# Preface

Nearly twenty years ago one of us (S. P. D., soon joined by G. H. S.), began a distillation of the elements of biochemistry into an alphabetical arrangement. The task was formidable and eventually other editors were recruited, an editorial board was established, and now the work is offered as the *Oxford Dictionary of Biochemistry and Molecular Biology*. It is hoped that the dictionary will serve the needs of the research biochemist or molecular biologist, as well as teachers of the subject and their students. In addition, it should prove of value to practitioners of other fields of study or work seeking the meaning of a biochemical term.

An important function of a dictionary is to provide guidance on current usage in the field within its scope. The original 12-volume *Oxford English Dictionary* was compiled from about five million slips of paper bearing sentences or phrases extracted by some thousands of 'readers' from classical works of literature and those of the best contemporary authors. It was thus firmly based on good usage. In scientific subjects, specialist terminology is often codified in sets of recommendations regarding nomenclature, meaning, abbreviations, symbols, and so on. These have been agreed by international commissions (e.g. those of The International Union of Pure and Applied Chemistry and The International Union of Biochemistry and Molecular Biology) as a means of preserving order and facilitating communication between scientists. We have striven to conform as far as possible to the relevant international recommendations, but in some cases, where usage so frequently diverges from a recommendation that adherence to it would seriously detract from ease of use of the dictionary, we have kept to the principle that the dictionary should reflect usage (see the definitions of *lexicographer*). This does not extend, of course, to cases where usage, however widespread, contradicts sound scientific principles. The internationally agreed recommendation is always also listed. The various compilations of these recommendations that have been drawn upon are listed in Appendix B, together with a number of other sources of information on nomenclature.

Biochemistry is the discipline that embraces the study of the structure and function of life-forms at the molecular level.

Molecular biology is a closely related discipline that originates in the study of DNA and its metabolism, and now embraces all those investigations that exploit the technology that has resulted from this work. Both disciplines aim to explain the behaviour of life-forms in molecular terms, and are so closely interrelated that separation is barely possible. It is inevitable that the content of this dictionary is to a degree arbitrary, but it is hoped that all important aspects of these subjects have received consideration. The compilers have attempted to offer a broad coverage of terms encountered in the literature of biochemistry and molecular biology by including an appreciable number from cognate sciences. Although the compilation is designed primarily to serve readers of contemporary material, the needs of those who turn to older literature have also been borne in mind. Some of the entries thus have a historical flavour, some obsolete terms are included (e.g. zymase), and in some cases a historical approach has been used as the best means of presenting an explanation of a term, as for example in the case of the entry for *gene*. The value of a scientific dictionary is enhanced by inclusion of contextual information as well as mere explanations of meaning or terminology. This dictionary will be found to have some of the attributes of an encyclopedia, although the extent to which it veers in this direction has varied with the whim of its compilers. It is our hope that in a single volume the reader has easy access to basic definitions as well as a generous helping of other information.

In the present-day world, we are assailed by floods of 'information'. It has been suggested that the average weekday edition of a newspaper of record (e.g. *The New York Times*) provides more information than Shakespeare and his contemporaries would have acquired in a lifetime. With the availability of much information through the Internet, it may be asked whether a dictionary in paper form is actually necessary. In answer, we note that the Internet can be slow, and is not readily accessible in some parts of the world; the databases may be inadequate, and although usually very up-to-date, the high cost of their maintenance restricts them to specialized knowledge in a limited number of fields. Moreover, books have a

## Preface

quality of their own, which is enabling them to maintain their popularity. It appears that the increasing use of the Internet is actually paralleled by the rate of publication of printed dictionaries; in an information-hungry age, there cannot be too many sources of good-quality information.

We are deeply indebted to the Leverhulme Trust for the award of an emeritus fellowship to one of us (A. D. S.), to University College London, which has provided us with friends and expert colleagues, and to Dr O. Theodor Benfey, Dr Mary Ellen Bowden, and Professor Arnold Thackray, The Beckman Center for History of Chemistry, Chemical Heritage Foundation, Philadelphia, and Dr John Edsall, Harvard University for assistance with biographical data.

Particular thanks are due to Dr H. B. F. Dixon for much advice on nomenclature and related matters. Help on questions of nomenclature from Dr G. P. Moss and Dr A. D. McNaught is also acknowledged. We are grateful to Dr D. H. Jenkinson for his help with the recommendations of the International Committee on Nomenclature in Pharmacology. We are also grateful for the valuable advice of Professor K. W. Taylor and Dr J. L. Crammer, on clinical topics, and Professor M. C. W. Evans, on plant biochemistry, and to Dr Margaret McKenzie, for reading the proofs.

During the earlier stages of the project, Mrs S. Gove gave much valuable assistance and Miss A. Straker was most helpful in suggesting terms for inclusion. We also wish to thank all those other friends and colleagues, in addition to those separately listed, who have unstintingly given us help and advice.

## Preface to the revised edition

It must be inevitable with any work of this nature that a number of imperfections and errors occur. So the opportunity provided by the need to reprint this dictionary has been taken to effect some improvements within the limitation imposed by retention of the original pagination. As well as the correction of a variety of minor misprints and other minor defects, over four hundred entries have been either revised or completely rewritten, and fifty or so new entries have been provided, some to remedy deficiencies and others to provide additional terms that have become of topical interest. To help make way for the new ones, about half as many original entries have been

We are pleased to acknowledge the collaboration and material support given to us by Oxford University Press. We also acknowledge the very friendly cooperation of Market House Books, especially the patience and good humour of Dr John Daintith through all the complications of the production. The copy editors, Robert Hine and Jane Cavell, made a number of helpful suggestions.

The compilers offer no apology for their failure to include many deserving terms in the dictionary, but would be pleased to have their attention drawn to errors and to receive suggestions for additional entries in any future edition.

Correspondence concerning the dictionary is best addressed to the Managing Editor, *Oxford Dictionary of Biochemistry and Molecular Biology*, c/o Oxford University Press, Great Clarendon Street, Oxford OX2 6DP

## Note on proprietary status

This dictionary includes some words which are, or are asserted to be, proprietary names or trade marks. Their inclusion does not imply that they have acquired for legal purposes a non-proprietary or general significance, nor is any other judgement implied concerning their legal status. In cases where the editor has some evidence that a word is used as a proprietary name or trade mark this is indicated by the designation *proprietary name*, but no judgement concerning the legal status of such words is made or implied thereby.

# Guide to the Dictionary

## 1. Alphabetical order

### 1.1 Main order of headwords

Alphabetical order is determined on a letter-by-letter basis, not word by word; spaces are disregarded:

acid  
acid anhydride  
acid-base balance  
acid-base catalysis  
acid dissociation constant  
acid dye  
acidemia

### 1.2 Nonalphabetic characters

Numbers, hyphens, primes, and subscript/superscript text are ignored for the purpose of indexing; an example is the following sequence of entries:

FSH-RH  
F1 sphere  
F'strain  
F-type penton phosphate pathway  
*ftz*

### 1.3 Locants and modifiers

In chemical names, any locants and other hyphenated modifiers such as *cis*-, *trans*-, *PQ*, and alphabetic Greek characters are not used to determine primary alphabetical order; hence the following entries all appear under the letter A:

N-acetylgalactosamine  
p-aminobenzoic acid  
 $\gamma$ -aminobutyrate shunt  
6-aminohexanoic acid

However, the unhyphenated letters 'c' in 'cDNA' and 'd' in 'dCTP', for example, are treated as integral parts of the word and are used to determine alphabetical order.

### 1.4 Secondary order involving locants

When such modifiers constitute the only difference between two headwords, they determine the alphabetical order of the entries:

benzodiazepine	encephalitis
o-benzoquinone	3'-end
p-benzoquinone	5'-end
benzoyl	end+

### 1.5 Format differences in headwords

The order for entries where the headword is identical except for format is

b, b, b-, b-, -b, B, B, B-, 8-, -B, -B

### 1.6 Subscripts and superscripts

Single letters with subscripts or superscripts are treated as single letters for the purposes of indexing, so entries for  $k_{\text{cat}}$  and  $K_m$  will both be found in the list of single-letter entries at the beginning of the letter K. The primary order of these single-letter entries is determined by their format (see section 1.5); where there is more than one entry with a given format (e.g. italic, lower case *k*), these are arranged by alphabetical order of their subscripts/superscripts.

### 1.7 Greek letters

- Where Greek letters form part of a chemical name, they are not used to determine alphabetical order (see section 1.3). Otherwise they are written out in full in the headword, e.g. nu body, beta strand.
- The names of the letters of the Greek alphabet, together with their English transliterations used in etymologies, are listed in Appendix A. The meanings assigned to Greek alphabetic characters used as symbols are also given in Appendix A.
- Greek characters are set in italic type when the character represents a variable or locant and in roman type when it represents a unit or subtype e.g. of a protein or particle.

## 2. Format of entries

### 2.1 Summary of typefaces

- The following distinguishing typefaces are employed in addition to the text light serif typeface used for definitions:

large bold sans serif	headwords
text bold serif	alternative terms for and variant spellings of headwords; hidden entries; run-ons
text bold sans serif	cross-references
<i>text italic serif</i>	usage notes and field labels; parts of speech; foreign language terms (including scientific and medical Latin); symbols for physical quantities and fundamental physical constants; stereochemical prefixes and alphabetical locants

### 2.2 Headwords

- For each entry, the headword is in bold, sans serif type.
- Upper-case (capital) initial letters are used only for proper names (or terms derived from them) and for proprietary names. Abbreviations and symbols are printed in upper and/or lower case as appropriate.
- If a term would normally be set in bold type, this is indicated in the entry:

*B symbol for* 1 Napierian absorbance (*see* absorbance).  
2 magnetic flux density (bold italic).

- Where the same basic term is used in different typefaces, such as roman/italic, or upper case/lower case, or as a prefix or suffix, each usage is given as a separate headword. For example, h, h, H, and Heach have a separate entry.
- The order in which such entries are given is listed in section 1.5.

### 2.3 Alternative terms and variant spellings

#### 2.3.1 Choice of headword

Where alternative terms for a headword, or variant spellings of it, exist (*see* section 1.3), the headword selected for the main entry is generally the recommended or preferred term, or the one judged to be the commonest. Exceptions to this generalization are those instances where the name of a Greek alphabetic character is written out for convenience of indexing:

beta globulin or  $\beta$  globulin....

#### 2.3.2 General

Any alternative terms and alternative spellings are listed following the headword in bold, serif type:

retrovirus or ribodeoxyvirus or RNA-DNA virus any virus belonging to the family Retroviridae....

Notes regarding the usage of these alternatives may be given in brackets and in italics; for example

DNA glycosylase or (sometimes) DNA glycosidase any of a group of enzymes....

bacteremia or (esp. Brit.) bacteraemia the presence of live bacteria in the blood.

bilirubin or (formerly) bilirubin IX $\alpha$  the recommended trivial name for the linear tetrapyrrole....

- These alternative terms and spellings also appear as entries in the alphabetical sequence, with a cross-reference to the main entry where the term is defined, unless the variant would appear close to the main entry. Additional information is given where appropriate:

demoxycytocin an alternative name for deaminooxytocin.  
fructose-1,6-diphosphatase a former name for fructose-bisphosphatase.  
lipide a variant spelling of lipid.  
molecular exclusion chromatography a less common name for gel-permeation chromatography.  
oleomargarine an alternative name (esp. US) for margarine.  
penatin an obsolete name for glucose oxidase.

#### 2.3.3 Chemical names

- Synonyms may be given following the headword, in the order: other trivial names (if any); the semi-systematic or semi-trivial name(s); older systematic name in style, if still in widespread use; the systematic name in currently recommended style.
- The headword used to represent a chemical compound that can exist in ionized form(s) is in most cases the name of its physiologically predominant form. So, for example, an entry is headed 'succinate' rather than 'succinic acid'.

#### 2.3.4 Enzyme names

Alternative names may be listed following the headword, which is normally the recommended name; otherwise alternative names include the recommended name (if the headword is the common name), the systematic name, and other names. The EC number is also given.

### 2.4 Multiple definitions

- Where a term has more than one meaning, the different senses are numbered with bold Arabic numerals.

blockade 1 (in pharmacology) the saturation of a specific type of receptor with an antagonist to its normal agonist. 2 (in immunology) the overloading or saturation of the reticuloendothelial system with inert particles, such as carbon particles. 3 to impose any such blockade.

- The order of the numbered entries is generally determined by their biochemical significance.
- The different senses may be further subdivided into def. 1a, def. 1b, etc.

di+ comb. form 1 (in chemical nomenclature) (distinguish from bis+ (def. 2)) a indicating the presence in a molecule of two identical unsubstituted groups, e.g. diethylsulfide, 1,3-dihydroxyacetone. b indicating the presence in a molecule of two identical inorganic oxoacid residues in anhydride linkage, e.g. adenosine 5'-diphosphate. 2 or bis+ (def. 1) denoting two, twofold, twice, doubled.

- Homographs are not distinguished.

### 2.5 Hidden entries

Hidden entries are terms that are not defined at their normal headword position. Instead, they are treated (implicitly or ex-

plicitly) at some other headword. They are set in bold serif type. In the following example, 'bentonite flocculation test' is the hidden entry:

**bentonite** a colloidal, native hydrated aluminium silicate clay consisting principally of montmorillonite, a complex aluminosilicate,  $\text{Al}_2\text{O}_3 \cdot 4\text{SiO}_2 \cdot \text{H}_2\text{O}$ , which has marked adsorptive properties. It is used as an inhibitor of nucleases and also in the bentonite flocculation test, a passive agglutination test in which antigen-coated bentonite particles are used to detect specific antibody.

## 2.6 Other information

### 2.6.1 Plurals

The plural form (or forms) of a headword is (are) given in parenthesis following the headword if its formation is non-standard, e.g. for Latin headwords, or where there is more than one form of the plural.

**medulla** (*pl.* medullas or medullae) the innermost part of an organ, tissue, or structure; marrow, pith. — *medullary ad.*

### 2.6.2 Affixes and combining forms

- In common with other dictionaries, this Dictionary lists and defines many word elements that are used to compose terms or to modify existing terms. These are either combining forms (which are derived from parent words) or affixes (infixes, prefixes, and suffixes, none of which have parents).
- The usual lexicographical convention is to add a hyphen to suffixes and combining forms when listing them as headwords, although generally the hyphen is omitted in formation of composite terms. However, chemical and biochemical terminology also includes a considerable number of specialized affixes that retain the hyphen in the formation of composite terms (e.g. '*meso-*' in '*meso-cystine*').

In order to make an explicit distinction between these alternatives, this Dictionary departs from the common convention by adding a hyphen to an affix in a headword only when a linking hyphen is retained in a combination:

**meso-** *abbr.: ms-*; *prefix (in chemical nomenclature)* designating a substance whose individual molecules contain ...

By contrast, combining forms (e.g., 'meso' in 'mesoderm') together with affixes producing unhyphenated composite terms, are listed with an added plus sign, placed after and/or before the word-element as appropriate:

**meso+** or (*sometimes before a vowel*) mes+ *comb. form* denoting middle, or intermediate.

**+agogue** or (*US*) +agog *suffix* denoting an agent that elicits or enhances the secretion of...

### 2.6.3 Abbreviations and symbols

- Where a term may be abbreviated or indicated with a symbol, this is noted after the headword.

**nuclear magnetic resonance** *abbr.: NMR or nmr;* the phenomenon that occurs when atomic nuclei....

**electric potential** or *potential symbol: Vor f;* the work done in bringing unit electric charge....

- The distinction between an abbreviation and a symbol is a little blurred, since some abbreviations (e.g. Ig) also may be

used as symbols. In general, the term 'symbol' is used here for

units and their decimal prefixes (e.g. m, mol;  $\mu$ , M)  
physical quantities and constants (e.g. *a*, *H*; *k*, *R*)  
mathematical functions (e.g. exp, ln)  
chemical elements (e.g. K, Mg)  
groups of letters that can be used in place of a chemical group or compound in an equation or formula (e.g. CoA, Me)  
recommended abbreviations for nucleotides, bases, or amino acids.

- The symbols for SI base and derived units and their decimal prefixes are mandatory; all other symbols are recommendations of IUBMB or IUPAC. In conformity with these recommendations, symbols for physical quantities and fundamental physical constants are printed in a sloping (italic) typeface.
- No distinction is made between acronyms, contractions, abbreviations, etc. All are classed as abbreviations. Abbreviations formed from the initial letters of two or more words are printed without periods (full-stops), in line with contemporary practice, but abbreviations that are shortened forms of single words have a terminal period.
- In addition to recommended abbreviations, the Dictionary lists a selection of others commonly encountered in the scientific literature.

### 2.6.4 Derived terms

Derived terms not meriting separate definition are listed at the end of the entry for the parent term, preceded by a bold em dash and followed by an abbreviation indicating the part of speech.

**bactericide** or bactericide any agent (biological, chemical, or physical) that destroys bacteria. -bactericidal or bacteriocidal *ad.*

### 2.6.5 Etymology

- Generally, the derivation of words is not explained in entries. The exceptions are for eponymous terms and other entries of particular etymological interest.
- The etymology is given within square brackets at the end of the entry.

**ångström** or Angstrom symbol: Å; a unit of length equal to  $10^{-10}$  metres. " [After Anders Jonas Ångström (1814-74), Swedish physicist noted for his work on spectroscopy.]

- Greek elements of etymologies are transliterated:

**chirality** topological handedness; the property of non-identity of an object with its mirror image.... [From Greek *kheir*, hand.]

### 2.6.6 Usage

- The field within which the term is used may be specified in italics and in parenthesis before the definition.

**malonyl** 1 (*in biochemistry*) the univalent acyl group,  $\text{HOOC}-\text{CH}_2-\text{CO}-$ , derived from malonic acid by loss of one hydroxyl group. 2 (*in chemistry*) the bivalent acyl

group, -CO-CH<sub>2</sub>-CO-, derived from malonic acid by loss of both hydroxyl groups.

- Notes may also be given regarding the use of alternative terms and variant spellings: *see* section 2.3.2.

## 2.7 Cross-references

### 2.7.1 Format

- Cross-references are set in bold sans serif type, e.g. thiouridine.
- Where a cross-reference refers to only one sense of a word with multiple definitions, this is indicated as in the following example:

siderophage *an alternative name for* siderophore (def. 1).

### 2.7.2 Types of cross-reference

- There are cross-references from a variant spelling, or a less commonly used term, etc., to the entry where the term is defined. For examples, *see* section 2.3.2.
- Some cross-references are to related entries giving more information. These may be either embedded in the text:

octulose any ketose having a chain of eight carbon atoms in the molecule.

or listed at the end of the entry:

vacuum evaporation a technique for .... *See also* shadow casting.

- Cross-references may also be used to draw attention to contrasting terms:

heterochromatin ... *Compare* euchromatin.

or to pairs of easily confused terms:

prolidase *another name for* X-Pro dipeptidase. *Distinguish from* prolinase.

prolinase *the recommended name for* Pro-X dipeptidase. *Distinguish from* prolidase.

## 3. Abbreviations

<i>abbr.</i>	abbreviation
<i>ad.</i>	adjective
<i>adv.</i>	adverb
<i>Brit.</i>	British
<i>comb. form</i>	combining form ( <i>see</i> section 2.6.2)
<i>3-D</i>	three-dimensional
<i>def.</i>	definition
<i>e.g.</i>	[Latin, <i>exempli gratia</i> ] for example
<i>esp.</i>	especially
<i>etc.</i>	etcetera
<i>Fr.</i>	French
<i>i.e.</i>	[Latin, <i>id est</i> ] that is
<i>max.</i>	maximum
<i>n.</i>	noun
<i>pl.</i>	plural
<i>sing.</i>	singular
<i>sp. or spp.</i>	species (singular and plural respectively)
<i>US</i>	United States
<i>vb.</i>	verb

Other abbreviations are defined in the text itself.

## 4. Other conventions

### 4.1 Spelling and hyphenation

#### 4.1.1 Spelling

- For chemical and biochemical terms, recommended international usage is followed; thus, for example, 'heme' is used rather than 'haem', 'estrogen' rather than 'oestrogen', 'sulfur' rather than 'sulphur', and 'oxytocin' rather than 'ocytocin'. All variants are listed as headwords, however, with cross-references to the corresponding main entries.
- For common terms, e.g. 'colour', British spelling is used.

#### 4.1.2 Hyphenation

- Hyphens are used attributively:

'T cell' but 'T-cell receptor'

'amino acid' but 'amino-acid residues'

- This also applies to enzyme names; thus for example, there is no hyphen following the 'glucose' in 'glucose 6-phosphate', but where this substrate forms part of an enzyme name, it is hyphenated, e.g. in 'glucose-6-phosphatase' or 'glucose-6-phosphate isomerase'.

### 4.2 Nomenclature

In most cases, headwords conform with the recommendations of the various nomenclature bodies of IUB, IUBMB, and IUPAC (*see* Appendix B for information regarding their nomenclature publications). Other usages are, however, given (*see* Preface). The phrase 'not recommended' has been used to indicate that certain forms are not the recommendation of one of these nomenclature bodies.

#### 4.2.1 Drug names

The recommended international nonproprietary names are used (*International nonproprietary names (INN) for pharmaceutical substances*. World Health Organization, Geneva, 1992); hence, for example, main entries are found under epinephrine and norepinephrine rather than under adrenaline and noradrenaline.

#### 4.2.2 Proprietary names

A few commonly used proprietary names are included; these may be listed at the end of an entry if considered to be of particular interest, especially to non-scientists:

acetaminophen or paracetamol ... *Proprietary names:* Tylenol, Panadol. It inhibits ....

or may be the main headword:  
Sephadex.

#### 4.2.3 Other substances

The main entry is under the name used most widely in the scientific literature. Where this is not the recommended name, a cross-reference is given from the recommended name to the main entry. For example, the name 'follicle-stimulating hormone (FSH)' is widely employed instead of the recommended name 'follitropin', hence the former name has been used as the main headword. In such cases there is a cross-reference from the recommended name back to the entry where the substance is defined:

follitropin *the recommended name for* follicle-stimulating hormone.

## 4.3 Representation of chemical structures

### 4.3.1 Typeset formulae

In conformity with IUPAC nomenclature recommendations for typeset chemical formulae, parentheses (round brackets) indicate a side chain:

and square brackets indicate a condensed chain:

### 4.3.2 Carbohydrates

- The cyclic forms of monosaccharides are depicted by Haworth representations as are some other compounds; for clarity, the carbon atoms of the heterocyclic ring, and their attached hydrogen atoms, are not shown. See the **Haworth representation** entry for more detail.
- Where an abbreviated terminology is included for oligosaccharide chains, the extended or condensed forms described in the publication entitled *Nomenclature of carbohydrates (recommendations 1996)* (see Appendix B, item 22) are variously used.
- Wherever possible, structure diagrams show absolute configurations.

## 4.4 Periodic table of the elements

The group numbers used in the text are those of the 18-column format of the table given in the 1990 edition of the IUPAC 'Red Book' (see Appendix B, item 2). The correspondence between this and other versions of the table is described in the **periodic table** entry and shown below the table displayed on the endpapers.

## 4.5 Amino-acid sequences

- For peptide sequences of up to 18 amino-acid residues, the three-letter code is used; longer sequences are given in the one-letter code.
- Motifs are given in the one-letter code.
- The full sequences of many proteins can be found in protein sequence databases, and database codes are given to facilitate access to these. The database codes relate to a number of different databases. The style of the code gives an indication of the database from which the data origi-

nate, but if the user does not recognize the code, it is necessary to search for it in a composite database that integrates data from all the major databases. Further information is offered in Appendices D and E.

## 4.6 Genes

- The accepted format of gene names (i.e., whether lower case or upper case or a mixture) varies between different organisms. Where an entry covers genes from various species, the convention for human genes is generally followed in the headword, i.e. all letters are given in upper case, e.g. 'JUN'.
- However, when an entry refers only to a gene from a specified organism, the accepted convention for that organism is followed.

## 4.7 Names of organisms

- Those organisms whose Latin names are used frequently are listed in Appendix H.
- Where a binomial Latin name is repeated within an entry, the genus name is abbreviated after the first occurrence of the name; for example, the full form '*Escherichia coli*' is used when first mentioned in any entry, but subsequent references to this organism in the same entry are abbreviated to '*E. coli*'.

## 5. Appendices

A number of appendices have been included after the main alphabetical text, as follows:

- Appendix A - The Greek alphabet and Greek characters used as symbols (page 697).
- Appendix B - Nomenclature publications (page 700).

*This page intentionally left blank*

# Aa

**a** 1 abbr. for adsorbed. 2 symbol for atto+ (SI prefix denoting  $10^{-18}$ ). 3 axial. 4 year.

**a'** symbol for pseudoaxial.

**a** symbol for 1 absorption coefficient. 2 acceleration (in vector equations it is printed in bold italic (*a*)). 3 activity (def. 3). 4 van der Waals coefficient. 5 as subscript, denotes affinity.

**a<sub>0</sub>** symbol for Bohr radius.

**A** symbol for 1 acid-catalysed (of a reaction mechanism). 2 a residue of the α-amino acid L-alanine (alternative to Ala). 3 a residue of the base adenine in a nucleic-acid sequence. 4 a residue of the ribonucleoside adenosine (alternative to Ado). 5 uronic acid. 6 ampere.

**A** symbol for 1 absorbance. 2 activity (def. 2). 3 affinity. 4 Helmholtz function. 5 mass number/nucleon number.

**A<sub>r</sub>** symbol for relative atomic mass.

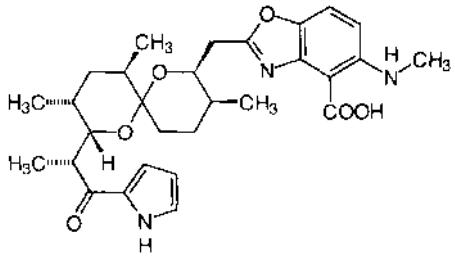

**A**. symbol for area.

**[A]₀ₜ or [A]ₜ₄** symbol (in enzyme kinetics) for the value of the concentration of a substrate, A, in mol dm⁻³, at which the velocity of the reaction, v, is half the maximum velocity, V; Le. when  $v = 0.5V$ .

[Also symbol for the molar concentration of an agonist that produces 50% of the maximal possible effect of that agonist. Other percentage values ([A]₀ₜ, etc.) can be specified. The action of the agonist may be stimulatory or inhibitory. Compare EC<sub>50</sub>.

**2'-⁵'A** symbol for any member of a series of oligonucleotides of the general formula PaA[2'p5'A]<sub>n</sub>, where p and A are phosphoric and adenosine residues, respectively, and a and n are small integers (a = 1, 2, or 3 and n commonly = 2, 3, or 4). Potent inhibitors of protein biosynthesis *in vivo* and *in vitro*, they are believed to mediate the action of interferon on virus-induced cells.

**A23187** or calcimycin a toxic and weakly antibiotic substance isolated from cultures of *Streptomyces chartreusensis*. It is a lipophilic 523 Da monocarboxylic acid of complex structure, two molecules of which form stable lipid-soluble complexes at pH 7.4 with one atom of certain divalent metal cations, especially Mn<sup>2+</sup>, Ca<sup>2+</sup>, and Mg<sup>2+</sup>; monovalent cations are bound only weakly. It also forms lipid-soluble complexes with certain amino acids. It is used experimentally as a calcium ionophore.

**Å** symbol for Ångström (unit of length equal to  $10^{-10}$  m).

**aa** 1 symbol for an unknown or unspecified aminoacyl group when acting as a substituent on a base or internal sugar in a (poly)nucleotide. 2 abbr. for amino acid.

**AA** (formerly) symbol for an unknown or unspecified amino-acid residue. See Xaa.

**AAA** a codon in mRNA for L-lysine.

**AAC** a codon in mRNA for L-asparagine.

**Aad** symbol for a residue of the α-amino acid L-a-aminoacidic acid, L-2-aminohexanedioic acid.

**βAad** symbol for a residue of the β-amino acid L-ft-aminoacidic acid, L-3-aminohexanedioic acid.

**AAG** a codon in mRNA for L-lysine.

**A** antigen the antigen defining the A blood group. See also blood-group substance, ABH antigens.

**AAU** a codon in mRNA for L-asparagine.

**Ab** abbr. for antibody.

**abamectin** or avermectin B<sub>1</sub> a metabolite of *Streptomyces avermitilis* used as an acaricide, insecticide, and a veterinary anthelmintic.

**A-band** an anisotropic band in a sarcomere.

**Abbe refractometer** a refractometer in which the critical angle for total reflection at the interface of a film of liquid between two similar glass prisms is used in determining the refractive index of the liquid. [After Ernst Abbe (1840-1905), German physicist famous for his researches in optics.]

**ABC** abbr. for 1 antigen-binding capacity. 2 ATP-binding cassette (see ABC transporter).

**ABC transporter** membrane transport proteins having the ABC molecular domain, named after ATP-binding cassette, characteristic of all members of a large superfamily of membrane transport proteins that hydrolyse ATP and transfer a diverse array of small molecules across membranes. See also CITR, MDR protein, sugar transporter.

**abductin** an insoluble, rubber-like protein from the internal triangular hinge ligament of scallops.

**Abe** symbol for abequose.

**abequose** symbol: Abe; 3,6-dideoxy-o-xylo-hexose; 3,6-dideoxy-o-galactose; a deoxysugar that occurs, e.g., in a-specific chains of lipopolysaccharides in certain serotypes of *Salmonella*. For the Lenantiomer see colitose.

**ABH antigens** one of the systems of blood group antigens having determinants associated with oligosaccharide structures. It is the basis of the ABO system, which was the first human blood group antigen system to be detected, by Landsteiner in 1901, and it remains the most important in blood transfusion. Individuals having neither A nor B antigen express the H antigen, the product of an independent gene belonging to the Hh system. Antigens of the ABH system are oligosaccharide chains, in the erythrocyte carried on band 3 (the anion transporter) and band 4.5 (the glucose transporter), or on ceramide. A highly branched N-glycan, consisting of a trimannosyl-di-N-acetyl-chitobiosyl core with Gal(β1-4)GlcNAc(β1-3) repeats, forms the basis of ABH antigens. The H determinant is the precursor; antigen A is formed by addition of N-acetyl-o-galactosamine by fucosylgalactose a-N-acetylgalactosaminyltransferase (EC 2.4.1.40); antigen B is formed by addition of o-galactose by fucosylglycoprotein 3-a-galactosyltransferase (EC 2.4.1.37). The terminal sugar residues of importance are: H determinant, Fuc(al-2)Gal,B-R; A determinant, GaINAc(al-3)(Fucal-2)Galft-R; B determinant, Gal(al-3)(Fucal-2)Galp-R. The enzyme responsible for adding the terminal fucosyl residue of the H determinant is galactoside 2-a-L-fucosyltransferase (EC 2.4.1.69). See also A-transferase, B-transferase.

**abiogenesis** or spontaneous generation the discredited doctrine that living organisms can arise from nonliving materials under current conditions. Compare biogenesis (def. 2).

**abiotic** characterized by the absence of life.

**abl** an oncogene from murine Abelson leukemia virus. The viral oncogene (*v-abl*) resulted from recombination of the Maloney murine leukemia virus with the protooncogene (*c-abl*). The protooncogene encodes a 145 kDa protein, which, together with the highly related *arg* gene, forms a unique family within the nonreceptor tyrosine protein kinases; database code KABL\_HUMAN, 1130 amino acids (122.81 kDa). It was one

## ABM

of the first protooncogenes identified by the study of retroviruses. The transforming ability of *v-abl* results from increased tyrosine kinase activity of the *gag-abl* p160 oncoprotein. In humans, inappropriate activation of *c-abl* occurs via a reciprocal translocation between chromosomes 9 and 22 in which *c-abl* (9q34) is joined at the breakpoint cluster region (bcr) of the *phi* gene on chromosome 22(q11). In the translocation, a 3' portion of *c-abl* is spliced in-frame to a 5' portion of the *phi* gene, resulting in an altered chromosome 22, which is referred to as the Philadelphia chromosome (*Ph*). The protein product of the spliced genes in the *Ph* chromosome is a molecule of 210 kDa, which has increased tyrosine kinase activity compared with the *c-abl* product and is similar in structure to the *v-abl* product in that the N-terminal portion of Abl is removed. The *Phi* chromosome occurs in more than 90% of individuals with chronic myelogenous leukemia and was the first description of a specific genetic translocation associated with a human malignancy. c-Abl can potentially regulate cell growth and may participate in growth regulation at multiple cellular locations, interacting with different cell components. It possesses SH2 and SH3 domains (see SH domains) and also domains involved in binding to F-actin and DNA. Thus it has been found in both cytoplasmic and nuclear locations and its DNA-binding activity appears to be cell cycle regulated by Cdc-2-mediated phosphorylation; it binds the retinoblastoma protein indicating involvement in transcriptional regulation.

**ABM** abbr. for 2-aminobenzoyloxymethyl, a group used for derivatizing cellulose or paper. It is converted by diazotization into DBM.

**abortive complex** or dead-end complex or nonproductive complex any enzyme-substrate complex in which the substrate is bound to the enzyme in a manner that renders catalysis impossible so that products cannot be formed.

**abortive infection** infection of a bacterium by phage lacking phage DNA, e.g. in generalized transduction.

**abortive transconjugate** see transconjugate.

**abortive transduction** a type of transduction in which the donor DNA is not integrated with the recipient chromosome but persists as a nonreplicating fragment that can function physiologically and can be transmitted to one daughter cell at each cell division.

**ABO system** one of the systems of human blood groups, of great importance in blood transfusion because human plasma contains natural antibodies against A and B blood group antigens of the ABH system (see ABH antigens). The antigens on the red blood cells and the plasma antibodies corresponding to the various phenotypes are shown in the table. See also A-transferase, B-transferase, 0 antigen (def. 2).

Phenotype (blood group)	Antigen on red cells	Antibody in plasma
A	A	anti-B
B	B	anti-A
AB	A and B	neither
O	H	anti-A + anti-B

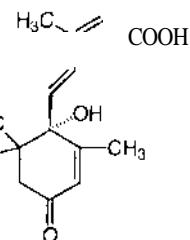

**abrin** a highly toxic  $\approx$ 65 kDa glycoprotein obtained from the seeds of jequirity or Indian liquorice (*Abrus precatorius* L.), a tropical Asian vine that also occurs in Florida. It consists of an acidic A chain,  $\approx$ 30 kDa, and a neutral B chain,  $\approx$ 35 kDa, held together by disulfide bonds. The A chain is a powerful inhibitor of protein synthesis while the B chain functions as a carrier to bind abrin to the membrane and perhaps to assist penetration of the A chain into the cell. One well-chewed seed can be fatal. The A and B chains are derived from a common precursor: database code ABRA\_ABRPR, 528 amino acids (59.24 kDa). Compare abrine, ricin. See also ribosome-inactivating protein.

**abrine** trivial name for Na-methyl-L-tryptophan,  $\alpha$ -methyl-

## absorbance

amino-f:1-(3-indole)propionic acid; an imino acid obtained from seeds of jequirity (*Abrus precatorius*). Not to be confused with abrin.

**abscisic acid** or (formerly) abscisin II or dormin abbr.: ABA; 5-(1-hydroxy-2,6,6-trimethyl-4-oxocyclohex-2-en-1-yl)-3-methylpenta-2,4-dienoic acid; a chiral sesquiterpene. The naturally occurring form, the 22,4E,S isomer, also designated (S)-abscisic acid, is a phytohormone formed by the degradation of carotenoids. It controls abscission in flowers and fruit but probably not in leaves, and is also implicated in geotropism, stomatal closure, bud dormancy, dormancy of seeds requiring stratification (i.e. those that will only germinate after exposure to low temperatures), and possibly tuberization.

**abscissa** the horizontal or *x* coordinate in a plane rectangular (Cartesian) coordinate system. Compare ordinate.

**abscission** the natural shedding of leaves, fruits, and other parts by a plant.

**absolute** 1 pure, unmixed; e.g. absolute alcohol. 2 not relative; e.g. absolute configuration. 3 describing a measurement defined in fundamental units of mass, length, and time that does not depend on the characteristics of the measuring apparatus; e.g. absolute temperature.

**absolute alcohol** the common name for pure ethanol, i.e. ethanol that has been freed of water. It may contain small amounts of benzene that have been added to aid in removing water. Substances may be added to absolute alcohol to render it unfit for human consumption and hence free of excise duty: industrial spirit contains 5% v/v methanol, while methylated spirit also contains pyridine, petroleum oil, and methyl violet dye, and surgical spirit also contains castor oil, diethyl phthalate, and methyl salicylate.

**absolute configuration** the actual three-dimensional arrangement of the atoms in a chiral molecule.

**absolute reaction rate theory** a theory that sets out to predict the absolute reaction rate of a chemical reaction from the quantum mechanical description of the potential energy changes during the interaction between chemical species. It is most widely drawn upon in applying thermodynamic reasoning to equilibria between reactants in the ground state and chemical species in the activated state or transition state.

**absolute temperature** see thermodynamic temperature.

**absolute zero** zero thermodynamic temperature, i.e. 0 K or  $-273.15^{\circ}\text{C}$ .

**absorb** see absorption.

**absorbance symbol:** *A*; a measure of the ability of a substance or a solution to absorb electromagnetic radiation incident upon it. It equals the logarithm of the ratio of the radiant power of the incident radiation,  $\Phi_0$ , to the radiant power of the transmitted radiation,  $\Phi$ . For a solution, absorbance is expressed as the logarithm of the ratio of the radiant power of light transmitted through the reference sample to that of the light transmitted through the solution, the observations being made using identical cells. (Traditionally, radiant intensity was measured instead of radiant power, which is now the accepted form.) Two quantities are defined: (decadic) absorbance (symbol:  $A_{10}$  or *A*), and napierian absorbance (symbol:  $A_e$  or *B*).

$$A_{10} = \lg(\Phi_0/\Phi) = 10 T^{-1} = -\lg(1 - \alpha), \text{ and}$$

## absorbancy

$$A = \ln(\Phi_0/\Phi) = \ln T^{-1} = -\ln(1 - a),$$

where  $T$  is the (internal) transmittance and  $a$  is the absorptance. These definitions suppose that all the light incident upon the sample is either transmitted or absorbed, reflection and scattering being negligible. The more general term attenuance should be used when scattering is considerable, as when the quantity  $\lg(\Phi_0/\Phi)$  is measured to estimate the cell density of a culture. The older terms absorbancy, extinction, and optical density should no longer be used. Compare absorption coefficient.

