upper cervical spine fractures following trauma. This is important as implementation of such adjunct procedures

to the medicolegal autopsy may strengthen the degree of detail of the investigation. Although this is a small group of selected trauma cases, this presentation highlights some of the major advantages achieved by expanding the forensic investigations to also include forensic imaging procedures.

A number of cases that have in common the presence of upper cervical spine fractures will be discussed. The contributions to the medicolegal investigations from advanced computed-tomography scanning will be presented and it is recommended that forensic specialists become familiar with the potential of advanced imaging procedures to the medicolegal investigations.

Cervical Fracture, Forensic Imaging, Postmortem Autopsy

G20 Ankylosing Spondylitis in Traumatic Death: A Case Report

Asser H. Thomsen, MD, Lars Uhrenholt, PhD, and Annie Vesterby, MD, DMSc, Institute of Forensic Medicine, University of Aarhus, Brendstrupgaardsvej 100, Aarhus N, DK-8000, DENMARK*

After attending this presentation, attendees will have a better understanding of the possible impact of pre-existing structural skeletal disease in traumatic death, illustrated by a case report.

This presentation will impact the forensic community by reminding it of the importance of taking all natural disease into account when investigating deaths, even those diseases not normally considered fatal. Furthermore, it will present the possibilities of advanced radiological imaging as a facilitator in death investigation in the evaluation of the mechanism and manner of death.

Ankylosing spondylitis is a rheumatic disease which is associated with tissue type HLA-B27 and is considered non-fatal. Main structural features in severely affected individuals are osseous fusion of the sacroiliac joints, and rigidity of the spinal column caused by bone bridging between vertebral bodies (syndesmophyte formation). Due to this rigidity there is an increased risk of spinal fractures, especially cervical fractures, even from low energy trauma.

A middle-aged man rode his bike home from a bar while intoxicated. A witness saw him swaying and at low speed riding the bike into a curbstone. During the crash he went over the handlebars and collided with the pavement face first. His breathing ceased immediately, soon followed by cardiac arrest. Resuscitation efforts at the scene were unsuccessful. Due to the rapidity of the cardiac arrest, the attending emergency physician ruled that it was a natural death caused by a cardiovascular event secondary to the fall from the bike. According to the antemortem information obtained from the police report and the general practitioner, the deceased was healthy without prior cardiovascular disease. Postmortem computed tomography scanning revealed multiple fractures of the spine, including a fracture of the odontoid process of C2, disco-vertebral avulsion through C3-C4, and Th10-Th11. Associated with the upper cervical fractures there was displacement of fragments into the spinal canal affecting the spinal cord. Furthermore, there were ankylosing changes of the anterior longitudinal ligament throughout the spinal column with extensive syndesmophyte formation bilaterally, also known as bamboo spine configuration, particularly in the lumbar spine. The sacroiliac joints were closed by osseous fusion. All the radiological findings were in agreement with the diagnosis of ankylosing spondylitis. The medicolegal autopsy showed abrasions in the face, on the back, on hands, and legs; bleeding in and around the spinal fractures; rib fractures with sparse bleeding; bone bridging of the intervertebral joints; an enlarged heart, insignificant atherosclerosis; a fatty liver, and an enlarged spleen. Blood alcohol was 189 mg/dl. The microscopical examination revealed hypoxic changes in the brain, granuloma formation in the lungs consistent with sarcoidosis, and bone marrow emboli in the pulmonary arteries. The bone marrow

emboli were thought to come from the primary spinal fractures or the secondary rib fractures caused by the resuscitation efforts.

Further investigation into the medical history, by requesting relevant hospital records, revealed that the deceased had received treatment in an outpatient clinic nine years prior, due to ankylosing spondylitis with rigidity of the spine. He had furthermore been under evaluation for lung sarcoidosis. The cause of death was ruled to be upper cervical spinal cord injury due to upper cervical spine fractures, complicated by spinal rigidity secondary to ankylosing spondylitis. The manner of death was ruled to be accidental.

This case report illustrates the fatal outcome of spinal injuries in an individual who suffered from a structural skeletal disease, where the ankylosing spondylitic changes acted as predisposing factors leading to his death. Thus, knowledge of pre-existing skeletal disease is important in the medicolegal evaluation, as diseases that are considered non-fatal can contribute to the cause of death. In this case report the understanding of the conditions leading to death was recognized and supported by the postmortem computed tomography.

This presentation will impact the forensic community by reminding it of the importance of taking all natural disease into account when investigating deaths, even those that are not normally considered fatal. Furthermore, it will present the possibilities of advanced radiological imaging as a facilitator in death investigation in the evaluation of the mechanism and manner of death.

Ankylosing Spondylitis, Postmortem Examination, Forensic Imaging

G21 An Unsolved Cold Case in Iowa: A Probable Case of Dragging

Dawnie W. Steadman, PhD, Binghamton University, SUNY, Department of Anthropology, Binghamton University, PO Box 6000, Binghamton, NY 13902-6000; Dennis Klein, MD, Iowa Department of Public Health, 321 East 12th Street, Des Moines, IA 50319-0075; and Blythe Bloemendaal, BA, Lyon County Sheriff's Office, 410 South Boone, Rock Rapids, IA 51246*

After attending this presentation, attendees will learn about differential diagnosis for trauma due to dragging. Dragging injuries to human remains is rarely described in the literature and is limited to accidental long-range towing behind large vehicles.

This presentation will impact the forensic community by describing the skeletal morphological changes associated with dragging from a different context than is currently found in the literature.

Dragging injuries to human remains is rarely described in the literature and is limited to accidental long-range towing behind large vehicles. The goal of this presentation is to provide a differential diagnosis for trauma due to dragging. This presentation will impact the forensic community by describing the skeletal morphological changes associated with dragging from a different context than is currently found in the literature.

On October 4, 1978, decomposed human remains were found lying face down in a ditch in a rural portion of Northwestern Iowa. The female victim was partially clad in knee-high white "go-go" boots with her panties and pants bunched up under the torso. Her arms were stretched over her head and her ankles were tied together with a knotted rope. An autopsy the following day revealed no obvious traumatic injuries to the soft tissue or skeleton other than damage to the maxilla that was originally attributed to animal gnawing. The hands were retained and the skull, clavicles, pubic symphyses and possibly other bones were sent to a forensic anthropologist for analysis. Ultimately the identity of the victim and the cause of death were unknown and the case became "cold."