**absorbancy or absorbency (formerly) an alternative term (no longer recommended) for absorbance.**

**absorbate** a substance that is absorbed into another substance. **absorbed dose (in radiation physics)** a measure of the energy deposition produced by ionizing radiation in any (specified) medium as a result of ion-pair formation. The CGS unit of absorbed dose is the rad; the SI derived unit is the gray (symbol: Gy); compare exposure (def. 3). See also dose equivalent, dose rate.

**absorbence** a variant spelling of absorbance.

**absorbent** 1 a substance that absorbs another substance. 2 having the capacity to absorb another substance.

**absorptance or absorption factor symbol:**  $a$ ; the ratio of absorbed to incident radiant or luminous flux. A dimensionless physical quantity given by  $a = \Phi_{\text{abs}}/\Phi_0$ , where  $\Phi_0$  and  $\Phi_{\text{abs}}$  are the incident and absorbed radiant powers, respectively.

**absorptiometer** 1 an apparatus, frequently a photoelectric device, for measuring light absorption by solids, liquids, or gases. 2 an apparatus for measuring the amount of gas absorbed by a liquid.

**absorption** 1 the act or process whereby one substance, such as a gas or liquid, is taken up by or permeates another liquid or solid. Compare adsorption. 2 the retention by a material of energy removed from electromagnetic radiation passing through the material. 3 the removal of any form of radiation, or the reduction of its energy, on passing through matter. 4 the process whereby a neutron or other particle is captured by an atomic nucleus. 5 a (in cellular physiology) the uptake of fluids by living cells or tissues. b (in animal physiology) the totality of the processes involved in causing water, the products of digestion, and exogenous substances of low molecular mass such as drugs, salts, vitamins, etc. to pass from the lumen of the gastrointestinal tract into the blood and lymph. c (in plant physiology) the uptake of water and dissolved salts through the roots. 6 (in immunology) the process of removing a particular antibody (or antigen) from a mixture by adding the complementary antigen (or antibody) and discarding the antigen-antibody complex so formed. Compare immunosorption.

**absorption band or absorption line** a region of darkness or absorption of radiation in the spectrum of heterochromatic radiation that has passed through an absorbing material.

**absorption coefficient** four different coefficients are defined. The (linear) decadic absorption coefficient (symbol:  $a$ ) is defined by  $a = A_{10l}$ ; units m<sup>-1</sup>. The (linear) napierian absorption coefficient (symbol:  $\alpha$ ) is defined by  $\alpha = A_{lH}$ ; units m<sup>-1</sup>. The molar (decadic) absorption coefficient (symbol:  $e$ ) is defined by  $e = ale = A_{10d}$ ; units m<sup>2</sup> mol<sup>-1</sup>. The molar napierian absorption coefficient (symbol:  $\kappa$ ) is defined by  $\kappa = ale = A_{lH}$ .  $A_{10}$  and  $A_e$  are the decadic and napierian absorbances respectively (see absorbance),  $l$  = path length, and  $c$  = amount-of-substance concentration.

**absorption cross-section** the probability that a photon passing through a molecule will be absorbed by that molecule multiplied by the average cross-sectional area of the molecule. The net absorption cross-section (symbol:  $a_{ne}$ ) is defined by  $a_{ne} = KINA$ , where  $\kappa$  is the molar napierian absorption coefficient and  $N_A$  is the Avogadro constant.

**absorption factor** an alternative name for absorptance.

**absorption index symbol:**  $k$ ; it is given by  $k = \alpha/4\pi\nu$ , where  $\alpha$

## acceptor

is the (linear) napierian absorption coefficient and  $\nu$  the wavenumber in vacuum of the radiation.

**absorption line** an alternative name for absorption band.

**absorption spectrometry** the process of measuring an absorption spectrum with a spectrometer. Absorption spectrophotometry is a related process employing a spectrophotometer. See also absorbance, absorptivity.

**absorption spectroscopy** the spectroscopy of an absorption spectrum.

**absorption spectrum** a spectrum produced when electromagnetic radiation is absorbed by a sample. The frequencies of the radiation absorbed are those able to excite the atoms or molecules of the sample from their ground states to excited states. The frequency,  $\nu$ , at which a particular absorption line occurs depends on the energy difference,  $\Delta E$ , between that of a particular ground state and that of the corresponding excited state. It is given by  $\nu = \Delta E/h$ , where  $h$  is the Planck constant. Compare emission spectrum.

**absorptivity** a measure of the ability of a material to absorb electromagnetic radiation. It equals the absorptance of a sample of the material divided by the optical path-length. For very low attenuation, it approximates the absorption coefficient. Use of the term is not recommended.

**Abu symbol** for a residue of the  $\alpha$ -amino acid L-2-aminobutyric acid L- $\alpha$ -aminobutyric acid.

**Azbu or Dab symbol** for a residue of the  $\alpha,\gamma$ -diamino acid L- $\alpha,\gamma$ -diaminobutyric acid, L-2,4-diaminobutyric acid.

**abzyme abbr.** for antibody enzyme (an antibody with enzyme activity; also known as catalytic monoclonal antibody).

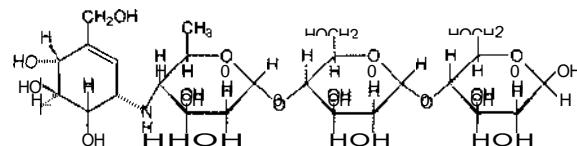

**a.c. or AC or ac abbr.** for alternating current.

**Ac symbol** for 1 actinium. 2 the acetyl group, CH<sub>3</sub>CO-.

**ACA** a codon in mRNA for L-threonine.

**acanthosome** an organelle of fibroblasts isolated from the dermis of hairless mice after chronic UV irradiation. It exists as a spinous membranous vesicle.

**acarbose** a pseudotetrasaccharide, 0-4,6-dideoxy-4-((IS-(1 $\alpha$ ,4 $\alpha$ ,5 $\beta$ ,6 $\alpha$ )-4,5,6-trihydroxy-3-(hydroxymethyl)-2-cyclohexen-1-yl)amino)- $\alpha$ -D-glucopyranosyl-(1 $\rightarrow$ 4)-O- $\alpha$ -D-glucopyranosyl-(1 $\rightarrow$ 4)-glucose, that inhibits  $\alpha$ -glucosidase, thereby reducing gastrointestinal absorption of glucose. It is a putative antidiabetic agent.

**ACC** a codon in mRNA for L-threonine.

**a.c. calorimetry** a technique in which the thermal response of a sample to an oscillating heat signal is measured in the form of a temperature wave propagating through the sample. The technique allows the measurement of the heat capacity of the sample on both cooling and heating and the monitoring of its isothermal time-dependence. It is useful in the study of phase transitions in solids and in gel to liquid-crystal systems.

**accelerator** 1 (in chemistry) catalyst, especially one that increases the rate of a polymerization reaction. 2 (in physics) a device or machine used for imparting high kinetic energy to charged subatomic particles, e.g. electrons, protons, or alpha particles, by means of electric and/or magnetic fields.

**accelerator globulin** an alternative name for factor V. See blood coagulation.

**accelerin** an alternative name for factor Va. See blood coagulation.

**acceptor** 1 (in chemistry) a chemical entity that in a chemical reaction receives an electron, atom, or group of atoms. Compare donor, donor atom. See also electron acceptor. 2 (in physiol-

## accessory cell

*ogy*) a receptor that binds a hormone without a biological response being demonstrable. 3 (*in pharmacology*) a receptor that binds a drug but has no identified endogenous ligand.

**accessory cell** anyone of various types of cell that assist in the immune response. The term includes antigen-presenting cell, basophil, eosinophil, mast cell, and platelet.

**accessory chromosome** *an alternative name for* 1 a B chromosome. 2 a sex chromosome.

**accessory DNA** surplus DNA present in certain cells or during certain stages of cell development owing, for example, to gene amplification.

**accessory food factor** or **accessory growth factor** a term originally used to describe any unknown substance - subsequently called vitamin - found in small amounts in some foods, such as milk, that was necessary for the normal growth of animals fed on diets of purified carbohydrates, fats, proteins, and salts.

**accessory pigment** any of the pigments, such as the yellow, red, or purple carotenoids and the red or blue phycobiliproteins in photosynthetic cells. The carotenoids are always present, whereas the phycobiliproteins occur only in algae belonging to the Rhodophyceae, the Cyanophyceae, and the Cryptophyceae. Strictly speaking, chlorophyll b is also an accessory pigment.

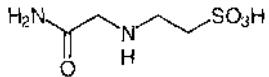

**ACE abbr.** for 1 amplification control element (a DNA sequence in vertebrates that functions as the origin for amplification). 2 angiotensin converting enzyme.

**ACeDB** or **acedb** a partly object-oriented database of genetic and sequence information devised for the nematode *Caenorhabditis elegans* but applied to other eukaryotes including *Arabidopsis thaliana*.

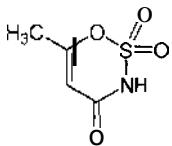

**A cell** or (*formerly*) alpha cell or **α cell** one of the three main histological cell types found in the islets of Langerhans of the pancreas, also found in the gastric oxytic mucosa. A cells produce, store, and secrete the hormone glucagon.

**A, cell** (*formerly*) an alternative name for 0 cell.

**Aces** or **ACES abbr.** for N-(2-acetamido)-2-aminoethane sulfonic acid; 2-[(2-amino-2-oxoethyl)amino]ethane sulfonic acid; a Good buffer substance,  $pK_a$  (20 DC) = 6.9.

**acesulfame** 6-methyl-1,2,3-oxathiazin-4(3H)-one 2,2'-dioxide; a sweet-tasting material that, as the potassium salt, has been used in foods and cosmetics.

**acetal** any member of a class of organic compounds having the general formula  $R^1HC(OR^3)OR^4$  or  $R^1R^2C(OR^3)OR^4$  - in a thioacetal the corresponding formulae are  $R^1HC(SR^3)SR^4$  or  $R^1R^2C(SR^3)SR^4$  - where  $R^3$  and  $R^4$  are alkyl groups (or  $R^4$  is H in a hemiacetal or hemithioacetal). An acetal molecule is formed by the acid-catalysed combination of the carbonyl group of an aldehyde or ketone molecule with either one or two alcohol (or mercaptan) molecules (which may be the same or different), or with a diol (or dithiol), by a reaction of the following general type, where X is O (or S in a mercaptan or dithiol):

The hemiacetal (or hemithioacetal) so formed may then undergo a further reaction:

or

In carbohydrates such compounds are formed at the carbonyl group of the acyclic form of a saccharide or saccharide derivative. The terms 'ketal' (or 'thioketal') and 'hemiketal' (or 'thiohemiketal'), may be applied respectively to any acetal of general formula  $R^1R^2C(XR^3)XR^4$  or  $R^1R^2C(OH)XR^3$ , i.e. to those derived from ketones. These terms, at one time abandoned, have recently been reintroduced as the respective names of subclasses of acetals and hemiacetals and as functional class names.

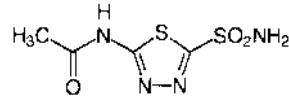

**acetaminophen** or **paracetamol** 4-acetamidophenol; N-acetyl-p-aminophenol; N-(4-hydroxyphenyl)acetamide; a drug widely used as an analgesic and antipyretic. It inhibits formation of prostaglandins within, but not outside the brain. It is metabolized within the liver mostly to glucuronide and sulfate conjugates. A small amount is oxidized to a highly reactive intermediate, N-acetylbenzoquinoneimine, that is normally detoxified by conjugation with glutathione. If it is produced in excess of the capacity of the liver to detoxify it, hepatic necrosis can result. It can be administered with methionine, which increases glutathione in the liver. N-Acetylcysteine is administered in cases of poisoning to act as a glutathione substitute. Proprietary names include: Panadol, Tylenol.

**acetate** 1 the traditional name for ethanoate; the anion,  $CH_3COO^-$ , derived from acetic acid (ethanoic acid). 2 any salt or ester of acetic acid.

**acetate-CoA ligase** EC 6.2.1.1; *systematic name*: acetate:CoA ligase (AMP-forming); *other names*: acetyl-CoA synthetase; acyl-activating enzyme; acetate thiokinase; acetyl-activating enzyme. An enzyme that catalyses a reaction between ATP, acetate, and CoA to form AMP, pyrophosphate, and acetyl-CoA. It is an important enzyme in organisms (e.g. *Escherichia coli*, many fungi, protozoans, algae) that utilize acetate as a carbon source. Example from *E. coli*: database code ACUA\_ECOLI, 652 amino acids (72.01 kDa). Distinguish from acetate-CoA ligase (ADP-forming), EC 6.2.1.13.

**acetate thiokinase** see acetate-eOA ligase.

**acetazolamide** an inhibitor of carbonic anhydrase that is useful as a diuretic. It acts by preventing bicarbonate reabsorption in the proximal tubules of the kidney.

**(+)**aceto+ *comb. form* denoting the acyl group derived from acetic acid.

**acetoacetate-CoA ligase** EC 6.2.1.16; *other name*: acetoacetyl-CoA synthetase; an enzyme that catalyses the formation of acetoacetyl-CoA from ATP, acetoacetate, and CoA with release of AMP and pyrophosphate. In bacteria that carboxylate acetone to acetoacetate, it activates the latter for further metabolism. It is also present in animals, but utilization of blood acetoacetate after its entry into tissues involves 3-oxoacid CoA-transferase.

**acetoacetyl acetyltransferase** see acetyl-CoA C-acetyltransferase.

**acetoacetyl-CoA synthetase** see acetoacetate-CoA ligase.

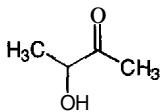

**acetoacetyl-CoA thiolase** see acetyl-CoA C-acetyltransferase.

**acetogenin** any substance built up of two-carbon units that may formally be considered to derive from a polyacetyl chain intermediate; the carbon atoms derived from the carboxyl carbon atoms of acetic acid frequently remain oxidized. It is not a recommended term. See polyketide.

**acetoin** 3-hydroxy-2-butanone; a compound formed by action

## acetone body

of acetolactate decarboxylase (EC 4.1.1.5) and, under some conditions, pyruvate decarboxylase (EC 4.1.1.1).

acetone body *see* ketone body.

acetone powder any preparation of ruptured cells obtained from a tissue or single-celled organisms that involves dehydration with acetone to form a powder. It is relatively stable, and is used in the preparation of some enzymes.

acetyl the acyl group ethanoyl,  $\text{CH}_3\text{CO}-$ , derived from acetic acid (= ethanoic acid).

acetylation an acylation reaction in which an acetyl group,  $\text{CH}_3\text{CO}-$ , is introduced into an organic compound. -acetylated *adj.*

acetylation coenzyme *the original name for* coenzyme A.

acetylcholine receptor *see* cholinoreceptor.

acetylcholinesterase *abbr.:* AChE; EC 3.1.1.7; *systematic name:* acetylcholine acetylhydrolase; *other names:* true cholinesterase; cholinesterase I; an esterase enzyme that catalyses the hydrolysis of acetylcholine to choline and acetate; it also acts on a variety of acetic esters and catalyses transacetylations. It is found in or attached to cellular or basement membranes of presynaptic cholinergic neurons and postsynaptic cholinoreceptive cells. A soluble form occurs in cerebrospinal fluid and within cholinergic neurons. It is inhibited by a number of drugs, e.g. physostigmine, and by several organophosphates. Example from human: database code ACES\_HUMAN, 614 amino acids (67.72 kDa). The 3-D structure is known for fragments obtained from the electric ray (fish).

acetylcholine transporter protein an integral membrane protein of synaptic vesicles of cholinergic neurons. It transports newly synthesized acetylcholine molecules into the synaptic vesicles in exchange for protons, thereby replenishing vesicular stores of the neurotransmitter. Example from *Caenorhabditis elegans*: database code UNI7\_CAEEL, 532 amino acids (58.58 kDa).

acetyl-CoA *abbr. for* acetyl coenzyme A.

acetyl-CoA e-acetyltransferase EC 2.3.1.9; *other names:* acetoacetyl acetyltransferase; acetoacetyl-CoA thiolase; an enzyme that catalyses the formation of two molecules of acetyl-CoA from CoA and acetoacetyl-CoA. During beta oxidation it catalyses the formation of acetyl-CoA from acetoacetyl-CoA, whereas it acts in the reverse direction to form acetoacetyl-CoA during ketogenesis. It is important in regulating the metabolic pathways for the production of acids, i.e. acetate, butyrate, or solvents, i.e. acetone, butanol, ethanol, during the growth of *Clostridium acetobutylicum*. Reduced activity of the enzyme favours production of acetate and ethanol, while increased activity favours production of butyric acid, butanol, and acetone. Example from human (mitochondrial, precursor): database code THIL\_HUMAN, 427 amino acids (45.15 kDa).

acetyl-CoA e-acyltransferase EC 2.3.1.16; *systematic name:* acyl-CoA:acetyl-CoA C-acyltransferase; *other names:* 3-ketoacyl-CoA thiolase; jj-ketothiolase; an enzyme that catalyses the formation of acyl-CoA and acetyl-CoA from CoA and 3-oxoacyl-CoA. This is the concluding reaction of each cycle of the fatty acid oxidation pathway (beta oxidation). Different enzymes exist in the mitochondrion and peroxisome, both being included in the thiolase family. Examples include rat peroxisomal enzyme A (one of two), homodimer: database code for precursor THII\_RAT, 424 amino acids (43.77 kDa); also from yeast (precursor): database code THIK\_YEAST, 417 amino acids (44.68 kDa); mitochondrial enzyme, homotetramer: database code THIM\_RAT, 397 amino acids (41.82 kDa).

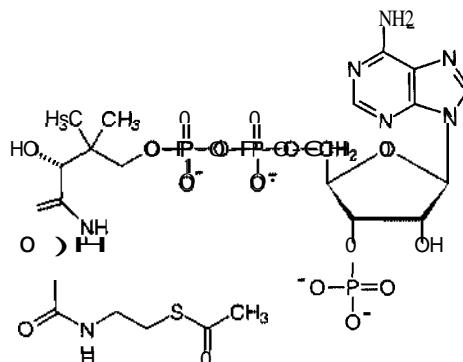

## N-acetylcysteine

acetyl-CoA carboxylase EC 6.4.1.2; *systematic name:* acetyl-CoA:carbon-dioxide ligase (ADP-forming); a multienzyme complex involved in the formation of malonyl-eoA, the first step in fatty-acid biosynthesis. It catalyses a reaction between ATP, acetyl-CoA, and  $\text{HCO}_3^-$  to form ADP, orthophosphate, and malonyl-CoA. Biotin is a cofactor. In bacteria it is a heterohexamer of biotin-carboxyl-carrier-protein, biotin carboxylase, and a 2:2 complex of the two subunits of carboxyl transferase. Examples from *Escherichia coli*: biotin carboxylase (EC 6.3.4.14), which catalyses the reaction between ATP, biotin-carboxyl-carrier-protein, and  $\text{CO}_2$  to form ADP, orthophosphate, and carboxybiotin-carboxyl-carrier-protein; database code ACCC\_ECOLI, 449 amino acids (49.26 kDa); biotin-carboxyl-carrier-protein: database code BCCP\_ECOLI, 156 amino acids (16.67 kDa); carboxyl transferase  $\alpha$ -subunit, database code ACCA\_ECOLI, 318 amino acids (35.07 kDa); carboxyl transferase  $\beta$ -subunit, database code ACCD\_ECOLI, 304 amino acids (33.31 kDa). Biotin-carboxyl-carrier-protein is carboxylated by biotin carboxylase and the carbonyl group is then transferred to acetyl-CoA by carboxyl transferase, thus forming malonyl-CoA. In mammals the activity is part of a trifunctional enzyme that has in a single protein the activities carboxyl carrier protein, biotin carboxylase (EC 6.3.4.14), and acetyl-CoA carboxylase (EC 6.4.1.2). Example from rat: database code COAC\_RAT, 2345 amino acids (264.89 kDa).

[acetyl-CoA carboxylase] kinase EC 2.7.1.128; an enzyme that catalyses the phosphorylation by ATP of [acetyl-CoA carboxylase] with release of ADP. This phosphorylation step is one of the regulatory mechanisms for acetyl-CoA carboxylase, causing that enzyme to dissociate from an active polymeric form to an inactive monomeric form.

[acetyl-CoA carboxylase] phosphatase EC 3.1.3.44; an enzyme that catalyses the hydrolysis of phosphate from [acetyl-CoA carboxylase] phosphate. It reverses the phosphorylation catalysed by [acetyl-CoA carboxylase] kinase.

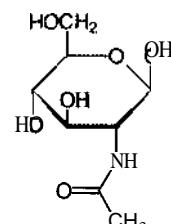

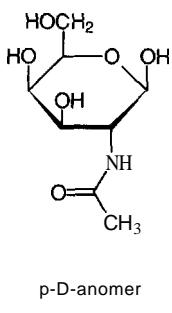

acetyl coenzyme A *abbr.:* acetyl-CoA; a derivative of coenzyme A in which the sulphydryl group is acetylated. Originally termed 'active acetate', it is an important metabolite, derived from pathways such as glycolysis, fatty-acid oxidation, and degradative metabolism of some amino acids. It is further metabolized by the tricarboxylic-acid cycle and represents a key intermediate in lipid and terpenoid biosynthesis and other anabolic reactions.

N-acetylcysteine or N-acetyl-L-cysteine a thiol-protecting agent used intravenously as an antidote in acetaminophen poisoning. It acts by enhancing glutathione synthesis, thereby increasing the capacity for detoxification and excretion of acetaminophen as a mercapturic acid. Methionine can be similarly used. It also has mucolytic properties, and is used in aiding the isolation of mycobacteria from sputum.

## N-acetylgalactosamine

**N-acetylgalactosamine** symbol: D-GalpNAc; abbr.: NAGA; the D isomer, 2-acetamido-2-deoxy-D-galactopyranose, is a common structural unit of oligosaccharides, such as the blood-group substances and O-linked glycoproteins, in which the sugar is in glycosidic linkage to a protein or serine residue, or, in the case of the blood-group substances, to a lipid hydroxyl group. The reactant in synthetic reactions is UDP-N-acetylgalactosamine, which is formed by epimerization of N-acetylglucosamine.

## acetylglutamic acid

**N-acetylgalactosamine-4-sulfatase** EC 3.1.6.12; other names: arylsulfatase B; chondroitinsulfatase; chondroitinase; an enzyme that hydrolyses the 4-sulfate groups of the N-acetyl-D-galactosamine 4-sulfate units of chondroitin sulfate and dermatan sulfate. It is a lysosomal enzyme involved in the degradation of proteoglycans, which accumulate in Maroteaux-Lamy syndrome (mucopolysaccharidosis VI), a storage disease resulting from a deficiency of the enzyme. Example (precursor) from human: database code ARSB\_HUMAN, 533 amino acids (59.62 kDa).

**N-acetylgalactosamine-6-sulfatase** EC 3.1.6.4; other names: chondroitinsulfatase; chondroitinase; galactose-6-sulfate sulfatase; an enzyme that hydrolyses the 6-sulfate groups of the N-acetyl-D-galactosamine 6-sulfate units of chondroitin sulfate, and also the D-galactose 6-sulfate units of keratan sulfate. It is a lysosomal enzyme involved in the degradation of proteoglycans. Keratan sulfate and chondroitin 6-sulfate accumulate in Morquio A syndrome, a storage disease resulting from a deficiency of the enzyme. Example (precursor) from human: database code GA6S\_HUMAN, 522 amino acids (57.96 kDa).

**N-acetylgalactosaminidase** EC 3.2.1.53; either of two types of enzyme that catalyse the hydrolysis of respectively  $\alpha$ - and  $\beta$ -linked terminal nonreducing N-acetyl-D-galactosamine residues. Both are lysosomal enzymes. Deficiency of  $\alpha$ -N-acetylgalactosaminidase is associated with a storage disease in which sialyloligosaccharides are found in urine.

**N-acetylglucosamine** symbol: D-GlcNAc; abbr.: NAG; the D isomer, 2-acetamido-2-deoxy-D-glucopyranose, is a common structural unit of plant glycoproteins and of many animal and bacterial glycoproteins. It is often the terminal sugar of an oligosaccharide moiety of a glycoprotein, linked glycosidically to the amide nitrogen of a protein asparagine residue. The acetyl group is introduced in a reaction between acetyl-CoA and glucosamine 6-phosphate to give N-acetylglucosamine 6-phosphate, which undergoes a mutase reaction to form N-acetylglucosamine 1-phosphate, from which UDP-N-acetylglucosamine is formed. The latter is the reactant in pathways of oligosaccharide synthesis and is also a precursor of N-acetylneurameric acid (see sialic acid).

**N-acetylglucosamine phosphotransferase** EC 2.7.1.69; systematic name: protein-Nn-phosphohistidine: sugar N-prosphotransferase; other name: enzyme II of the phosphotransferase system; an enzyme that catalyses the reaction:

It is a component of the phosphoenolpyruvate-dependent sugar phosphotransferase system, a major carbohydrate active-transport system; the phosphoryl group from phosphoenolpyruvate is transferred to phosphoryl carrier protein HPR by enzyme I, and from phospho-HPR to the sugar by enzyme II. It is an integral membrane protein. Example from *Escherichia coli*: database code PT2N\_ECOLI, 648 amino acids (68.27 kDa).

**N-acetylglucosamine-6-sulfatase** EC 3.1.6.14; an enzyme that catalyses the hydrolysis of sulfate groups of N-acetyl-D-glucosamine 6-sulfate units of heparan sulfate and keratan sulfate. It is a lysosomal glycoprotein. A deficiency is associated with the storage disease mucopolysaccharidosis VII. Example (precursor) from human: database code GL6S\_HUMAN, 552 amino acids (62.01 kDa).

**N<sup>4</sup>-( $\beta$ -N-acetylglucosaminyl)-L-asparaginase** EC 3.5.1.26; other names: aspartylglucosylamine deaspartylase; aspartylglucosylaminase; glycosylasparaginase; an enzyme that catalyses the hydrolysis of N<sup>4</sup>-( $\beta$ -D-N-acetyl-D-glucosaminyl)-L-asparagine, released from glycoproteins, to N-acetyl-D-glucosaminylamine and L-aspartate. A deficiency of the enzyme results in the lysosomal storage disease, aspartylglucosaminuria, in which there is an accumulation of the enzyme's substrate. Example (precursor) from human: database code ASPG\_HUMAN, 346 amino acids (37.15 kDa).

**N-acetylglucosaminyl transferase** any of various glycosyltransferase enzymes within the subclass EC 2.4.1 that transfer an N-acetylglucosaminyl residue from UDP-N-acetylglucosamine to an oligosaccharide, and which are important in oligosaccharide synthesis. An example is EC 2.4.1.144,  $\beta$ 1,4-mannosyl-glycoprotein  $\beta$ 1,4-N-acetylglucosaminyltransferase; other name: N-glycosyl-oligosaccharide-glycoprotein N-acetylglucosaminyltransferase III. It catalyses the addition of N-acetylglucosamine in  $\beta$ (1-4) linkage to the  $\alpha$ -linked mannose of the trimannosyl core of N-linked sugar chains. It is a type II membrane protein of the Golgi stack. Example from rat: database code GNT3\_RAT, 536 amino acids (61.69 kDa). See also N-acetyllactosamine synthase, lipopolysaccharide, N-acetylglucosaminyltransferase, UDP-N-acetylglucosamine-dolichyl phosphate-N-acetylglucosamine phosphotransferase.

**$\beta$ 6-N-acetylglucosaminyltransferase** see  $\beta$ -1,3-galactosyl-D-glycosyl-glycoprotein  $\beta$ -1,6-N-acetylglucosaminyltransferase.

**N-acetylglutamate synthase** (abbr. AGS) see amino-acid N-acetyltransferase.

**acetylglutamic acid** the Lisomer, N-acetyl-L-glutamic acid, is a key intermediate in ornithine formation in bacteria and plants. It is converted to N-acetyl-L-glutamic  $\gamma$ -semialdehyde, from which N-acetyl-L-ornithine is formed in a transamination reaction. It activates carbamoyl-phosphate synthase (ammo-

**fJ-N-acetylhexosaminidase**

nia). It is formed from acetyl-CoA and glutamate by the action of amino acid N-acetyltransferase, EC 2.3.1.1.

**β-N-acetylhexosaminidase** EC 3.2.1.52; *other names:* p-hexosaminidase; hexosaminidase; an enzyme that catalyses the hydrolysis of terminal nonreducing N-acetyl-D-hexosamine residues in N-acetyl-p-D-hexosaminides. Example from human: database code HEXA\_HUMAN, 529 amino acids (60.62 kDa).

**N-acetyllactosamine synthase** EC 2.4.1.90; *systematic name:* UDPgalactose:N-acetyl-D-glucosamine 4-p-D-galactosyltransferase; *other names:* N-acetylglucosamine P-(1→4)-galactosyltransferase; UDPgalactose-N-acetyl-glucosamine p-D-galactosyltransferase. An enzyme, located in the rough endoplasmic reticulum, that catalyses a reaction between UDPgalactose and N-acetyl-D-glucosamine to form UDP and N-acetyllactosamine. In humans the enzyme also has the activity of p-N-acetylglucosaminyl-glycopeptide p-I,4-galactosyltransferase (EC 2.4.1.38); *other names:* glycoprotein 4-p-galactosyltransferase; thyroid galactosyltransferase; UDPgalactose-glycoprotein galactosyltransferase. It catalyses a reaction between UDPgalactose and N-acetyl-p-D-glucosaminylglycopeptide to form UDP and p-D-galactosyl-1,4-N-acetyl-p-D-glucosaminylglycopeptide. **a-Lactalbumin** is an allosteric regulator and converts this activity to **lactose synthase**. Database code NALS\_HUMAN, 400 amino acids (44.22 kDa).

**N-acetylmuramoyl-L-alanine amidase** see **autolysin**.

**N-acetylneuraminic acid** see **sialic acid**.

**acetyloleoylglycerol** see **oleoylacylglycerol**.

**acetylsalicylic acid** see **aspirin**.

**ACG** 1 a codon in mRNA for L-threonine. 2 *abbr. for* acycloguanosine (*see acyclovir*).

**Ach** symbol for the arachidoyl (i.e. eicosanoyl) group.

**A<sub>2</sub>Ach** symbol for the (all-Z)-eicosa-8,II-dienoyl group; *see eicosatrienoic acid*.

**A<sub>3</sub>Ach** symbol for the (all-Z)-eicosa-5,8,II-trienoyl group; *see eicosatrienoic acid*.

**A<sub>4</sub>Ach** symbol for the arachidonoyl (i.e. (all-Z)-eicosa-5,8, 11,14-tetraenoyl) group; *see arachidonoyl*.

**ACh** *abbr. for* acetylcholine.

**Achaete-Scute complex** *see AS-C protein*.

**A chain** 1 the shorter polypeptide chain of **insulin**, containing 21 amino-acid residues. 2 the heavy chain (H chain) of an **immunoglobulin**.

**achatin-1** an endogenous neuroexcitatory tetrapeptide, Gly-D-Phe-Ala-Asp, isolated from the ganglia of the giant African snail, *Achatina fulica*: database code ACHI\_ACHFU.

**AChE** *abbr. for* acetylcholinesterase.

**achiral** not chiral. -achirality *n*.

**achlorhydria** an inability to secrete gastric acid. It is a disorder, probably autoimmune, that is linked with pernicious anemia.

**achromic point** the point in time during the action of amylase on starch at which the reaction mixture no longer gives a colour with iodine, i.e. the reaction has proceeded to the point when the starch has all been degraded at least as far as **achriodextrins**.

**achroodextrin** any **dextrin** that is small enough not to give a colour with iodine.

**acid** 1 in the Bronsted-Lowry concept, a molecular species having a tendency to lose a hydron forming a conjugate base, e.g.

2 in the Lewis concept, a substance capable of accepting from

**acidosome**

a base an unshared pair of electrons, which then form a covalent chemical bond, e.g.

**acid anhydride** any compound formed by the elimination of the elements of water from the acidic groups of two acids, e.g. acetic anhydride (two acetic acid molecules) or acetyl phosphate (one molecule each of acetic and phosphoric acids).

**acid-base balance** term descriptive of the hydrogen-ion status of the blood, the mechanisms that regulate it, and the causes of its deviation from normal.

**acid-base catalysis** catalysis of a chemical reaction in which either an acid or a base mediates the formation of a reactive intermediate.

**acid-base titration** a titration in which either acid or base is added to a solution and the progress of the titration is followed by pH measurements, either electrometrically or with the use of pH indicators.

**acid carboxypeptidase** *see cysteine-type carboxypeptidase*.

**acid dissociation constant or acidity constant** symbol:  $K_a$ ; the thermodynamic equilibrium constant for the dissociation of an **acid**. For a dilute solution of a weak acid, HA, dissociating in water according to the equilibrium:

$$K_a = (a_{H_3O^+} \times a_{A^-})/a_{HA}$$

where  $a$  is the **activity** of the species designated by the subscripts. The activity of the water has been omitted from the equation since it may be taken as unity for a dilute aqueous solution.  $K_a$  is a measure of the strength of the acid, i.e. of its ability to donate hydrons to water. Compare **basic dissociation constant**. See also **pK**.

**acid dye** a **dye** containing an anionic acidic organic group that binds to and stains positively charged macromolecules.

**acidemia** or (esp. Brit.) **acidaemia** (archaic) a condition in which there is excessive acidity (i.e. increased hydrogen-ion concentration, lowered pH) of the blood. Compare **acidosis**, **alkalemia**.

**acid-fast bacillus** any bacterium able to resist decolorization by mineral acids after the application of specific basic aniline dyes; this property is possible due to the presence in these organisms of **mycolic acid**, together with a semipermeable membrane that allows the passage of the stain but not of the decolorizing acid.

**acid p-glucosidase** *see glucosylceramidase*.

**acid hydrolase** any **hydrolase** enzyme that is active in mildly acidic conditions (pH 5–6); often found in **lysosomes**.

**acidic** 1 of, relating to, containing, or characteristic of an **acid**. Compare **basic** (def. 1). 2 having an acid reaction in water; or of relating to an aqueous solution having a pH < 7.0. Compare **basic** (def. 2).

**acidic amino acid** any amino acid containing more potentially anionic groups than potentially cationic groups. All such amino acids have a net negative charge at neutral pH. Examples are aspartic and glutamic acids.

**acid mucopolysaccharide** any of a group of related heteropolysaccharides, found widely distributed in animal connective tissues, that contain N-acetylated hexosamine in its characteristic repeating disaccharide unit. They include chondroitin, **chondroitin sulfates**, **dermatan sulfates**, hyaluronic acid (*see hyaluronate*), and **keratan sulfates**.

**acid number or acid value** the mass, in milligrams, of potassium hydroxide required to neutralize the free fatty acid in one gram of fat; a measure of the mass of free acid in the sample.

**acidophilic** 1 staining readily with **acid dyes**. 2 (of organisms) preferring or thriving in a relatively acid environment.

**acidosis** a clinical condition in which excess acid or a base deficit tends to cause increased hydrogen-ion concentration (i.e. lowered pH) in the blood.

**acidosome** a non-lysosomal vesicle found in the ciliate proto-

### acidotropic

**l**oan *Paramecium*. The organelle is involved in acidification of digestive phagocytic particles through fusion.

acidotropic seeking an acid environment. The term is used e.g. in connection with Ser/Thr protein kinases that require Glu or Asp as part of the recognition site. The resulting Ser(P) or Thr(P) then acts as an acidic residue, extending the site with the result that further Ser or Thr residues are phosphorylated.

**acid phosphatase abbr.** (*in clinical biochemistry*): ACP; EC 3.1.3.2; **systematic name:** orthophosphoric monoester phosphohydrolase (acid optimum); **other names:** alkaline phosphomonoesterase; phosphomonoesterase; glycerophosphatase; a lysosomal enzyme (except in red cells). It catalyses the hydrolysis of orthophosphoric monoester to an alcohol and orthophosphate. Zinc and magnesium are cofactors. It is present in high concentrations in the prostate gland, and is also present in red cells, platelets, bone, liver, and spleen. Its measurement in blood may be of use clinically in monitoring progress in cases where prostatic cancer has metastasized, but not where cancer is confined to the prostate, being elevated in only about 30% of cases. Normal range in human plasma 4-11 IU L<sup>-1</sup>. Example: human lysosomal acid phosphatase precursor: database code PPAL\_HUMAN, 423 amino acids (48.29 kDa).

**acid proteininase** *an older name for* enzymes of the sub-subclass aspartic endopeptidase, EC 3.4.23. It was suggested by their characteristic low optimum pH.

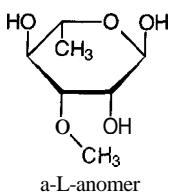

acid sphingomyelinase *see* sphingomyelin phosphodiesterase.  
acinus (*pl.* acini) 1 a saclike structure that forms the terminal

**acinus** (a'ne-in) A sac-like structure that forms the terminal part of a gland. It comprises a cluster of cells surrounding a small duct. 2 one of the collection of small drupes making up an aggregate fruit such as a raspberry. -acinar adj.

acee or akee a tree, *Blighia sapida*, native to tropical Africa and widely cultivated in the West Indies, especially Jamaica, for its fruit, the fleshy aril of which is edible when cooked and forms an important item of local diet. Unripe fruits contain toxic amounts of hypoglycin and can cause Jamaican vomiting sickness.

**AcNm** *(formerly) symbol for N-acetylneuraminic acid (see sialic acid)*

acofriose 6-deoxy-3-O-methylmannose; the L enantiomer is a component of some cardiac glycosides.

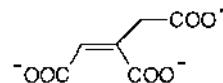

aconitase EC 4.2.1.3; other name: aconitate hydratase; systematic name: citrate (isocitrate) hydro-lyase. A hydrolase enzyme that catalyses the reaction:

it also reversibly converts isocitrate into cis-aconitate + H<sub>2</sub>O. An iron-sulfur protein, it removes H<sub>R</sub> from the pro-R-CH<sub>2</sub>-COOH group of citrate (see citrate for structure). Under kinetic conditions in which it forms isocitrate from citrate the product is (IR,2S)-1-hydroxypropane-1,2,3-tricarboxylate (<2R,3S)-isocitrate). Example from pig: database code NRL\_5ACN, 754 amino acids (82.60 kDa); 3-D structure known.

aconitate the *cis* isomer, (*Z*)-prop-1-ene-I,2,3-tricarboxylate, is an intermediate in the conversion of citrate to isocitrate in the tricarboxylic-acid cycle, by the action of aconitase.

### *cis*-aeonitate

aconitase hydratase *see* aconitase.

aconitate A-isomerase EC 5.3.3.7; systematic name: aconitate A2-A3-isomerase. An enzyme that catalyses the reaction:

*trans*-aconitate = *cis*-aconitate.

**acoustic gene transfer** a method of transforming (typically plant) cells by using ultrasound.

**ACP** abbr. for 1 acyl carrier protein. 2 (in clinical biochemistry) acid phosphatase.

$\text{fAcp}$  (*formerly*) symbol for a residue of the e-amino acid *e*-caproic acid, now known as 6-aminohexanoic acid.  $\text{eAhx}$  is the preferred symbol.

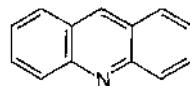

**acquired immune deficiency syndrome** abbr.: AIDS; defined by the Centers for Disease Control in the USA as a reliably diagnosed disease that is at least moderately indicative of an underlying immune deficiency or any other cause of reduced resistance reported to be associated with that disease. In humans it is a fatal condition (unless a successful therapy can be found), commonly associated with infection by HIV.

acquired immunity or adaptive immunity (active or passive, humoral or cellular) that is established during the life of an individual, as contrasted with innate or natural immunity. Such immunity is specific for the inducing agent and is marked by an enhanced response on repeated encounters with that agent. The key features are memory (*see* memory cell) and specificity.

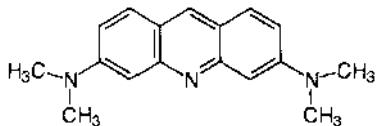

acquired tolerance 1 (*in immunology*) tolerance to an antigen that is established during the life of an individual. Immunological tolerance can (rarely) be produced in an adult animal by prolonged injection of massive doses of antigen. The tolerance persists as long as antigen persists in the animal. See also self tolerance. 2 (*in pharmacology*) tolerance (generally to psychoactive compounds) that develops on prolonged or repeated drug administration. It can be either pharmacokinetic usually by increased drug metabolism, or pharmacodynamic. See tachyphylaxis, tolerance.

acrasin a chemotactic substance produced by the myxamoebae of the cellular slime mould *Dictyostelium discoideum*, now identified as cyclic AMP.

acridine the parent compound of a series of derivatives e.g. 3,6-diaminoacridine (proflavin), that are potent mutagens. Some acridines are found in coal tar. They induce frameshift mutations during the replication of DNA by binding to DNA and distorting the double helix, causing additional bases to be incorporated or bases to be omitted. They are used as topical antiseptics and antimalarial agents.

**Acridine Orange** 3,6-bis(dimethylamino)acridine; a dye used as a probe of nucleic acids in microscopy and related techniques. When illuminated under UV light it yields a green (DNA) or reddish-orange (RNA) fluorescence.

Acridine Orange

acriflavin a mixture of the acridine derivatives 3,6-diamino-10-methylacridinium chloride (about 65%) and proflavin.

acrocentric describing a chromosome in which the centromere is very close to one end.

acrolein 3-propenal; CH<sub>2</sub>=CH-CHO; an unstable flammable liquid with a pungent odour that irritates the eyes and mucosae. It polymerizes (especially under light) to form a plastic solid.

acrolein test a qualitative test for the presence of glycerol, either free or esterified, based upon its oxidative dehydration to acrolein when heated with solid potassium hydrogen sulfate.

acromegaly a chronic disease marked by the gradual enlargement of the bones of the hands, feet, head, and chest with thickening of the skin, lips, and vocal chords. It is caused by excessive secretion of, or increased sensitivity to, somatotropin, and is often due to a tumour of the somatotrope cells of the pituitary.

acrosin EC 3.4.2J.10; a trypsin-like serine endopeptidase. A major proteinase of mammalian spermatozoa, synthesized in a zymogen form, proacrosin, and stored in the acrosome. It comprises a heavy chain (catalytic) and a light chain linked by two disulfide bonds; it is not inhibited by u-antitrypsin. It catalyses the hydrolysis of Arg-I-Xaa and Lys-I-Xaa bonds, with preferential cleavage in the order Arg-I-Xaa » Lys-I-Lys » Lys-I-Xaa. Example (precursor) from human: database code ACRO\_HUMAN, 421 amino acids (45.75 kDa).

acrosomal process a long thin actin-containing spike produced from the head of certain types of sperm when they make contact with the egg at fertilization. It is seen in sea urchins and other marine invertebrates having eggs surrounded by a thick gelatinous coat.

acrosome a structure in the head of a spermatozoon that contains acid hydrolases concerned in the breakdown of the outer membrane of the ovum during fertilization. It lies anterior to the nucleus just beneath the plasma membrane. See also acrosin.

acrylamide or acrylamide monomer *the trivial name for propenamide*, CH<sub>2</sub>=CH-CONH<sub>2</sub>; a water-soluble solid that is highly toxic and irritant, and readily polymerizes under the action of UV light or chemical catalysts into polyacrylamide.

**ACTH** abbr. for adrenocorticotrop(h)ic hormone (corticotropin). 1-24 **ACTH** abbr. for tetacosactrin.

actidione *see cycloheximide*.

actin a major protein constituent of the thin filaments of muscle and of the microfilaments found in practically all eukaryotic cells - it comprises 5-10% of the protein of such cells (*see actin filament*). In solutions of low ionic strength, actin is a globular 42 kDa monomer called G-actin. At physiological ionic strengths, G-actin polymerizes into a fibrous form called F-actin, which resembles two strings of beads wound round each other. F-actin is a helix of actin monomers with a helix diameter of about 7 nm, the structure repeating at intervals of 36 nm along the helix axis. When a solution of actin is mixed with a solution of the muscle protein myosin a complex called actomyosin is formed and the viscosity of the solution increases markedly. This increase in viscosity is reversed by the addition of ATP, which acts to dissociate the actomyosin complex. It is thought that the force of muscle contraction arises from an interaction of actin, myosin, and ATP. Example, u-cardiac actin

(human): database code ACTC\_HUMAN, 377 amino acids (41.97 kDa); seven motifs.

actin-binding domain a structural feature found in actin-binding proteins.

actin-binding protein any of several proteins that associate with either actin monomers or actin filaments in cells and modify their properties. Many of these proteins are found in the cell cortex, an actin-rich layer just below the plasma membrane. Examples include dystropin, profilin, spectrin and ankyrin, fimbrin and u-actinin (*see actinin*), filamin, gelsolin, and the myosins. The term is sometimes applied specifically to filamin.

actin depolymerizing factor *see* desmin.

actin filament a two-stranded helical polymer of the protein actin. Actin filaments form the thin filaments of muscle and also the microfilaments of the cytoskeleton of eukaryotic cells. Hence they are a major component of the contractile apparatus of skeletal muscle, and one of the three types of protein filament that form the cytoskeleton, the others being microtubules and intermediate filaments. The filaments, comprising polymerized globular actin molecules, appear as flexible structures with a diameter of 5-9 nm. They are organized into a variety of linear bundles, two-dimensional networks, and three-dimensional gels. In the cytoskeleton they are most highly concentrated in the cortex of the cell just beneath the plasma membrane.

actinic describing electromagnetic radiation, especially higher frequencies of visible light and UV radiation, capable of initiating photochemical reactions.

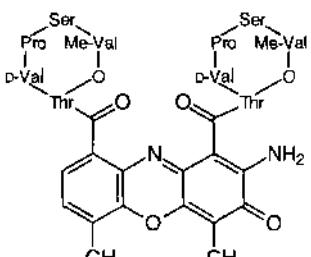

actinidine a monoterpeneoid alkaloid occurring in *Actinidia polygama*.

actinin a minor protein constituent of muscle, found to be concentrated in both the Z line and the I band. Two components of actinin have been identified:  $\alpha$ -actinin, F-actin cross-linking protein, is a dimer of  $\approx$ 200 kDa with an action similar to that of actinogelin. Example from human: database code AACT\_HUMAN, 892 amino acids (102.86 kDa); and  $\beta$ -actinin, a dimer of  $\approx$ 70 kDa, is similar in action to gelsolin.

actinogelin a protein factor that effects Ca<sup>2+</sup>-sensitive gelation of actin filaments. It was first obtained from Ehrlich ascites tumour cells, and has a molecular mass of 100-120 kDa. u-Actinin (*see actinin*) has a similar action.

actinoid or actinide any member of the series of 15 metallic elements with proton numbers 89 (actinium) to 103 (lawrencium) inclusive that occur together in group 3 and period 7 of the IUPAC periodic table; sometimes the term is restricted to the 14 elements following actinium. Actinoid is now the preferred name. All actinoids are radioactive, and those of proton number 93 or greater are artificial. They are all electropositive, and their chemical properties are similar, due usually to the filling of an inner electron subshell (5f) progressively across the series. Like the lanthanoids, they thus represent a series of inner transition elements.

actinomycin any of a large group of antibiotics isolated from various species of *Streptomyces* bacteria and characterized by having a substituted phenoxazine ring linked to two cyclic heterodetic peptides. The principal member of the group is actinomycin D (also called actinomycin C<sub>1</sub>, actinomycin IV), which, at low concentrations, inhibits transcription without appreciably affecting DNA replication in both prokaryotic and eukaryotic cells. Actinomycin D binds tightly to duplex DNA thereby preventing it from being an effective template for RNA synthesis. Spectroscopic and hydrodynamic studies of complexes of actinomycin D and DNA suggest that the phenoxazine ring of actinomycin is intercalated between neighbouring base pairs in DNA. Other conformational studies indicate that actinomycin D recognizes the base sequence GpC in DNA.

actinomycin D

**actinomyosin** (formerly) the contractile system in muscle comprising **actin** and **myosin**. Compare **actomyosin**.

**action potential** the localized change of electrical potential across a nerve fibre or muscle membrane that marks the position of an impulse as it is propagated. It is caused by sodium ion fluxes across the membrane resulting from transitory opening of **sodium channels**.

**action spectrum** a graph or table showing the relative efficiencies of different frequencies of radiation in causing a chemical or biochemical reaction, e.g. in photosynthesis or gas exchange. Efficiency, or **quantum yield**, is given by the measurable effect divided by the intensity of the (monochromatic) incident radiation.

**activate** 1 to make or render active, reactive, or capable of action. 2 to make radioactive. **-activated adj.; activation n.**

**activated alumina** particles of alumina, aluminium oxide, that have been rendered more adsorbent by heating strongly.

**activated amino acid** an amino-acid residue in an aminoacyladenylate molecule. The amino acid reacts with ATP to form aminoacyl-AMP in a reaction catalysed by an aminoacyl-tRNA synthetase. It is the first metabolic step in the biosynthesis of a polypeptide. The same enzyme catalyses the transfer of the amino acid to an ester link with the 3'-terminal hydroxyl of tRNA.

**activated complex** term that may be used to denote the assembly of atoms at the transition state of a chemical reaction.

**activation** 1 the action or process of rendering an atom, molecule, or other substance reactive or more reactive, whether physicochemically, chemically, or biochemically. 2 the process of rendering material artificially radioactive: radioactivation. See **radioactivation analysis**. 3 the initial changes in an ovum during fertilization, covering the period from first contact with a sperm to dissolution of the nuclear membranes. 4 the initial changes in the conversion of a spore to a vegetative cell. This can be effected by various agents or processes and may involve alteration of one of the spore's outer layers.

**activation analysis** an alternative term for **radioactivation analysis**.

**activation energy** see **Arrhenius equation**.

**activation hormone** a polypeptide hormone synthesized in the neurosecretory brain cells of insects. It regulates the functioning of the whole endocrine system, stimulating the secretory activity of other glands.

**activator** any substance that activates a chemical or enzymic reaction. The term was formerly used in biochemistry especially to describe metal-ion **cofactors** for enzymes.

**activator constant** symbol:  $K_A$ ; the equilibrium **dissociation constant** of the reaction of an enzyme with an activator. For example, in the reaction:

$$K_A = [EA]/[E][A],$$

where  $[EA]$ ,  $[E]$ , and  $[A]$  are the concentrations of enzyme-activator adduct, free enzyme, and free activator respectively.

**active acetaldehyde** (sometimes) the  $\alpha$ -hydroxyethyl derivative, on C-2 of the thiazolidine ring, of thiamine diphosphate.

**active acetate** (formerly) an alternative name for **acetyl eDenzymeA**.

**active C<sub>t</sub>** abbr. for active one-carbon.

**active centre** all the features of primary, tertiary, and quaternary structure of an enzyme - including the **active site** - that are required for substrate binding, specificity, and catalysis.

**active-enzyme centrifugation** a technique for determining the sedimentation and diffusion coefficients of an enzyme-substrate complex. A thin lamella of an enzyme solution is layered onto a substrate solution in an ultracentrifuge cell and, on rotation, as the enzyme molecules sediment in a band through the substrate solution they catalyse the enzymic reaction, the progress of which is observed optically (e.g. by spectrophotometry). The required coefficients are then calculated from either the rate of appearance of the product of the reaction or the rate of disappearance of the substrate. The centrifugation may be performed on impure enzyme preparations and at the very low concentrations of enzyme used in kinetic studies.

**active fatty acid** (formerly) an alternative term for an **acyl-CoA derivative**.

**active formaldehyde** (formerly) an alternative term for **N<sub>5</sub>,N<sub>10</sub>-methylenetetrahydrofolate**.

**active immunity or adaptive immunity** a type of immunity resulting from the stimulation of the immune response by an immunogen.

**active immunization** stimulation of the reactivity of the immune system of an individual towards an immunogen by administration of the immunogen, thereby producing a state of active immunity.

**active methionine or active methyl** name sometimes used for **S-adenosylmethionine**.

**active methyl** 1 an alternative name for **active methionine**. 2 one form of **active one-carbon** (e.g. 5-methyltetrahydrofolate).

**active one-carbon** any of the one-carbon units carried on tetrahydrofolate and concerned in a wide variety of biosynthetic reactions. They include the methyl-, methylene-, formimino-, formyl-, and methenyl- substituents.

**active site** 1 the general region of an enzyme molecule containing the **catalytic residues** identified with the binding and reaction of substrate(s). It includes those amino-acid residues that are, in the enzyme-substrate complex, either **contact amino acids**, i.e. those that at some point are only one bond distance removed from some point of the substrate molecule, or **auxiliary amino acids**, i.e. those that are not in such intimate physical contact with the substrate but nonetheless play a definite role in the action of the enzyme. See also **contributing amino acid**. 2 (sometimes) the portion of a peptide hormone responsible for its biological activity. Isolated fragments containing the active site may show some activity, but may function less efficiently than the intact hormone. See also **message sequence**.

**active site-directed irreversible inhibitor** a custom-made inhibitor of a given enzyme. Such inhibitors are typically trifunctional molecules containing: (1) a functional group able to bind to the enzyme's active site; (2) a nonpolar part that can interact with a nonpolar region on the enzyme, serving to align the inhibitor; and (3) an alkylating group capable of reacting with a susceptible group on the enzyme and irreversibly forming a covalent bond with it.

**active sulfate** an alternative name for **1 adenosine-5'-phosphosulfate**. 2 **J'-phosphoadenosine-5'-phosphosulfate**.

**active transport** any energy-dependent process by which molecules or ions are transported across membranes against a chemical potential gradient. Compare **facilitated diffusion**, **simple diffusion**.

**activin** one of two gonadal glycoproteins related to **transforming growth factor-β** (the other is **inhibin**); present in two forms in

## activity

human gonads, it exists as a dimer of inhibin  $\beta_A$  or  $\beta_B$  chains linked by disulfide bonds. Activin A is a dimer of  $\beta_A$  chains; activin AB is a dimer of  $\beta_A$  and  $\beta_B$  chains. A potent selective stimulator of FSH secretion by the anterior pituitary gland, not via GnRH receptors, it modulates induction of hemoglobin accumulation and proliferation of erythroid progenitor cells in human bone marrow culture and is important in embryonic axial development.

**activity** 1 the natural or normal functioning of an enzyme, hormone, inhibitor, or other agent; or the intensity with which such an agent functions. *See also* enzymic activity. 2 the number of nuclear transformations (def. 5) that occur or that can be detected in a given quantity of radioactive material in unit time (*see also* becquerel, curie). This term is also often used in this sense for radioactivity and, loosely, for the radioactive material itself or its emitted radiation; *see also* specific activity. 3 or relative activity symbol:  $a$ ; the apparent or effective concentration of a chemical substance as judged by the behaviour of the substance in a standard state. The activity of an entity B is defined by

$$a_B = \exp[(\mu_B - \mu_B^0)/RT]$$

where  $\mu_B$  and  $\mu_B^0$  are respectively the chemical potential and standard chemical potential of entity B,  $R$  is the gas constant, and  $T$  the thermodynamic temperature. 4 absolute activity symbol:  $\lambda$ ; the absolute activity of an entity B is defined by

$$\lambda_B = \exp(\mu_B/RT).$$

where  $\mu_B$  is the chemical potential of entity B,  $R$  is the gas constant, and  $T$  is the thermodynamic temperature. *See also* activity coefficient.

**activity coefficient symbol:**  $y$ ; the ratio of the activity (def. 3) of a component of a solution to its concentration. When expressed on an amount concentration basis it is denoted  $Y_C$ , when on a molality basis  $\gamma_m$ , and when on a mole fraction basis  $\gamma_x$ . *See also* mean ionic activity coefficient.

**activity stain** any reagent that develops a colour when acted on by a particular enzyme. Such a reagent is used to detect the presence of an enzyme in a gel or paper electrophoresis strip, in which it differentially stains the enzyme protein in question but not other proteins.

**actobindin** a monomeric protein capable of binding two molecules of monomeric (i.e. G-) actin. Example from *Acanthamoeba castellanii*: database code ACTO\_ACACA, 88 amino acids (9.53 kDa).

**actomyosin** *see* actin.

**ACU** a codon in mRNA for L-threonine.

**acumentin** an actin-modulating protein, Ca<sup>2+</sup>-nondependent, isolated from rabbit alveolar macrophages.

**acute-phase protein** any of the non-antibody proteins that show raised plasma concentrations soon after the onset of infection or tissue injury in homoiothermic animals. They include complement (def. 3) proteins, C-reactive protein, fibrinogen and other coagulation proteins, and interferon.

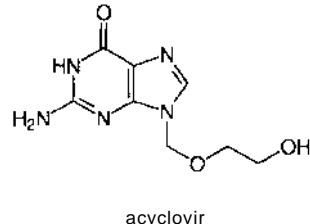

**acute transfection** the short-term infection of cells with DNA.

**acyclic** describing an organic compound devoid of a ring of atoms.

**acycloguanosine** an alternative name for acyclovir.

**acyclovir** or acycloguanosine 9-(2-hydroxyethoxymethyl)guanine; an antiviral agent widely used in the treatment of human herpes infections. It is selectively phosphorylated by herpesvirus-induced thymidine kinase and the phosphorylated compound is a potent inhibitor of herpesvirus-induced DNA polymerase. One proprietary name is Zovirax.

## 1-acylglycerol-3-phosphate (acyltransferase)

**acyl** generic name for any group formally derived by removal of a hydroxyl group from the acid function of an organic acid. Examples include any group of general structure R-CO- derived from a carboxylic acid; R-SO<sub>2</sub>- from a sulfonic acid; and R-PO(OH)- from a phosphonic acid. However, unless the context indicates otherwise the term refers to such groups derived from carboxylic acids.

**acyl-ACP dehydrogenase** *see* enoyl-[acyl-carrier protein] reductase INADPH-A-specific.

**acyl-activating enzyme** *see* long-chain-fatty-acid-CoA ligase.

**acylation** the process of introducing an acyl group into a compound by substitution for a hydrogen atom. -acylated adj.

**acyl carrier protein abbr.:** ACP; any of the relatively small acidic proteins that are associated with the fatty acid synthase system of many organisms, from bacteria to plants. They contain one 4'-phosphopantetheine prosthetic group bound covalently by a phosphate ester bond to the hydroxyl group of a serine residue. The sulphydryl group of the 4'-phosphopantetheine moiety serves as an anchor to which acyl intermediates are (thio)esterified during fatty-acid synthesis. In animals the fatty acid synthase system is a 500 kDa polyfunctional enzyme containing two identical chains, each with one ACP unit. *Escherichia coli* ACP, a separate single protein, contains 77 amino-acid residues (8.85 kDa); the phosphopantetheine group is linked to serine 36. Example (ACP-I precursor) from *Arabidopsis thaliana*: database code ACPI\_ARATH, 137 amino acids (15.04 kDa).

**acyl-CoA** generic name for any derivative of coenzyme A in which the sulphydryl group is in thioester linkage with a fatty-acyl group.

**acyl-CoA reductase** EC 1.2.1.50; recommended name: long-chain-fatty-acyl-CoA reductase; systematic name: long-chain-aldehyde:NADP<sup>+</sup> oxidoreductase (acyl-CoA-forming). An enzyme that catalyses a reaction between a long-chain aldehyde, CoA, and NADP<sup>+</sup> to form long-chain acyl-CoA and NADPH. It is part of the bacterial luciferase system. Example: *see* Lux proteins.

**acyl-CoA synthetase** *see* long-chain-tatty-acid-CoA ligase.

**acyl enzyme** any intermediate formed in an enzymic acyl-transfer reaction in which a group at the active site of the enzyme is acylated.

**acylglycerol** 1 any mono-, di-, or triester of glycerol with (one or more) fatty acids (termed respectively monoacylglycerol, diacylglycerol, or triacylglycerol); formerly known as mono-, di-, or triglyceride. 2 acylglycerols (*plural*), also denotes any mixture of mono-, di-, and/or triacylglycerols whatever its degree of complexity, including any comprising a neutral fat.

**2-acylglycerol D-acyltransferase** EC 2.3.1.22; other names: acylglycerol palmitoyltransferase; monoglyceride acyltransferase; an enzyme that catalyses the acylation by acyl-CoA of 2-acylglycerol to form diacylglycerol and CoA. It is an enzyme involved in the monoacylglycerol pathway of triacylglycerol biosynthesis.

**1-acylglycerol-3-phosphate D-acyltransferase** EC 2.3.1.51; systematic name: acyl-CoA:1-acyl-sn-glycerol-3-phosphate 2-O-acyltransferase. An enzyme that catalyses the acylation by acyl-CoA of 1-acyl-sn-glycerol 3-phosphate (lysophosphatidic acid) to form 1,2-diacyl-sn-glycerol 3-phos-

## 1-acylglycerophosphocholine

phate (phosphatidic acid) with release of CoA. Acylated acyl carrier protein can also act as substrate. In animals, the enzyme specifically transfers unsaturated fatty acyl groups, a preference that contributes to the high proportion of unsaturated fatty acids on the 2-position of phosphoglycerides. Example from *Escherichia coli*: database code PLSC\_ECOLI, 245 amino acids (27.42 kDa).

**1-acylglycerophosphocholine o-acyltransferase** EC 2.3.1.23; *other name*: lysolecithin acyltransferase; an enzyme that catalyses the acylation by acyl-CoA of l-acyl-sn-glycero-3-phosphocholine to form 1,2-diacyl-sn-glycero-3-phosphocholine and CoA. It is involved in the resynthesis of phosphatidylcholine in situations where the latter has been degraded to lysophosphatidylcholine.

**acylhomoserine** *see* o-succinylhomoserine.

**acyl migration** any intramolecular rearrangement reaction in which, under certain conditions, an acyl group moves from one functional group to another, which may be of the same or of a different kind. N → O acyl migration (*also termed* N → O acyl shift, N → O acyl transfer, or N → O peptidyl shift) is a reaction that can occur in polypeptides and proteins subjected to hydrolysis by concentrated acid at room temperature or in the presence of an acid chloride (e.g. POC<sub>1</sub><sub>3</sub>), whereby the {3-hydroxyl group of a serine or threonine residue displaces the amino group of the same residue from its amide (=peptide) linkage with the carboxyl group of the adjacent residue, thus forming an acid-sensitive p-ester linkage. The reaction may be used to advantage in partial acid hydrolysis of polypeptides and proteins. In the presence of alkali the ester reverts to the original amide by O → N acyl migration, a reaction that can also occur during the Edman degradation of a peptide. An acyl group, e.g. acetyl or maleyl, that happens to be present on the {3-hydroxyl group of a serine or threonine residue, moves to the free amino group of such a residue when it becomes N-terminal, so preventing the next cycle of the degradation.

**N-acetylneuraminate glycohydrolase** *see* sialidase.

**acylphosphatase** EC 3.6.1.7; *systematic name*: acylphosphate phosphohydrolase. An enzyme that catalyses the hydrolysis of acyl phosphate to fatty-acid anion and orthophosphate. Example from chicken: database code ACYM\_CHICK, 102 amino acids (11.27 kDa); three motifs.

**acyl-protein synthase** *see* myelin-proteolipid O-palmitoyltransferase.

**acyl shift** *see* acyl migration.

**acylsphingosine deacylase** *see* ceramidase.

**N-acylsphingosine galactosyltransferase** EC 2.4.1.47; an enzyme that catalyses the formation of the cerebroside D-galactosylceramide from UDPgalactose and N-acylsphingosine with release of UDP.

**acyltransferase** any enzyme of sub-subclass EC 2.3.1. Such enzymes transfer acyl groups, forming either esters or amides, by catalysing reactions of the type:

For example if acyl =acetyl, carrier =CoA, and reactant = choline, the reaction is that of choline acetyltransferase.

**AD** (*in clinical biochemistry*) *abbr.* for alcohol dehydrogenase (preferred to ADH because of possible confusion with anti-diuretic hormone).

**Ada** or **ADA** *abbr.* for N-(2-acetamido)iminodiacetic acid; [(carbamoylmethyl)imino]diacetic acid; a Good buffer substance, *pK<sub>a</sub>* (20 0c) = 6.6.

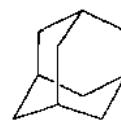

**Adair equation** an equation describing the oxygen saturation curve of hemoglobin:

$$R = \frac{K_1[pO_2] + 2K_2[pO_2]^2 + 3K_3K_4[pO_2]^3 + 4K_1K_2K_3K_4[pO_2]^4}{4(1+K_1[pO_2] + K_2[pO_2]^2 + K_3K_4[pO_2]^3 + K_1K_2K_3K_4[pO_2]^4)}$$

where R is the fractional saturation of hemoglobin with oxygen, *K*<sub>1</sub>, *K*<sub>2</sub>, *K*<sub>3</sub>, and *K*<sub>4</sub> are the stepwise intrinsic association constants for the four oxygen-binding sites, and *pO*<sub>2</sub> is the par-

tial pressure of oxygen. For a generalized form of this equation *see* Sierrum formation function. [Defined by Gilbert Smithson Adair (1896-1979), British biophysicist, in 1925.] **adamalysin** EC 3.4.24.46; *other name*: proteinase II; a metalloendopeptidase that catalyses the cleavage of Phe<sup>1</sup>-I-Val<sup>2</sup>, His<sup>5</sup>-I-Leu<sup>6</sup>, His<sup>10</sup>-I-Leu<sup>11</sup>, Ala<sup>14</sup>-I-Leu<sup>15</sup>, Leu<sup>15</sup>-I-Tyr<sup>16</sup>, and Tyr<sup>16</sup>-I-Leu<sup>17</sup> in the insulin B-chain. Zn<sup>2+</sup> and Ca<sup>2+</sup> are cofactors. It is a snake venom proteinase whose natural substrate(s) are protease inhibitor(s), such as the serpins. Example from the Eastern diamondback rattlesnake, *Crotalus adamanteus*: database code ADAM\_CROAD, 203 amino acids (23.05 kDa).

**1-adamantanamine** or *a*-adamantanamine *see* amantadine. **adamantane** tricyclo[3.3.1.1<sup>3,7</sup>]decane; a substance isolated from petroleum and said to have virostatic activity. *See also* amantadine.

**adaptation** (*in biology*) 1 any change in an organism's structure or function that allows it better to deal with its environmental conditions. 2 the mechanism whereby bacterial cells that approach cells of the opposite mating type, but fail to mate, can recover and continue dividing.

**adapted gradient** in gradient elution, a form of gradient in which the composition of the eluate is adjusted, on the basis of information obtained in a trial separation, to be optimal at each moment of the elution, so that the optimum resolution between the desired components of the sample is obtained.

**adapton** a major coat protein of clathrin-coated vesicles. It functions as a component of the adaptor complexes that link clathrin to the receptors being taken into the cell in the coated vesicles, recognizing a motif of four amino acids (FRXY) in the cytoplasmic domain of the receptor. Example from rat: database code ADA5\_RAT, 435 amino acids (49.60 kDa).

**adaptive** describing changes in an organism, induced by environmental factors, that tend to increase its viability.

**adaptive enzyme** *see* inducible enzyme.

**adaptive immunity** *an alternative name for* active immunity. **adaptor** 1 any of various devices useful for joining together two or more parts, otherwise incompatible, such as electrical connectors or pieces of glassware. 2 any synthetic single- or double-stranded oligodeoxynucleotide useful in recombinant DNA technology for joining two incompatible cohesive ends of restriction fragments. *Compare* linker. 3 *or* adaptor molecule the molecule that was postulated as carrying the amino acid to the (messenger) RNA in the adaptor hypothesis of protein synthesis, now known to be a tRNA molecule.

**adaptor hypothesis** the hypothesis, first postulated by Crick, that during protein biosynthesis each amino-acid residue is carried to the RNA template by its appropriate small adaptor RNA molecule, and that the adaptor is the part that fits on to the messenger RNA. The hypothesis was subsequently confirmed by the discovery of transfer RNA.

**ADCC** *abbr.* for antibody-dependent cell-mediated cytotoxicity. **Addison's disease** a disease due to deficiency of production of cortisol and other cortical steroids. It results from atrophy of the adrenal cortex, a condition having a variety of causes. [Described by Thomas Addison (1793-1860), British physician and endocrinologist, in 1849.]

**addition** 1 (*in chemistry*) the formation of an adduct. 2 an addition reaction.

**addition compound** *see* adduct.

**addition reaction** or *addition* any organic chemical reaction involving the combination of two or more substances to form a single product in which there are more groups attached to carbon atoms than there were in the original reactants. Such

## address

reactions thus involve a net reduction of bond multiplicity in one of the reactants, as in the example:

**address** 1 that part of the information contained within the amino-acid sequence of a hormonal polypeptide or its biosynthetic precursors that determines the receptor-specific affinity of the hormone. *Compare* message (def. 4). 2 (*in computer technology*) a label, name, or number identifying a device or a location in a memory.

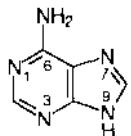

**address sequence** or address region that segment of the amino-acid sequence of a polypeptide hormone or prohormonal polypeptide in which the address of the hormone resides and through which the hormone is considered to bind to its specific receptor. *Compare* message sequence.

**adducin** a membrane skeleton protein (heterodimer) that interacts with a junctional complex that links spectrin assemblies. The complex in the red blood cell consists of tropomyosin and actin with band 4.1 (see band). Adducin probably binds to band 4.1. Examples from human erythrocyte: adducin  $\alpha$ , database code S18207, 737 amino acids (80.88 kDa); adducin  $\beta$ , database code S18208, 726 amino acids (80.76 kDa).

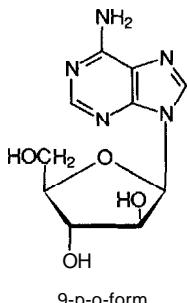

**adduct** 1 any new chemical species, AB, formed by direct combination of two separate chemical species, A and B, in such a way that there is no change in connectivity of atoms within the moieties A and B. This term is preferred to complex, which is less explicit. 2 (*formerly*) the product of a reaction between molecules occurring in such a way that the original molecules or their residues have their long axes parallel to one another. Ade symbol for a residue of the purine base adenine (alternative to A).

**ADE2** a gene that encodes a multifunctional protein with activities for phosphoribosylaminoimidazole carboxylase and phosphoribosylaminoimidazolesuccinocarboxamide synthase. It has been studied as a model of position effect in gene expression. The gene is expressed in all cells if in its normal position near the middle of the chromosome, but if moved experimentally to the end of the chromosome it is silenced. The lack of the enzyme produces a red pigmentation in these colonies.

**adenine symbol:** A or Ade; 6-aminopurine; IH-purin-6-amine; a purine base. It is one of the five main bases found in nucleic acids and a component of numerous important derivatives of its corresponding ribonucleoside, adenosine. It can exist in a tautomeric imino form.

**adenine arabinoside** other names: vidarabine, ara-A; 9-P-D-arabinofuranosyladenine; an antibiotic produced by *Streptomyces* bacteria that acts as an antiviral agent, causing mispairing of purines and pyrimidines in nucleic-acid synthesis.

## adenosine 5'-diphosphate

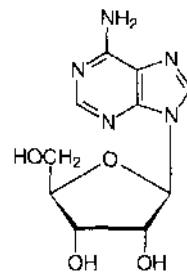

adenine nucleotide translocase *see* ADP,ATP carrier protein. adenine phosphoribosyltransferase abbr.: APRT; EC 2.4.2.7; other names: AMP pyrophosphorylase; transphosphoribosidase; an enzyme that catalyses the formation of AMP from 5-phospho-a-D-ribose 1-diphosphate and adenine with release of pyrophosphate. It is an enzyme of purine metabolism that salvages adenine released by degradative enzymes, converting it back to a nucleotide. Example: from human: APLHUMAN, 179 amino acids (19.45 kDa).

**adeno+** or (*before a vowel*) aden+ comb. form meaning of, pertaining to, or like a gland; glandular; found in glands.

**adenohypophysis** the glandular anterior lobe of the hypophysis (or pituitary gland). It produces corticotropin, gonadotropin, lipotropin, somatotropin, thyrotropin, and other hormones. *Compare* neurohypophysis. -adenohypophyseal or adenohypophysial ad.

**adenoma** any benign tumour formed by the multiplication of the epithelial cells that form the ducts and acini of glandular organs. The meaning has been broadened to include the benign tumours that arise from the solid masses of epithelium that form some of the endocrine glands. Adenomas often accurately reproduce the tissues from which they are derived and produce a secretion identical with or similar to that produced by the normal glandular tissue.

**adenosine symbol:** A or Ado; adenine riboside; 9-j3-D-ribofuranosyladenine; a ribonucleoside found widely distributed in cells of every type as the free nucleoside and in combination in nucleic acids and various nucleoside coenzymes. It is a potent regulator of physiological transmission in both central and peripheral nervous systems, where it activates specific receptors (*see* adenosine receptor). It can inhibit or stimulate the release of a number of neurotransmitters, including acetylcholine, j3-aminobutyrate, catecholamines, excitatory amino acids, and 5-hydroxytryptamine. The effect depends on whether the receptor involved inhibits adenylyl cyclase (and thus inhibits release) or stimulates it.

**adenosine aminohydrolase** *see* adenosine deaminase.

**adenosine 2',3'-(cyclic)phosphate** *see* adenosine phosphate. **adenosine 3',5'-(cyclic)phosphate** *see* adenosine 3',5'-phosphate.

**adenosine deaminase** EC 3.5.4.4; systematic name: adenosine aminohydrolase; an enzyme that catalyses the hydrolysis of adenosine to inosine and NH<sub>3</sub>. It is involved in the degradation of adenosine, the inosine thereby formed being then converted to hypoxanthine and thence to uric acid. The enzyme is also found on the outer surface of T cells, and a form that acts on double-stranded RNA (dsRNA) converts adenosines to inosines within dsRNA. Example from mouse, 3-D structure with 6-hydroxy-1,6-dihydropurine ribonucleoside: database code NRL\_IADA, 349 amino acids (39.62 kDa).

**adenosine diphosphatase** *see* apyrase.

**adenosine 5'-diphosphate** symbol: Ad05'PP or ppA; the recommended name for adenosine diphosphate (abbr.: ADP); 5'-diphosphoadenosine; 5'-adenylyl phosphate; adenosine 5'-trihydrogen diphosphate); a universally distributed nucleotide that occurs both in the free state and as a component

## adenosinediphosphoglucose

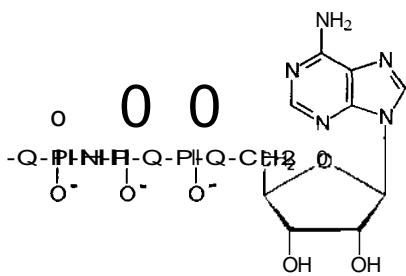

of certain nucleotide coenzymes. It is a metabolic precursor of adenosine 5'-triphosphate, ATP, and is the product of many enzyme reactions in which ATP is hydrolysed by an adenosine triphosphatase or in which the terminal phosphoric residue of ATP is transferred to another organic compound by a kinase (including adenylate kinase).

**adenosinediphosphoglucose** or adenosine (5')diphospho(1)-*a*-D-glucose symbol: *AdoPPGlc* or *Ado-5'PP-Glc* or *A5'ppIGlc*; the alternative recommended names for adenosine diphosphate glucose (abbr.: ADPG or ADP-Glc or ADPglucose); adenosine 5'-(*a*-D-glucopyranosyl diphosphate);  $\alpha$ -D-glucopyranosyl 5'-adenylyl phosphate; a nucleoside-diphosphosugar in which the distal phosphoric residue of adenosine 5'-diphosphate is in glycosidic linkage with glucose. ADPglucose is synthesized from glucose I-phosphate and adenosine 5'-triphosphate, ATP, through the action of glucose I-phosphate adenylyltransferase (EC 2.7.7.27). It is an intermediate in the incorporation of glucosyl groups into starch in plants and into storage glucans in bacteria.