Interest in the case was renewed nearly two decades later when, in January 2006, the victim's fingerprints were matched to those on a

fingerprint card of a woman arrested in California in 1973. Mitochondrial DNA tests of metacarpal bones of the victim positively matched the mtDNA of a known daughter of the California woman. The victim was identified as a 23-year old prostitute from California who was last seen in Georgia in February of 1978. Throughout 2006 investigators created a list suspects, including the victims' ex-husband, but most of these individuals were deceased or could not be found for questioning. In 2007 the remains were exhumed, the bones that had been sent to other anthropologists were returned, and a new autopsy was ordered to further investigate the cause of death.

The soft tissue of the dorsal aspect of the entire body was remarkably well preserved while the ventral aspect (which had been in contact with the ground) was skeletonized. A comprehensive drug panel on decomposed skeletal muscle was positive only for caffeine and cotinine. Following the forensic pathological examination the bones were macerated in warm water with detergent and examined by the anthropologist. Bone loss of the maxillary alveolar bone, hard palate, anterior nasal spine, and nasal aperture was extensive. Adherent bone fragments, radiating fractures, tool marks, or animal gnawing were absent and the morphology was most consistent with abrasion. Similarly, abrasion injuries were apparent on the medial aspects of both elbows (distal humeri and proximal ulnae) and the anterior iliac spine of the right ilium. No bony modifications were observed below the pelvis.

The abrasion injuries are consistent with dragging in a prone position with the arms over the head as the lower face, medial elbows and one or both ilia would be in contact with the ground. The mandible and anterior rib cage are also expected to be affected but unfortunately these elements were not retained from the original autopsy. Only two known cases of dragging are published in the literature and these involve dragging behind or under a vehicle for significant distances (at least 2.5 miles). One case (Klintschar et al. 2003) reports a body dragged prone by one foot with the arms over the head such that the medial aspect of the elbows faced outwards. The medial humeri and ulnae as well as the lower teeth were extensively abraded. In the current case the injury pattern, the position of the pants (pulled up under the torso), the position of the ligature around the ankles and the final resting position of the body in the ditch suggest the victim was pulled by the feet while in a prone position such that the legs were off the ground and the arms over the head. The remote location and terrain implies the victim may have been dragged by a vehicle down a gravel road but most likely was pulled by hand. While coffin abrasion cannot be completely ruled out, these particular bones were not observed to be in direct contact with the metal sides when the coffin was unsealed. Thus, a mechanism of manual dragging is proposed to explain the morphology and distribution of the skeletal injuries.

Trauma, Forensic Pathology, Forensic Anthropology

G22 An Unusual Death Involving a Sensory Deprivation Tank

Meredith A. Lann, MD, University of Colorado at Denver Health Sciences Center, AIP - Department of Pathology, 12605 East 16th Avenue, Room 3026, Aurora, CO 80045; and Amy Martin, MD, Denver Office of the Medical Examiner, 660 Bannock Street, Denver, CO 80204*

After attending this presentation, attendees will understand the intended use of sensory deprivation tanks and understand possible risks associated with improper use. A practical investigative approach to similar deaths involving water tanks and spas will be discussed.

This presentation will impact the forensic community by familiarizing the forensic community about the use of sensory deprivation or flotation tanks, as well as risks associated with improper use.

Deaths involving sensory deprivation tanks, also called flotation tanks, are very rare. A thorough literature search using PubMed and

Ovid MEDLINE search engines yielded no such cases; however, recently a preliminary report on a similar case from Berkshire, UK was reported online in late 2007. This is the first known death associated with a flotation tank to be reported in the medical literature.

Flotation REST (Reduced Environmental Stimulation Therapy) is used by some as a modality for stress-reduction or for behavioral modification programs. REST was initially a research tool for neuropsychiatric studies in the 1960s, but became more popular in the United States in 1970s-1980s when the tanks became available for commercial and personal use. Most recently some medical practitioners ascribe to its use as an alternative therapy for various medical illnesses, as it may reduce hypertension and alleviate chronic pain. The medical literature discusses the effects of chamber REST for many psychiatric, behavioral and addiction disorders; however controlled studies using flotation REST are very limited.

A unique case in which a previously healthy 50-year-old woman apparently died while floating in a sensory deprivation tank within the basement of her own home will be described. The deceased reportedly had not previously used the tank, although had purchased it approximately three years previously, and was likely not familiar with the proper use of the tank. At the time of the scene investigation the unit's filtration system, which was situated close to the flotation tank, was noted to be on and running. The temperature of the water in the flotation tank was elevated at 116 deg F, approximately 20 deg F higher than the usual target temperature for flotation sessions. Examination of the tank and accessories found all components operating within specifications, with no malfunctions or electrical hazards identified. There was no evidence the decedent drowned, as the nose and mouth were not submerged. A full medicolegal autopsy was performed. No anatomic cause of death was identified at autopsy. Postmortem laboratory studies demonstrated a vitreous creatinine of 5.2 mg/dl, a blood ethanol level of 0.270%, an elevated blood doxylamine level, and the presence of sertraline and diphenhydramine. It has been concluded that the deceased inadvertently left the pump on during her flotation session, which resulted in the elevation of water temperature after she fell asleep during the session. The cause of death was determined as due to acute mixed drug and ethanol toxicity with probable hyperthermia contributing. Manner was ruled as accident.

It is recommended that mind-altering or CNS depressant drugs including alcohol not be used during flotation REST sessions. This case report and discussion will help the forensic community understand the use of flotation tanks and the risks associated with improper use. Investigation of deaths involving these units or similar devices such as bathtubs or spas should include special precautions aimed to prevent harm to the investigation crew. In addition, full examination of the tank and accessories should be performed by professionals familiar with the equipment to confirm any product malfunctions or other potential safety hazards.

Sensory Deprivation Tank, Flotation Tank, Intoxication

G23 Preliminary Analyses of Carrion Colonization of Necrophagous Flies (Diptera: Calliphoridae) in Central Oklahoma

JeAnna R. Redd, BS, University of Central Oklahoma, 100 North University Drive, Evans Hall 101 (Box 208), Edmond, Oklahoma 73034; and Wayne D. Lord, PhD, Forensic Science Institute, University of Central Oklahoma, 100 North University Drive, Edmond, OK 73034*

After attending this presentation, attendees will have a better understanding of the colonization of carrion by necrophagous flies in two suburban habitats in central Oklahoma. In addition, attendees will

better understand factors that impact necrophagous fly colonization of carrion and their diversity suburban habitat.

From this presentation, the forensic community will attain a better appreciation for carrion insects in central Oklahoma and environmental conditions for postmortem interval (PMI) estimations of human remains based on associated arthropod fauna.