**adenosinediphosphoribose** or adenosine(5')diphospho(5)-P-D-ribose symbol: *AdoPPRib* or *A5'pp5Rib* or *(Rib5)ppA*; the alternative recommended names for adenosine diphosphate ribose (abbr.: ADP-Rib or ADPructose); adenosine 5'-(P-D-ribofuranose 5-diphosphate); a nucleoside diphosphosugar in which the explicit sugar moiety is a second residue of D-ribose and is in ester linkage with the distal phosphoric residue of adenosine 5'-diphosphate atypically at C-5 instead of at C-1. ADP-ribose is synthesized from D-ribose 5-phosphate and ADP through the action of ribose-5-phosphate adenylyltransferase (EC 2.7.7.35), releasing orthophosphate. In addition, free ADP-ribose is released from nicotinamide-adenine dinucleotide, NAD<sup>+</sup>, on hydrolytic cleavage of the glycosylamine bond to nicotinamide through the action of NAD<sup>+</sup> nucleosidase (EC 3.2.2.5). See also cyclic adenosinediphosphoribose.

**adenosinediphosphoribosyl** abbr.: ADPribosyl; the glycosyl group formally derivable from adenosinediphosphoribose by loss of the anomeric (i.e. C-I) hydroxyl group from its distal ribose moiety. The ADPribosyl group of nicotinamide-adenine dinucleotide may be utilized for ADP-ribosylation.

**adenosine 5'-IP,y-imidoltriphosphate** symbol: *AdoPP(NH)P* or *p[NH]ppA*; the recommended name for  $\beta$ ,y-imidoadenosine 5'-triphosphate (abbr.: ATP[fl,y-NH]); 5'-adenylyl imidodiphosphate; 5'-adenylyl iminodiphosphonate (abbr.: AMP-PNP); adenosine (5'→O<sup>3</sup>)-1,2-μ-imidotriphosphate; a synthetic analogue of adenosine triphosphate, in which the oxy group between the latter's intermediate and terminal phosphorus atoms is replaced by an imido group. It competitively inhibits ATP-dependent enzymes, including mitochondrial ATPase.

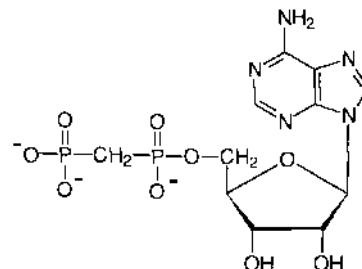

adenosine kinase EC 2.7.1.20; an enzyme that catalyses the reaction:

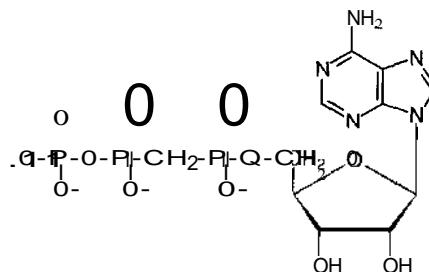

**adenosine 5'-[a,p-methylene]diphosphate** symbol: *AdoP(CH<sub>2</sub>)P* or *p(CH<sub>2</sub>)pA*; the recommended name for  $\alpha$ , $\beta$ -methyleneadenosine 5'-diphosphate (abbr.: ADP[a,J-CH<sub>2</sub>]); 5'-adenylyl methylenephosphonate (abbr.: AMP-CP); adeno-

## adenosine 5'-[β,y-methylenetriphosphate]

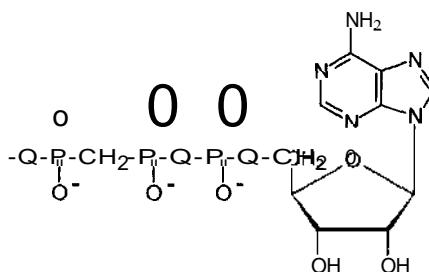

sine (5'→O<sup>1</sup>)-I,2- $\mu$ -methylenediphosphate; a synthetic analogue of adenosine 5'-diphosphate, ADP, in which the oxy group between the latter's two phosphorus atoms is replaced by a methylene group. It inhibits 5'-nucleotidase obtained from rat-heart membranes.

**adenosine 5'-Ia,p-methylenetriphosphate** symbol: *AdoP(CH<sub>2</sub>)PP* or *pp(CH<sub>2</sub>)pA*; the recommended name for  $\alpha$ , $\beta$ -methyleneadenosine 5'-triphosphate (abbr.: ATP[a,J-CH<sub>2</sub>]); 5'-adenylyl methylenediphosphate (abbr.: AMP-CPP); adenosine (5'→O<sup>1</sup>)-I,2- $\mu$ -methylenetriphosphate; a synthetic analogue of adenosine 5'-triphosphate, ATP, in which the oxy group between the latter's innermost and intermediate phosphorus atoms is replaced by a methylene group. It competitively inhibits rat-liver adenylate cyclase.

**adenosine 5'-[β,y-methylene]triphosphate** symbol: *AdoPP(CH<sub>2</sub>)P* or *p(CH<sub>2</sub>)ppA*; the recommended name for  $\beta$ , $\gamma$ -methyleneadenosine 5'-triphosphate (abbr.: ATP[J,y-CH<sub>2</sub>]); 5'-adenylyl methylenediphosphonate (abbr.: AMP-PCP); adenosine (5'→O<sup>1</sup>)-1,2- $\mu$ -methylenetriphosphate; a synthetic analogue of adenosine 5'-triphosphate, ATP, in which the oxy group between the latter's intermediate and terminal phosphorus atoms is replaced by a methylene group. It inhibits the binding of ouabain to Na<sup>+</sup>/K<sup>+</sup>-transporting ATPase, the sodium pump.

## adenosine monophosphate

adenosine monophosphate *abbr.*: AMP; *an alternative name for* any adenosine phosphate, but in particular for adenosine 5'-phosphate, especially when its distinction from adenosine (5')-diphosphate and adenosine (5')-triphosphate requires emphasis.

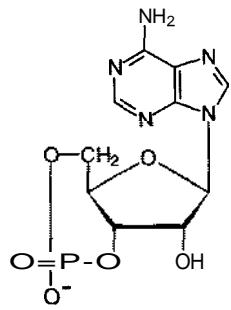

adenosine phosphate *symbol*: AdoP; adenosine monophosphate (*abbr.*: AMP); any phosphoric monoester or diester of adenosine. There are three monoesters - adenosine 2'-phosphate, adenosine 3'-phosphate, and adenosine 5'-phosphate - and two diesters - adenosine 2',3'-phosphate and adenosine 3',5'-phosphate - although adenosine 5'-phosphate is the ester commonly denoted (the locant being omitted if no ambiguity may arise). Adenosine 2'-phosphate (*symbol*: Ado2'P) is also named adenosine 2'-monophosphate (*abbr.*: 2'AMP) or 2'-adenylic acid or adenylic acid a, and adenosine 3'-phosphate (*symbol*: Ado3'P) is also named adenosine 3'-monophosphate (*abbr.*: 3'AMP) or 3'-adenylic acid or adenylic acid b or (*formerly*) yeast adenylic acid.

adenosine 2'-phosphate *see* adenosine phosphate.

adenosine 2',3'-phosphate *see* adenosine phosphate.

adenosine 3'-phosphate *see* adenosine phosphate.

adenosine 3',5'-phosphate *symbol*: Ado-3',5'-P; *the recommended name for* cyclic adenosine 3',5'-monophosphate (*abbr.*: cyclic AMP or cAMP); adenosine 3',5'-cyclophosphate; adenosine 3',5'-(cyclic)phosphate; a monophosphoric diester of adenosine. It is a universally distributed key metabolite, produced by the action of adenylate cyclase on adenosine 5'-triphosphate, ATP. The first compound to be named a second messenger, it mediates many effects in signal transduction pathways. It was first identified as a heat-stable activator of glycogen phosphorylase kinase, and is now known also to activate cyclic-AMP-dependent protein kinase and to regulate numerous other enzymic activities or physiological processes.

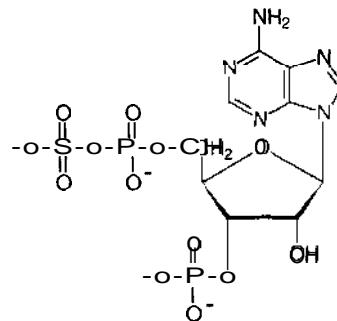

adenosine 5'-phosphate or 5'-adenylic acid or 5'-phosphoadenosine or 5'-O-phosphoadenosine *symbol*: Ado5'P; *alternative recommended names for* adenosine 5'-monophosphate (*abbr.*: 5'AMP); adenosine 5'-(dihydrogen phosphate); adenosine (mono)ribonucleotide or (*formerly*) muscle adenylic acid. (The locant is commonly omitted if there is no ambiguity as to the position of phosphorylation.) It is a metabolic regulator, biosynthesized from inosine 5'-phosphate, 5'-inosinic acid; it is formed also by pyrophosphatase-catalysed cleavage of (inorganic) diphosphate from ATP.

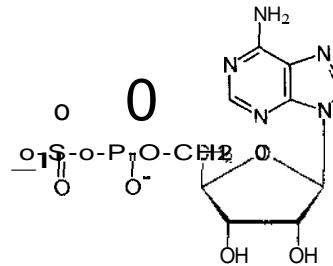

adenosine 3'-phosphate 5'-phosphosulfate or 3'-phosphoadenosine 5'-phosphosulfate *symbol*: PAdoPS; *abbr.*: PAPS; *alternative recommended names for* active sulfate; 3'-phospho-5'-adenylyl sulfate; adenosine 3'-phosphate 5'-P-phosphatosulfate; 3'-phospho-5'-adenylic sulfuric monoanhydride; a naturally occurring mixed anhydride. It is synthesized from adenosine 5'-phosphosulfate by phosphorylation with ATP through the action of adenylylsulfate kinase (EC 2.7.1.25). It is an intermediate in the formation of a variety of sulfo compounds in biological systems. For example, in animals it is involved in sulfate transfer in the formation of sulfatides and in

## adenosine 5'-P-thiodiphosphate

the synthesis of chondroitin sulfate and other sulfated polysaccharides, while in bacteria, by a process analogous to that involving adenosine 5'-phosphosulfate in plants, adenosine 3'-phosphate 5'-phosphosulfate interacts with reduced thioredoxin to yield adenosine 3',5'-bis(phosphate) and sulfite; the latter can then undergo further reduction to sulfide, from which cysteine may be synthesized.

adenosine 5'-phosphosulfate *symbol*: AdoPS; *abbr.*: APS; *the recommended name for* 5'-adenylyl sulfate; adenosine 5'-P-phosphatosulfate; 5'-adenylic sulfuric monoanhydride. It is synthesized from ATP and (inorganic) sulfate by the action of sulfurylase, sulfate adenyllyltransferase (EC 2.7.7.4), and is an intermediate in the formation of adenosine 3'-phosphate 5'-phosphosulfate. In plants, by a process analogous to that involving adenosine 3'-phosphate 5'-phosphosulfate in bacteria, adenosine 5'-phosphosulfate can undergo reduction to yield sulfide, which may then be utilized for cysteine synthesis.

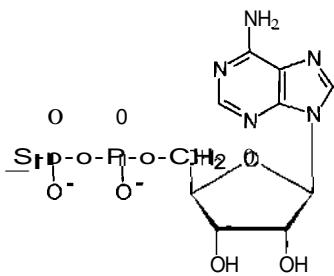

adenosine receptor or PI purinoceptor one of three types, A<sub>1</sub>, A<sub>2</sub>, and A<sub>3</sub> of membrane protein that bind adenosine or its analogues; they are seven-transmembrane-domain proteins. The selective agonist for A<sub>1</sub> is N<sup>6</sup>-cyclopentyladenosine; that for A<sub>2</sub> is (2-p-carboxyethyl)phenylamino-5'-N-carboxamidoadenosine. Binding of agonist to A<sub>1</sub> causes inhibition of adenylate cyclase, opening of K<sup>+</sup> channels, and inhibition of Ca<sup>2+</sup> channels. Activation of A<sub>2</sub> brings about stimulation of adenylate cyclase. Activation of A<sub>3</sub> causes stimulation of adenylate cyclase. In some cases, particularly where A<sub>1</sub> receptors are involved, inositolphospholipid turnover may be stimulated. Examples (all from human): A<sub>1</sub> receptor; database code AA1R\_HUMAN, 326 amino acids (36.15 kDa); A<sub>2A</sub> receptor; database code AA2A\_HUMAN, 412 amino acids (44.71 kDa); A<sub>3</sub> receptor; database code AA3R\_HUMAN, 318 amino acids (36.18 kDa). *See also* purinoceptor.

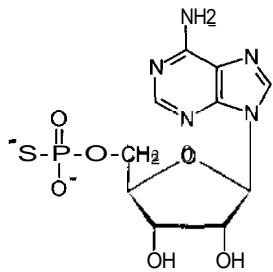

adenosine **5'-β-thiodiphosphate** *symbol*: AdoPP[S] or [S]ppA; *abbr.*: ADP[S] or ADP-p-S; *the recommended name for* adenosine 5'-[P-thio]diphosphate; adenosine 5'-(2-thiodiphosphate); adenosine (5'→O<sup>2</sup>)-1-thiodiphosphate; a synthetic

## adenosine 5'-thiophosphate

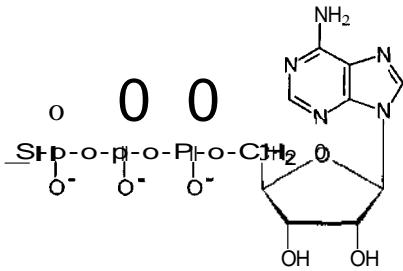

analogue of adenosine 5'-diphosphate, ADP, in which an oxygen atom of its terminal phosphoric residue is replaced by a sulfur atom. It acts variously as a substrate or an inhibitor of ADP-dependent systems.

**adenosine 5'-thiophosphate** symbol: AdoP[S] or [S]pA; the recommended name *Jor* adenosine 5'-[a-thio]monophosphate (abbr.: AMP-S); a synthetic analogue of adenosine S'-phosphate, AMP, in which an oxygen atom of its phosphoric residue is replaced by a sulfur atom. It acts variously as a substrate or an inhibitor of AMP-dependent systems.

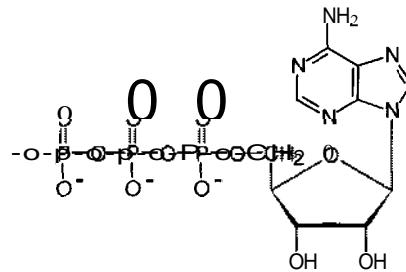

**adenosine 5'-y-thiotriphosphate** symbol: AdoPPP[S] or [S]pppA; abbr.: ATP[S] or ATP-y-S; the recommended name *Jor* adenosine S'-[y-thio]triphosphate; adenosine ( $S' \rightarrow O^3$ )-1-thiotriphosphate; a synthetic analogue of adenosine 5'-triphosphate, ATP, in which an oxygen atom of its terminal phosphoric residue is replaced by a sulfur atom. It can variously substitute for ATP or act as an inhibitor of ATP-dependent systems.

**adenosinetriphosphatase** abbr.: ATPase; 1 EC 3.6.1.3; ATP phosphohydrolase; an enzyme catalysing the hydrolysis of ATP to ADP and orthophosphate. 2 any of various enzymes listed separately as EC 3.6.1.32 to EC 3.6.1.38. Some function as exchangers or transporters for  $\text{Na}^+$ ,  $\text{K}^+$ , or  $\text{Ca}^{2+}$  (see calcium-transporting ATPase, sodium-potassium ATPase); myosin ATPase (EC 3.6.1.32) is involved in muscle contraction;  $\text{H}^+$ -

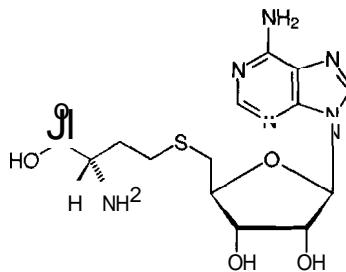

## 5-adenosylmethionine

transporting ATP synthase (also called mitochondrial or chloroplast ATPase) (EC 3.6.1.34) is involved in ATP synthesis.  
**adenosine 5'-triphosphat8 symbol:** AdoS'PPP or pppA; the recommended name *Jor* adenosine triphosphate (abbr.: ATP); 5'-triphosphoadenosine; 5'-adenylyl diphosphate; adenosine S'-(tetrahydrogen triphosphate); a universally important coenzyme and enzyme regulator. It is formed from adenosine S'-diphosphate by oxidative phosphorylation in coupled mitochondria, by photophosphorylation in plants, and by substrate-level phosphorylation. Reactions in which it participates are often driven in the direction leading to hydrolysis of ATP. The chemical energy so released may be utilized in active transport; it may be converted to mechanical energy (e.g. for muscular contraction, movement of cilia, etc.), to light energy (for bioluminescence), or to electrical energy (in electric fish); or it may be released as heat. ATP also participates in numerous synthetic reactions by the transfer to other metabolites of a phosphoric or a diphosphoric residue, of an adenosyl residue, or of an adenylyl residue.

**adenosyl** any chemical group formed by the loss of a 2', a 3', or a 5'-hydroxyl group from the ribose moiety of adenosine. Compare adenylyl.

**\$-adenosylhomocysteine** the L enantiomer, *S*-(5'-adenosyl)-L-homocysteine (symbol: AdoHcy; abbr.: SAH), *S*-(S'-deoxyadenosine-S'-yl)-L-homocysteine, is formed from *S*-adenosylmethionine. It is a strong inhibitor of *S*-adenosylmethionine-mediated methylation reactions and is cleaved to adenosine and homocysteine.

***S*-adenosylmethionine** the L enantiomer, active methionine, *S*-(*S*'-adenosyl)-L-methionine (symbol: AdoMet; abbr.: SAM), *S*-(5'-deoxyadenosine-5'-yl)-L-methionine, is an important intermediate in one-carbon metabolism, the methionine's methyl group (activated by the adenosyl moiety bonded through sulfonium) being donated to an acceptor molecule by transmethylation and *S*-adenosylhomocysteine being produced. It is important also as an intermediate in the production of ethylene from L-methionine in plants, being cleaved to *S*'-methylthioadenosine and I-aminocyclopropane-l-carboxy-

**adenosylmethionine decarboxylase**

late. The latter compound is then fragmented under aerobic conditions to ethylene, formate, ammonium, and carbon dioxide.

**adenosylmethionine decarboxylase** EC 4.1.1.50; *systematic name*: S-adenosyl-L-methionine carboxy-lyase. An enzyme of polyamine (and hence trypanothione) biosynthesis that catalyses the decarboxylation of S-adenosyl-L-methionine to (5'-deoxyadenosin-5'-yl)(3-aminopropyl)methylsulfonium salt; pyruvate acts as a cofactor. The product participates in reactions in which its 3-aminopropyl group is transferred to putrescine to form spermidine, and a second 3-aminopropyl group is then transferred to spermidine to form spermine. In most cases its subunits ( $\alpha$  and  $\beta$ ) are derived from a single proenzyme. Example from yeast: database code DCAM\_YEAST, 396 amino acids (46.18 kDa);  $\alpha$ , 1-87;  $\beta$ , 88-end.

**5-adenosylmethionine synthetase** see methionine adenosyltransferase.

**adenovirus** any of a group of non-enveloped icosahedral viruses, the Adenoviridae, containing linear double-stranded DNA. They affect mammals or birds (usually being specific to one or a few closely related host species) and are often associated with disease of the respiratory tract.

**adenyl** a misnomer for adenylvl or adenylate.

adenylate 1 either the monoanion or the dianion of adenylic acid. 2 any mixture of the acid and its anions. 3 any salt or ester of adenylic acid.

**adenylate cyclase** or adenylylcyclase or (sometimes, incorrectly) adenyl cyclase EC 4.6.1.1; *systematic name*: ATP pyrophosphate-lyase (cyclizing); a phosphorus-oxygen lyase enzyme that catalyses the elimination of a moiety of diphosphate from a molecule of adenosine 5'-triphosphate (ATP) to form adenosine 3',5'-phosphate (cyclic AMP). It thereby is involved as an effector of signal transduction and other fundamental regulatory mechanisms. Its distribution is very wide, as also is its structural variation and the variation of its properties among the different forms. In mammals it is a membrane-bound glycoprotein, the various isoforms being in the mass range 115 to 180 kDa. They all have a predicted general structure indicating two structurally related cytoplasmic domains, relatively well conserved among the isoforms, having homology to the guanylate cyclase catalytic domain. One of them bears an ATP-binding site. In addition they have two membrane-spanning domains, each of which contains six membrane spans, the sequence differing significantly among the isoforms. Types I to VI have been described. Type I, 1134 amino acids, is brain-specific,  $\text{Ca}^{2+}$ /calmodulin activated, and inhibited by G-protein  $\beta\gamma$  subunits. Types II (1088 amino acids) and IV (1064 amino acids) are calmodulin insensitive and activated by  $\beta\gamma$  subunits; type II is found in brain and olfactory tissue, type IV is widely distributed except in testis. Type III, from olfactory sensory neurons, is calmodulin sensitive and not regulated by  $\beta\gamma$  subunits. Types V and VI form a subgroup that is widely distributed and not stimulated by  $\beta\gamma$  subunits.

*Saccharomyces cerevisiae* enzyme (2026 amino acids) has a weak structural relationship with the mammalian enzyme. It is positively regulated by the *RAS1* and *RAS2* gene products, but this property is not shared by a recombinant enzyme from *Schizosaccharomyces pombe*. A plant gene has been cloned, the deduced protein sequence having no similarity to prokaryotic counterparts, but showing striking similarity to the catalytic region of *S. cerevisiae* adenylylcyclase, and with the cytoplasmic domains of bovine adenylylcyclase and two mammalian guanylylcyclases. Soluble adenylylcyclases are found in some bacterial toxins. Example from *Escherichia coli*: database code CYAA\_ECOLI, 848 amino acids (97.43 kDa). Example from human: database code HSADCYCL, 476 amino acids (53.37 kDa).

**adenylate energy charge** (or energy charge) a measure of the phosphorylating power of an adenylyl pool, equal to one half the average number of anhydride-bound phosphoric groups per adenosine moiety present in the pool. It may be defined in

**adhesion molecules**

terms of the concentrations of AMP, ADP, and ATP in the pool and expressed by the quotient:

$$([ATP] + 0.5[ADP])/([ATP] + [ADP] + [AMP]).$$

Compare phosphorylation state ratio.

**adenylate isopentenyltransferase** EC 2.5.1.27; *other name*: cytokinin synthase; an enzyme that catalyses the reaction between A2-isopentenyl diphosphate and AMP to form ( $N^6\text{-A}^2$ -isopentenyl)adenosine 5'-monophosphate, an intermediate in the formation of zeatin riboside, and pyrophosphate. Example from *Agrobacterium vitis* plasmid pTIS4: database code S30106, 236 amino acids (25.81 kDa).

**adenylate kinase** abbr. (in clinical biochemistry): AK; EC 2.7.4.3; *systematic name*: ATP:AMP phosphotransferase; *other name*: myokinase. An enzyme that catalyses the reaction:

Example, adenylate kinase isoenzyme I (human): database code KADI\_HUMAN, 194 amino acids (21.65 kDa), five motifs.

**adenylate pool** or adenylyl system the total amount of AMP, ADP, and ATP in a cell, tissue, or organism.

**adenyl cyclase** a misnomer for adenylylcyclase.

**adenylic acid** the trivial name for any phosphoric monoester of adenosine. The position of the phosphoric residue on the ribose moiety of a given ester may be specified by a prefixed locant; see adenosine phosphate, adenosine. However, 5'-adenylic acid is the ester commonly denoted, its locant usually being omitted if no ambiguity may arise. 5'-Adenylic acid is also an alternative recommended name for adenosine 5'-phosphate.

**adenylyl** the adenosine[mono]phospho group; the acyl group derived from adenylic acid (see adenosine 5'-monophosphate). Compare adenosyl.

**adenylylate** to introduce adenylyl groups into a compound generally through the action of an adenylyltransferase. -adenylylated adj.; adenylylation n.

**adenylyl cyclase** a misnomer for adenylylcyclase.

**adenylyl sulfate** see adenosine 5'-phosphosulfate

**adenylylsulfate kinase** EC 2.7.1.25; *other name*: APS kinase; an enzyme that synthesizes 3'-phosphoadenosine-5'-phosphosulfate from ATP and adenylylsulfate with release of ADP. Example from yeast: KAPS\_YEAST, 202 amino acids (23.03 kDa). See phosphoadenosine-5'-phosphosulfate.

**adenylyltransferase** generic name for any of a number of enzymes within sub-subclass EC 2.7.7, nucleotidyltransferases, that are specific for the transfer of an adenylyl group from a donor (usually adenosine triphosphate, ATP) to an acceptor (such as a nucleotide, a polynucleotide, a protein, a sugar phosphate, or sulfate); e.g. FMN adenylyltransferase (EC 2.7.7.2), ribose-5-phosphate adenylyltransferase (EC 2.7.7.35).

**ADH** abbr. for: 1 antidiuretic hormone. 2 (in clinical biochemistry) alcohol dehydrogenase (preferred form: AD).

**adhalin** or DAG2 a dystrophin-associated glycoprotein of skeletal muscle sarcolemma that is specifically deficient in severe childhood autosomal recessive muscular dystrophy. It has a 17-residue signal sequence and one transmembrane domain, and there are two sites for N-linked glycosylation. Example from rabbit: database code OCDAGII, 387 amino acids (42.45 kDa).

**adherens junction** a cell junction in which the cytoplasmic face of the plasma membrane is attached to actin filaments.

**adhesion** (in pathology) the abnormal union of surfaces or parts, usually due to the formation of fibrous tissue following inflammation.

**adhesion molecules** molecules expressed on the surface of a cell that mediate the adhesion of the cell to other cells or to the extracellular matrix. They bind to receptors, classed collectively as integrins. Adhesion molecules are grouped into classes such as selectins; the immunoglobulin superfamily, which includes ICAM, MadCAM, NCAM, PECAM, and VCAM; the

## adiabatic

cadherins; and CD44. Adhesion molecules play a part in morphogenesis (e.g. cadherins) and in the treatment of inflammation and wounds (e.g. selectins and the immunoglobulin superfamily).

**adiabatic** describing any thermodynamic process that occurs with neither gain nor loss of heat between the system and its surroundings. -adiabatically *adv.*

**adiabatic calorimeter** a calorimeter in which the temperature of the outer jacket is kept as close as possible to that of the inner compartment so that heat losses from the latter are minimized.

**adiabatic system** (*in thermodynamics*) any geometrically defined volume that does not exchange thermal energy with its surroundings. *Compare* closed system, open system.

**adipocyte** a cell of adipose tissue; a fat cell or lipocyte of an animal.

**adipogenesis** the formation of fat or adipose tissue.

**adipokinetic** fat-mobilizing; lipotropic.

**adipokinetic hormone** *abbr.:* AKH; *an alternative name for* lipotropin.

**adipose tissue** fat or fatty tissue. *See also* brown adipose tissue, white adipose tissue.

**adipsin** *1 another name for* complement factor D. *2 a protein of the serine endopeptidase family secreted into serum by adipocytes. It is expressed abundantly in adipocytes and sciatic nerve. There are two forms, of M<sub>r</sub> 37 000 and 44 000.*

**adiuretin** (*sometimes*) *an alternative name for* antidiuretic hormone. **adjuvant** *1 (in immunology)* any substance or mixture of substances that increases or diversifies the immune response to an antigen. *See also* Freund's adjuvant. *2 (in pharmacology)* any remedy or drug that assists or modifies the action of other remedies or drugs.

**adjuvant peptide** *an alternative name for* muramyl-dipeptide.

**ad lib** without restraint. Short for the Latin *ad libitum*, meaning literally 'at pleasure'.

**A-DNA** *abbr. for* A-form of DNA.

**Ado** *symbol for* a residue of the ribonucleoside adenosine (alternative to A).

**AdoHcy** *symbol for* S-adenosylhomocysteine.

**AdoMet** *symbol for* S-adenosylmethionine.

**adonitol** *a former name for* ribitol.

**adenose** *a former name for* ribulose.

**AdoP** *symbol for* any adenosine phosphate.

**Ado2'P** *symbol for* adenosine 2'-phosphate.

**Ado-2',3'-P** *symbol for* adenosine 2',3'-phosphate.

**Ado3'P** *symbol for* adenosine 3'-phosphate.

**Ado-3',S'-P** *symbol for* adenosine 3',5'-phosphate.

**AdoS'P** *symbol for* adenosine S'-diphosphate (alternative to pAdo).

**AdoP[CH<sub>2</sub>]P** *symbol for* adenosine 5'-[a,fl-methylene]diphosphate (alternative to p[CHz]pA).

**AdoP[CH<sub>2</sub>]PP** *symbol for* adenosine S'-[a,p-methylene]triphosphate (alternative to pp[CHz]pA).

**Ado5'PP** *symbol for* adenosine S'-diphosphate (alternative to ppA).

**AdoPP[CH<sub>2</sub>]P** *symbol for* adenosine 5'-[p,y-methylene]triphosphate (alternative to p[CHz]ppA).

**AdoPPGlc** or **Ado-5'PP-Glc** *symbol for* adenosinediphosphoglucose (alternatives to AS'ppl Glc).

**AdoPP[NH]P** *symbol for* adenosine S'-[p,y-imido]triphosphate (alternative to p[N]ppA).

**AdoS'PPP** *symbol for* adenosine S'-triphosphate (alternative to pppA).

**AdoPP[S]** *symbol for* adenosine S'-P-thiodiphosphate (alternative to [S]ppA).

**AdoP[S]** *symbol for* adenosine 5'-thiophosphate (alternative to [S]pA).

**AdoPPP[S]** *symbol for* adenosine 5'-y-thiotriphosphate (alternative to [S]pppA).

**AdoPPRib** *symbol for* adenosine diphosphoribose (alternative

to AS'ppSRib or (RibS)ppA).

**AdoPS** *symbol for* adenosine 3'-phosphate 5'-phosphosulfate. adoptive immunity *immunity conferred by transfer of immunologically active cells from one individual to another. ADP abbr. for* adenosine S'-diphosphate.

**ADPase** *abbr. for* adenosine diphosphatase (*see* apyrase).

**ADP**, **ATP carrier protein** or adenine nucleotide translocase an integral membrane protein of the inner mitochondrial membrane, responsible for the transport of ADP and ATP across the membrane. It exchanges one molecule of ADP<sup>3-</sup> for one molecule of ATP<sup>4-</sup>, and is thought to be driven by the proton gradient established across the inner membrane. It is a homodimer, each chain having three homologous domains. Different types occur in different mammalian tissues but all are related. Example, muscle isoform I (human): database code ADTI\_HUMAN, 298 amino acids (33.03 kDa).

**ADP[α,β-CH<sub>2</sub>]** *abbr. for* a,p-methyleneadenosine 5'-diphosphate; i.e. adenosine 5'-[a,p-methylene]diphosphate.

**ADPG** *abbr. for* adenosinediphosphoglucose; ADP-Glc is preferred.

**ADP-Glc** or **ADPglucose** (*preferred*) *abbr. for* adenosine-diphosphoglucose; *see also* ADPG.

**ADP-Rib** or **ADPribose** *abbr. for* adenosinediphosphoribose.

**ADP-ribose** (*cyclic*) *see* cyclic adenosine 5'-diphosphoribose.

**ADPribosyl** *abbr. for* the adenosinediphosphoribosyl group.

**ADP-ribosylation** the transfer of one or more adenosine-diphosphoribosyl (*abbr. ADPribosyl*) groups from nicotinamide-adenine dinucleotide, NAD<sup>+</sup>, to a protein through the action of an ADP-ribosyltransferase. In eukaryotic cells the transfer occurs particularly to the  $\alpha$  subunits of G proteins, and then is stimulated by treatment with certain bacterial toxins such as cholera toxin or pertussis toxin. Linear poly(ADPribosyl) attachments, which may consist of up to 50 ADPribose units, are found on nuclear proteins and also on some cytoplasmic proteins. In the stepwise generation of such attachments an incoming ADPribosyl group forms a (12') glycosidic bond to the nucleosidic ribose moiety of the most recently attached ADP-ribose unit. ADP-ribosylation occurs also in cells of *Escherichia coli* infected with bacteriophage T4, where single ADPribosyl groups become attached to the host's RNA polymerase. --ADP-ribosylated *adj. See also* ADP-ribosyltransferase, NADP(+)-arginine ADP-ribosyltransferase.

**ADP-ribosylation factor** a protein that acts as activator for ADP-ribosyltransferase. Example (human and bovine): cholera toxin activator: database code ARFI\_HUMAN, 181 amino acids (20.67 kDa).

**ADP-ribosyltransferase** EC 2.4.2.30; *recommended name: NAD+ ADP-ribosyltransferase; systematic name: NAD+: poly(adenine-diphosphate-D-ribosyl)-acceptor ADP-D-ribosyl-transferase; other names: poly(ADP) polymerase; poly(adenosine diphosphate ribose) polymerase; NAD+ ADP-ribosyltransferase (polymerizing); poly(ADP-ribose) synthetase; abbr.: PARP or ADPRT. An enzyme that catalyses a reaction between NAD<sup>+</sup> and (ADP-D-ribosyl)n+1-acceptor to form nicotinamide and (ADP-D-ribosyl)n+1-acceptor. The enzyme acts on a number of nuclear proteins and thereby regulates events in differentiation and cell proliferation. The presence of DNA is necessary, and zinc is a cofactor. Example from *Bos taurus*: database code PPOL\_BOVIN, 1015 amino acids (113.36 kDa).*

**ADP[S]** or **ADP-β-S** *abbr. for* adenosine 5'-P-thiodiphosphate. adren+ or adreno+ *comb. form* denoting 1 the adrenal glands. 2 epinephrine or a related catecholamine.

**adrenal** 1 pertaining to or produced by the adrenal glands. 2 the adrenal gland itself.

**adrenal androgen** any of the C<sub>19</sub> steroid hormones produced in the cortex of the adrenal gland, including androstenedione and testosterone.

**adrenal cortex** *see* adrenal gland.

**adrenal cortical hormone** or adrenocortical hormone any (cor-

## adrenalectomize

tico)steroid hormone elaborated and secreted by the cortex of the adrenal gland.

**adrenalectomize or adrenalectomise** to carry out adrenalectomy. -adrenalectomized or adrenalectomised *adj.*

**adrenalectomy** surgical removal of one or (usually) both adrenal glands.

**adrenal gland** or (less commonly) suprarenal gland an endocrine organ in vertebrates. There is a single pair in mammals, one near each kidney; in other vertebrates there may be multiple adrenal glands. The gland has two components: an inner medulla, derived from the neural crest, that biosynthesizes and secretes epinephrine and norepinephrine; and an outer cortex, derived from the coelom, that is concerned in the biosynthesis and secretion of steroid hormones. The cortex consists in turn of three histologically defined zones: an outer zona glomerulosa, the cells of which are responsible for the biosynthesis of aldosterone and deoxycorticosterone; an intermediate zona fasciculata; and an inner zona reticularis. The cells of the zona fasciculata and zona reticularis are responsible for the biosynthesis of the glucocorticoid cortisol and the androgens dehydroepiandrosterone and androstenedione.

adrenaline *see* epinephrine.

**adrenal medulla** *see* adrenal gland.

**adrenal medullary hormone** any catecholamine hormone elaborated and secreted by the adrenal medulla. *See* adrenal gland.

**adrenergic** 1 describing a nerve or other cell, or cell receptor (*see* adrenoceptor) that is activated by epinephrine, norepinephrine, or an epinephrine-like substance. 2 any nerve that acts by releasing epinephrine, norepinephrine, or an epinephrine-like substance from its nerve ending. *See also* cholinergic, GABAergic, noradrenergic, peptidergic, purinergic, serotonergic. -adrenergically *adv.*

**adrenergic receptor** *an alternative term for* adrenoceptor.

**p-adrenergic-receptor kinase abbr.:  $\beta$ ARK,  $\beta$ AR kinase or BARK; EC 2.7.1.126;** an enzyme that phosphorylates specifically only the agonist-occupied form of the  $\beta$ -adrenoceptor and closely related receptors at the C terminus. It appears to be important in mediating rapid agonist-specific (homologous) desensitization. Its cDNA codes for a precursor protein of 689 amino acids, database code ARKLHUMAN (79.58 kDa). The purified protein migrates as a single band of 80 kDa on electrophoresis. It has a protein kinase catalytic domain that has sequence similarity to protein kinase C and cyclic AMP-dependent protein kinase.

**adrenic acid** *see* docosatetraenoic acid

**adreno+** *see* adren+.

**adrenoceptor or adrenergic receptor or adrenoreceptor or adrenotropic receptor** any receptor on an effector cell that is activated by epinephrine or related catecholamines. Structurally they are all of the seven-transmembrane-domain type. Adrenoceptors may be classified phenomenologically into different types according to their sensitivities to agonists and antagonists.

**$\alpha$**  Adrenoceptors have a relative order of agonist potency: epinephrine  $\geq$  norepinephrine  $>$  isoproterenol (isoproterenol), and a relative order of antagonist potency: phentolamine  $\gg$  propranolol. They are associated with stimulatory effects such as vasoconstriction and contraction of the iris, initiating membrane, urinary bladder, seminal vesicles, and vas deferens and with relaxation of propulsive smooth muscle in the gut. In some species they mediate stimulation of gluconeogenesis and hepatic glycogenolysis. There are two groups,  $\alpha_1$  and  $\alpha_2$ :  $\alpha_1$  Receptors act through the phosphoinositide/Ca<sup>2+</sup> second messenger system and are of four subtypes:  $\alpha_1A$ , norepinephrine  $>$  epinephrine, 560 amino acids (rat);  $\alpha_1B$ , norepinephrine = epinephrine, 515 amino acids (rat);  $\alpha_1C$ , norepinephrine = epinephrine (different antagonist sensitivity from  $\alpha_1B$ ), 466 amino acids (bovine);  $\alpha_1D$ , 560 amino acids (rat).  $\alpha_2A$  Receptors all inhibit the formation of cyclic AMP; they also open K<sup>+</sup> chan-

## adsorptiochromism

nels and inhibit Ca<sup>2+</sup> channels; 450 amino acids (human).  $\alpha_2B$  Receptors inhibit Ca<sup>2+</sup> channels; 450 amino acids (human).  $\alpha_2C$  Receptors have no effect on ion channels; 461 amino acids (human). Examples:  $\alpha_1A$  receptor, database code A1AA\_HUMAN, 572 amino acids (60.46 kDa);  $\alpha_2A$  receptor (subtype c1O), database code A2AA\_HUMAN, 450 amino acids (48.96 kDa).

**$\beta$**  Adrenoceptors have actions that can be ascribed to the activation of adenylate cyclase. They may be divided phenomenologically into three classes: (1)  $\beta_1$  adrenoceptors, in which the relative order of agonist potency is isoprenaline  $>$  norepinephrine  $\geq$  epinephrine and the relative order of antagonist potency is practolol  $>$  propranolol. They are associated with cardiac stimulation and glycogenolysis, lipolysis in white adipose tissue, and calorigenesis in brown adipose tissue; (2)  $\beta_2$  adrenoceptors, in which the relative order of agonist potency is isoprenaline  $>$  epinephrine  $>$  norepinephrine and the relative order of antagonist potency is propranolol  $>$  practolol; they are associated with skeletal muscle glycogenolysis, promotion of secretion of glucagon and insulin, vasodepression, and bronchodilation; and (3)  $\beta_3$  adrenoceptors with agonist potency norepinephrine  $>$  epinephrine. Examples from human:  $\beta_1$ , database code BIAR\_HUMAN, 477 amino acids (51.16 kDa);  $\beta_2$ , database code B2AR\_HUMAN, 413 amino acids (46.50 kDa);  $\beta_3$ , database code B3AR\_HUMAN, 408 amino acids (43.47 kDa). *See also* p-adrenergic receptor kinase,  $\beta$ -arrestin.

**adrenoceptor kinase** *see* p-adrenergic receptor kinase.

**adrenocortical** of, pertaining to, or derived from the cortex of the adrenal gland, e.g. adrenocortical hormone. *See* adrenal androgen, corticosteroid.

**adrenocorticotrophic hormone or adrenocorticotrophic hormone abbr.: ACTH; an alternative name for corticotropin.**

**adrenocorticotrophic hormone-releasing factor an alternative name for corticotropin releasing hormone.**

**adrenocorticotropin or adrenocorticotrophin an alternative name for corticotropin.**

**adrenodoxin or (sometimes) adrenodoxin** a ferredoxin isolated from adrenal-cortex mitochondria that acts as an electron carrier in hydroxylase systems acting on steroids. It transfers electrons from adrenodoxin reductase to cholesterol monooxygenase. Example from *Bos taurus*: database code ADXLBOVIN, 186 amino acids (19.76 kDa); residues 1–58 are the mitochondrial transit sequence, 59–186 adrenodoxin. *See also* NADPH:adrenodoxin oxidoreductase precursor. *Compare* putidaredoxin.

**adrenodoxin reductase** *see* NADPH:adrenodoxin oxidoreductase precursor.

**adrenomedullary** of, pertaining to, or derived from the medulla of the adrenal gland.

**adrenomedullin** a hypotensive peptide that may function as a hormone in circulation control. Example from human: database code ADML\_HUMAN, 185 amino acids (20040 kDa).

**adrenoreceptor a variant spelling of adrenoceptor.**

**adrenoredoxin (sometimes) a variant spelling of adrenodoxin.**

**adrenosterone** androst-4-ene-3,11,17-trione; a hormone with weak androgenic effect, originally called Reichstein's substance G.

**adrenotropic receptor** *an alternative name for* adrenoceptor.

**adrex or adx abbr. for adrenalectomized.**

**adriamycin former (generic) name for doxorubicin.**

**adseverin another name for scinderin.**

**adsorb to undergo or elicit adsorption. -adsorbable adj.; adsorbability n.**

**adsorbate** a substance that is adsorbed to the surface of another substance from either a gas or a liquid phase.

**adsorbent** 1 capable of adsorption. 2 a solid that adsorbs another substance from either a gas phase or a liquid phase.

**adsorptiochromism** the colour change that sometimes ac-

**adsorption**

companies adsorption of organic compounds onto inorganic substances, e.g. onto alumina.

**adsorption** 1 any process in which a gas, liquid, or solute adheres to the exposed surfaces of a material, especially a solid, with which it is in contact. In physical adsorption the adhesion is through van der Waals forces of interaction, whereas in chemisorption (or chemical absorption) the adhesion is through formation of weak chemical bonds. *Compare* absorption. 2 (in immunology) the nonspecific attachment of an antigen (or antibody) onto the surfaces of red cells or inert particles so that the antibody (or antigen) to it may be detected by agglutination of the cells or particles. *Compare* immunosorption. 3 (in microbiology) the process of attachment of a phage or other virus to a cell.

**adsorption chromatography** any form of chromatography in which separation of the components of a mixture is based mainly on differences between the adsorption affinities of the components for the surface of an active solid.

**adsorption coefficient** in any adsorption equilibrium (of a substance from a solution), the mass of adsorbed substance per unit mass of adsorbent divided by the concentration of the substance in solution. It has the dimensions of reciprocal concentration. *Compare* distribution coefficient, partition coefficient.

**adsorption isotherm** any plot of the amount of solute adsorbed by an adsorbent (or of ligand bound by, e.g., a macromolecule, often expressed as the saturation fraction) versus the concentration of the free solute (or ligand), at constant temperature. *Compare* Langmuir adsorption isotherm.

**adx** see adrex.

**AEBSF** abbr for aminoethylbenzenesulfonyl fluoride.

**+aemia** see +emia.

**aequorin** a  $\text{Ca}^{2+}$ -dependent photoprotein responsible for luminescence by oxidation of the chromophore coelenterazine. It is obtainable from the hydrozoan jellyfish *Aequorea forskaolea*. In the absence of any other cofactors or oxygen it emits light on the addition of calcium ions, making it useful for the determination of free calcium ions. Example, aequorin I from *Aequorea victoria*: database code AEQ1\_AEQVI, 196 amino acids (22.49 kDa).

**aerate** 1 to supply with or expose to air. 2 to pass air through a liquid. -aeration *n.*

**aerobe** any organism or class of organisms that can grow in the presence of dioxygen. Facultative aerobes are also capable of growing in the absence of dioxygen, whereas obligate (or strict) aerobes have an absolute requirement for dioxygen. *Compare* anaerobe.

**aerobic** 1 describing conditions in which gaseous or dissolved dioxygen is present. 2 describing an organism or process that requires or is able to use dioxygen. 3 of or produced by an aerobe. *Compare* anaerobic.

**aerolysin** a channel-forming protein secreted by the human pathogen *Aeromonas hydrophila*. The cytolytic toxin is a dimer but forms stable heptameric structures that insert into lipid bilayers to produce well-defined channels, leading to destruction of the membrane permeability barrier and osmotic lysis. Example (precursor) from *A. hydrophila*: database code AERA\_AERHY, 493 amino acids (54.28 kDa).

**aerosol** a colloidal dispersion of solid particles or liquid droplets in air or another gas.

*Aet symbol* for the aminoethyl group,  $-\text{CH}_2-\text{CH}_2-\text{NH}_2$ .

**aetiology** see etiology.

**afamin** a mammalian serum protein similar to albumin,  $\alpha$ -fetoprotein, and vitamin D-binding protein. Example from human: database code HUMAFAMIN, 599 amino acids (68.99 kDa).

**afferent** 1 conveying inwards to a part, organ, or centre, as of a blood vessel, nerve, or duct. 2 an afferent part, e.g. an afferent blood vessel or afferent nerve. *Compare* efferent.

**affine** the quality of having affinity.

**affinity** 1 chemical attraction; the tendency of a chemical substance to combine with, bind to, or dissolve in other chemical

**affinity-purified**

substances. 2 any measure of such chemical attraction. 3 denoting biomolecular interaction that exhibits specificity. **affinity adsorbent** any biospecific adsorbent used in affinity chromatography.

**affinity chromatography** a general chromatographic method that may, in principle, be used to isolate either of the components of a reversibly reacting chemical system provided that one component can be coupled to an insoluble matrix through a covalent linkage. The other component can then be bound to the immobilized component and the system eluted with a buffer that liberates the bound component. The technique has been applied to the separation of various substances, including enzymes, substrates, antigens, antibodies, nucleic acids, and even whole living cells. Pure antibodies can be prepared by this means: the antigen is covalently coupled to the dextran beads in the chromatography column, the antibody-containing solution is run into the column in neutral buffer, the specific antibody binds to the antigen, and the antibody is subsequently released with a buffer of high or low pH or with a denaturing reagent. The technique can also be used to isolate antigen. *See also* affinity-elution chromatography, dye-ligand chromatography, -affinity-chromatographic ad).

**affinity constant** or **binding constant** an alternative name for association constant (especially in relation to the binding of and/or to macromolecules, as in antigen-antibody, hormone-receptor, and enzyme-inhibitor reactions).

**affinity cytochemistry** a technique for detecting the distribution of specific cell-surface receptors. An easily visible (or electron-dense) material conjugated with a reagent specific for a particular cell-surface receptor is allowed to react with the cells in question and is then detected by light or electron microscopy.

**affinity electrode** a type of electrode useful for assaying specific proteins. It comprises a metal (e.g. titanium) wire whose surface has been oxidized and then covalently attached to a ligand capable of interacting biospecifically and reversibly with the protein in question. Binding of the complementary protein to the electrode results in a measurable change in electrical potential relative to that given by a reference electrode. The latter is prepared in a similar way but lacks the specific ligand.

**affinity electrophoresis** or **affinoelectrophoresis** a type of electrophoresis in which the support medium contains an agent, immobilized by entrapment or by covalent linkage, that interacts specifically and selectively with certain of the components of the mixture to be analysed, thereby altering the electrophoretic mobility of those components.

**affinity-elution chromatography** a technique in which a compound that is nonspecifically bound to the matrix of a chromatographic column is specifically eluted by binding to a ligand in the eluting solvent. Biospecific-elution chromatography is a variant of this technique.

**affinity gel** any gel that serves as an affinity matrix.

**affinity-isolated** an alternative term for affinity-purified.

**affinity label** an active-site-directed irreversible inhibitor of an enzyme, antibody, or other protein. It is a chemically reactive compound that resembles a substrate or other specific ligand and bonds covalently to the active site or specific site on the protein. The affinity labelled groups can then be identified by fingerprinting and thus reveal the composition at the active site. It is sometimes termed Trojan horse inhibitor.

**affinity matrix** or **affinity support** any supporting material to which the biospecific reagent is attached in affinity chromatography.

**affinity precipitation** the precipitation of an enzyme by a homo- or hetero-bifunctional derivative of its coenzyme or/and a substrate or inhibitor. An example is the precipitation of lactate dehydrogenase by N2'-adipodihydrazido-bis-(N6-carboxymethyl-NAD), a reactive derivative of its coenzyme, NAD.

**affinity-purified** or **affinity-isolated** describing a specified sub-

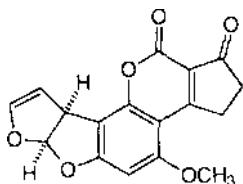

**affinity support**

stance, usually a biological macromolecule such as an antigen or antibody, that has been purified (or isolated) by a technique such as **affinity chromatography** or **affinity electrophoresis**, thus implying high purity.

**affinity support** an alternative term for **affinity matrix**.

**affinoelectrophoresis** an alternative term for **affinity electrophoresis**.

**aflatoxin** any of a group of related and highly toxic secondary metabolites (**mycotoxins**) produced by strains of the moulds *Aspergillus f. avus* or *A. parasiticus*, together with further metabolites of these mycotoxins. Their main structural feature is a fused coumarin-bis(dihydrofuran) ring system. The most important are aflatoxins B<sub>1</sub>, B<sub>2</sub>, G<sub>1</sub>, and G<sub>2</sub> - so designated from the colour of their fluorescence (B, blue; G, green). The mycotoxins are produced naturally by the moulds growing on various seed crops, especially groundnuts (peanuts), and certain cereals (e.g. maize) during storage under moist conditions. They are acutely toxic and highly carcinogenic to many species of animals (probably including humans), and are responsible for turkey X disease. The main organ affected is the liver; aflatoxin B<sub>1</sub> is the most potent hepatocarcinogen known. The term is derived as a contraction of *A. f. avus* toxin.

aflatoxin 6,

**AFLP** abbr. for amplification fragment length polymorphism. The use of the **polymerase chain reaction** to amplify DNA in the study of **restriction fragment length polymorphism**.

**A form** 1 A form of DNA (abbr.: A-DNA or DNA-A); the molecular conformation adopted by fibres of the sodium salt of duplex DNA at a relative humidity of 75% or less. It consists of a right-handed double helix containing about 11 nucleotide residues per turn, with the planes of the base pairs inclined at about 70° to the axis of the helix. Unlike the **B form** of DNA it has a large hole ( $\approx 0.8$  nm diameter) at the axis and a very deep major groove. See also **Cform**, **Z form**. 2 A form of RNA (abbr.: A-RNA); the molecular conformation of double-stranded regions of RNA that is favoured at low-salt concentrations and moderate temperatures; it resembles the A form of DNA. (see def. 1).

**AFP** abbr. for a-fetoprotein.

**Ag** 1 abbr. for antigen. 2 symbol for silver.

**AGA** 1 a codon in non-mitochondrial mRNA for L-arginine. 2 a codon in human mitochondrial mRNA for chain termination. 3 abbr. for N-acetylglutamic acid.

**agameric reproduction** see **asexual reproduction**.

**agamogeny** the development of a new individual from a single cell. Compare **vegetative reproduction**.

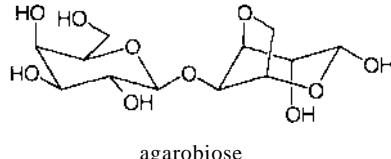

**agar** or **agar-agar** a complex sulfated galactan extracted from certain seaweeds, especially *Gelidium* and related genera. The two main components are **agarose** and **agaropectin**. Agar forms an aqueous gel suitable for the solidification of microbiological culture media and for use as a support medium in zone electrophoresis or (immuno)diffusion techniques. It is not metabolized by most organisms. The gelling temperature varies from about 25 to 35°C for different types of preparation. The gel is then stable to about 90 °C.

**agar-diffusion method** a method for determining the sensitivity of a microorganism to an antimicrobial drug. The zone of growth inhibition is measured around a ditch, hole, or a fil-

**aglycon**

ter-paper disk containing the drug and located on an agar culture medium seeded with the microorganism in question.

**agarobiose** 4-O-fJ-O-galactopyranosyl-3,6-anhydro-L-galactose; a **disaccharide** that forms the basic unit of **agarose**.

agarobiose

**agaropectin** a charged component of **agar** consisting of a mixture of polysaccharides containing o-galactose, 3,6-anhydro-L-galactose, and monoesterified sulfuric acid units. Samples from some algae may contain other components such as pyruvate, L-arabinose, and o-glucuronate units.

**agarose** an essentially uncharged component of **agar** comprising a  $\approx 120$  kDa alternating carbohydrate polymer. It consists of  $\text{-}(\text{3})\text{o-Galp-(fJl-4)-3,6An-L-Galp(alt-}$  repeating units, containing small amounts of ionized sulfate and pyruvate groups. It is widely used as a matrix in zone and immunoelectrophoresis, immunodiffusion, and gel filtration and affinity chromatography. See also **agarobiose**.

**AGe** a codon in mRNA for L-serine.

**agenized flour** see **methionine sulfoximine**.

**AGG** 1 a codon in non-mitochondrial mRNA for L-arginine. 2 a codon in human mitochondrial mRNA for chain termination.

**agglutinate** 1 to adhere or cause to adhere. 2 to cause the clumping of cells, particles, etc., or to undergo such clumping.

**agglutination** 1 the act or process of adhering. 2 the process in which suspended cells or other **antigen** coated particles clump together when **antibody** is added due to an antigen-antibody reaction. 3 the result of such a process. See also **agglutinin**.

**agglutinin** an **antibody** that has the ability to agglutinate the corresponding antigen, e.g. when the antigen is present on the surface of a suspended cell or other particle.

**agglutinogen** an **antigen**, usually particulate, that stimulates the production of **agglutinin**.

**aggrecan** the major proteoglycan of cartilage. It has approximately one **glycosaminoglycan** chain for every 20 amino-acid residues, and a total mass of about 3 MDa. It assembles with glycosaminoglycans, especially hyaluronan, into aggregates several micrometres in diameter. Example (of protein precursor) from human juvenile cartilage chondrocyte: database code HUMAGPRO, 2316 amino acids (238.97 kDa). See also **versican**.

**aggregate** 1 formed of separate units or particles collected into a whole or into larger units. 2 an assemblage or sum of many separate units or particles. 3 to form or be formed into a single body or larger body.

**aggregation** 1 the process of forming an **aggregate** (def. 2). 2 a cluster or group of particles held together into larger units.

**aggregation number** the number of monomers of an amphiphatic substance that form a micelle under any particular conditions.

**aggressin** a diffusible nontoxic substance produced by a microorganism that promotes the invasive power of the microorganism in the host.

**aglucon** or (formerly) **aglucone** an **aglycon** derived from a glucoside (i.e. where the sugar moiety was a glucose residue).

**aglycon** or **aglucon** or (formerly) **aglycone** or **aglucone** the part

## agmatine

## AIR carboxylase

of any glycoside that remains after the sugar moiety has been chemically or enzymically removed.

**agmatine** l-amino-4-guanidobutane; a putative endogenous ligand for imidazoline receptors synthesized from arginine by the enzyme arginine decarboxylase (EC 4.1.1.19). In some invertebrates e.g. the sponge *Geodia gigas* and some cephalopods, the guanidine group can undergo phosphorylation to phospho-agmatine, which acts as a phosphagen.

**agnotobiotic** pertaining to the growth of organisms of a single species in the presence of one or more other species of which at least one is unknown. *Compare synxenic.*

+**agogue** or (*US*) +*agog* suffix denoting an agent that elicits or enhances the secretion of the indicated substance. [from the Greek *agogos*, leading, drawing forth.]+-*agogic adj.*

**agonist** any ligand, especially a drug or hormone, that binds to receptors and thereby alters the proportion of them that are in an active form, resulting in a biological response. A conventional agonist increases this proportion, whereas an inverse agonist reduces it. *See also* full agonist, partial agonist. *Compare antagonist. -agonistic adj.*

**Agranoff's turtle** a zoomorphic mnemonic for avoiding the confusion that has tended to occur over the numbering of the carbon atoms of *myo-inositol* and its chiral derivatives, especially when their Haworth projections are converted into diagrams representing their normal chair conformations. The chair conformation of the parent compound is likened to a turtle, with its body corresponding to the C<sub>6</sub> ring, its coplanar limbs and tail representing the five equatorial hydroxyl groups, and its erect head the axial hydroxyl group. The turtle is viewed from above; then, for derivatives named as members of the O series, numbering of the turtle's appendages proceeds counterclockwise, commencing with its right front paw (i.e. its *dextro* 'hand'), which is designated 10; its head becomes 20, its left front paw is 30, and so on around its body. Conversely, numbering of the L series of derivatives commences with the left front paw (the *laevo* 'hand'), designated 1L, and then proceeds clockwise, the head becoming 2L, and so on. [After its originator Bernard William Agranoff (1926- ), who devised it in 1978.]

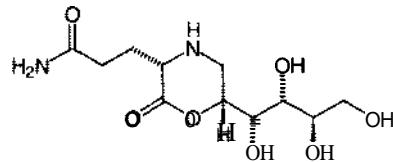

**agrin** a component of the synaptic basal lamina that causes aggregation of acetylcholine receptors and acetylcholinesterase on the surface of muscle fibres of the neuromuscular junction. It occurs in embryonic nervous tissue and muscle, especially during early development. At least five different forms arise by alternative splicing; they differ in their acetylcholine receptor clustering activity. An EGF-like domain is present. Example (precursor) from rat: database code AGRI\_RAT, 1959 amino acids (208.41 kDa).

**Agrobacterium** genus of Gram-negative aerobic rod-shaped soil bacteria. Most strains can initiate formation of galls in plants (*see* crown-gall disease). A feature of the infection of plants by *Agrobacterium* species is that the bacterium can subvert the host plant tissue to produce amino acids known as opines, which the bacterium can use as an energy, carbon, and nitrogen source. The type of opine produced is determined by the bacterial strain. Continued presence of the bacteria is not necessary for transformation of the cells of the host plant. Transformation by *Agrobacterium tumefaciens* has been shown to be due to large plasmids (140 - 235 kb). These are known as tumour-inducing or Ti plasmids, and they have been exploited in the production of transgenic plants.

**agrochemical** a chemical that is used in agriculture or horticulture, especially as a biocide, fertilizer, etc.

**agroclavine** 8,9-didehydro-6,8-dimethylergoline; a nonpeptide ergot alkaloid.

**agropine** an opine; a rare amino-acid derivative that is produced by a certain type of crown-gall tumour. The genes responsible for its synthesis are part of the T-DNA from a Ti plasmid. *See also* crown-gall disease.

agropine

**AGU** a codon in mRNA for L-serine.

**Ah** abbr. for aromatic hydrocarbon; the name of a genetic locus in higher organisms that governs biological responses to some aromatic hydrocarbons. The proteins it encodes include cytochrome P450 1A1, a liver microsomal monooxygenase that oxidizes a variety of unrelated compounds, including xenobiotics such as the environmental carcinogens, benzo[a]pyrene and 3-methylcholanthrene. This enzyme is induced by these compounds and, more potently, by polychlorinated biphenyls such as 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), acting through the Ah receptor. The 5'-flanking region of the gene for this enzyme contains several short sequence motifs known as xenobiotic response elements (XREs).

**ahnak** a human gene that encodes a giant protein of  $\approx$ 700 kDa with a large internal domain ( $\approx$ 4300 amino acids) of highly conserved repeated sequences, much of which are 128 amino-acid residues in length and contain a heptad repeat. The ahnak protein is found in human nuclei and is of unknown function. [From Hebrew *Ahnak*, giant.]

**Ah receptor** abbr. for aryl hydrocarbon receptor; a protein encoded by the Ah gene that binds a number of aryl hydrocarbons and mediates their biochemical and toxic effects. It is activated when it binds a ligand, and then translocates from the cytoplasm to the nucleus, where it is believed to enhance gene transcription by binding to the xenobiotic-response element sequence. It contains a basic helix-turn-helix motif; the DNA-binding form is a heterodimer of this protein and ARNT. Example (precursor) from human: database code AHR\_HUMAN, 808 amino acids (91.62 kDa).

**£Ahx or (formerly) £Acp** symbol for a residue of the e-amino acid 6-aminohexanoic acid (formerly known as e-aminocaproic acid).

**aHyl** symbol for a residue of the a-amino acid L-allohydroxylysine; *threo*-5-hydroxy-L<sub>s</sub>-lysine.

**AlB** abbr. for 2-aminoisobutyric acid.

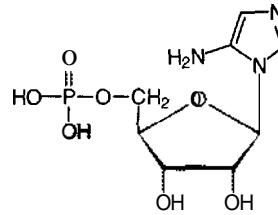

**AlCAR** abbr. for 5-amino-4-imidazolecarboxamide ribonucleotide (an intermediate in purine biosynthesis).

**AlCAR transformylase** see phosphoribosylaminoimidazolecarboxamide formyltransferase.

**AIDS** abbr. for acquired immunodeficiency syndrome.

**aile** (Alle) symbol for a residue of the a-amino acid L-alloisoleucine, (2S,3R)-2-amino-3-methylpentanoic acid.

**AIR** abbr. for 5-aminoimidazole ribonucleotide, an intermediate in purine biosynthesis.

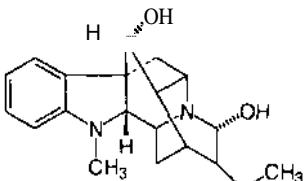

**AIR carboxylase** see phosphoribosylaminoimidazole carboxylase.

## air-lift bioreactor

air-lift bioreactor a bioreactor in which the reaction medium is kept mixed and gassed by the introduction of air or another gas at the base of a column-like reactor.

ajmaline ajmalan-17,20-diol; an alkaloid from the roots of *Rauvolfia serpentina*. It is used clinically as an antihypertensive and antiarrhythmic, having the effect of normalizing heart rhythm.

AK (*in clinical biochemistry*) abbr. for adenylate kinase.

AKAP abbr. for A-kinase anchor protein or cAMP-dependent protein kinase anchor protein; a protein that anchors the kinase to cytoskeletal and/or organelle-associated proteins, targeting the signal carried by cyclic AMP to specific intracellular effectors. The N-terminal region, which is highly basic, is required for interaction with calmodulin. Example (human): database code AK79\_HUMAN, 427 amino acids (47.02 kDa). akaryotic describing a cell without a nucleus.

akee a variant spelling of ackee.

AKH abbr. for adipokinetic hormone.

A-kinase an enzyme that phosphorylates target proteins in response to a rise in intracellular cyclic AMP. See cyclic AMP-dependent protein kinase.

*Akt* the mouse or human homologue of *v-akt*, the oncogene of the transforming retrovirus AKT8. *v-akt* encodes a serine/threonine protein kinase that contains an SH2 domain. Database code KAKT\_MLVAT, 501 amino acids (57.87 kDa).

al+ prefix denoting an acyclic monosaccharide or monosaccharide derivative. See also aldehydo-.

+al suffix denoting an unbranched acyclic mono- or dialdehyde.

Al symbol for aluminium.

Ala symbol for a residue of the α-amino acid L-alanine, 2-aminopropanoic acid (alternative to A).

βAla symbol for a residue of the p-amino acid p-alanine, 3-aminopropanoic acid.

ALA or dALA abbr. for δ-aminolevulinic acid.

Ala AT or ALAT (*in clinical biochemistry*) (formerly) abbr. for alanine aminotransferase. ALT is preferred.

ALA dehydratase see porphobilinogen synthase.

alamethicin a linear ionophorous antibiotic polypeptide containing a high proportion of 2-methylalanine residues and blocked at both ends. See also peptaibols.

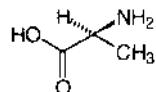

Ac-2-MeAla-L-Pro-2-MeAla-L-Ala-2-MeAla-L-Ala-L-Gln-2-MeAla-L-Val-2-MeAla-GIY-L-Leu-2-MeAla-L-Pro-O-LVal-2-MeAla-2-MeAla-L-Glu-L-Gln-L-phenylalaninol

alaninal the aldehyde obtained by reduction of the carboxyl group of alanine.

alaninate 1 alanine anion, the anion  $\text{CH}_3\text{-CH}(\text{NH}_2)\text{-COO}^-$ . 2 any salt containing alanine anion. 3 any ester of alanine.

alanine the trivial name for α-aminopropanoic acid; 2-aminopropanoic acid;  $\text{CH}_3\text{-CH}(\text{NH}_2)\text{-COOH}$ ; a chiral α-amino acid. L-alanine (symbol: A or Ala), (S)-2-aminopropanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: GCA, GCC, GCG, or GCU. In mammals it is a nonessential dietary amino acid and is glucogenic. Residues of D-alanine (symbol: D-Ala or DAla), (R)-2-aminopropanoic acid, are found in cell-wall peptidoglycans of various bacterial species and in other materials, e.g. cyclosporin.

## albumin

L-alanine

**β-alanine** symbol: pAla; the trivial name for p-aminopropionic acid; 3-aminopropanoic acid;  $\text{HzN-CH}_2\text{CH}_2\text{-COOH}$ ; an achiral p-amino acid. It occurs free in brain and in combination in pantothenate (and hence in coenzyme A) and in the isopeptides anserine and carnosine, but it is not a constituent of proteins. It has an inhibitory effect on the central nervous system.

alanine cycle see glucose-alanine cycle.

**β-alanine-oxoglutarate** aminotransferase see 4-aminobutyrate transaminase.

alanine transaminase abbr. (*in clinical biochemistry*): ALT; EC 2.6.1.2; systematic name: L-alanine:2-oxoglutarate aminotransferase; other names: glutamic-pyruvic transaminase; glutamic-alanine transaminase. An enzyme that catalyses the reversible reaction:

Widely distributed in all tissues and organisms, it is a pyridoxal-phosphate enzyme. Example, cytoplasmic isoform: database code ALAT\_HUMAN, 495 amino acids (54.38 kDa). In clinical chemistry its assay alongside aspartate transaminase (AST) normally present in plasma in higher concentrations, may be useful as an indicator of liver damage, as levels of ALT are higher in liver than those of AST, in contrast to other tissues. In hepatitis, plasma levels of ALT may exceed those of AST.

alaninium alanine cation,  $\text{CH}_3\text{-CH}(\text{NH}_3^+)\text{-COOH}$ .

alanino the alkylamino group,  $\text{CH}_3\text{-CH}(\text{COOH})\text{-NH}-$ , derived from alanine.

alaninol the alcohol obtained by the successive reduction of the carboxyl group of alanine.

alanyl the acyl group,  $\text{CH}_3\text{-CH}(\text{NH}_2)\text{-CO-}$ , derived from alanine.

alarmone any signal molecule that serves to reorient a cell's economy in response to stress. Such molecules include ppGpp, which is produced, e.g., in microorganisms, in response to growth-rate limitation caused by amino-acid stress and acts to correct this in various ways, and diadenosine tetraphosphate (ApppA), which stimulates proliferation when DNA replication is halted at a replication fork.

ALA synthetase see 5-aminolevulinate synthase.

ALAT See Ala AT.

albinism an inherited metabolic disorder in which there appears to be a complete or nearly complete failure to form melanin. It was first listed in 1908 by the British physician Archibald Garrod (1857-1936) in his lecture entitled 'Inborn Errors of Metabolism'. In some cases it is due to a deficiency of 'tyrosinase' (monophenol monooxygenase), but other types are known in which this enzyme is present, and for which the precise cause is unknown.

albumin any of a group of globular proteins that are soluble in distilled water and solutions of half-saturated ammonium sulfate, but insoluble in fully saturated ammonium sulfate solutions. Serum albumin, the major protein of serum, has a good binding capacity for water,  $\text{Ca}^{2+}$ ,  $\text{Na}^+$ ,  $\text{K}^+$ , fatty acids, hormones, bilirubin, and drugs. Its main function is the regulation of the colloidal osmotic pressure of blood; it has structural similarity to  $\alpha$ -fetoprotein and vitamin D-binding protein. Example (precursor) from human: database code ALBU\_HUMAN, 609 amino acids (69.29 kDa). See also endosperm albumin, lactalbumin, ovalbumin, serum albumin. [The name origi-

## albuminoid

nates from Latin *albus*, white, as it exists in nearly pure form in egg-white, from which it was easily obtained by the ancients.]

albuminoid 1 of or relating to an albumin. 2 *an alternative name for scleroprotein.*

albuminuria the presence of excessive amounts of protein in the urine. It is usually a sign of renal disease.

albuterol *see* salbutamol.

Alcalase *the proprietary name for a proteolytic enzyme preparation obtained by fermentation of a strain of *Bacillus subtilis*. It is characterized by stability and activity at high temperatures and alkaline pH values, and is used in enzymic laundering and various industrial processes.*

alcapton 2,5-dihydroxyphenylacetic acid. *See* alcaptonuria, homogentisate.

alcaptonuria or alkapttonuria a rare hereditary metabolic disease, usually due to an autosomal recessive gene, in which the enzyme homogentisic acid oxidase (homogentisate 1,2-dioxygenase, EC 1.13.11.5) is virtually absent. This leads to the inability to metabolize further the homogentisate produced by the normal metabolism of phenylalanine and tyrosine. Homogentisate therefore accumulates in the body and is excreted in the urine, which gradually turns dark as homogentisate is oxidized to a melanin-like product - a process speeded up at an alkaline pH.

alcohol 1 any of a class of alkyl compounds containing a hydroxyl group. An alcohol is called primary, secondary, or tertiary according to whether the carbon atom bearing the hydroxyl group is itself attached to one, two, or three other carbon atoms. 2 specifically, ethyl alcohol, ethanol. *See also* absolute alcohol. -alcoholic *adj.*, *n.*

alcohol dehydrogenase any of the nicotinamide-nucleotide-linked dehydrogenase enzymes of groups EC 1.1.1.1 (NAD+) or EC 1.1.1.2 (NADP+) that catalyse the oxidation of alcohols to aldehydes. These are zinc proteins. Also EC 1.1.1.71, alcohol dehydrogenase [NAD(P)+]; *other name:* retinal reductase; EC 1.1.99.8, alcohol dehydrogenase (acceptor), a quinoprotein. Examples: alcohol dehydrogenase I from *Saccharomyces cerevisiae*: database code ADHI\_YEAST, 347 amino acids (36.66 kDa); alcohol dehydrogenase 6 (human): database code ADH6\_HUMAN, 368 amino acids (39.03 kDa).

alcoholic fermentation the conversion of glucose to ethanol by a group of reactions that are characteristic of yeast.

alcohol oxidase *abbr.:* AOX or methanol oxidase *abbr.:* MOX; EC 1.1.3.13; a flavoprotein (FAD) enzyme that catalyses the oxidation by dioxygen of a primary alcohol to the corresponding aldehyde. It is important in methylotrophic yeasts, in which it is the first enzyme in the pathway for utilization of methanol, converting this to formaldehyde, thence to CO<sub>2</sub>.

alcoholysis the solvolysis of a covalent derivative of an acid by a reaction in which one of the products combines with the H atom of an alcohol's hydroxy group and the other product with the alcohol's alkoxy group.

aldaric acid any dicarboxylic acid formed by oxidation of both terminal groups of an aldose to carboxyl groups. There are three tetric acids (D-, L-, and meso-tartaric acids), four pentaric acids (D- and L-arabinic acids, xylaric acid [*meso*]), and ribaric acid [*meso*]), and ten hexaric acids (D- and L-glucaric acids, D- and L-idaric acids, D- and L-mannaric acids, D- and L-talaric acids, allaric acid [*meso*], and galactaric acid [*meso*]).

aldehyde 1 *an alternative name for the formyl group, -CHO.* 2 any organic compound with the formula R-CH=O. *Compare* ketone. -aldehydic *adj.*

aldehyde dehydrogenase any enzyme that catalyses the oxidation of an aldehyde group to a carboxylic acid. Many examples are known, acting specifically on a wide range of substrates. Those acting on aliphatic aldehydes are divided into four classes. Class 1, or Ald C, are tetrameric cytosolic enzymes, and include aldehyde dehydrogenase (NAD+), EC 1.2.1.3; *systematic name:* aldehyde:NAD+ oxidoreductase; an

## aldonic acid

enzyme of wide specificity. Example from human: database code DHAC\_HUMAN, 500 amino acids (54.73 kDa). This EC designation also includes Class 2 enzymes, or Ald M, which are tetrameric mitochondrial enzymes. Class 3, or Ald D, are dimeric cytosolic enzymes, and include aldehyde dehydrogenase [NAD(P)+], EC 1.2.1.5; *systematic name:* aldehyde: NAD(P)+ oxidoreductase. Example from human: database code DHAP\_HUMAN, 453 amino acids (50.35 kDa).

aldehyde ferredoxin oxidoreductase an enzyme that catalyses the reversible oxidation of aldehydes to the corresponding carboxylic acid, using ferredoxin as an electron acceptor. Containing tungsten, molybdopterin molecules, and Fe4S4 clusters, the enzyme has remarkable thermostability. Its 3-D structure is known.

**aldehydo-** *abbr.:* al-; prefix designating an uncyclized monosaccharide or monosaccharide derivative. It is used in (semi)systematic nomenclature to stress the acyclic nature of such compounds. *Compare keto-.*

aldimine any imine that is an analogue of an aldehyde; the general structure is RCH=NR where R may be any organyl group or H. *Compare* ketimine.

alditol any polyhydric alcohol derived from the acyclic form of a monosaccharide by reduction of its aldehyde or keto group to an alcoholic group. Older names for these compounds include glycitol and sugar alcohol.

**aldo+** *prefix* indicating aldehydic; e.g. aldohexose.

aldoketose any monosaccharide derivative containing both a (potential) aldehydic carbonyl group and a (potential) ketonic carbonyl group.

aldol 1 any organic compound that is both an aldehyde and an alcohol, especially where the two functions are separated by two linked carbon atoms in accordance with the general structure: HO-C-C-CH=O. 2 *the trivial name for acetaldol (3-hydroxybutanal) a compound formed by the self-condensation of two acetaldehyde molecules.*

aldolase 1 *a generic name for nearly every enzyme of the subclass EC 4.1.2, the aldehyde-Iyases, enzymes catalysing aldol condensations and their reversal.* 2 *abbr. (in clinical biochemistry): ALS; common name for the enzyme fructose-bisphosphate aldolase; EC 4.1.2.13; systematic name: D-fructose-1,6-bisphosphate D-glyceraldehyde-3-phosphate-Iyase; other name: fructose-1,6-bisphosphate triosephosphate-Iyase.* An enzyme that catalyses the reversible fission of D-fructose 1,6-bisphosphate to glyceraldehyde 3-phosphate and D-glyceraldehyde 3-phosphate. It acts also on (3*S*,2*R*)-ketose 1-phosphates. In mammals three isoenzymes are known: aldolase A in muscle; aldolase B in liver, kidney, and small intestine; and aldolase C in brain. All three isoenzymes catalyse the reversible splitting of both D-fructose 1,6-bisphosphate and D-fructose 1-phosphate, but with different relative limiting rates; liver aldolase B shows approximately the same limiting rate with both substrates, while aldolase A and aldolase C show, respectively, a 50-fold and a 10-fold lower maximal activity with fructose 1-phosphate than with fructose 1,6-bisphosphate. Each is of ~160 kDa and is composed of four subunits, which are immunologically distinct in the three isoenzymes. Examples, aldolase A from *Mus musculus*: database code ALFA\_MOUSE, 363 amino acids (39.22 kDa); aldolase from *Pisum sativum*: database code ALFLPEA, 357 amino acids (38.44 kDa). Three different but related aldolase genes (probably formed from a single ancestral gene) have been identified; in humans the aldolase-A gene is in chromosome 16, the aldolase-B gene is present as a single copy in chromosome 9, and the aldolase-C gene is in chromosome 17. *See also* hereditary fructose intolerance.

aldol condensation the base-catalysed addition reaction of two aldehydes or an aldehyde and a ketone to form an aldol (def. 1).

aldonic acid a monocarboxylic acid having a chain of three or more carbon atoms and formally derived from an aldose by oxidation of the aldehydic group.