This presentation will impact the forensic community by demonstrating the potential influence of environmental factors on carrion colonization by necrophagous flies and vertebrate carcass recycling in non-vegetated habitats in central Oklahoma, and the importance of insular suburban woodlots as a refuge and species pool for dipteran decomposers. With the possible onset of global warming and the continuing expansion of human habitation, maintaining suburban woodlots and vegetated green zones may prove critical for the preservation of terrestrial decomposer populations and other wildlife.

Necrophagous flies are important ecologically and forensically. Ecologically, carrion frequenting flies (Diptera: Calliphoridae) are dominant members of the terrestrial decomposer community and, as such, play a significant role in the recycling of vertebrate remains, improving public health. Additionally, analyses of immature and adult flies colonizing remains can provide a broad spectrum of forensically meaningful information, including estimates of the minimum postmortem interval (PMI). Central to an understanding of the ecological and forensic significance of necrophagous Diptera is knowledge of the environmental factors potentially limiting carrion detection, access, and colonization. This study examined the impact of high temperatures and surface winds on the colonization of carrion (liver) by necrophagous Diptera in two suburban Oklahoma habitats. Standardized samples of beef liver (uniformed attractant) were placed in a suburban woodlot and turf grass field in Central Oklahoma. Wind speed, wind direction, and temperature were measured at each site and correlated with carrion fly colonization rates and species diversity. Over 100 replicates were conducted over the course of 8 weeks. Fly colonization patterns were compared with commercial flytrap (Pherotech ®) and rodent carcass trials.

Study results indicated a clear difference between habitats, with the turf field characterized by stronger winds, higher temperatures, more rapid carrion desiccation, reduced fly colonization rates, and lower species abundance and diversity. Additionally, the turf field habitat was characterized by a significantly greater number of days devoid of carcass colonization by carrion flies. Vegetative stratification, characteristic of the suburban woodlot habitat, provided mediation of wind and heat effects and facilitated increased carrion fly abundance, diversity, and activity.

The study demonstrates the potential influence of environmental factors on carrion colonization by necrophagous flies and vertebrate carcass recycling in non-vegetated habitats in central Oklahoma, and the importance of insular suburban woodlots as a refuge and species pool for dipteran decomposers. With the possible onset of global warming and the continuing expansion of human habitation, maintaining suburban woodlots and vegetated green zones may prove critical to the preservation of terrestrial decomposer populations and other wildlife.

Forensic Entomology, Carrion Colonization, Necrophagous Diptera

G24 Two Fatal Cases of Hidden Pneumonia in Young People

Francesco Ventura, MD, and Alessandro Bonsignore, MD, Department of Forensic Pathology, University of Genova, Via De Toni, 12, 16132, Genova, 16132, ITALY; Raffaella Gentile, MD, Department of Clinical Pathology, University of Genova, Largo Rosanna Benzi, 10, Genova, 16132, ITALY; and Francesco De Stefano, MD, Department of Forensic Pathology, University of Genova, Via De Toni, 12, Genova, 16132, ITALY*

The goal of this presentation is to review two fatal cases of hidden pneumonia in young people.

This presentation will impact the forensic science community by demonstrating how acute respiratory distress syndrome (ARDS) can result in death. Also young people generally, in cases of pneumonia, can be treated and consequently prevent death. Therefore, these cases illustrate the importance of early diagnosis of this condition.

ARDS is a severe lung disease characterized by inflammation of the lung parenchyma leading to impaired gas exchange with concomitant systemic release of cytokines and inflammatory mediators frequently resulting in multiple organ failure (MOF). This condition usually requires a rapid application of mechanical ventilation and admission to an intensive care unit.

When the endothelium of lung capillaries and the alveolar epithelium are damaged, plasma and blood spread in the interstitial and intralveolar spaces. Such a change induces decreased lung compliance, pulmonary hypertension, reduced functional capacity, modified ventilation/perfusion ratio, and hypoxemia. ARDS can occur within 24 to 48 hours of an attack of acute illness. In such a case the patient usually has shortness of breath and tachypnea.

Typical histological presentation involves diffuse alveolar damage (DAD) and hyaline membrane formation in alveolar walls.

If the underlying disease is not diagnosed and treated, the condition of the patient will worsen resulting in shock and/or MOF potentially resulting in sepsis.

Supposedly over 30% of ARDS cases are due to "sepsis syndrome," which is characterized by leukocytosis or leukopenia, fever, hypotension and leading to the identification of a potential source of systemic infection via positive blood culture for pathogenic agents.

The rate of survival in case of severe ARDS with appropriate and early treatment is 50%. However, if the severe ARDS induced hypoxemia is not recognized or treated, or if the disease reaches is not diagnosed until the terminal phase, cardio-respiratory arrest occurs in more than 90% of patients.

Case 1: A 29-year-old man was found lifeless at home by his girlfriend. Death scene investigation was unremarkable. He took psychotropic drugs, and he was known to be an abuser of alcohol and drugs. Family history was negative for sudden death. A complete postmortem examination was performed four days after death. External examination was insignificant. The internal examination revealed polyvisceral congestion, microthrombosis, cerebral and pulmonary oedema. Free citrine liquid was found on both sides of the pleural cavities.

Marked congestion and release of foamy material on sectioning of both lungs was observed. Hydrostatic docimasia for large and small fragments was positive in all fields such as an index of bilateral consolidation. The histological lung examination, performed with routine haematoxylin-eosin staining, revealed diffuse alveolar damage, endobronchial and endoalveolar infiltrates of polymorphonuclear neutrophilic leukocytes and focal emphysema. No fungal infections

were detected using slides by PAS and Grocott staining. Gram staining didn't reveal evidence of bacteria. Toxicology was negative for drugs and alcohol.

Case #2: A 31-year-old man was with a history of pharyngodinia, fever, and cough taken to the hospital. The clinical symptoms progressed to acute onset of increasing shortness of breath rapidly progressing to acute respiratory failure with haemoptysis. Chest x-ray demonstrated bilateral diffuse airspace opacification; the high resolution CT confirmed the presence of bilateral diffuse airspace consolidation associated with liquid in pleural cavities. The patient, with a severe leukopenia, was admitted to the intensive care unit, but died after a few hours. Two blood cultures were positive for group A beta-hemolytic *Streptococcus*. No other pathogenic agents were present. An autopsy was performed within 48 hours. The internal examination revealed an increase in lung weight and findings were consistent with intense congestion attributable to a bilateral pneumonia. The histological examination of lung specimens showed a pattern of diffuse alveolar damage and the presence of intralveolar bacterial and fungal colonies. In the kidneys a thrombotic microangiopathy compatible with DIC was found.

In conclusion, the cause of death was, in both cases an acute cardio-respiratory failure secondary to acute bilateral pneumonia with DAD and consequently ARDS, sepsis and DIC.

Hidden Pneumonia, Diffuse Alveolar Damage, Adult Respiratory Distress Syndrome

G25 Methodologies for Heteroplasmy Identification

Simona Ricci, MD, Department of Legal Medicine, Viale Regina Elena 336, Roma, ITALY*

After attending this presentation, attendees will receive information about the detection and study of heteroplasmy in the forensic field.

This presentation will impact the forensic community because it shows two caseworks in which different techniques were implemented to achieve good results.

Mitochondrial DNA (mtDNA) sequencing has been considered a useful tool for forensic analysis, and it is typed routinely in forensic analyses to assist in determining the source of old bones, teeth, hair shafts, and other biological samples where nuclear DNA content is too low or degraded to genotype by analyzing autosomal short tandem repeat (STR) loci.

Typically, forensic mtDNA data are obtained by sequencing (i.e. Sanger method, followed by electrophoresis and fluorescent detection) the two hypervariable regions (HV1 and HV2) of the noncoding control region of the human mtDNA genome. Traditionally, sequencing has been the method of choice because all polymorphisms contained within the amplified fragment can be detected. The definition of heteroplasmy is the existence of two types of mtDNA within an individual. It is known that the sensitivity of heteroplasmy detection is method-dependent, and the most fundamental approach to sampling the individual mtDNA present in an individual is achieved through cloning.

The most common form of heteroplasmy observed in the mtDNA control region is length heteroplasmy. Depending on its extent, length heteroplasmy may result in an inability to read or interpret sequence data and must be compensated for with alternative sequencing strategies. There are different methods to evaluate the mutation load of defective mtDNAs: primer extension, TTGE, RT-PCR, restriction fragment analysis and SSCP. In addition heteroplasmy using SSO typing, DHPLC/nuclear loci and DGGE can be detected. These methods are highly sensitive and can detect and sometimes quantitate heteroplasmy at levels lower than 1%. In this study, information regarding the management of different cases using clonage and DHPLC respectively

will be presented. In both cases heteroplasmies were present. The aim of this work is to demonstrate the utility of these two techniques showing the main indications and advantages for the forensic community.

mtDNA, Heteroplasmy, Clonage vs. DHPLC

G26 Internal Validation of Quantifiler™ DUO DNA Quantification Kit and AmpFℓSTR® Yfiler™ PCR Amplification Kit

Maria J. Illescas, BS, Virginia Commonwealth University, 1000 West Cary Street, PO Box 842012, Richmond, VA 23284-2012; Fernando Mercedes, MS*, Institute of Forensic Science of Puerto Rico, Calle Maga Esq. Casia, Urb. Reparto Metropolitano, San Juan, PR 00922; Tracey Dawson Cruz, PhD*, 1000 West Cary Street, PO Box 842012, Virginia Commonwealth University, Richmond, VA 23284; and Carmen A. Tirado, MS*, Institute of Forensic Science of Puerto Rico, Calle Maga Esq. Casia, Urb. Reparto Metropolitano, San Juan, PR 00922*

After attending this presentation, attendees will learn about the methods and results from the validation study of two Y specific kits performed at the Institute of Forensic Science of Puerto Rico.

This presentation will impact the forensic community by communicating the methods and results from a validation study of two available forensic kits. Y-locus specific kits are an important forensic tool to aid in the discrimination of the male contribution in a sample, such as rape cases.

The DNA-Serology Laboratory of the Institute of Forensic Sciences of Puerto Rico is the only Latin American laboratory accredited by ASCLD-LAB. Y-STR's have become an important forensic tool in cases in which male-male or male-female mixtures arise, such as rape cases. Y-locus STR's have also gained importance in the clarification of erroneous Amelogenin tests from autosomal STR amplification kits. Quantitation of human male DNA and Y-STR analysis are not currently performed in-house. Therefore, this study was designed to validate two commercially available forensic kits, Quantifiler® Duo DNA Quantification, and AmpFℓSTR® Yfiler™ PCR Amplification for in-house quantitation of human male DNA and Y-STR detection. These kits were validated for use with one real-time PCR instrument model for DNA quantitation (ABI Prism® 7500 Sequence Detection System) and two capillary electrophoresis instrument models (ABI Prism® 3130xl and 3100-Avant Genetic Analyzers) for Y-STR detection.

Quantifiler® Duo DNA Quantification Kit is designed to simultaneously quantify the total amount of amplifiable human DNA and human male DNA in one reaction. The quantification assay combines three 5' nuclease assays, namely: target-specific human DNA assay, target-specific human male DNA assay, plus an internal PCR control (IPC). The human target is Ribonuclease P RNA Component H1 (RPPH1) located at 14q11.2 and 140 bases long is detected by TaqMan® MGB probe labeled with VIC dye. The male target is the sex-determining region Y (SRY) located at Yp11.3 and 130 bases long is detected by TaqMan® MGB probe labeled with FAM dye. The internal PCR control is a synthetic sequence not found in nature. It is 130 bases long and is detected by TaqMan® MGB probe labeled with NED dye. AmpFℓSTR® Yfiler™ PCR amplification kit is a short tandem repeat multiplex for human male-specific DNA amplification that includes the European minimal haplotype loci (DYS19, DYS385a/b, DYS389I/II, DYS390, DYS391, DYS392, and DYS 393), the SWGDAM recommended loci (DYS 438 and DYS439), and additional highly polymorphic loci (DYS437, DYS448, DYS456, DYS458, DYS635, and Y GATA H4) for a total of 17 Y-STR loci in a single PCR reaction.

Internal validation studies included: precision, accuracy, sensitivity, male:male mixture evaluation, female:male mixture evaluation, stutter determination for each locus, as well as forensic casework. Forensic

casework includes a double-rape case, an incest case, a proficiency test from Collaborative Testing Services, Inc., and a case with null Amelogenin typed with AmpF[®]STR IdentifilerTM PCR Amplification kit. In addition to these studies, 106 samples were used to create a Y-STR database for Puerto Rico. All validation study data is being analyzed and will be discussed.

Internal validation of available DNA typing kits for human identification allows for the evaluation of a procedure's efficiency, reliability, performance characteristics, and limitations. The internal validation of the Y-locus specific kits (AmpF[®]STR YfilerTM and Quantifiler[®] Duo) will allow the Puerto Rico Institute of Forensic Science DNA laboratory to save time and money, as well as the ability to offer reliable male DNA typing services.

Y-STR, Male Quantitation, YfilerTM

G27 The Effect of Clothing on Scavenger Visits and Decomposition

Amanda J. Marshall, BS, Jennifer R. Simon, BS*, and Phillip L. Watson, PhD*, Ferris State University, Department of Biology, 2004 ASC, 808 Campus Drive, Big Rapids, MI 49307*

After attending this presentation, attendees will learn the differences clothing can make on the timing and frequency of scavenger visits to remains. Clothing will be shown to significantly affect when scavengers visit and alter the death event.