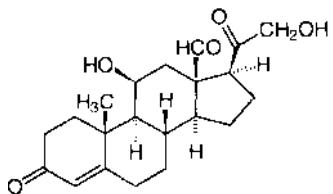

## aldopentose

aldopentose any of the eight possible five-carbon-atom aldoses.

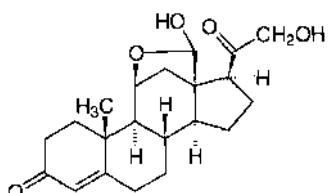

aldopyranose any aldose in the pyranose form.

alrose a monosaccharide in which the (potential) carbonyl group is terminal (i.e. aldehydic). The term is frequently modified to indicate the number of carbon atoms in the chain, as in aldotriose, aldotetrose, etc.

aldosterone  $\text{II}\beta,21\text{-dihydroxy-3,20-dioxopregn-4-en-18-al}$ ; the most powerful naturally occurring mineralocorticoid hormone, originally named electrocortin by its discoverers Sylvia Simpson and James Tait in 1954. The name was changed to aldosterone after its structure had been determined by Reichstein in 1953. It exists in solution as an equilibrium mixture of the aldehyde and the hemiacetal formed with the hydroxyl at position II. Produced by the cells of the zona glomerulosa of the adrenal cortex, its main action is to increase reabsorption of sodium ions by the distal renal tubules and thus to regulate water and electrolyte metabolism. The biosynthesis of aldosterone is stimulated by angiotensin II (see angiotensin, renin-angiotensin system), corticotropin, and increased potassium-ion concentrations. II-Deoxycorticosterone is converted into aldosterone by aldosterone synthase. Aldosterone exerts its effects through binding to cytosolic receptors. The resulting complex is transferred to the nucleus, where it acts to stimulate production of mRNA for sodium transport proteins. The action is thus on a timescale of many minutes.

aldehyde form

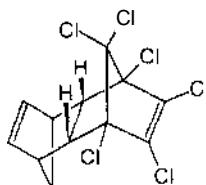

hemiacetal form

aldosterone synthase EC 1.14.15.4; recommended name: steroid  $\text{II}\beta$ -monooxygenase; other names: cytochrome P450 IIB2; steroid 18-hydroxylase; P450C18. A heme-thiolate enzyme that converts II-deoxycorticosterone to aldosterone, by successive hydroxylations at the  $\text{II}\beta$  and 18 positions. Reduced adrenodoxin is a reactant, being converted to oxidized adrenodoxin. Example, human (precursor): database code CPN2\_HUMAN, 503 amino acids (57.58 kDa).

aldotetrose any of the four possible four-carbon-atom aldoses. aldotriose either D- or L-glyceraldehyde; see aldose.

aldrin 1,2,3,4,10,10-hexachloro-1,4,4a,5,8,8a-hexahydro-1,4:5,8-dimethanonaphthalene; an organochlorine compound formerly used as an insecticide, but now banned in certain countries on account of its toxicity.

aldrin

aleuron or aleurone 1 granules of insoluble protein found in plant cells, especially in the seeds of cereals, where they appear to act as storage material. 2 the single layer of cells on the outside of the endosperm of cereal seeds containing such granules. Translocated gibberellins stimulate the cells to synthesize a-amylase, which is secreted into the endosperm to hydrolyse the stored starch.

aleuroplast any colourless plastid or leukoplast storing protein. Aleuroplasts are found in plant cells, particularly seeds.

alexin or alexine former term for complement; hence alexinated means treated with complement.

ALG abbr. for anti-lymphocyte globulin.

alga (pl. algae) any of a group of simple eukaryotic photosynthetic protists. They may be unicellular or multicellular, and are generally aquatic. The prokaryotes formerly called blue-green algae are now known as cyanobacteria.-algal adj.

algicide any chemical agent that selectively kills algae.

algin the sodium salt of alginic acid

alginic lyase EC 4.2.2.3; recommended name: poly(fJ-o-mannuronate) lyase; systematic name: poly(fJ-o-1,4-mannuronide) lyase. An enzyme that catalyses a reaction resulting in eliminative cleavage of polysaccharides containing fJ-o-mannuronate residues to give oligosaccharides with 4-deoxy-a-L-erythrohex-4-enopyranuronosyl groups at their ends. Example from *Pseudomonas aeruginosa*: database code PSEALGL, 367 amino acids (40.78 kDa).

alginic acid a hydrophilic polysaccharide ( $\approx 240$  kDa) occurring in brown algae (brown seaweeds), especially the Californian giant kelp (*Macrocystis pyrifera*) and horsetail kelp (*Laminaria digitata*). Sodium alginate is used commercially as an emulsifier and thickener in foodstuffs, pharmaceuticals, etc. It has an interrupted structure of stretches of al-4-linked a-L-gulopyranosyluronic acid residues, stretches of fJL-4-linked fJ-o-mannopyranosyluronic acid residues, and stretches where both uronic acids occur in alternating sequence. Similar glycans are secreted by some bacteria.

algorithm any systematic mathematical procedure that allows a problem to be solved in a finite number of steps. Compare heuristic, stochastic.

alicyclic describing an organic compound derived from a saturated cyclic hydrocarbon. Compare aliphatic, aromatic.

aliphatic describing organic compounds in which the carbon atoms form open (nongyclic) chains. Compare alicyclic, aromatic.

aliquant one of a number of unequal parts of a whole.

aliquot one of number of equal parts of a whole; often used loosely, and erroneously, for a sample.

alizarin 1,2-dihydroxyanthraquinone; the aglycon of ruberythic acid.

alkalemia or (esp. Brit) alkalaemia a condition in which there is increased alkalinity (i.e. lowered hydrogen-ion concentration and hence raised pH) of the blood. Compare acidemia, alklosis.

alkali any of a class of bases that neutralize acids and are themselves neutralized by acids, and form caustic and/or corrosive aqueous solutions. The term is applied in particular to hy-

## alkali metal

## allele

droxides of the alkali metals, though the term is often extended to other substances with similar though weaker properties.

**alkali metal** any element of group 1 of the IUPAC periodic table; the group comprises lithium (Li), sodium (Na), potassium (K), rubidium (Rb), cesium (Cs), and francium (Fr).

**alkaline 1** having the properties of an alkali; basic. 2 describing an aqueous solution having a pH > 7.

**alkaline earth** any metallic element belonging to group 2 of the IUPAC periodic table; the group comprises beryllium (Be), magnesium (Mg), calcium (Ca), strontium (Sr), barium (Ba), and radium (Ra).

**alkaline phosphatase** EC 3.1.3.1; *systematic name*: orthophosphoric monoester phosphohydrolase (alkaline optimum); *other names*: alkaline phosphomonoesterase; phosphomonoesterase; glycerophosphatase. An enzyme that catalyses the hydrolysis of orthophosphoric monoester to an alcohol and orthophosphate. The cofactors are zinc and magnesium. In human plasma the level is raised in the last trimester of pregnancy. Plasma levels may also be greatly elevated in cases of Paget's disease of bone, osteomalacia, and cirrhosis or biliary obstruction; levels may become moderately elevated in other types of bone disease. The assay of tissue-specific isoenzymes increases the value of these estimations; e.g. the placental isoenzyme is elevated in plasma in testicular seminoma. The normal range in human plasma is 30–90 IU L<sup>-1</sup>. Example from intestine (bovine): database code PPB1\_BOVIN, 44 amino acids (4.77 kDa); example from *Escherichia coli* (precursor): database code PPB\_ECOLI, 471 amino acids (49.38 kDa).

**alkaline tide** the slight increase in plasma and urine pH that occurs after meals. It is believed to be due to withdrawal of hydrogen ions from the blood during the formation of gastric HCl.

**alkali reserve** or **alkaline reserve** a term formerly used to denote the bicarbonate-CO<sub>2</sub> extractable from blood plasma.

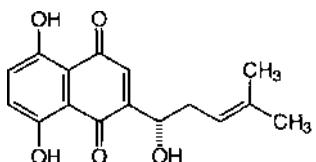

**alkaloid** any member of a broad group of nitrogen-containing basic organic compounds present in various dicotyledonous plants and some fungi. Although only about 5% of the world's plant species have so far been examined, they have yielded over 2000 different alkaloids. Heterocyclic alkaloids derived from amino acids are termed true alkaloids. Alkaloids with and without heterocyclic rings and not derived from amino acids are termed pseudoalkaloids; in these the carbon skeleton is usually isoprenoid derived. Alkaloids often have marked and specific pharmacological activity.

**alkalosis** a clinical condition in which total base excess or total acid deficit has the potential to cause decreased hydrogen-ion concentration (i.e. raised pH) in the blood, in the absence of compensating biochemical and physiological changes.

**alkane** any saturated aliphatic hydrocarbon compound.

**alkanet** the plant, *Alkanna tinctoria*, and its root, which contains the pigment alkanin.

**alkannin** (S)-5,8-dihydroxy-2-(1-hydroxy-4-methyl-3-pentenyl)-1,4-naphthalenedione; a red pigment derived from the root of the alkanet plant, and used as a dye in cosmetics and food. The (+)(R) enantiomer is also a natural product, shikonin, and the racemate is known as shikarkin.

**alkaptonuria** a variant spelling of alcaptonuria.

**alkatriene** any unsaturated aliphatic hydrocarbon containing two (conjugated or unconjugated) double bonds.

**alkatrienyl** any group derived from an alkatriene by removal of a hydrogen atom.

**alkenyl** any group derived from an alkene by removal of a hydrogen atom.

**1-alkenyl-2-acylglycerol cholinophosphotransferase** EC 2.7.8.22; an enzyme that catalyses the formation of the plasmalogen, plasmenylcholine (i.e. 1-alkenyl-2-acylglycerophosphocholine), from CDPcholine and 1-alkenyl-2-acylglycerol with release of CMP.

**1-alkenylglycerophosphocholine (O)acyltransferase** EC 2.3.1.104; an enzyme that catalyses the formation of the plasmalogen, plasmenylocholine (i.e. 1-alkenyl-2-acylglycerophosphocholine) from acyl-CoA and 1-alkenylglycerophosphocholine with release of CoA.

**1-alkenylglycerophosphocholine hydrolase** EC 3.3.2.2; *other name*: lysosomal esterase; a phospholipase involved in the turnover of plasmalogens. It catalyses the hydrolysis of 1-(1-alkenyl)-sn-glycero-3-phosphocholine to an aldehyde and sn-glycero-3-phosphocholine.

**1-alkenylglycerophosphoethanolamine D-acyltransferase** EC 2.3.1.121; an enzyme that catalyses the formation of the plasmalogen, 1-alkenyl-2-acylglycerophosphoethanolamine, from acyl-CoA and 1-alkenylglycerophosphoethanolamine with release of CoA.

**1-alkenylglycerophosphoethanolamine hydrolase** EC 3.3.2.5; a phospholipase enzyme involved in the turnover of plasmalogens. It catalyses the hydrolysis of 1-(1-alkenyl)-sn-glycero-3-phosphoethanolamine to an aldehyde and sn-glycero-3-phosphoethanolamine.

**alkyl** any group derived from an alkane by the removal of one hydrogen atom. Alkyl groups are often designated by the symbol R.

**alkylating agent** any of a group of compounds that react with another compound so as to introduce an alkyl group into the second compound.

**alkylation** the process of replacing a hydrogen atom in a compound by an alkyl group.

**1-alkylglycerophosphocholine D-acetyltransferase** EC 2.3.1.67; an enzyme that catalyses the formation of 1-alkyl-2-acetyl-sn-glycero-3-phosphocholine (*see* platelet-activating factor) from acetyl-CoA and 1-alkyl-sn-glycero-3-phosphocholine with release of CoA. *See also* 1-alkylglycerophosphocholine O-acyltransferase.

**1-alkylglycerophosphocholine D-acyltransferase** EC 2.3.1.63; an enzyme that catalyses the formation of the ether lipid, 1-alkyl-2-acyl-sn-glycero-3-phosphocholine, from acyl-CoA and 1-alkyl-sn-glycero-3-phosphocholine with release of CoA.

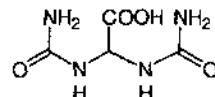

**O<sup>6</sup>-alkylguanine** alkyltransferase *see* O-&methylguanine.

**alkyne** any unsaturated aliphatic hydrocarbon compound containing one or more triple bonds.

**alkynyl** any group derived from an alkyne by the removal of one hydrogen atom.

All symbol for allose.

**allantoic acid** or diureidoacetate the end product of purine metabolism in mammals and some fish, formed from allantoin by a hydrolytic reaction. Most fish metabolize allantoic acid further to urea and glyoxalate. It is widely distributed in plants as an important source of stored nitrogen.

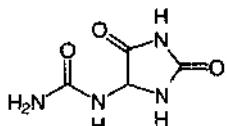

**allantoin** (2,5-dioxo-4-imidazolidinyl)urea; 5-ureidohantoin; an intermediate or end product of purine catabolism, formed from uric acid by urate oxidase. In certain animal groups it is converted to allantoic acid.

**allele** or **allelomorph** any of the forms of the same gene that occur at the same locus on a homologous chromosome but dif-

## allele-specific oligonucleotide

fer in base sequence. Two or more alleles are said to be allelic or allelomorphic to each other, and if more than two alleles exist in a population, the locus is said to show multiple allelism.

allantoin

**allele-specific oligonucleotide** abbr.: ASO; an oligonucleotide that is constructed with a DNA sequence homologous to a specific allele. Two ASOs can be made so that they differ in sequence at only one nucleotide base, thereby distinguishing a mutant allele with a point mutation from its corresponding wild-type allele.

**allelic exclusion** the process by which a cell uses either the gene from its maternal chromosome or the one from the paternal chromosome, but not both. It seems to occur only in genes that encode antibodies and T-cell receptors. Individual B-lymphocytes display allelic exclusion of their heavy and light IgG genes.

**allelomorph** another term for allele.

**allelopathic agent** any plant excretory product that may be autotoxic or affect neighbouring plants, such as salicylate in *Quercus falcata*.

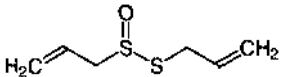

**allelozyme** any of two or more variants of a particular enzyme (with similar catalytic properties) whose amino-acid sequences are encoded in allelic structural genes (see allele); a class of isoenzyme. Compare multilocus enzyme.

**allergen** any antigen that stimulates an allergic reaction, inducing a type I hypersensitive reaction. See allergy, hypersensitivity.

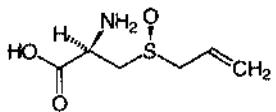

**allergic** of, relating to, or involving allergy.

**allergy or allergic reaction** 1 a state of altered (usually increased) reactivity of the body to foreign material. 2 hypersensitivity.

**alliin** 2-propene-1-sulfinothioic acid S-2-propenyl ester; an antibacterial compound derived from garlic (*Allium sativum*) and having an odour of garlic.

**alliin** 3-(2-propenylsulfinyl)-L-alanine; S-allyl-L-cysteine sulfide; a component of garlic (*Allium sativum*) and other plants that develops an odour of garlic following the action of allinase (alliin lyase; EC 4.4.1.4).

**allitol** a meso-hexitol; derived formally by reduction of the aldehyde group of either D- or L-allose.

**allo+** or (before a vowel) all+ comb.form 1 denoting other, dissimilar, different. Compare hetero+ (def. 1), homo+ (def. 1), iso+ (def. 1), xeno+ (def. 1). 2 referring to a dissimilar genome. Compare homo+ (def. 2), hetero+ (def. 2), iso+ (def. 2), xeno+ (def. 2). 3 referring to an isomeric form of an enantiomer of a

## allometry

compound that has more than one pair of enantiomers. Compare iso+ (def. 3), nor+ (def. 1).

**8/10+** prefix denoting the configuration of a set of four (usually) contiguous >CHOH groups, as in D- or L-allose. See monosaccharide.

**alloantigen** an antigen that is part of an animal's self-recognition system, e.g. major histocompatibility complex molecules. When injected into another animal, they trigger an immune response aimed at eliminating them. Compare alloreactivity.

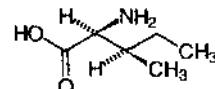

**allocystathionine** see cystathionine.

**allogeneic** or **allogenic** describing cells, tissues, organisms, etc. that are of different genetic constitution. Compare heterogenic, homologous.

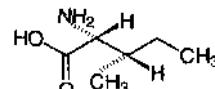

**allograft** any tissue graft between allogeneic individuals; i.e. from a donor of one genotype to a host of another genotype.

**allohydroxylysine** see hydroxylysine.

**alloisoleucine** trivial name for a-amino-p-methylvaleric acid; (2R\*,3S\*)-2-amino-3-methylpentanoic acid, CH<sub>3</sub>-CH<sub>2</sub>-CH(CH<sub>3</sub>)-CH(NH<sub>2</sub>)-COOH; an a-amino acid with two chiral centres. Because molecules of alloisoleucine possess a second chiral centre, at C-3, in addition to the chiral centre at C-2 common to molecules of all a-amino acids other than glycine, the enantiomers L-alloisoleucine (symbol: alle), (2S,3R)-2-amino-3-methylpentanoic acid, and D-alloisoleucine (symbol: D-alle), (2R,3S)-2-amino-3-methylpentanoic acid, are diastereoisomeric with those of isoleucine, (2R\*, 3R\*)-2-amino-3-methylpentanoic acid. L-Alloisoleucine does not occur in peptide linkage in proteins. Residues of D-alloisoleucine are found in the peptidolipid of the actinomycete, *Nocardia esteroides*, and various members of the actinomycin group of antibiotics contain (usually) two residues per molecule.

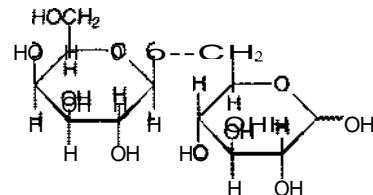

L-alloisoleucine

D-alloisoleucine

**allolactose** trivial name for p-D-galactopyranosyl-(1→6)-D-glucopyranose; an isomer of lactose and the natural intracellular inducer of the lac operon in *Escherichia coli*.

**allomerism** a state of similarity in the crystalline structures of substances of different chemical composition. -allomeric adj.

**allometric** 1 differing in relative growth rates. 2 of or relating to allometry.

**allometry** 1 the study of the growth of parts of an organism

## allomone

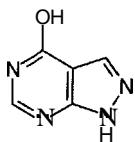

relative to the growth of the whole organism. 2 change in the proportion of any part of an organism occurring during growth.

**allomone** any chemical substance produced or acquired by an organism that, when it contacts an individual of another species in the natural context, evokes in the receiver a behavioural or developmental reaction adaptively favourable to the transmitter. *Compare* kairomone, pheromone.

**allomorphism** variability in the crystalline structure of certain substances having the same chemical composition.

**allophycocyanin** a phycobiliprotein present in small amounts in red algae and cyanobacteria.

**allopurinol** 4-hydroxypyrazolo[3,4-d]pyrimidine; a constitutional isomer of hypoxanthine and a competitive inhibitor of xanthine oxidase (EC 1.2.3.2). It is a synthetic drug used in the treatment of gout and other conditions characterized by raised blood urate content. Patients with gout excrete less urate and more xanthine and hypoxanthine than normal.

**alloreactivity** the T-cell response to non-self MHC molecules. **all-or-none** describing a chemical reaction, or a pharmacological or physiological response, that either occurs to the fullest extent or not at all, depending on the conditions.

**allose** symbol: All; alia-hexose; an aldohexose that differs from glucose only in the configuration of the hydroxyl on C-3.

**allosteric** describing protein molecules that are assumed to possess two or more stereospecifically different, nonoverlapping receptor sites. One of these, the active site, binds the substrate; the other, the allosteric site, is complementary to the structure of another, or the same, metabolite, the allosteric effector, which binds specifically and reversibly. The formation of the enzyme-allosteric effector complex does not activate or deactivate a reaction involving the effector itself; it is assumed only to bring about a discrete reversible alteration of the molecular structure of the protein, called allosteric transition. This modifies the properties of the active site, changing one or several of the kinetic parameters that characterize the biological activity of the protein. *See also* Monod-Wyman-Changeux model. **allosteric activation** any activation of an enzyme by a positive allosteric effector.

**allosteric constant** symbol: *L*; the equilibrium constant for the transition between two forms of an allosteric protein in the absence of ligand:  $L = T_a/R_o$ , where  $T_a$  and  $R_o$  are the concentrations of the less affine T-form and the more affine R-form of the protein, respectively. *See* Monod-Wyman-Changeux model. **allosteric effect** an effect that arises when the reaction of ligands with one site of any polyvalent molecule affects the reaction of ligand(s) at one or more other sites as a result of conformational changes. The reactions may or may not both be reversible; when they are, and represent equilibria, they are reciprocal effects or linked functions.

**allosteric effector** a specific ligand that binds to the allosteric site of a protein with different affinities in the two states of the protein (R and T) in the Monod-Wyman-Changeux model of allosteric transition. An effector may be described as positive if it has an activating effect, or as negative if it is inhibitory. *See also* allosteric. *Compare* autosteric effector.

**allosteric enzyme** designating any enzyme that: (1) contains a site topologically distinct from the active site; (2) shows sigmoid kinetics; (3) occurs at a branch point in a metabolic pathway; and (4) obeys the concerted model for allosteric proteins. Since all these properties may sometimes, but not always, go together, the term is somewhat imprecise.

## allotype

**allosteric inhibition** any inhibition of an enzyme by a negative allosteric effector.

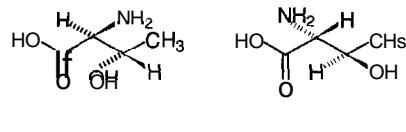

**allosteric protein** a protein that exhibits allosterism. *See also* allosteric.

**allosteric site** *see* allosteric.

**allosteric transition** *see* allosteric, Monod-Wyman-Changeux model.

**allosterism** or **allostery** a property of an enzyme or other macromolecule by which its principal biological reactivity is modified by the binding of an effector to a site other than the binding site of the principal reactant, thereby bringing about a conformational change in the macromolecule such as to alter its principal reactivity. *See also* allosteric.

**allothreonine** trivial name for *a*-amino-fJ-hydroxybutyric acid; ( $2R^*,3R^*$ )-2-amino-3-hydroxybutanoic acid;  $\text{CH}_3\text{CH}(\text{OH})\text{CH}(\text{NH}_2)\text{COOH}$ ; an *a*-amino acid with two chiral centres. Because molecules of allothreonine possess a second chiral centre, at C-3, in addition to the chiral centre at C-2 common to all *a*-amino acids other than glycine, the enantiomers L-allothreonine (symbol: aThr), ( $2S,3S$ )-2-amino-3-hydroxybutanoic acid, and D-allothreonine (symbol: D-aThr), ( $2R,3R$ )-2-amino-3-hydroxybutanoic acid, are diastereoisomeric with those of threonine, ( $2R^*,3R^*$ )-2-amino-3-hydroxybutanoic acid. [Note: The enantiomers of allothreonine may also be named semisystematically as derivatives of erythrose: Ls-allothreonine in amino-acid nomenclature is synonymous with 2-amino-2,4-dideoxy-L<sub>g</sub>-erythronic acid in carbohydrate nomenclature, and Ds-allothreonine with 2-amino-2,4-dideoxy-D<sub>g</sub>-erythronic acid (the subscript letters d or g being added to the configurational prefixes where there might be uncertainty regarding the reference centre of chirality; *see* *OL convention*).] L-Allothreonine does not occur in peptide linkage in proteins; however, one residue per molecule is present in the peptide antibiotic telomycin. Residues of D-allothreonine have been found in the glycolipid and peptidolipid of actinomycetes, and in mycobacteria.

L-allothreonine

D-allothreonine

**allotopic** 1 of, relating to, or having the property of allotopy. 2 (in genetics) describing a mutation that imparts to one tissue a particular metabolic characteristic normally found in another tissue.

**allotropy** the phenomenon of the formation of a membrane-enzyme complex resulting in alteration of the properties of both enzyme and membrane. For example, a change in enzymatic activity is sometimes observed when a soluble enzyme is adsorbed on an interface.

**allotrope** any of the different physical forms in which a chemical element can exist; e.g. diamond, graphite, and fullerenes are allotropes of carbon.

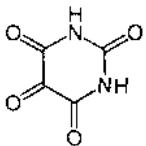

**allotropy** or **allotrophy** or **allotropism** the phenomenon of a substance, especially an element, existing in more than one physical form (allotrope), usually in the same phase; e.g. the different crystalline forms of carbon or phosphorus, or the different molecular forms of dioxygen and ozone. *Compare* polymorphism (def. 2). -allotropic adj.

**allotype** an antigenically distinct variant of a protein or other antigen arising from intraspecies genetic differences. Each individual has a particular variant at each immunoglobulin gene locus, which will often differ from those in other individuals of the same species.

## allotypic specificity

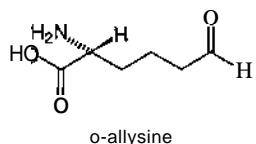

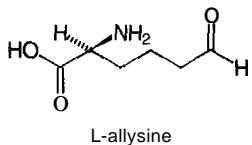

allotypic specificity an antigenic specificity that is not the same in a given protein in all normal individuals of a species. allotypy the property, possessed by certain proteins and other antigens, of existing in antigenically distinct forms or allotypes. Thus allotypes of the same protein, although not distinguished by usual physicochemical and chemical criteria, can elicit specific antibodies in some other members of the same species. They are those idiotypes that behave as xenotypes in other individuals of the same species.

**alloxan** mesoxalylurea; 2,4,5,6-(IH,3H)-pyrimidinetetrone; a compound used experimentally to induce diabetes through its action in selectively destroying pancreatic B-cells.

**allozyme** any enzyme variant produced by a particular allele. **allulose** trivial name (*not recommended*) for psicose.

**allysine** 6-oxonorleucine; 2-aminoadipaldehydic acid; an *a*-amino acid not normally found in proteins but enzymically formed from lysine *in situ* as an intermediate in the creation of covalent cross-links between adjacent polypeptide strands during the maturation of certain connective-tissue proteins (e.g. collagen, elastin). The enzyme lysyl oxidase oxidizes the terminal amino-methylene groups of residues of either lysine or 5-hydroxylysine to aldehyde groups, forming residues of allysine or hydroxyallysine respectively. See also desmosine, isodesmosine, lathyrism, noncoded amino acid, syndesine.

**almond emulsin** see 1,3-a-L-fucosidase.

**ALP** (*in clinical biochemistry*) abbr. for alkaline phosphatase. **alpha symbol:** *a* (lower case) or *A* (upper case); the first letter of the Greek alphabet. For uses see Appendix A.

**alpha cell** an alternative term for Acell.

**alpha-1 cell** an alternative term for Dcell.

**alpha chain** or *α chain* 1 the heavy chain of IgA immunoglobulin molecules. 2 one of the two types of polypeptide chain present in normal adult hemoglobin (Hb A) molecules.

**alpha effect** the enhancement of nucleophilicity that occurs when the atom adjacent to a nucleophilic site bears a lone pair of electrons. It has been invoked to explain the high toxicity of, e.g., hydroxylamine and the cyanide ion.

**alpha-fetoprotein** see *a*-fetoprotein.

**alpha globulin** or *α-globulin* any of a group of plasma proteins that migrate most anodically among the globulins in electrophoresis at pH values slightly above 7.

**alpha helix** or *α-helix* a helical, or spiral, configuration of a polypeptide chain in which successive turns of the helix are

## alum precipitation

held together by hydrogen bonds between the amide (peptide) links, the carbonyl group of any given residue being hydrogen-bonded to the imino group of the third residue behind it in the chain. This is the case for all of the carbonyl and amide groups of the peptide bonds of the main chain. The alpha helix has 3.6 residues per turn and the translation (def. 2), or pitch, along the helical axis is 1.5 Å per residue and 5.4 Å per turn. The helix may be left- or right-handed, the latter being much more common. It is one of the two basic elements of the secondary structure adopted by a polypeptide chain within the hydrophobic core of a globular protein (the other being beta strand). The alpha helix was first described by Pauling and Corey in 1951, based on model building. See also gamma helix.

**alpha hemolysis** or *α-hemolysis* a type of hemolysis, characterizing certain strains of streptococci, in which a greenish tinge occurs around the bacterial colonies in a blood-agar plate. Compare beta hemolysis.

**alphabetic** describing any coding system or data set that provides for letters, numbers, and other symbols such as punctuation. [From 'alphabetic' and 'numeric'.]

**alpha oxidation** or *α-oxidation* a series of reactions occurring in plant tissue by which a free fatty acid of chain length ranging from CIS to C<sub>13</sub> is oxidatively degraded with the simultaneous release of a molecule of CO<sub>2</sub> from the carboxyl group and the formation of a free fatty acid containing one carbon atom fewer. NAD<sup>+</sup> is the only cofactor required.

**alpha particle** or *α particle* a fast-moving positively charged helium nucleus, 4He<sup>2+</sup>, emitted in the decay of certain radio-nuclides.

**alpha radiation** radiation consisting of fast-moving alpha particles.

**alpha ray** a directed stream of alpha particles.

**alpha receptor** see adrenoceptor.

**ALS** abbr. for 1 antilymphocyte serum. 2 (*in clinical biochemistry*) (fructose-bisphosphate) aldolase, EC 4.1.2.13.

**Alt symbol** for altrose.

**ALT** (*in clinical biochemistry*) abbr. for alanine transaminase.

**alternate pathway** see alternative pathway (def. 2).

**alternating axis of symmetry** see symmetry.

**alternating current** abbr.: a.c. or AC; an electric current that varies with time in a sinusoidal manner. The abbreviation a.c. may also be applied to a voltage of varying polarity.

**alternative pathway** 1 a misleading term sometimes applied to any of the metabolic pathways by which glucose is broken down in animals, especially the pentose (phosphate) pathway. 2 (*or alternate pathway*) a pathway by which complement components C3–C9 are activated without a requirement for CI, C2, or C4.

**alternative splicing** the occurrence of alternative patterns of splicing of a primary RNA transcript of DNA to produce different mRNAs. After excision of introns, selection may determine which exons are spliced together to form the mRNA. An example is the production of mRNA for 19S IgM, which is secreted, and 7S IgM, which is inserted into the lymphocyte membrane, both products being coded for by the same gene, but the mRNA for 7S IgM having fewer of the original exons. Altman, Sidney (1939– ), Canadian-born US biochemist; Nobel Laureate in Chemistry (1989) jointly with T. R. Cech 'for their discovery of catalytic properties of RNA'.

**altro+** prefix denoting a particular configuration of a set of four (usually) contiguous >CHOH groups, as in D- or L-altriose. See monosaccharide.

**altriose** symbol: Alt; *altrio-hexose*; an aldohexose that differs from glucose in the configuration of the hydroxyl groups on C-2 and C-3.

**alum-precipitated toxoid** any preparation in which a toxoid is adsorbed onto an adjuvant containing an aluminium compound, e.g. aluminium hydroxide gel or an alum. The term is applied especially to diphtheria toxoid.

**alum precipitation** a technique in which a soluble immunogen is converted into particulate form by mixing with a solution of

**Alu sequence**

ambo-

an alum (e.g. aluminium potassium sulfate) and adjusting the pH to near 6.5. The antigen is adsorbed on the aluminium hydroxide precipitate so formed, which acts as an adjuvant in immunization.

**Alu sequence or AluI sequence or Alu repeat or AluI repeat** any of various base sequences dispersed in human, rat, and mouse (and perhaps other) genomes of  $\approx 0.3$  kbp and spaced at approximately 5 kbp. Each Alu sequence comprises two similar 130 bp boxes (Alu left and Alu right). The name derives from the presence in such sequences of sites for the restriction enzyme *AluI*.

**alveolus** (*pl.* alveoli) any small pit, cavity, or saclike dilatation, such as an air cell of the lungs, an acinus of a compound gland, or a tooth socket. -alveolar *ad.*

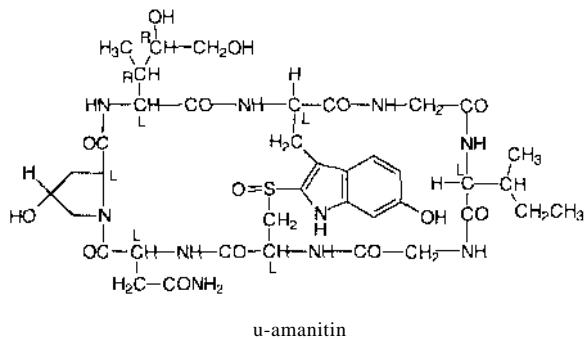

**Alzheimer's disease or Alzheimer's dementia or Alzheimer sclerosis** a genetically and phenotypically complex syndrome of progressive cognitive failure. It is the most common cause of late-life dementia (senile dementia) in developed nations, but early onset before the age of 65 (presenile dementia) may also occur. All cases develop numerous extracellular deposits of the I3-amyloid peptide in the brain, and almost all have intraneuronal bundles of abnormal filaments composed of highly phosphorylated forms of the microtubule-associated tau protein. Missense mutations in the chromosome 21 gene coding for the 13-amyloid peptide precursor have been described, and a chromosome 14q gene coding for a 467-amino-acid protein with seven putative membrane-spanning domains has been linked with the early-onset disease. Inheritance of the E4 allele of the gene encoding apolipoprotein E is one of the main risk factors for late-onset Alzheimer's disease. [After Alois Alzheimer (1864-1915), German neurologist who in 1907 described the condition of a patient referred to as Auguste D.]

**Am symbol** for americium.

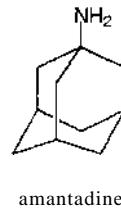

**Amadori rearrangement** an acid- or base-catalysed chemical rearrangement reaction in which an N-substituted aldosamine is converted into the corresponding N-substituted 1-amino-1-deoxy-2-ketose. It occurs, e.g., in the Maillard reaction, in the reaction of carbohydrates with phenylhydrazine, in the formation of hemoglobin Ale' and in a step in tryptophan biosynthesis - isomerization of N-(5'-phosphoribosyl)-anthranilic acid into 1-(a-carboxyphenylamino)-1'-deoxyribose-5'-phosphate.

**Amanita toxin** see amatoxin.

**amanitin** any of various amatoxins, especially  $\alpha$ -,  $\beta$ -,  $\gamma$ -, and  $\epsilon$ -amanitin. These occur, together with other amatoxins, in the highly poisonous agaric commonly called the death-cap fungus or deadly agaric (*Amanita phalloides*), and in some related species.

**amantadine** *trivial name for* 1-adamantanamine; 1-aminoadamantane; C<sub>10</sub>H<sub>17</sub>N; a polycyclic antiviral agent that is especially effective as a prophylactic against influenza A virus. It appears not to affect viral attachment to cells but to block penetration or uncoating. *See also* adamantine.

**amatoxin** any member of a family of closely related bicyclic octapeptides present in the highly poisonous agaric commonly called the death-cap fungus or deadly agaric (*Amanita phalloides*), and in some related species.  $\alpha$ -Amanitin is the best known member and the chief toxic constituent of *A. phalloides*. The majority of amatoxins are highly toxic, though much slower in action than the congeneric and less potent phallotoxins. For example, the ingestion by an adult man of 10 mg  $\alpha$ -amanitin (the quantity in a single fruit body of *A. phalloides*) leads over the course of several days to death in the absence of treatment. The common elements of the molecular structure of amatoxins include residues of *trans*-4-hydroxy-L-proline, (usually mono- or dihydroxy-)L-isoleucine, and the bisfunctional amino acid (usually 6'-hydroxyY)-L,L-tryptathionine S-oxide (which forms a sulfoxide bridge across the molecule; *see structure at amanitin*), together with two residues of glycine.  $\alpha$ -Amanitin binds very tightly ( $K_{diss} = 10^{-8}$  M) to eukaryotic RNA polymerase II, thereby blocking the formation of mRNA precursors and hnRNA. It also binds, but rather less tightly ( $K_{diss} = 10^{-6}$  M), to eukaryotic RNA polymerase III, thereby blocking the formation of tRNA and 5S RNA. It has little action on RNA polymerase I. Hence the synthesis of RNA and protein is markedly inhibited in eukaryotic cells but not in prokaryotic cells.

**amber** 1 a fossil resin. 2 *see amber mutant.*

**amber codon or amber triplet symbol:** UAG; one of the three terminator codons or nonsense codons in an mRNA molecule. **Amberlite** *proprietary name for* various cation- and anion-exchange resins.

**amber mutant or amber** a T4 bacteriophage carrying an amber mutation. *See also* ochre mutant, opal mutant.

**amber mutation** a temperature-sensitive conditionally lethal mutation, capable of occurring in almost any gene of a bacterial virus, that causes the synthesis of a particular polypeptide chain to terminate prematurely. It is due to the alteration of one codon in the corresponding messenger RNA to an amber codon, i.e. a termination codon.