This presentation will impact the forensic community by demonstrating how time of death is determined by many factors, the presence or absence of clothing does affect the timing of visits.

The presence or absence of clothing can alter the decomposition rate (Anderson 2001, Kelly 2006). Quantifying the decomposition rate is difficult and complicated by the potential differences in timing of scavenger visits and alterations to the death scene by those visits. This study, which is a follow-up to one conducted in 2007, examined the rate of decomposition on a clothed and unclothed pig as a function of summer environmental conditions, but includes motion sensor cameras to capture scavengers frequenting the sites. Insects were collected twice a day until the dry remain stage occurred. Cameras were secured and pictures were obtained as motion was sensed by the camera. Temperature, relative humidity, rainfall, and wind speed data were collected on an hourly basis. The data show increased activity of forensically important insects as a function of temperature and clothing. The delay of the clothed victim to reach the dry remains stage was significantly different from the delay for the victim without clothing. The development stages of larvae collected from the clothed victim were also significantly smaller than the unclothed victim at all collection dates until the unclothed victim was no longer attractive to forensically important flies. The scavenger visits were significantly different between the two test animals in terms of time and abundance as determine by motion sensor cameras. How scavengers may be useful in determining state of decomposition will be discussed.

Data to be discussed will be the differences in larva size, insect species composition on each pig over time and identity, frequency and timing of scavenger visits. Comparisons were done as an ANOVA test and a species diversity comparison for all days. Results will be used to set up teaching mock crime scenes to illustrate the effects of clothing on PMI calculations.

Scavengers, Clothing, Insects

G28 Foreign Bodies: Three Cases of Projectile Maintenance Without Complications

Duarte N.P. Vieira, PhD, Carlos Abreu, MD, and Cristina Cordeiro, MSci, Instituto Nacional de Medicina Legal, Largo da Sé Nova, Coimbra, LB 3000-213, PORTUGAL*

After attending this presentation, attendees will learn about the possibility of retention of foreign bodies, like projectiles, in the body during long periods of time without any symptoms or evident complications, and that are only accidentally discovered during an autopsy performed due to another cause of death. However, there are some cases where problems may occur, being the bullets the cause of several symptoms and even sudden death. Thus, a regular follow up of the victim must be done in these situations and sometimes a surgical removal is needed.

This presentation will impact the forensic community by showing three cases where projectiles were maintained in the body for several years, due to previous gunshot injuries. In one of these cases, the projectile was found during the autopsy of a traffic accident victim. Surprisingly it had remained in the pericardial cavity for 12 years! In the other two cases, concerning living persons, the projectiles stayed in the corpse of a dorsal vertebra and in the sphenoid sinus, respectively, for many years.

The possible complications and risks of bullets maintenance in victim's bodies are reviewed and the authors stress the particular attention that these situations demand during the medical forensic assessment of these individuals.

The retention of projectiles in the body is an unusual situation. Sometimes these projectiles are maintained for life in the body without any symptoms or evident complications, and are only accidentally discovered during an autopsy performed due to another cause of death.

Foreign Bodies, Projectiles, Autopsy

G29 The Persistence of an Elevated Concentration of Ninhydrin-Reactive Nitrogen in Grave Soil

Brianna F. Anderson, and Jessica D. Wilkerson, University of Nebraska-Lincoln, 202 Entomology Hall, PO Box 830816, Lincoln, NE 68583-0816; and David O. Carter, PhD, University of Nebraska, Lincoln, Department of Entomology, 202 Plant Industry Building, Lincoln, NE 68583-0816*

After attending this presentation, attendees will understand that the concentration of ninhydrin-reactive nitrogen (NRN) in grave soil increases during the first year of decomposition while grave soil pH decreases.

This presentation will impact the forensic community by serving as a fundamental investigation into the estimation of extended PMI.

As time progresses, however, NRN concentrations fluctuate less making it difficult to estimate postmortem interval (PMI) over an extended period of time. This presentation will impact the forensic community by serving as a fundamental investigation into the estimation of extended PMI. Accurate estimates of extended PMI are currently difficult to achieve.

Although several methods to estimate postmortem interval (PMI) have been developed, there is no one method that can be used in all scenarios. Most of these methods focus on estimating early PMI (<30 days). As a consequence, relatively few methods have been developed to estimate extended PMI (>30 days). Recent investigations have shown that the decomposition of a body can have a significant effect on the chemistry of associated soil (grave soil) that persists into the extended

PMI. One effect is an increase in the concentration of materials (organic nitrogen and ammonium) that react with ninhydrin. This material is referred to here as ninhydrin-reactive nitrogen (NRN). Eventually, (NRN) concentrations will return to basal levels and it is believed that this can be used to estimate PMI. To determine how long NRN persists in soil, and develop a tool to estimate extended PMI, the NRN concentrations of grave soil associated with decomposing cadavers (after 0, 1 or 3 years) were measured.

The experimental site was located at the University of Nebraska Agricultural Research Development Center located approximately 48 km north of Lincoln, Nebraska, USA. The site is a pasture that is intermittently grazed by cattle and horses. The soil at the site is a deep silty clay loam of the Yutan series (Mollie Hapludalf). The climate is temperate midcontinental characterized by hot summers, cold winters, and moderately strong surface winds. Average annual precipitation is 695 mm. Approximately 75% of the precipitation occurs between April and September. Mean annual temperature is 9.8°C with mean minimum and maximum temperatures ranging from 0°C (January) to 31°C (July). The vegetation at site is dominated by non-native grass (smooth brougham) and forb (white clover) with some native vegetation, including daisy fleabane, yellowwood sorrel nut sedge, and pasture rose.

Swine (*Sus scrofa*) carcasses (~40 kg) plus a control (no cadaver) were used. Swine were killed with blunt force trauma to the cranium and placed on their right side on the soil surface facing west. Soil samples were collected (0-5 cm depth) from adjacent to the cadaver following 0 years, 1 year, and 3 years of decomposition and analyzed for NRN and pH. This experiment was replicated three times, which resulted in a total of six swine cadavers.

A significantly ($P < 0.01$) greater concentration of NRN was observed in grave soil after one year but not after three years. Also, a significantly ($P < 0.01$) lower pH was observed in grave soil after one year but not after three years. The current results demonstrate that the concentration of grave soil NRN and soil pH associated with a 40 kg cadaver can return to basal levels between one and three years postmortem. Thus, the maximum PMI that can be estimated using an increase in grave soil NRN or a decrease in grave soil pH is one year. Further research should be conducted to increase the accuracy of these approaches. In addition, other compounds and elements in grave soil should be investigated for their use in estimating PMI greater than one year.