**amber suppressor** any of a number of mutations in *Escherichia coli* that suppress an amber codon in mRNA thereby allowing insertion of one of several alternative amino acids into a polypeptide at that site. The mutations result in changed anticodons of the tRNA molecules, consequent on single base substitutions in their DNA coding sequences.

**ambi+ or ambo+** *comb. form* denoting on both sides, both. *Compare* amphi+. [From Latin *ambo*, both.]

**ambient** of or relating to the immediate environment.

**ambiquitous** describing an enzyme that has reversibly convertible soluble and membrane-bound forms. -ambiquity *n.*

**ambo+** *a variant form of ambi+.*

**ambo-** prefix designating chiral compounds in which both of the possible molecular configurations are present at an indicated chiral centre or residue but not necessarily in equimolar proportions. Such situations may arise especially with chiral compounds obtained by partial chemical synthesis from chiral precursors in asymmetric reactions. Examples: the amino-acid sequence Phe-ambo-Ala-Leu, representing a mixture of Phe-Ala-Leu and Phe-D-Ala-Leu; and the trivial name 4'-ambo-8'-ambo-a-tocopherol, representing a synthetic a-tocopherol in which C-2 has the natural, (*R*)-, configuration and C-4' and

**amboceptor**

C-8' have both (*R*)- and (*S*)-configurations though not necessarily in equimolar proportions. Compare OL-, rae-.

**amboceptor** (*formerly*) an alternative term for hemolytic antibody. [Named by Ehrlich, who pictured hemolysin as an antibody having specific receptors both for erythrocytes and for complement, thereby serving to link the two together.]

**ameba** an alternative US spelling of amoeba.

**amelogenin** the predominant protein in dental enamel during early development. Example (bovine): database code AMEG\_BOVIN, 170 amino acids (19.24 kDa).

**amidorphin** an opioid peptide corresponding to residues 104-129 of bovine proenkephalin A, but which is amidated at its C terminus.

**Ames test** see *Salmonella* mutagenesis test.

**amethopterin** another name for methotrexate.

**amidase** EC 3.5.1.4; acylamide amidohydrolase; an enzyme that catalyses the hydrolysis of a monocarboxylic acid amide to monocarboxylate and NH<sub>3</sub>.

**w-amidase** EC 3.5.1.3; w-aminodicarboxylate amidohydrolase; an enzyme that catalyses the hydrolysis of an w-amidodicarboxylic acid to dicarboxylate and NH<sub>3</sub>.

**amide** to convert any oxyacid into its corresponding amide. -amidated adj.; amidation n.

**amide** any compound containing one, two, or three acyl groups attached to a nitrogen atom. An amide may be derived formally or actually by condensation of an oxyacid with ammonia or a primary or secondary amine. Amides derived from carbon acids may be termed carboxamides, those from sulfonic acids sulfonamides, etc. Examples include: acetamide, methanamide, CH<sub>3</sub>-CO-NH<sub>2</sub>; sulfanilamide, 4-aminobenzenesulfonamide, H<sub>2</sub>N-C<sub>6</sub>H<sub>4</sub>-SO<sub>2</sub>-NH<sub>2</sub>; and diethylformamide, formdiethylamide, H-CO-N(C<sub>2</sub>H<sub>5</sub>)<sub>2</sub>. The term includes imide and peptide.

**amidination** the process or reaction of introducing an amidino group into a chemical entity.

**amidine** any compound of the type R-C(=NH)-NH<sub>2</sub>.

**amidino** the monovalent group -C(=NH)-NH<sub>2</sub>.

**amidino+** comb. form denoting the presence of an amidino group.

**N-amidinoglycine** see glycocystamine.

**amido+** comb. form denoting the presence of an amide group.

**Amido Black** see Naphthalene Black.

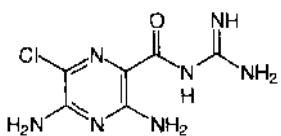

**amidolysis** any cleavage of an amide (including a peptide) to the parent oxyacid and ammonia or an amine.

**amidophosphoribosyltransferase** EC 2.4.2.14; systematic name: 5-phosphoribosylamine:pyrophosphate phospho-a-ribosyltransferase (glutamate-amidating); other names: glutamine phosphoribosylpyrophosphate amidotransferase; phosphoribosyldiphosphate 5-amidotransferase. An enzyme that catalyses the formation of 5-phospho-p-o-ribosylamine from L-glutamine, 5-phospho-a-o-ribose 1-diphosphate, and H<sub>2</sub>O with release of L-glutamate and pyrophosphate. This is an early reaction in purine biosynthesis. Example from *Escherichia coli*: database code PURI\_ECOLI, 504 amino acids (56.38 kDa).

**amidorphin** an opioid peptide corresponding to residues 104-129 of bovine proenkephalin A, but which is amidated at its C terminus.

**amidotransferase** see amidophosphoribosyltransferase, glutamine amidotransferase.

**ami/otide** N-amidino-3,5-diamino-6-chloropyrazinecarboxamide; a potent and specific inhibitor of Na<sup>+</sup> entry into cells. It inhibits Na<sup>+</sup>K<sup>+</sup>-ATPase at low concentrations. It is used as a potassium-sparing diuretic.

**amino acid-tRNA ligase**

**amiloride-binding protein** see amine oxidase (copper-containing).

**amine** any organic compound that is weakly basic in character and contains an amino or a substituted amino group. Amines are called primary, secondary, or tertiary according to whether one, two, or three carbon atoms are attached to the nitrogen atom. See also quaternary ammonium compound.

**amine oxidase (copper-containing)** EC 1.4.3.6; other names: diamine oxidase; diamino oxhydrolase; histaminase; an enzyme that catalyses the oxidation by dioxygen of an amino group to an aldehyde, with release of ammonium and hydrogen peroxide. 6-Hydroxydopa and copper are cofactors. Example, human amiloride-sensitive amine oxidase (copper-containing) precursor (amiloride-binding protein; abbr.: ABP): database code ABP\_HUMAN, 751 amino acids (85.27 kDa); this enzyme binds amiloride.

**amine oxidase (flavin-containing)** see monoamine oxidase.

**aminergic** describing a receptor that is activated by a specific (biogenic) amine. The term is usually applied to nerves that act by releasing a monoamine (norepinephrine, dopamine, or 5-hydroxytryptamine) from their nerve endings. Compare adrenergic, cholinergic, dopaminergic, peptidergic, purinergic, serotonergic.

**amino** the chemical group -NH<sub>2</sub> in an organic molecule. It is basic in character and formally derived by the removal of a hydrogen atom from ammonia.

**amino+** comb. form denoting the presence of an amino group.

**amino acid** any organic acid containing one or more amino substituents. The term is usually restricted to amino, especially a-amino, derivatives of aliphatic carboxylic acids, but it can also include p-amino derivatives.

**amino-acid accepting RNA** see transfer RNA.

**amino-acid N-acetyltransferase** EC 2.3.1.1; other name: N-acetylglutamate synthase (abbr.: AGS); an enzyme that catalyses the formation of N-acetyl-L-glutamate (abbr.: AGA) from acetyl-CoA and L-glutamate with the release of CoA. This is the enzyme responsible for the formation of AGA as an obligate activator of carbamoyl-phosphate synthase (def. I), the first step in the ornithine-urea cycle. Example from *Escherichia coli*: database code ARGA\_ECOLI, 443 amino acids (49.14 kDa). For another example, see glutamate N-acetyl transferase.

**amino-acid analyser** any instrument or apparatus for the automated analysis of mixtures of amino acids. The amino acids are separated individually and quantified spectrophotometrically.

**amino-acid arm** the base-paired segment of transfer RNA containing both the 3' and the 5' ends of the RNA molecule, on which the specific amino acid is attached to the 3'-hydroxyl at the 3' end.

**amino-acid oxidase** any enzyme that catalyses the oxidation by dioxygen of the amino group of an a-amino acid to an oxo acid with release of ammonium and hydrogen peroxide. L-amino-acid oxidase, EC 1.4.3.2, is specific for L-enantiomers and D-amino-acid oxidase, EC 1.4.3.3, is specific for D-enantiomers. Both enzymes have FAD as coenzyme. Examples: L-amino-acid oxidase from *Neurospora crassa*: database code OXLA\_NEUCR, 695 amino acids (76.80 kDa); D-amino acid oxidase (human) a peroxisomal enzyme: database code OXDA\_HUMAN, 347 amino acids (39.37 kDa).

**amino-acid residue** that part of any amino-acid molecule that is present when the amino acid is combined in a (poly)peptide, i.e. the amino acid less the atoms (a hydrogen atom or and a hydroxyl group) that have been removed during the formation of a peptide bond or bonds.

**amino-acid sequence or primary structure** the sequential order of amino-acid residues in a polypeptide or protein. It is usually given from the end carrying an a-amino group not in peptide linkage, i.e. from the N-terminal end.

**amino-acid site** a less correct term for aminoacyl site.

**amino acid-tRNA ligase** other name: aminoacyl-tRNA syn-

## amino aciduria

thetase. Any of the sub-subclass EC 6.1.1 of enzymes that catalyse the formation of aminoacyl-tRNA from ATP, amino acid, and tRNA with release of pyrophosphate and AMP. Each amino acid has its cognate amino acid-tRNA ligase and tRNA acceptor species; e.g. in the case of glutamate-tRNA ligase (EC 6.1.1.17), the tRNA is tRNAGlu and the product is Glu\_tRNAGlu. The enzymes are complicated. Aminoacyl adenylate is normally an intermediate and the initial aminoacyl-tRNA product usually involves 2'-substitution with subsequent rearrangement. Specificity is not perfect but the enzymes have one or more mechanisms for correcting mischarged aminoacyl-tRNAs, which occur with structurally similar amino acids (e.g. Ile-tRNAAval). Structurally the enzymes belong to several classes. Example of type I: tyrosine-tRNA ligase from *Bacillus stearothermophilus* (EC 6.1.1.1): homodimer, database code SYY\_BACST, 419 amino acids (47.25 kDa). The 3-D structure of this, along with its mutants and complexes with substrates, is known; it has a large helical content and a characteristic ATP-binding motif.

**amino aciduria** a condition in which, on a normal dietary intake, amino acids appear in the urine. It may be due to renal defects or an inherited disease of amino-acid metabolism. See Hartnup disease, maple syrup urine disease.

**aminoacyl** the acyl group, R-CH(NH<sub>2</sub>)-CO-, formed by removal of the hydroxyl group from the α-carboxyl group of an (unknown or unspecified) α-amino acid.

**aminoacylase 1** EC 3.5.1.14; an N-acyl amino-acid aminohydrolase; an enzyme that catalyses any reaction of the general type:

Example (human): database code ACYLHUMAN, 408 amino acids (45.88 kDa). 2 EC 3.5.1.15; *recommended name*: aspartoacylase; an enzyme that hydrolyses N-acetylaspartate to acetate and aspartate. Example (human): database code ACY2\_HUMAN, 313 amino acids (35.73 kDa).

**aminoacyl site or A site or (correctly) aminoacyl-tRNA site** the site on a ribosome to which the incoming aminoacyl-tRNA is bound during protein synthesis. In bacteria this involves ribosomal proteins L1, L5, L7/L12, L20, L30, L33, both 16S and 23S rRNA (L7 and L12 differ in acetylation only).

**aminoacyltransferase** any enzyme of sub-subclass EC 2.3.2 that transfers aminoacyl groups, forming either an ester or an amide.

**aminoacyl-tRNA** the form in which amino acids are transported to the ribosomes during protein synthesis. The amino acid is esterified through its carboxyl group to the 3'-hydroxyl group of the 3'-terminal adenosine of a molecule of transfer RNA.

**aminoacyl-tRNA synthetase** *an alternative name for amino acid-tRNA ligase.*

**α-amino adipate** 2-aminohexanedioate; an intermediate in the synthesis of lysine (*see* aminoacidic pathway). It is a competitive inhibitor of glutamate receptors.

**aminoacidic pathway** a metabolic pathway for the biosynthesis of lysine that occurs in some algae, *Euglena*, and fungi. It involves a two-carbon extension of 2-oxoglutarate to 2-oxoadipate (acetyl-CoA addition to form homocitrate, thence cis-homoaconitate, homoisocitrate, and oxidation to 2-oxoadipate), transamination to 2-aminoadipate, reaction of the latter with ATP to yield 5-adenylyl-2-aminoadipate, and further reductive reactions to 2-aminoadipic-5-semialdehyde, saccharopine, and finally L-lysine. Aminoacidate is also involved in lysine catabolism in mammals.

**amino alcohol** any aliphatic organic molecule or moiety containing both an amino and a hydroxyl substituent.

**p-aminobenzoic acid** abbr.: PABA; 4-aminobenzoic acid; a compound present in yeast as a factor in the B complex of vitamins, and a structural component of folic acid and related compounds. It is a substrate for the bacterial enzyme dihy-

## aminoethylbenzenesulfonyl fluoride

dropteroate synthase, EC 2.5.1.15, competitive inhibitors of which (e.g. sulfonamides) are effective antibacterial agents. It is used in sunscreen preparations. *De novo* synthesis is through the intermediate chorismate formed by the shikimate pathway. It is formed in a test of pancreatic function, the PABA test.

**γ-aminobutyrate receptor** *see* GABA receptor.

**γ-aminobutyrate shunt or GABA shunt** a variation of the tricarboxylic-acid cycle in which α-oxoglutarate is converted to L-glutamate either by transamination or by reductive amination. The glutamate is decarboxylated to form γ-aminobutyrate, which can re-enter the tricarboxylic-acid cycle after being oxidized to succinate. This metabolic pathway occurs in brain tissue, presumably to form γ-aminobutyric acid, and is also prominent in green plants.

**4-aminobutyrate transaminase** EC 2.6.1.19; *other names*: γ-aminobutyrate transaminase; GABA transaminase; β-alanine-oxoglutarate aminotransferase; an aminotransferase enzyme important in the metabolism of γ-aminobutyric acid (abbr.: GABA). It catalyses the reaction:

Example from yeast: database code GATA\_YEAST, 471 amino acids (52.90 kDa).

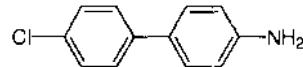

**α-amino-n-butyric acid** 2-aminobutanoic acid; a component of ophthalmic acid.

**γ-amino-n-butyric acid** abbr.: GABA; 4-aminobutanoic acid, H<sub>2</sub>N-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-COOH; an amino acid not found in proteins but occurring principally in the central nervous system, where it is an important inhibitory neurotransmitter. It is also found in some plants. *See also* GABA receptor.

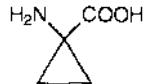

**ε-aminocaproic acid** symbol: sAcP; (*formerly*) *an alternative name for* 6-aminohexanoic acid.

**7-aminocephalosporanic acid** a compound obtained by the acid hydrolysis of cephalosporin C and used in the manufacture of semisynthetic cephalosporins.

**4-amino-4'-chlorodiphenyl** abbr.: pCPA; an irreversible inhibitor of tryptophan 5-hydroxylase an enzyme in the pathway for synthesis of 5-hydroxytryptamine.

**1-aminocyclopropane-1-carboxylic acid** a key intermediate in the conversion of L-methionine into ethylene in higher plants. It is also a potent and selective ligand for the glycine modulatory site of the NMDA receptor (*see* glutamate receptor). It is formed from S-adenosyl-L-methionine by l-aminocyclopropane-1-carboxylate synthase, EC 4.4.1.14.

**aminodeoxysugar or amino sugar or amino-saccharide or amino-monosaccharide** any monosaccharide or monosaccharide derivative in which an alcoholic hydroxyl group has been replaced by an amino group.

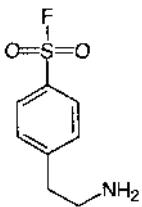

**aminoethoxyvinylglycine** abbr.: AVG; an inhibitor of ethylene formation in higher plants. It is produced by *Streptomyces* spp. It acts at the level of l-aminocyclopropane-1-carboxylate synthase (*see* l-aminocyclopropane-1-carboxylic acid).

**aminoethyl symbol**: Aet; the -CH<sub>2</sub>-CH<sub>2</sub>-NH<sub>2</sub> group.

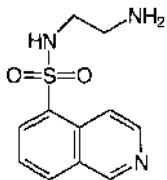

**aminoethylbenzenesulfonyl fluoride** abbr.: AEBSF; an inhibitor of serine endopeptidases. It is both soluble and stable in aqueous solutions, and is less toxic (LD<sub>50</sub> 2.8 g kg<sup>-1</sup>) than

## N-(2-aminoethyl)isoquinoline-5-sulfonamide

**phenylmethylsulfonyl fluoride**, but with the same action and similar potency. Compare **organophosphate**.

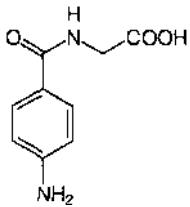

**N-(2-aminoethyl)isoquinoline-5-sulfonamide or H9** a selective inhibitor of casein kinase I, protein kinase A, and, less potently, protein kinase C.

**aminoglycoside antibiotic** any member of a group of broad-spectrum antibiotics, of similar toxicity and pharmacology, that contain an aminodeoxysugar, an amino- or guanidino-substituted inositol ring, and one or more residues of other sugars. The group includes **streptomycin**, **neomycin**, framycetin, **kanamycin**, paromomycin, and **gentamicin**.

**6-aminohexanoic acid** symbol: eAhx; a compound that acts as an inhibitor of **streptokinase** and **urokinase** and prevents the synthesis of **plasmin**.

**para-aminohippuric acid** abbr.: PAH; *N*-(4-aminobenzoyl)glycine; it is used in renal clearance tests. Its clearance exceeds that of inulin, indicating that it is actively secreted by renal tubular cells. It shares this transport system with penicillin and competitively inhibits penicillin secretion. PAH clearance is taken as a measure of effective renal plasma flow and the inulin:PAH clearance ratio as the filtration fraction, normally about 18%.

**a-amino-3-hydroxy-5-methylisoxazolepropionic acid receptor or AMPA receptor** an excitatory amino acid receptor coupled directly to a transmembrane cation channel. It was formerly known as the quisqualate receptor. It is a type of **glutamate receptor**.

**aminoimidazole carboxamide ribonucleotide** see AltAR.

**aminoimidazole ribonucleotide** see AIR.

**amino-imino tautomerism** a form of **tautomerism** in which the amino and the imino forms of a compound are in equilibrium, the change corresponding to the migration of a hydrogen atom. Compare **keto-enol tautomerism**.

**a-aminoisobutyric acid** *a*-methylalanine, 2-amino-2-methylpropanoic acid,  $(\text{CH}_3)_2\text{C}(\text{NH}_2)\text{COOH}$ ; a non-metabolizable amino-acid analogue used in metabolic and other studies.

## aminotransferase

**6-aminolevulinate** or (esp. Brit.) **6-aminolaevulinate** abbr.: ALA,  $\delta$ ALA, or DALA; 5-amino-4-oxopentanoate;  $\text{H}_2\text{N}-\text{CH}_2-\text{CO}-[\text{CH}_2]_2-\text{COO}^-$ ; a compound formed in animals and bacteria from glycine and succinyl-CoA (see **5-aminolevulinate synthase**); in plant chloroplasts it is formed from glutamate (see **glutamate-1-semialdehyde 2,1-aminomutase**). It is an intermediate in **tetrapyrrole** biosynthesis.

**5-aminolevulinate synthase** EC 2.3.1.37; systematic name: succinyl-CoA:glycine C-succinyltransferase (decarboxylating); other names: 6-aminolevulinate synthase;  $\delta$ ALA synthetase. The first and regulatory enzyme in the porphyrin biosynthetic pathway. It catalyses a reaction between succinyl-CoA and glycine to form 5-aminolevulinate, CoA, and  $\text{CO}_2$ . Pyridoxal phosphate is a cofactor. Example from human erythroid type (precursor): database code HEMO\_HUMAN, 587 amino acids (64.62 kDa).

**aminolysis** 1 any chemical reaction in which an amine reacts analogously to ammonia in **ammonolysis**. 2 any hydrolytic deamination reaction in which an amino group is replaced by a hydroxyl group.

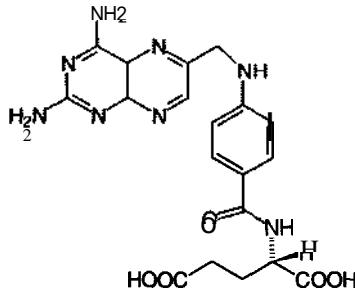

**2-amino-4-methylhex-4-enoic acid** a nonprotein amino acid found in plants, e.g. *Aesculus californica* (California buckeye). **amino-monosaccharide** an alternative name for **aminodeoxy-sugar**.

**6-aminopenicillanic acid** abbr.: 6-APA; a compound formally derived by the removal of the acyl side chain from **penicillin**. It is obtained industrially from fermentations in the absence of side-chain precursors but more usually by removal of the side chain using an amidase from *Escherichia coli* as an immobilized support. It is a very important intermediate for the manufacture of semisynthetic penicillins.

**aminopeptidase** any enzyme of sub-subclass EC 3.4.11,  $\alpha$ -aminoacylpeptide hydrolases, that hydrolyse N-terminal amino-acid residues from oligopeptides or polypeptides.

**4-aminophthalhydrazide** see **luminol**.

**aminopterin** 4-aminofolic acid; a potent inhibitor of dihydrofolate reductase ( $K_i < 10^{-9}$  M). It is used as an antineoplastic agent in the treatment of acute leukemia and choriocarcinoma. It blocks nucleotide biosynthesis and thus also DNA biosynthesis, and has a similar action to **amethopterin**.

**amino-saccharide** an alternative name for **aminodeoxysugar**.

**amino-terminal determination** the analysis of a peptide or a protein to determine the nature of the amino-acid residue at the N terminus. The free terminal  $\alpha$ -amino group is substituted with a reagent such as 2,4-dinitrofluorobenzene (Sanger's reagent), dansyl chloride, or phenylisothiocyanate (Edman's reagent). The substituted terminal residue is then removed by hydrolysis and identified by, e.g., chromatography.

**amino terminus** or **amino terminal** an alternative name for **N terminus** (of a polypeptide chain when the  $\alpha$ -amino, or  $\alpha$ -imino group is free). Compare **carboxyl terminus**.

**aminotransferase** or **transaminase** any enzyme, of the large sub-subclass EC 2.6.1, that catalyses the reversible transfer of a nitrogenous group, usually an amino group, to an acceptor, generally a 2-oxo acid. Pyridoxal phosphate is a coenzyme, the

## amitosis

intermediate pyridoxamine phosphate being formed in the reaction. *See also* transamination.

amitosis division of a cell nucleus by a process other than mitosis.

ammonification of nitrate *see* nitrate reduction.

ammonium 1 the  $\text{NH}_4^+$  ion, formed by hydronation of a molecule of ammonia. It is formed from  $\text{N}_2$  by root-nodule bacteria (*Rhizobium* spp.) in leguminous plants, and is an excretory product in ammonotelic animals. In higher animals it is toxic in elevated concentrations, and for excretion is converted to uric acid in uricotelic animals, and to urea in ureotelic animals. 2 the chemical group  $\sim\text{NH}_3^+$ .

ammonium sulfate ( $\text{NH}_4\text{HSO}_4$ ): a salt much used in the purification of proteins, which vary in their solubility in ammonium sulfate solutions. An early step in the purification of a protein is thus often an ammonium sulfate precipitation.

ammonolysis any chemical reaction in which a covalent bond is cleaved by the action of ammonia, one or more of the hydrogen atoms of the ammonia being replaced by other atoms or groups; e.g.

ammonotelic describing animal groups (e.g. crustaceans, marine mussels, octopods) in which ammonium is the principal end-product of the degradation of nitrogen-containing compounds.

amniocentesis the process of withdrawing a sample of amniotic fluid from the amnion by means of a hollow needle. It is particularly useful in the diagnosis of the status of a fetus with respect to proteins or DNA but, in the human, sampling can only be carried out during the second trimester of pregnancy.

amnion a membranous sac, filled with amniotic fluid, that surrounds and protects the embryo in higher animals. It is developed in reptiles, birds, and mammals but not in amphibians or fish.

amoeba or (US) ameba (*pl.* amoebae or amebae) any of a genus (*Amoeba*) of naked rhizopod protozoans in the order Amoeboidea, characterized by a thin pellicle and frequent alterations in shape due to the constant formation and retraction of pseudopodia. -amoebic or (US) amebic *adj.*

amoeboid or (US) ameoboid 1 of, pertaining to, or reminiscent of an amoeba or amoebae. 2 describing cells, etc. that move by forming pseudopodia.

amorph a mutant allele that is inactive and fails to produce a measurable effect. It may act as a genetic block to normal biosynthesis.

amorphous 1 lacking definite shape or form. 2 noncrystalline; devoid of real or apparent crystalline form.

amount concentration *see* concentration.

amount of substance or chemical amount symbol: *n*; a fundamental physical quantity – one of the seven SI base physical quantities – proportional to the number of specified elementary entities of a substance (i.e. atoms, molecules, ions, radicals, electrons, etc., or any specified group(s) of such particles). The SI base unit of the amount of substance is the mole. The proportionality factor is the same for all substances, and is the reciprocal of the Avogadro constant,  $N_A$ . It is given by:  $nB = NB/N_A$ , where  $nB$  and  $NB$  are the amount of substance B and the number of entities of substance B, respectively. The terms 'amount of substance' and 'chemical amount' may often usefully be abbreviated to 'amount'.

amount-of-substance concentration *see* concentration.

amp abbr. for ampere.

AMP abbr. for adenosine monophosphate; i.e. adenosine phosphate.

2'AMP abbr. for adenosine 2'-monophosphate; i.e. adenosine 2'-phosphate.

3'AMP abbr. for adenosine 3'-monophosphate; i.e. adenosine 3'-phosphate.

## amphion

5'AMP abbr. for adenosine 5'-monophosphate; i.e. adenosine 5'-phosphate.

AMPA receptor abbr. for DL-a-amino-3-hydroxy-5-methylisoxazolepropionic acid; *see* 1L-amino-3-hydroxy-5-methylisoxazolepropionic acid receptor.

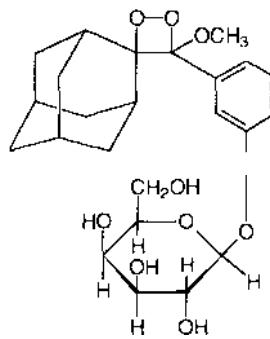

AMP-CP abbr. for 5'-adenyl methyl enephosphonate; i.e. adenosine 5'-[a,p-methylene]diphosphate.

AMP-CPP abbr. for 5'-adenyl methyl enediphosphate; i.e. adenosine 5'-[a,p-methylene]triphosphate

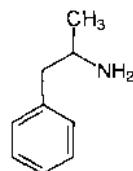

ampere symbol: A; abbr.: amp; the SI base unit of electric current. It is defined as that constant current, which if maintained in two straight parallel conductors of infinite length, of negligible circular cross-section, and placed 1 metre apart in a vacuum, would produce between these conductors a force equal to  $2 \times 10^{-7}$  newton per metre of length. [After André Marie Ampere (1775-1836), French physicist.]

amperometric titration any titration in which the end point is detected by measuring the electric current flowing when a potential is applied between two electrodes in a solution.

AMPGD abbr. for 3-(4-methoxyspiro)-1,2-dioxetane-3,2'-tricyclo[3.3.1.II]decan-(4-yl)phenyl-p-D-galactopyranoside; a chemiluminescent substrate for p-galactosidase (*see* chemiluminescence). It is used to detect the activity of the p-galactosidase gene when the latter is employed as a reporter gene in transgenic plants, etc.

amphetamine (*R,S*)-1-phenyl-2-aminopropane; ( $\pm$ )-a-methylphenethylamine; racemic desoxynorephedrine; a drug that has potent effects by stimulating the release of monoamines, inhibiting monoamine oxidase, and blocking neuronal reuptake of monoamines from the synapse. It is noted for its marked CNS stimulant actions. *See also* dextroamphetamine.

amphi+ or (before a vowel) amph+ prefix 1 denoting on both sides of, of both kinds. 2 denoting around.

Amphibia a class of anamniote vertebrate animals in the super-class Tetrapoda. They are characterized by having gills during the larval stage; these are typically replaced by lungs in the adults. The skin is moist, glandular, and scaleless.

amphibian 1 a member of the class Amphibia. 2 adapted for life both on land and in water; amphibious.

amphibolic describing an enzyme or metabolic pathway that is concerned in both anabolism and catabolism. -amphibolism *n.*

amphile *an alternative name for* amphiphile.

amphion or amphyion any molecule that contains ionic groups of opposite charge, not necessarily in equal numbers; an ion-

## amphipath

ized ampholyte. Compare dipolar iOD. -ampbionic or ampbo-  
ionic adj.

**amphipath** an alternative name for amphibile.

**amphipathic** or **ampbibilic** describing a molecule, such as a glycolipid or phospholipid, that contains both hydrophobic (i.e. lipophilic, nonpolar) and hydrophilic (i.e. aquaphilic, polar) parts; displaying amphipathy; being an amphiphile.

**amphipathic helix** an alpha helix with a specific topography consisting of opposite polar and nonpolar forces and a regular charge distribution. It is proposed as a basic structural element of the lipid-associating domains of apolipoproteins in very-low-density lipoproteins and high-density lipoproteins.

**amphipathy** or **amphiphilicity** the property (of a molecule, substance, etc.) of having affinity for both lipoidal and aqueous media; the extent or the degree to which a substance is amphipathic.

**amphiphile** or **amphile** or **ampbipath** a substance whose molecules have an affinity for both aqueous and nonaqueous media; an amphipathic substance. [From Greek *amphi-*, of both kinds, + *philos*, loving.]

**amphiphilic** an alternative term for amphipathic.

**amphiphysin** an acidic protein that is localized in many synapses of avian and mammalian nervous systems and also expressed in adrenal gland and anterior and posterior pituitary tissues. It is an autoantigen in paraneoplastic stiff-man syndrome, a generalized progressive muscular hypertonia. Example from human: database code HSAMPHI, 695 amino acids (76.17 kDa).

**amphiprotic** describing a substance that can either gain or lose one or more protons.

**amphiregulin** a bifunctional transmembrane glycoprotein with a C-terminal EGF-like domain. It inhibits growth of several human carcinoma cells in culture and stimulates proliferation of human fibroblasts and certain other tumour cells. It is induced by phorbol acetate. Example from human: database code AMPR\_HUMAN, 252 amino acids (27.86 kDa).

**amphoion** a variant spelling of amphion.

**Ampholine** the proprietary name for a series of mixtures of carrier ampholytes, which between them span the pH range 2.5–11. They consist of polyamino-polycarboxylic acids formed by reaction between acrylic acid and various polyethylene-polyamines. Each mixture contains a large number of ampholyte species of slightly differing isoelectric points. The mean and maximum apparent molecular masses are approximately 400 and 500 respectively. They are used in isoelectric focusing. They set up a pH gradient through the electrophoretic medium, and components being separated equilibrate to a point in the medium corresponding to their isoelectric point.

**ampholyte** any amphoteric electrolyte; see also carrier ampholyte, amphion.

**ampholyte-displacement chromatography** a technique for the fractionation of protein mixtures by displacement chromatography on an ion exchanger using a mobile phase containing a mixture of amphoteric substances of closely spaced isoelectric points (i.e. carrier ampholytes). Separation of the components is thought to involve specific interaction between the proteins and the carrier ampholytes as well as competition between them for sites on the ion exchanger.

**amphoteric** describing a molecule that can react as acidic towards strong bases and as basic towards strong acids, e.g. an amino acid.

**amphotericin B** Fungizone; a polyene macrolide antifungal antibiotic produced by *Streptomyces* spp. It is useful against many mycotic infections, acting as a membrane-active lytic agent. At appropriate concentrations it permeabilizes cells, creating pores formed of five to ten molecules of antibiotic in association with cholesterol. These pores allow the passage of

## amygdalin

low  $M_r$  substances. Because it is active only against sterol-containing membranes, mitochondria are not affected. It interacts preferentially with ergosterol, giving it a high affinity for plant membranes; hence its value as a fungicide. See also polyene antibiotic.

**ampicillin** a semisynthetic antibiotic of the penicillin type, and having a  $C_6H_5CH(NH_2)_2$  side chain.

**ampicillin-resistant symbol:** Apr; describing a cell, culture, organism, etc. that shows resistance to the lethal effects of the antibiotic ampicillin. This is a  $\beta$ -lactam antibiotic and resistance is often mediated by a class of enzymes called J3-lactamases, which are secreted either into the periplasmic space of Gram-negative bacteria or into the medium of Gram-positive bacteria. The cloning vector pBR322 contains an ampicillin-resistance gene.

**ampicillin-sensitive symbol:** Ap'; describing a cell, culture, organism, etc. that shows sensitivity to the antibiotic ampicillin.

**amplification** 1 the act, process, or result of amplifying. 2 the increase in the strength of an electromagnetic, chemical, or acoustic signal effected by an amplifier. 3 the production of additional copies of a stretch of genomic DNA, as a result of DNA either added to cells or originating in the chromosomes. These copies may result in tandem arrays in either an extrachromosomal or chromosomal location. This can result during selection of cells for resistance to certain agents; e.g. methotrexate blocks folate metabolism and may lead to amplification of dihydrofolate reductase genes. 4 the increase in the amount of a DNA with a specific sequence resulting from the polymerase chain reaction.

**amplifier** 1 an electronic device used to increase the strength of an electromagnetic signal; especially such a device used to increase the strength of an acoustic signal. 2 a combination of a receptor and various enzymes used to increase the strength of a chemical signal, as in a cascade sequence.

**amplify** to enlarge or to increase in strength or effect, especially an electromagnetic, acoustic, or chemical signal.

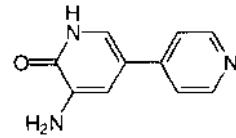

**amplimer** the amplified product of a polymerase chain reaction. **amplitude** 1 magnitude; greatness of extent. 2 symbol: *a*; the maximal displacement from zero or from a mean position of an oscillation or a curve.

**AMP-PCP** abbr. for 5'-adenylyl methylenediphosphonate; Le. adenosine 5'-[ $\beta,\gamma$ -methylene]triphosphate.

**AMP-PNP** abbr. for 5'-adenylyl imidodiphosphonate; Le. adenosine 5'-[ $\beta,\gamma$ -imido]triphosphate

**AMP-S** abbr. for adenosine 5'-[ $\alpha$ -thio]monophosphate; i.e. adenosine 5'-thiophosphate.

**amrinone** 5-amino-(3,4'-bipyridin)-6(1H)-one; an inhibitor of cardiac (type III) phosphodiesterase, resulting in increased cardiac contractility and vasodilatation. It is useful in the treatment of heart failure.

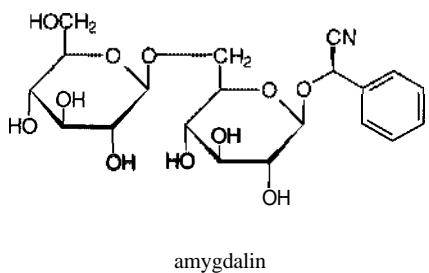

**AMS** (in clinical biochemistry) abbr. for a-amylase.

**amu** or **AMU** symbol for atomic mass unit. See also unified atomic mass unit.

**amunine** another name for corticotropin-releasing factor.

**amygdalin** (-)-o-mandelonitrile fl-o-gentibioside; a cyanogenic glycoside derived biogenically from phenylalanine and found principally in oil of bitter almonds, although it is present in other plants belonging to the Rosaceae.

## amygdalose

**amygdalose** former name for gentiobiose.

**amyl** former name for the pentyl group.

**amyl+** see amylo+.

**amylase** any enzyme able to hydrolyse O-glucosyl linkages in starch, glycogen, and related polysaccharides (see α-amylase, β-amylase).

**α-amylase** EC 3.2.1.1; systematic name: 1,4- $\alpha$ -D-glucan glucohydrolase. An enzyme that catalyses the endohydrolysis of 1,4- $\alpha$ -D-glucosidic linkages with the production of mainly  $\alpha$ -maltose from amylose, but also limit dextrins from glycogen and amylopectin since it cannot catalyse hydrolysis of 1,6 linkages. It is typical of animal cells (especially pancreas), and saliva. It has five motifs. The plasma level of α-amylase is raised in acute pancreatitis, and assay of the pancreas-specific isoenzyme aids diagnosis. Normal levels in human plasma are <300 IU L<sup>-1</sup>, (this is very method-dependent). Example,  $\alpha$ /β-amylase precursor from *Bacillus polymyxa*: database code AMYB\_BACPO, 1196 amino acids (130.75 kDa). The protein is cleaved proteolytically to form the  $\alpha$  (551 amino acids) and  $\beta$  (419 amino acids) enzymes.

**β-amylase** EC 3.2.1.2; systematic name: 1,4- $\alpha$ -D-glucan maltohydrolase; other names: saccharogen amylase; glycogenase. An enzyme that removes successive maltose units from the non-reducing ends of carbohydrate chains; the anomeric group undergoes inversion so that the major product is p-maltose. In some organisms it shares the same biosynthetic precursor as α-amylase. β-Amylases are characterized by their formation as insoluble zymogens during the process of seed maturation, and are also found in bacteria. Example from *Bacillus cereus* (precursor): database code AMYB\_BACCE, 544 amino acids (61.33 kDa).

**amylin** or islet amyloid polypeptide (abbr.: IAPP) a 37-residue peptide, sequence KCNTATCATQRLANFLVHSSNNFG AILSSTNVGSNTY-NH<sub>2</sub>, isolated from pancreatic islet amyloid deposits of an insulinoma and from amyloid-rich pancreases of type 2 diabetic patients; it is found in pancreatic cells and secreted with insulin. Structurally it closely resembles calcitonin gene-related peptide (CGRP), and has 43% and 46% amino-acid sequence homology with human  $\alpha$ - and  $\beta$ -CGRP respectively. Like CGRP it is C-terminally amidated and has an N-terminal disulfide bridge linking cysteines 2 and 7. It opposes the action of glycogen synthase in skeletal muscle and may modulate insulin action. The peptide inhibits insulin-stimulated glucose metabolism in muscle but not in adipocytes. Example, human precursor: database code IAPP\_HUMAN.