Forensic Taphonomy, Extended Postmortem Interval, Decomposition

G30 The Application of DNA Identification Technology to Large Wildlife Carnivore Attacks on Humans

Jeff Rodzen, PhD, California Department of Fish and Game Wildlife Forensic Laboratory, 1701 Nimbus Road, Rancho Cordova, CA 95670; Elizabeth Thompson, BS, Orange County Sheriff-Coroner Department, Forensic Science Services, 320 North Flower Street, Santa Ana, CA 92703; James D. Banks, BS, and Erin Meredith, MS, California Department of Fish and Game Wildlife Forensic Laboratory, 1701 Nimbus Road, Rancho Cordova, CA 95670; Hailu Kinde, DVM, California Animal Health and Food Safety Laboratory System, 105 Carousel Mall, San Bernardino, CA 92401; Joseph J. Halka, MD, Orange Coounty Sheriff-Coroner Department, Forensic Science Center, 1071 West Santa Ana Boulevard, Santa Ana, CA 92703; and Pennie Laferty, MS, and John M. Hartmann, MBA, Orange County Sheriff-Coroner Department, Forensic Science Services, 320 North Flower Street, Santa Ana, CA 92703*

The goal of this presentation is to demonstrate the use of DNA typing to confirm the identity of wildlife predators in attacks on humans.

The growth and encroachment of human populations into rural areas, and the consequences of several years of drought, especially in the western United States, has resulted in more frequent contact with large predators such as mountain lions and bears, with sometimes fatal consequences for one or both. Correct identification of the species and individual animal is essential to ensuring public safety with minimal loss of endangered wildlife. The application of modern DNA technology to a fatal mountain lion and non-fatal mountain lion and a recent bear attack on humans with two-way and one-way transfers of DNA that enabled certain identification of the predator will be presented.

Forensic DNA, STR, Puma

G31 Sudden Unexplained Death Due to Disseminated Malaria

Ritesh G. Menezes, MD, Kasturba Medical College, Mangalore, India, Department of Forensic Medicine, Light House Hill Road, Mangalore, Karnataka 575001, INDIA*

After attending this presentation, attendees will understand that the demonstration of parasitized red blood cells with malarial pigment in the blood capillaries of internal organs by histopathology is a reliable and easy method of postmortem diagnosis of disseminated malaria.

This presentation will impact the forensic community by understanding the possibility of disseminated malaria as a cause of sudden unexplained death in malaria-endemic regions.

Sudden unexplained deaths are mainly attributed to the cardiovascular system and the respiratory system. A case study of sudden unexplained death due to disseminated malaria in an apparently healthy individual will be presented. In the present case, histopathological examination demonstrated the presence of parasitized red blood cells with malarial pigment in the blood capillaries in the brain, myocardium, pericardium, lungs, kidneys, liver, and the spleen.

Sudden Death, Disseminated Malaria, Forensic Histopathology

G32 Chloride Levels of Sphenoid Sinus Fluid in Salt and Fresh Water Drownings on the Island of Oahu, Hawaii

Nicole Stalter, MSFS, Chaminade University, 3140 Waialae Avenue, Forensic Science Department, Honolulu, HI 96816; Gayle Suzuki, MD, and Erin Mitsunaga, BA, Honolulu Medical Examiner, 835 Iwilei Road, Honolulu, HI 96817; and M. Lee Goff, PhD, Forensic Sciences Program, Chaminade University of Honolulu, 3140 Waialae Avenue, Honolulu, HI 96816-1578*

After attending this presentation, attendees will walk away with better knowledge of how chloride levels of sphenoid sinus fluid can help support pathologist's diagnosis of drowning as the cause of death.

This presentation will impact the forensic community by broadening research about chloride levels of sphenoid sinus fluid in salt and fresh water drownings.

There are many potential criteria to be evaluated in the pathologist's diagnosis of drowning as the cause of death. One of these involves the analysis of the sphenoid sinus fluid. In the drownings reported from the island of Oahu, Hawaii, chloride levels of sphenoid sinus fluid in salt water drownings are typically greater than 140 mmol/L and for fresh water drownings they are normally less than 65 mmol/L, however, to date there has been little research on the topic. During July 2007 through July 2008, there were 37 drownings reported on the island of Oahu. Nineteen of these had sphenoid sinus fluid removed and analyzed for the chloride content, 14 salt water and five fresh water. Eight of the 14 salt water cases had the expected chloride readings of greater than 140

* Presenting Author

mmol/L. Due to specific circumstances, including decomposition, the other six presented different results. Of the five fresh water cases, two presented the expected chloride levels of less than 65 mmol/L, while three had concentrations greater than 65 mmol/L. Of these, two were recovered from chlorinated swimming pools. Other factors that must be taken into consideration for all cases include: time elapsed between death/discovery of the individual and collection of samples; and hospitalization following discovery with death occurring later during hospitalization.

Drowning, Sphenoid Sinus Fluid, Chloride Level

G33 Recovery of Transplantable Organs After Cardiac Arrest in France

Nathalie Jousset, MD, Arnaud Gaudin, MD, Damien Mauillon, MD, and Clotilde G. Rougé-Maillart, MD, CHU, Service de Médecine Légale, 4 rue Larrey, Angers, 49000, FRANCE*

After attending this presentation, attendees see an explanation of French legislation and summarize ethical problems linked to transplantation of organs coming from non-heart beating donors (NHBD).

This presentation will impact the forensic community by comparing situations, legislation, ethical problems, between countries concerning NHBD transplantation.

After being abandoned around the end of the 1960s, the transplantation of an allograft recovered after cardiac arrest has been resumed again in France in 2006 (decree of 2 August 2005: art R.1232-4-1,2 and 3 of the public health code).

Recently, according to the international scale, five situations that could lead to the recovery of transplantable organs after cardiac arrest were identified according to a classification called "Maastricht" which describes the potential donors. In France, the donors of class III (cessation of all medical care) were excluded.

To achieve an effective transplantation, the donor has to be legally dead in the eyes of the law, and the organs still viable medically. A legal definition of death, in the purpose of the recovery of the transplantable organs of the "dead" donors comes up against this contradiction.

In front of this issue, certain countries recommend against giving a legal definition of the death criteria. It is not the orientation chosen by France that continues to attempt to define a legal framework in order to obtain the society acceptance of the recovery of transplantable organs of "dead" donors.

Despite this, ethical questions arise. Are criteria adopted to define death enough? What is the place of non-heart beating donor transplantation with new technical resuscitation as extracorporeal life support for prolonged cardiac arrest? How does family and medical staff support this protocol?

Non-Heart Beating Donors, Legislation, Ethical Reflection

G34 Veterinary Forensic Science: Documentation, Processing, and Interpretation of Physical Evidence at Scenes of Animal Crimes

Jason H. Byrd, PhD, University of Florida, Department of Agriculture & Consumer Services, University of Florida, PO Box 147100, Gainesville, FL 32614-7100; Kenneth F. Cohrn, DDS*, Heritage Dental of Central Florida, 422 Teague Trail, Lady Lake, FL 32159; Jeffery K. Tomberlin, PhD, Department of Entomology, TAMU 2475, College Station, TX 77843-2475; David W. Hall, PhD*, David Hall Consultant, Inc., 3666 NW 13th Place, Gainesville, FL 32605; John J. Schultz, PhD*, University of Central Florida, Department of Anthropology, PO Box 25000, Orlando, FL 32816; Melinda Merck, DVM*, ASPCA, 6175 Hickory Flat Highway Suite 110-2, Canton, GA 30115; and Randall Lockwood, PhD*, ASPCA, 2214 Tulip Drive, Falls Church, VA 22046; Micah Flores, BSc*, Texas A&M, 2475 TAMU, College Station, TX 77840*

After attending this presentation, attendees will gain an understanding of the current issues faced by prosecutors, judges, law enforcement officials, and veterinarians when attempting to bring cases of animal cruelty and death to trial in the courtroom. Participants will also gain a more detailed understanding of how modern forensic science as practiced at scenes of human death can be readily applied to the animal crime scene.

This presentation will impact the forensic community by giving a more detailed description of current problems and issues involved in the application of forensic science techniques to scenes of animal crime. Additionally, the participant will gain an improved understanding of the needs within the veterinary community and will be better prepared to utilize their own knowledge and forensic specialty to provide assistance to those in the veterinary forensic science community.

With the passage of many animal cruelty laws, the need to apply current forensic science methodologies to these investigations has increased dramatically. Animals have many similarities to humans in their response to traumatic injury with some noted exceptions. Forensic science techniques utilized at human crime scenes and applied human victims can often be easily applied to scenes involving cruelty or death to animals. This symposium will address the application of forensic techniques developed for the investigation of human death to animal cases and unique findings at animal crime scenes.

Veterinary Science, Veterinary Forensics, Animal Cruelty

G35 Natural Causes of Sudden Unexpected Infant Death: A Seven Year Retrospective Forensic Autopsy Study in Hubei, China

Ling Li, MD, Office of the Chief Medical Examiner, State of Maryland, 111 Penn Street, Baltimore, MD 21201; Lan Zhou, BM, Department of Forensic Medicine, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, 430030, PEOPLES REPUBLIC OF CHINA; Xiang Zhang, MD*, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Liang Lui, MD, Tongji Medical College, 13 Hong Kon Road, Wuhan, Hubei 430030, PEOPLES REPUBLIC OF CHINA; Lin Chang, MD, Key Laboratory of Evidence Science, China University of Political Science and Law, Beijing, MD 100040, PEOPLES REPUBLIC OF CHINA; Guangzhao Huang, BM, Department of Forensic Medicine, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, MD 430030, PEOPLES REPUBLIC OF CHINA; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will become familiar with the common natural causes of sudden unexpected infant death in Hubei province, China and will better understand the difference in the diagnosis of sudden infant death between China and western countries.

This presentation will have an impact on the forensic science community as it suggests that further studies are needed to focus on the differences in the diagnosis of sudden infant death between developing countries and developed countries.

The importance of a forensic investigation and autopsy in cases of sudden infant death has only recently received attention in China. An analysis of forensic autopsy data on sudden infant deaths in Hubei, China has never been undertaken. This report describes the epidemiological characteristics and pathological findings of sudden infant death cases investigated by the Department of Forensic Medicine at the Tongji Medical College in Hubei, China from 1999 to 2006.

A retrospective study of forensic autopsy cases conducted at the Department of Forensic Medicine, Tongji Medical College in China over a seven year period between 1999 and 2005 yielded a total of 68 infants who died suddenly and unexpectedly in Hubei province. The age ranged between newborn and 12 months. A total of 41 cases (60%) of the deaths occurred in the neonatal period, 13 (22%) infants in the first six months of life, and the remaining 12 cases (18%) in the age between seven months and one year. There were 54 males and 14 females (M: F = 3.8:1). The most common cause of sudden neonatal death was pneumonia (N=14), followed by congenital abnormalities (N=9); asphyxia due to amniotic fluid aspiration (N=7); respiratory distress of newborn (N=3); intrauterine hypoxia and birth asphyxia (N=3); complications of prematurity (N=2); newborn affected by complications of cord (N=1), birth trauma (N=1); and tetanus (n=1); and one death with undetermined cause.

The three leading causes of sudden death in infants, age 1 to 12 months were pneumonia (N=11), congenital heart disease (N=3), and meningitis (N=2). Only one infant was diagnosed as SIDS death.

Infectious diseases are a frequent cause of death in infants who died suddenly and unexpectedly in Hubei, China. These findings contrast with those from developed countries in which Sudden Infant Death Syndrome is the commonest cause of sudden unexpected death in infancy. This study demonstrates that it is important to document autopsy-based data such as these in the planning of medical services in a developing country.

Sudden Infant Death, Forensic Investigation, Autopsy

G36 Biomedical Engineering in Root Cause Analysis – Example: Assessing Infant Apnea-Related Deaths

Bruce H. Barkalow, PhD, William E. Grant, MA, and Farrah J. Curran, BS, B.H. Barkalow, PC, 490 Quarterline St., Newaygo, MI 49337-9125*

After attending this presentation, attendees will gain a better understanding by example of how Biomedical Engineering can assist in root cause analysis by examining how testing of subject apnea monitors and analyses of downloaded patient data can be useful in determining device failure versus human error.

This presentation will impact the forensic community by demonstrating how Biomedical Engineering analysis can shed light on important information involving medical devices. In this example, testing of subject apnea monitors and analyses of downloaded patient data can be useful in determining whether such devices have failed, or whether other factors (including human error) led to infant deaths.

Infants (primarily those of low birth weight) who are at risk for Sudden Infant Death Syndrome (SIDS) are often prescribed apnea monitors for at-home use. Infant apnea monitors are designed to alert caregivers if a child has become apneic and/or has heart rate changes outside of the preset limits. These monitors are not fool proof, however, and every year some children who are being monitored die. When this happens, it is the responsibility of the Medical Examiner to ascertain why the death occurred. Biomedical Engineers trained in this technology can play a vital role in these death investigations.

Apnea in neonates and infants occurs most likely because of immaturity of their respiratory and neurologic systems. Though it is common for infants to pause in their breathing for short periods, pauses lasting longer than 20 seconds are cause for concern, as are pauses of shorter duration accompanied by decreased heart rate. Infant apnea monitors are designed to detect increases and decreases in heart rate along with pauses in breathing, and sound an alarm if they occur. This is accomplished by attaching a belt with a series of electrodes around the infant's chest. The electrodes are attached to the monitoring unit itself. Monitors should have a battery backup, a remote alarm, a power loss alarm, a battery charge or AC power indicator, a sibling alarm as well as an internal memory for event and physiological data storage.

In cases where a child monitored with one of these devices has unexpectedly expired, a technical analysis should be performed by a trained Biomedical Engineer. A physical examination of the monitor itself should be conducted, along with an assessment of the electrical circuitry and analysis of monitor-downloaded data. A combination of downloaded patient and monitoring compliance data from the apnea monitor memory can be cross-correlated with events, such as feeding schedules or EMS run sheets. Deaths of monitored infants have been related to such issues as monitor hardware and software failures, obstructive apnea (often not detected), parental monitoring compliance, inability to hear the alarms, cardiac artifact in the transthoracic impedance signal, or electromagnetic interference, to name a few. If an apnea monitor is sent to the Medical Examiner's office along with an infant who has expired, it should be maintained as evidence, and the stored data downloaded and analyzed along with statements of the caregivers.

Case material corresponding to several of these failure-related issues will be presented to illustrate how a root cause approach can assist in making sense of why such tragic events may have occurred.

Biomedical Engineering, Infant Apnea Monitor, Sudden Infant Death Syndrome (SIDS)

G37 In Utero Traumatic Head Injuries During a Motor Vehicle Collision: Case-Report and Review of the Literature

Sean A. Swiatkowski, DO, 1 Middlebridge Court, Silver Spring, MD 20906; Anna Rubio, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201; Michael Johnson, MD, and Juan C. Troncoso, MD, Johns Hopkins University School of Medicine, 111 Penn Street, Baltimore, MD 21201; and David R. Fowler, MD, Office of the Chief Medical Examiner, 111 Penn Street, Baltimore, MD 21201*

After attending this presentation, attendees will understand the importance of fetal brain injury in utero after a motor vehicle collision which can lead to hypoxia, direct impact and acceleration-deceleration injuries. A discussion of maternal restraint will also be presented.

This presentation will impact the forensic community by highlighting the possible neurologic complications associated with motor vehicle collision and the fetal brain in utero, especially in relation to acceleration-deceleration forces

Fetal brains differ from neonatal and infantile brains in development and the environment surrounding them, namely the protection offered by the amniotic fluid, uterus, and maternal abdominal wall. Head injuries inflicted during motor vehicle collision result from both direct impact and from acceleration-deceleration forces. The effects of these forces on the fetal brain and eyes are poorly described in the literature. The American College of Obstetrician and Gynecologists and the National Highway Traffic Safety Administration recommend that pregnant women use a 3-point restraint system with the lap belt positioned under the uterus based on the hypothesis that the amount of fetal head acceleration and abdominal force is significantly reduced.

A 32-week pregnant, 31-year-old Hispanic woman was the restrained front seat passenger in a mini van that was rear-ended by a full sized tractor-trailer. Following the collision she was alive but in a deep coma, tachycardiac and with a blood pressure of 119/62. She was intubated in the field and transported to the hospital. Fetal heart monitoring revealed 40 beats per minute. An emergency C-section was performed slightly more than one hour following the impact, and a 1,580 gram baby girl with Apgar scores of 0, 0 and 0 was retrieved. Examination of the uterus revealed placental abruption. Maternal injuries detected by CT included a complete torso passenger-site shoulder and lap seat-belt contusion with the lap section located on the pelvis, C4-C5 fractures with bilateral internal carotid injuries, fractured ribs, pneumo and hemothoraces, liver lacerations, fractured T3 and L1 through L5 vertebrae, retroperitoneal hematoma and acetabular fractures. The mother was pronounced dead two and a half hours after the collision. A complete postmortem examination of the stillborn female was performed including neuropathologic and ophthalmic pathologic assessment. The findings obtained at the autopsy of the stillborn, which will be presented, included the external and internal traumatic injuries, head and spinal injuries, including direct impact and acceleration-deceleration injuries to the brain, spinal cord, and eyes, grossly and microscopically. These findings will be discussed in relation to previous literature reports and the seat-belt recommendations for pregnant women.

Hypoxia, direct impact, and acceleration-deceleration forces are the usual components producing complex neuropathologic injuries. The resulting lesions depend on the age of the victim; the susceptibility of the immature brain to trauma and the resulting pattern of injuries differ between fetal, childhood and adult brains. There are few reports in the literature of traumatic fetal brain injuries resulting from motor vehicle collision, rare reports including autopsy or eye pathology findings. In addition, findings are correlated with the use of a 3-point restraint system with the lap belt positioned under the uterus as recommended.

Fetus, Brain, Traumatic

G38 Return of an Old Acquaintance - A Case of Septic Abortion

Karen B. Looman, DO, Hamilton County Coroner's Office, 3159 Eden Avenue, Cincinnati, OH 45219*

After attending this presentation, attendees will become acquainted, or reacquainted, with septic abortion and some of the associated anatomical and microscopic findings.

This presentation will impact the forensic community by reminding everyone of a time when illegal abortions, septicemia and death were more common in the United States. After Roe vs. Wade, the frequency of cases dwindled. New and seasoned medical examiners may benefit from a reminder of what to expect in a septic abortion case, especially in an ever changing political arena.

On January 22, 1973, the Supreme Court decision regarding Roe vs. Wade allowed women to have legal medical abortions in the United States. In the past, women who were seeking an abortion for a reason other than to protect the health of the mother were limited to often questionably sterile and clandestine procedures. Cases of septic deaths from improperly performed procedures and post-operative infections were high. The numbers of such cases dropped off dramatically after the landmark legal decision. Some of the more experienced medical examiners may remember physical and microscopic findings in such cases. Less experienced doctors should be aware of some of the possible findings in a septic abortion case.

A 31-year-old married woman, with four living children, was rushed to a local hospital after becoming hypotensive at a small medical clinic. She was presented to the clinic with a complaint of food poisoning which included nausea, vomiting, diarrhea, and malaise. The clinic diagnosed pyelonephritis and gave her intramuscular ceftriaxone. Within minutes, the woman complained of tongue swelling, shortness of breath, and hypotension likely indicating an allergic reaction.