**amyo-** or (before a vowel) **amyl+** comb. form denoting starch. **amyo-1,6-glucosidase** EC 3.2.1.33; other name: dextrin 6- $\alpha$ -D-glucosidase; an enzyme that catalyses the endohydrolysis of 1,6- $\alpha$ -D-glucoside linkages at points of branching in chains of 1,6-linked 6- $\alpha$ -D-glucose residues. Example (human) also has glycogen debranching enzyme (4- $\alpha$ -glucanotransferase) activity: database code GDE\_HUMAN, 1515 amino acids (172.30 kDa). **amyloid** 1 a waxy eosinophilic translucent material deposited in tissues in amyloidosis. Originally thought to be polysaccharide, it is now known to be fibrils made of protein molecules of various origins with a twisted β-pleated sheet structure. It is insoluble, and exhibits a green fluorescence when stained with Congo

## Amytal

Red and viewed through crossed Nicol prisms. Amyloid fibres are relatively inert and resistant to solution in physiological solvents and to proteolytic enzymes. 2 pertaining to or characterized by the production of amyloid. 3 any non-nitrogenous substance resembling starch. 4 like or containing starch.

**amyloid A protein** or serum amyloid A (abbr.: SAA or AA) any of various plasma proteins synthesized by liver and induced by cytokine stimulation. The extracellular accumulation in various tissues of amyloid proteins results in secondary amyloidosis in human and other species. These deposits are highly insoluble and resistant to proteolysis. They disrupt tissue structure and compromise function. Four motifs are characteristic of SAAs. Example, SAA-I (human) precursor: database code SAA\_LHUMAN, 122 amino acids (13.43 kDa).

**amyloidosis** any of various pathological states in which the deposition of amyloid (def. 1) occurs in tissues. It is often associated with chronic infections and immunocyte dyscrasias. In the absence of medical intervention amyloid accumulates implacably, causing pressure atrophy of the affected tissue(s). Death subsequently results from interference with the normal physiological processes of affected vital organs. The descriptive term β-fibrilliosis has been suggested for amyloidosis, after the beta-pleated sheet structure of the amyloid fibrils. However, the term is not commonly used. See also amyloid A protein.

**β-amylloid** peptide a glycoprotein associated with Alzheimer's disease and derived from a precursor, A4, capable of several forms through alternative splicing. It has three motifs. Database code (for human A4): A4\_HUMAN, 770 amino acids (86.85 kDa).

**amylolysis** the process of converting starch into soluble oligo- and monosaccharides, especially by enzymic action. -amylolytic ad.

**amylopectin** a polydisperse highly branched glucan composed of chains of D-glucopyranose residues in  $\alpha$ (1→4) glycosidic linkage. The chains are joined together by  $\alpha$ (1→6) glycosidic linkages. A small number of  $\alpha$ (1→3) glycosidic linkages and some 6-phosphate ester groups also may occur. The chains are of similar structure to those of glycogen but with fewer and longer branches. Those in amylopectin have been found variably to contain 24 to 30 glucose residues per nonreducing end-group. The size of the molecule varies greatly according to source and method of measurement, with average *M*<sub>n</sub> values of 10<sup>6</sup> to 10<sup>8</sup> reported. Amylopectin occurs in starch, commonly as a mixture with about one-third its mass of amylose. However, some starches, notably the so-called waxy starch of maize (*Zea mays*), are almost pure amylopectin. Starch granules serve as the principal cellular store of glucose in most plants. **amylopectin 6-glucanohydrolase** see α-dextrin endo-1,6- $\alpha$ -glucosidase.

**amylopectinosis** see glycogen disease.

**amyloplast** a colourless plastid or leukoplast in which starch is stored. It occurs in various plant tissues, e.g. cotyledons, endosperm, and storage organs such as potato tubers.

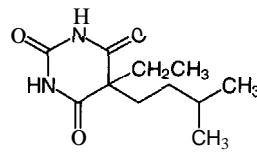

**amylopsin** former term for pancreatic α-amylase.

**amylose** a form of starch comprising a long unbranched glucan with  $\alpha$ (1→4) glycosidic linkages.

**amylosucrase** an alternative name for sucrase (def. 3).

**amyo-(1,4-1,6)-transglycosylase** see branching enzyme.

**Amytal** proprietary name for the barbituric sedative 5-ethyl-5-isoamylbarbituric acid, 5-ethyl-5-isopentylbarbituric acid. It inhibits the electron-transport chain between flavoproteins and ubiquinone.

an+

**an+** or (*before a consonant*) **a-** prefix indicating not, without.  
**+an** suffix used in forming the semisystematic name of a parent chemical structure from the trivial name of the key compound to which the parent structure is related if the parent structure contains a heteroatom and is saturated e.g. glucosan, any internal anhydride of glucose.

**An** symbol for **anhydro-**.

**anabiosis** a return to life after apparent death; a state of suspended animation induced in an organism by, e.g., desiccation or freezing, and reversed by rehydration or warming.

**anabolic** pertaining to, involving, or exhibiting **anabolism**.

**anabolic pathway** any sequence of reactions involving **anabolism**; i.e. one in which energy is taken up. Compare **catabolic pathway**. See also **amphibolic**.

**anabolic steroid** any of various synthetic steroids that stimulate protein production *in vivo* by mimicking the action of **androgens**. Drug design aims to minimize masculinizing effects when used in female patients.

**anabolism** the energy-requiring part of metabolism in which simpler substances are transformed into more complex ones, as in growth and other biosynthetic processes. Compare **catabolism**.

**anabolite** any product of an **anabolic pathway**.

**anabolize** or **anabolise** to effect **anabolism**.

**anaemia** a variant spelling (*esp. Brit.*) of *anemia*.

**anaerobe** any organism that can grow in an atmosphere devoid of dioxygen. A **facultative anaerobe** is also capable of growing in a dioxygen-containing atmosphere whereas an **obligate anaerobe** (or strict anaerobe) can only grow in the absence of dioxygen.

**anaerobic** 1 describing an organism that is able to grow in the absence of dioxygen. 2 of or produced by an **anaerobe**. 3 (of an atmosphere) devoid of dioxygen. 4 (of a process) characterized by the absence of dioxygen.

**anaerobic fermentation** any of several catabolic pathways used by living organisms to extract chemical energy from various organic substances in the absence of dioxygen. Compare **anaerobic respiration**.

**anaerobic glycolysis** the metabolic pathways by which glucose is degraded anaerobically to lactate or ethanol. See **glycolysis**.

**anaerobic indicator** any indicator of the attainment and maintenance of anaerobic conditions in an **anaerobic jar**. It may be based on a dye that is decolorized in anaerobic conditions or consist of a culture of a strict anaerobe in one of the dishes in the jar.

**anaerobic jar** or **McIntosh & Fildes jar** an apparatus used to hold culture dishes or tubes under anaerobic conditions. It usually consists of an upright jar with an airtight lid; the air is evacuated and replaced by dihydrogen, which combines with any remaining dioxygen, the reaction being catalysed by a palladium catalyst. [After James McIntosh (1882-1948) and (Sir) Paul (Gordon) Fildes (1882-1971), British bacteriologists who first described the apparatus in 1916.]

**anaerobic respiration** the metabolic processes by which organisms degrade organic compounds in the absence of dioxygen to yield energy. They make use of inorganic oxidizing agents or accumulate reduced coenzymes. Compare **anaerobic fermentation**.

**anaerobiosis** life in the absence of dioxygen or air.

**anagenesis** the progressive or 'upward' evolution of a species; any evolutionary process that results in biological improvement. Compare **cladogenesis**. -**anagenetic** *adj.*; **anagenetically** *adv.*

**anaglyph** a stereoscopic moving or still picture made up of two superimposed images of the same object, taken from slightly different angles and reproduced in complementary colours (usually red and bluish green) so as to produce a three-dimensional effect when viewed through spectacles having one lens of each colour.

**AnalaR** proprietary name for any analytical (chemical) reagent

**anaphase**

that conforms to the tests and purity standards in '*AnalaR' Standards for Laboratory Chemicals* (1977) AnalaR Standards Ltd.

**analbuminemia** or (*esp. Brit.*) **analbuminaemia** a rare inherited disease in which there are very low plasma albumin levels but few symptoms.

**analogous** 1 having or showing similar or corresponding attributes. 2 (*in biology*) describing parts, organs, or tissues that have a similar function but differ in structure or evolutionary origin.

**analogue** or (*esp. US*) **analog** a chemical compound that is structurally similar to another. Such compounds can be used as probes to investigate specificity of, e.g. enzyme activity.

**analogue enrichment** or **analog enrichment** enrichment of microorganisms capable of co-metabolic degradation of organic pollutants by application of biodegradable analogues of the pollutant to the microbial ecosystem. See **co-metabolism**.

**analyser** or (*US*) **analyzer** 1 the **Nicol prism** of a polariscope or **polarimeter** that receives the light and indicates the degree and/or direction of rotation of its plane of polarization. Compare **polarizer**. 2 an instrument for routinely performing chemical analyses, often automatically and/or on a succession of samples. See **amino-acid analyser**, **autoanalyzer**, **sequenator**.

**analysis** (*pl. analyses*) 1 the process of determining the nature of the chemical constituents of a mixture or of the chemical groups present in a compound (**qualitative analysis**), or the process of determining the amounts of the constituents of a mixture (**quantitative analysis**). 2 the results of such an analysis. 3 the branch of mathematics concerned with the concepts of algebra and calculus. -**analytic** or **analytical** *adj.*

**analysis of covariance** a statistical method for determining the extent of the variance of one variable that is due to variability in some other variable.

**analysis of variance** a statistical method for segregating the experimentally observed variance between two populations into portions traceable to specific sources.

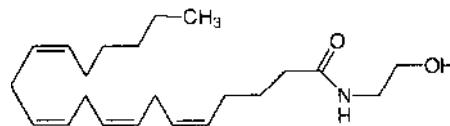

**analyte** a component to be measured in an **analysis** (def. I).

**analytical chemistry** the branch of chemistry concerned with analysing materials by chemical (or physical) methods.

**analytical ultracentrifuge** an **ultracentrifuge** equipped with optical systems designed to determine concentration distributions at any time during the measurement. It is used in determinations of **sedimentation coefficients** and **sedimentation equilibrium**.

**anamnestic reaction** any immunological response in which a second or subsequent exposure to an antigen causes a greater and more rapid reaction than that elicited by the initial exposure. It is a manifestation of immunological memory.

**anandamide** arachidonoyl ethanolamide; a specific endogenous agonist that serves as a neurotransmitter of the **cannabinoid receptor**. It is formed in neurons by phosphodiesterase cleavage of N-arachidonoyl-phosphatidylethanolamine, and is probably then released to the extracellular space. A series of analogues such as N-linoleoyl ethanolamide and *N-palmitoyl* ethanolamide are formed simultaneously from appropriate precursors, but their role remains unclear. It may also be formed by condensation of arachidonate with ethanolamine. It is inactivated by reuptake into neurons and hydrolysis by *N*-acyl-ethanolamine amidohydrolase to ethanolamine and arachidonate.

**anaphase** a stage in **mitosis** or **meiosis** during which the two

## anaphylactic shock

sister chromatids of each chromosome separate and move towards opposite poles of the spindle.

**anaphylactic shock** a severe generalized form of anaphylaxis in which there is widespread release of histamine and other vasoactive substances causing edema, constriction of the bronchioles, heart failure, circulatory collapse, and sometimes death.

**anaphylactoid reaction** an acute syndrome resembling anaphylactic shock though caused not by an immunological reaction but by injection of a variety of substances such as bee or snake venom.

**anaphylatoxin** any of a group of substances that mediate inflammation and are produced in serum during the fixation of complement, especially during the production of C3a and C5a. They cause mast cell degranulation and histamine release.

**anaphylaxis** extreme immunological sensitivity of the body or tissues to the reintroduction of an antigen. It is a form of anamnestic reaction and is accompanied by pathological changes in tissues or organs due to the release of pharmacologically active substances. -anaphylactic *adj.*

**anaphylotoxin inactivator** see lysinarginine) carboxypeptidase.

**anaplasia** the reversion by a cell or tissue to a more primitive, embryonic, or undifferentiated form with loss of its characteristics and increased capacity for multiplication.

**anaplerosis** 1 the filling up of a deficiency; the repair or replacement of losses, especially of tissue. 2 (*in biochemistry*) the process in which an intermediate in a central metabolic pathway is replenished through a distinct anaplerotic metabolic pathway. This prevents the central pathway from ceasing to function because of withdrawal of the intermediate for some other metabolic purpose. [From Greek *ana*, again, back, up + *plero*in, to fill.)-anaplerotic *adj.*

**anaplerotic metabolic pathway** any sequence of metabolic reactions that serves to maintain the operation of the central pathways of metabolism and which allows the operation and coordination of other metabolic pathways that enter and leave the central pathways.

**anchorin E11** see annexin V.

**ancrod** an enzyme, extractable from the venom of the Malayan pit viper, *Agiistrodon rhodostoma*, that produces unstable fibrin from fibrinogen by proteolysis. The resulting fibrinogen depletion results in an anticoagulant effect.

**Andersen's disease** *an alternative name for type IV glycogen disease.* [After Dorothy Hansine Andersen (1901-63), American physician.]

**androgamone** see gamone.

**androgen** any substance, natural or synthetic, that is able to stimulate the development of male sexual characteristics. Naturally occurring androgens are C<sub>19</sub>-steroid hormones. They are produced especially by the testis (e.g. testosterone) and also by the adrenal cortex, ovary, and placenta. *Compare estrogen. -androgenic adj.*

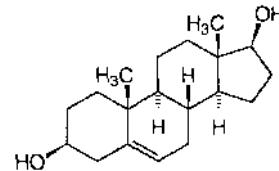

**androgen receptor** any of the androgen-binding nuclear proteins that mediate the effects of androgens by regulating gene expression; they are zinc-finger proteins that bind discrete DNA sequences upstream of transcriptional start sites when the hormone-receptor complex is formed. The steroid-binding domain is in the C-terminal region. In humans, many variants are known that are associated with abnormalities, including testicular feminization syndrome, and complete or partial androgen insensitivity leading to external genitalia varying between female and nearly normal male. Example from human: database code ANDR\_HUMAN, 919 amino acids (98.99 kDa).

**androgen resistance** see testicular feminization.

**androstane** the C<sub>19</sub> parent compound from which androgens are structurally derived.

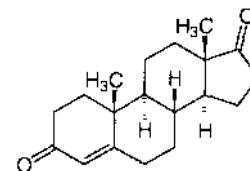

**androstenediol** 5-androstan-3 $\beta$ ,17 $\beta$ -diol; a metabolite of dehydroepiandrosterone, from which it is formed by the action of 17 $\beta$ -hydroxysteroid dehydrogenase, EC 1.1.1.51.

anemia

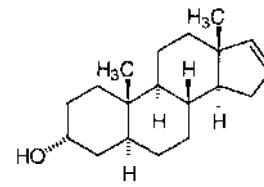

androstenediol

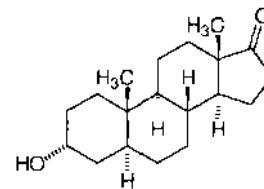

**androstenedione** 4-androstan-3,17-dione: a precursor of testosterone and estrone, formed in the testis and ovary from 17 $\alpha$ -hydroxyprogesterone by the action of 17 $\alpha$ -hydroxyprogesterone aldolase (17,20-lyase), EC 4.1.2.30, or from dehydroepiandrosterone by the action of 3 $\beta$ -hydroxy- $\Delta^5$ -steroid dehydrogenase, EC 1.1.1.145. It is also formed in adrenal cortex, from 17-hydroxypregnolone by an isoenzyme of the 17,20-lyase. Androstenedione is secreted by the adrenals into the circulation and serves as a precursor for sex-hormone formation in peripheral tissues.

**androst-16-en-3 $\alpha$ -ol** 3 $\alpha$ -hydroxy-5 $\alpha$ -androst-16-ene; 'boar taint'; a major constituent of boar pheromone. It is also present in truffles, which may account for the ability of pigs to locate these underground delicacies.

**androsterone** 5 $\alpha$ -androstan-3 $\alpha$ -ol-17-one; a metabolite of testosterone, from which it is formed in the liver via androstenedione. The latter is converted to androstanedione by 3-oxo-5 $\alpha$ -steroid 4-dehydrogenase, EC 1.3.99.5. Androstanedione in turn is acted on by 3 $\alpha$ -hydroxysteroid dehydrogenase, EC 1.1.1.2]3, forming androsterone.

**+ane suffix** (*in systematic chemical nomenclature*) denoting 1 an alkane, e.g. pentane. 2 a saturated heterocyclic compound in which the heteroatom is other than nitrogen, e.g. thioline. 3 a a hydride of boron, silicon, germanium, tin or lead, e.g. borane, silane; b a hydride of an unbranched chain of identical atoms of certain elements.

**anemia** or (*esp. Brit.*) anaemia any condition in which the blood has an abnormally low number of red cells (i.e. erythrocytes) or hemoglobin content, or is deficient in total volume.

**anergy**

There are many causes, including hypersensitivity reactions to (e.g.) drugs (hemolytic anemia) and imbalance of  $\text{Fe}^{2+}$  metabolism (iron deficiency anemia). Pernicious anemia is characterized by defective production of erythrocytes and the presence of megaloblasts in the bone marrow; sometimes it is accompanied by neurological changes. It is caused by deficiency of vitamin  $\text{B}_{12}$  due either to a dietary deficiency of the vitamin or to a failure to produce intrinsic factor required for its absorption from the gut.

**anergy (in immunology)** any deficiency in the immune response to an agent that normally induces a response.

**aneuploid** describing a nucleus or organism in which the chromosome number is not an exact multiple of the haploid number ( $n$ ). In humans ( $n = 23$ ) examples include the presence of an extra copy of a single chromosome, e.g. trisomy 21 (Down's syndrome), or the absence of a single chromosome, e.g. monosomy (as found in Turner's syndrome, 45,X). Compare euploid, monosomic, nullisomic, trisomic.

**aneurine or aneurine a former name for thiamine.**

**Anfinsen**, Christian Boehmer (1916-95), US protein chemist; Nobel Laureate in Chemistry (1972) 'for his work on ribonuclease, especially concerning the connection between the amino-acid sequence and the biologically active conformation' [prize shared with S. Moore and W. H. Stein].

**angiogenesis** the formation of blood vessels, whether during embryogenesis, tissue repair, or invasive growth of tumours.

**angiogenin** a cytokine, produced by fibroblasts, lymphocytes, and colon epithelial cells, that induces neovascularization and can serve as a substratum for endothelial and fibroblast cell adhesion. A monomeric protein, it is a member of the pancreatic ribonuclease family and specifically hydrolyses tRNAs, thus inhibiting protein synthesis. Example from *Mus musculus* (precursor): database code ANGLMOUSE, 145 amino acids (16.23 kDa).

**angiosperm** a flowering plant; any member of the class Angiospermae, division Spermatophyta (seed plants). Compare gymnosperm.

**angiotensin** any of three related peptides, two of which regulate adrenal activity and also increase vasoconstriction and raise blood pressure. Angiotensin I, the decapeptide

is cleaved off angiotensinogen by the kidney enzyme renin; this peptide has no physiologically important action. Angiotensin II, the octapeptide formed from angiotensin I by removal of -His-Leu-OH by the action of angiotensin converting enzyme, is the most powerful pressor agent known, and the substance responsible for essential hypertension. It is also one of the most potent known stimulators of aldosterone production by the adrenal gland. It is rapidly destroyed by tissue peptidases, including angiotensinase. Angiotensin III, the heptapeptide formed by removal of the N-terminal Asp residue from angiotensin II (and the only one of its breakdown products to have activity), appears to be as active on the adrenal gland as angiotensin II and may also have significant vasoconstrictor activity.

**angiotensinase** an enzyme with proteinase activity that inactivates angiotensin II. Angiotensinase A is an alternative name for glutamyl aminopeptidase, EC 3.4.11.7, and angiotensinase C is another name for lysosomal Pro-X carboxypeptidase, EC 3.4.16.2.

**angiotensin converting enzyme** EC 3.4.15.1; *recommended name:* peptidyl dipeptidase A; *other names:* serum converting enzyme; peptidase P; peptidyl carboxypeptidase I; carboxypeptidase; kininase II. A  $\text{Cl}^-$ -dependent zinc-containing dipeptidase present in lung, the brush borders of the proximal renal tubule, the endothelium of vascular beds, and plasma. It catalyses the release of a C-terminal dipeptide, -Xaa-I-Xbb-Xcc, when neither Xaa nor Xbb is proline, hence its conversion of angiotensin I to angiotensin II. It also acts on bradykinin. It is a transmembrane glycoprotein; two types (testis and somatic)

arise by alternative splicing and different transcriptional start points. Example, somatic type precursor (human): database code ACE\_HUMAN, 1306 amino acids (149.55 kDa).

**angiotensin converting enzyme inhibitors** compounds that prevent the synthesis of angiotensin II from its precursor, angiotensin I, e.g. captopril, enalapril. Such inhibitors are used in the treatment of cardiac failure and hypertension.

**angiotensinogen** a plasma  $\alpha_2$ -globulin formed in liver and the precursor of angiotensin I, II, and III; it is similar to the serpins. Example, precursor from human: database code ANGT\_HUMAN, 485 amino acids (53.09 kDa).

**angiotensinogenase** see renin.

**angiotensin receptor** any of several membrane proteins that bind angiotensin and mediate its intracellular effects. Two types of receptor,  $\text{AT}_1$  and  $\text{AT}_2$ , have been identified on the basis of their response to drugs. The  $\text{AT}_1$  receptor (previously known as  $\text{AlI}_1$  or  $\text{AlI}_2$ ) has high affinity for losartan, and lower affinity for CGP42112A; the reverse is true for  $\text{AT}_2$  receptors. The potency of endogenous ligands is angiotensin II > angiotensin III. In peripheral tissues,  $\text{AT}_1$  receptors, but not  $\text{AT}_2$  receptors, interact with G-proteins, inhibit adenylate cyclase, and activate phospholipases C and A<sub>2</sub>.  $\text{AT}_2$  receptors may stimulate a phosphotyrosine phosphatase leading to inhibition of guanylate cyclase. Sulphydryl reducing agents inhibit the binding of angiotensin II to  $\text{AT}_1$  receptors but enhance its binding to AT. Both types are G-protein-coupled seven-transmembrane domain proteins. Examples:  $\text{AT}_1$  receptor, database code AG2R\_BOVIN, 359 amino acids (41.09 kDa);  $\text{AT}_2$  receptor, database code AG22\_MOUSE, 363 amino acids (41.37 kDa).

**angle I** the inclination between two lines or planes: plane angle. It is dimensionless and given in radians (*symbol:* rad), degrees (*symbol:* 0;  $10^\circ = \pi/180$  rad); minutes (*symbol:* ') 1' =  $\pi/10800$  rad; or seconds (*symbol:* '') 1'' =  $\pi/64800$  rad. 2 the (three-dimensional) vertex of a cone: solid angle. It is dimensionless but may be expressed in steradians (*symbol:* sr).

**angle head or angle rotor** any rotor for a centrifuge in which the tubes containing the liquid are at a fixed angle to the axis of rotation. Compare swinging bucket rotor.

**ångström or Angstrom symbol:** Å; a unit of length equal to  $10^{-10}$  metres. It is used in atomic measurements and for wavelengths of electromagnetic radiation, and is temporarily approved for use with SI units. [After Anders Jonas Ångström (1814-74), Swedish physicist noted for his work on spectroscopy.]

**angular velocity symbol:**  $w$ ; the rate of rotation of an object expressed as its rate of motion through an angle about an axis. It is expressed in rad s<sup>-1</sup>.

**anhydrase** see carbonic anhydrase.

**anhydride** a derivative of a substance that yields the substance when combined chemically with water.

**anhydro+** symbol: An; prefix (in a chemical name) denoting the loss of the elements of water from within one molecule or residue. The positions from which removal has occurred may be indicated by a pair of locants, e.g. 2,5-anhydro-D-gluconic acid.

**anhydrosialidase** EC 3.2.1.138; *other names:* anhydroneuraminidase; sialidase L; an enzyme that catalyses the hydrolysis of a-sialosyl linkages in N-acetylneuraminc acid glycosides, releasing 2,7-anhydro-a-N-acetyleneuraminc acid.

**anhydrosugar** any intramolecular ether formed by the elimination of water from two (indicated) alcoholic hydroxyl groups of a single molecule of a monosaccharide, whether aldose or ketose; i.e. any anhydromonosaccharide whose formation does not involve the reducing group.

**anhydrous** devoid of water, especially (of a substance or material) lacking water of crystallization or adsorbed water, or (of an environment) very dry. See also dehydration.

**animal pole** see vegetal pole.

**animal protein factor** a name formerly used for a growth factor for livestock, found to be present in meat and fish but not

**anion**

in feeds of plant origin. It was later shown to be identical with anti-pernicious anemia factor, i.e. vitamin B12<sup>1</sup>.  
**anion** an ion with a net negative charge; during electrolysis of a solution anions migrate towards the **anode**. Compare **cation**.-  
**anionic adj.**

**anion exchanger or anion-exchange resin** any **ion-exchange resin** that carries positively charged groups, e.g. quaternary ammonium groups, and binds anions.

**anion gap** (*in clinical chemistry*), the difference, in meq L<sup>-1</sup>, between the concentrations of serum sodium plus potassium and of the serum chloride plus bicarbonate; i.e.

$$\text{anion gap} = [\text{Na}^+ + \text{K}^+] - [\text{Cl}^- + \text{HCO}_3^-].$$

Normal values are  $12 \pm 2$  meq L<sup>-1</sup>. Variations in the anion gap provide a useful insight into the acid-base status of a subject.

**anionic detergent** a detergent in which the polar part of the molecule carries a negative charge. Compare **nonionic detergent**.

**anisotropic** describing a medium in which physical properties, such as the velocity of electromagnetic radiation transmission, electrical or heat conductivities, or compressibility, have different values when measured along axes in different directions. **-anisotropically adv.; anisotropy or anisotropism n.**

**anisotropic motion** rotation about a single axis, especially of a molecule or a **spin label**.

**ankyrin or band 2.1 (protein) or nexin or syndein** a 200 kDa cytoskeletal protein that attaches other cytoskeletal proteins to integral membrane proteins. It is bound tightly to the cytoplasmic surface of the human erythrocyte membrane, to which it attaches the cytoskeletal protein **spectrin**. Example from human: database code ANKI\_HUMAN, 1880 amino acids (206.14 kDa). [After the Greek *ankyra*, anchor].

**annealing** 1 the renaturation of heat-denatured nucleic acids or proteins by slow cooling. 2 the formation of hybrid double-stranded nucleic-acid molecules by the slow cooling of a mixture of denatured, single-stranded nucleic acids. It is used to detect complementary regions of different nucleic-acid molecules. 3 the slow regulated cooling, especially of metals or glasses, to relieve the stresses caused by heating or other treatments. **-annealer n.**

**annexin** any of a ubiquitous family of Ca<sup>2+</sup>-dependent phospholipid-binding proteins. They have been isolated from organisms as diverse as mammals, *Drosophila melanogaster*, and *Hydra vulgaris*. Characteristically they have a low intrinsic affinity for Ca<sup>2+</sup> ( $K_d$  25–1000 μM), although annexin VI has  $K_d \approx 1$  μM, but in the presence of phospholipid the affinity for Ca<sup>2+</sup> increases up to 100-fold. The Ca<sup>2+</sup>- and phospholipid-binding properties that typify the family derive from a region of common primary structure (identity with any other member of the family is 40–60%) in a conserved 34 kDa C-terminal region (the 'core'); each different type of annexin has a unique N-terminal domain known as the 'tail'. The C-terminal region in all cases except one consists of four repeats of a ≈70 amino-acid sequence, in which there is a high homology region known as the **endonexin fold**, with a characteristic motif GXGTDE; the exception is annexin VI, which has eight repeats. The true physiological roles of the annexins remain unknown, but their main characteristics, exhibited variously by different annexins and reflected in the alternative names they acquired in the course of discovery, include: the ability to aggregate membranes and vesicles (all annexins); inhibition of phospholipase A<sub>2</sub> (especially I, but also II to VI); formation of ion channels (especially I and V to VII); anticoagulant properties (especially I, and VIII); and acting as substrates for tyrosine kinases (I and II) and protein kinase C (I, II, IV, and XIT). Alternative names and database codes are given under the individual entries.

**annexin I** *other names:* lipocortin I; p35 (EGF receptor substrate); calpastatin II; chromobindin 9; GIF; lipomodulin; macrocortin; renocortin. Example from rat: database code ANXI\_RAT, 345 amino acids (38.65 kDa).

anodic to

**annexin II** *other names:* calpastatin I heavy chain; lipocortin II; p36 (pp60<sup>src</sup> substrate); chromobindin 8; protein I; placental anticoagulant protein (PAP)-IV. Example from human: database code ANX2\_HUMAN, 338 amino acids (38.43 kDa).

**annexin III** *other names:* lipocortin III; placental anticoagulant protein (PAP)-III; 35-a-calcimedin; calphobindin III; inositol 1,2-cyclic phosphate hydrolase. Example from rat: database code ANX3\_RAT, 324 amino acids (36.28 kDa).

**annexin IV** *other names:* endonexin I; protein II; 32.5K calelectrin; lipocortin IV; chromobindin 4; placental anticoagulant protein (PAP)-II; placental protein PP4-X; 35-p-calcimedin; placental anticoagulant protein II. Example from human: database code ANX4\_HUMAN, 318 amino acids (35.68 kDa).

**annexin V** *other names:* placental anticoagulant protein (PAP)-I; inhibitor of blood coagulation (IBC); lipocortin V; 35K calclectrin; endonexin II; placental protein PP4; vascular anticoagulant (VAC)-a; 35-y-calcimedin; calphobindin I; anchorin CIT. Example from human: database code ANX5\_HUMAN, 319 amino acids (35.76 kDa).

**annexin VI** *other names:* p68; p70; 73K; 67K calelectrin; lipocortin VI; protein III; chromobindin 20; 67K calcimedin; calphobindin II; synhibin. Example from human: database code ANX6\_HUMAN, 672 amino acids (75.66 kDa).

**annexin VII** *another name for synnexin.*

**annexin VIII** *other name:* vascular anticoagulant (VAC)-β. Example from human: database code ANX8\_HUMAN, 327 amino acids (36.84 kDa).

**annexin IX** *other name:* *Drosophila melanogaster* annexin. Database code (fragment) from *D. melanogaster*: ANX9\_DROME.

**annexin X** *other name:* intestine-specific annexin. Example from human: database code ANX1\_HUMAN, 315 amino acids (35.29 kDa). A similar protein occurs in *Drosophila melanogaster*.

**annexin XI** *other names:* (sometimes, e.g. in rabbit) calcyclin-associated annexin (CAP); CAP-50. There are two variants (derived by alternative splicing). Example, variant I, bovine: database code ANXA\_BOVIN, 503 amino acids (53.96 kDa).

**annexin XII** a member of the annexin family obtained from *Hydra attenuata* (*Hydra vulgaris*). It is of unknown function. Example from *H. vulgaris*: database code ANXC\_HYDAT, 316 amino acids (35.07 kDa).

**annihilation radiation** electromagnetic radiation of wavelength 2.4 pm (energy 0.51 MeV) that is emitted as a pair of photons when a positron absorbed into matter reaches the end of its range and combines with an electron in mutual destruction.

**anode** 1 the electrode of an electrolysis cell or electrophoresis apparatus towards which anions of the electrolyte migrate under the influence of an electric field applied between the electrodes. 2 the positive electrode, pole, or terminal of such a cell or apparatus, or of a discharge tube, solid-state rectifier, or thermionic valve; the electrode by which electrons flow out of the device. 3 the negative pole or terminal of an electric (primary or secondary) cell or battery (of cells). Compare **cathode**. **-anodal or anodic adj; anodally or anodically adv.**

**anodic stripping voltammetry** abbr.: ASV; an electrochemical procedure for estimating the concentration of metal ions in a solution. Exhaustive or partial (depending on the concentrations involved) deposition of the metal occurs on the cathode of an electrolytic cell at a constant applied electric potential (controlled potential deposition can be used for selectivity when mixtures are involved). The metal deposit is then anodically stripped by using a rapid sweep of voltage of opposite polarity and a peak-type current-voltage curve is obtained. The amount of metal deposited may be calculated coulometrically from the area under the peak, or by other means, and hence the concentration of metal ions in the initial solution may be determined.

**anodic to** during electrophoresis, migrating further towards

**anolyte**

the anode or less far towards the cathode than (the specified substance).  
anolyte the electrolyte in immediate contact with the anode in isoelectric focusing.

**anomalous dispersion** 1 an X-ray crystallographic dispersion that occurs when the frequency of the X-rays used falls near an absorption frequency of an atom in the crystal. Anomalous dispersion techniques are frequently used in the determination of absolute configuration. 2 an optical rotatory dispersion that cannot be expressed by a simple one-term Drude equation.

**anomer** either of the two stereoisomers of the cyclic form of an aldose or a ketose, or an aldose or ketose derivative, dependent on the position of the free hydroxyl group belonging to the internal hemiacetal grouping. The anomer having the same configuration, in the Fischer projection, at the anomeric and the reference asymmetric carbon atom is designated *α*; the other anomer is designated *β*. In correct usage in regard to carbohydrates, the anomeric and configurational descriptors must always be linked together; e.g. *α*-D-glucopyranose, not *α*-glucose.

**anomeric** 1 of or pertaining to an anomer. 2 *or* glycosidic of or pertaining to the free hydroxyl group belonging to the internal hemiacetal grouping in the cyclic form of a monosaccharide or monosaccharide derivative.

**anomeric effect** the tendency for an electronegative substituent at C-1 of a pyranose to assume the axial orientation, in contrast to the equatorial orientation predicted on steric grounds.

**anorexia** absence of desire for food.

**anosmia** loss of the sense of smell.

**anoxia** the absence or a deficiency of dioxygen. *Compare hypoxia. -anoxic adj.*

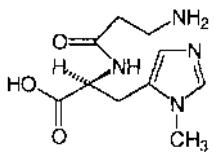

**ANP abbr.** for atrial natriuretic peptide. *See* natriuretic peptide.

**ANPR abbr.** for atrial natriuretic peptide receptor.

**ANS abbr.** for 1-anilino-8-naphthalene sulfonate; a common fluor used in extrinsic fluorescence studies of proteins.

**ansamycin** any antibiotic belonging to the rifamycin or the streptovaricin classes.

**anserine** N-p-alanyl-N<sub>n</sub>-methyl-L-histidine; an isopeptide occurring in skeletal muscle and brain of some animals and humans (up to 20 mmol kg<sup>-1</sup>). *Compare* carnosine.

**Anson unit** an old measure of the activity of a proteinase. It was based upon the extent to which a sample containing a particular proteinase can digest denatured hemoglobin, under standard conditions appropriate to the enzyme in question, with liberation of nonprecipitable material giving the same colour value as one millimole of tyrosine on reaction with a diluted Folin-Ciocalteau reagent. [After Mortimer Lewis Anson (1901-68), US protein chemist, who described it in 1958.]

**ant+** a variant of *anti+*.

**Antabuse** proprietary name for disulfiram.

**antagonism** 1 opposition; counteraction. 2 the mutual opposition of an agonist and an antagonist. 3 the interference with, or inhibition of, the growth of an organism by one of another kind, as by competing for nutrients or producing an antibiotic substance.

**antagonist** 1 anything that antagonizes. 2 any agent, especially a drug or hormone, that reduces the action of another

**anthralin**

agent, the agonist. Many act at the same receptor as the agonist. Such antagonists may be either surmountable or insurmountable, depending on prevailing conditions. Antagonism may also result from combination with the substance being antagonized (chemical antagonism), or the production of an opposite effect through a different receptor (functional antagonism or physiological antagonism), or as a consequence of competition for the binding site of an intermediate that links receptor activation to the effect observed (indirect antagonism). The term 'functional antagonism' is also used to describe a less well-defined category in which the antagonist interferes with other events that follow receptor activation. 3 a muscle that works in opposition to another (the agonist). *See also* competitive antagonism, noncompetitive antagonism. *Compare* agonist, inverse agonist, synergist. *-antagonistic adj.; antagonistically adv.*

**antagonize** or **antagonise** to act in opposition to; to counteract. *-antagonized or antagonised ad.*

**antanamide** a highly lipophilic homodetic cyclic decapeptide, cyclo-(Pro-Phe-Phe-Val-Pro-Pro-Ala-Phe-Phe-Pro-). It occurs in the death-cap fungus, *Amanita phalloides*, together with the amatoxins and phallotoxins. When administered to experimental animals (at 1 mg per kg of body weight), either before or at most a few minutes after a lethal dose of phallotoxin, it acts as an antidote to the toxin, apparently by competing for binding sites. *In vitro* it readily forms complexes with sodium and calcium ions, and can act as a sodium ionophore.

**ANT-C abbr.** for antennapedia complex; one of two major families of homeotic genes of *Drosophila* (the other being *aX-C*), mutation which affects head and thoracic segments.

**ante+** prefix denoting before in time or position.

**antegrade** a variant of anterograde.

**anteiso+** prefix denoting a branched-chain fatty acid having a methyl group at the *n*-3 position; e.g. 16-methyloctadecanoic acid, also named anteisononadecanoic acid.

**antenna complex** any of the light-harvesting pigment-protein complexes of photosynthetic organisms that funnel absorbed incident radiation to the photochemical reaction centres.

**antennapedia complex** see ANT-C.

**anterograde** or **antegrade** 1 moving forwards; extending towards the front. 2 moving along the axon of a nerve cell in a direction away from the cell body (as in anterograde transport of vesicles). *Compare* retrograde.

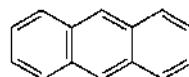

**atheridiol** a steroid hormone produced by water moulds (e.g. *Achyla* spp.) to regulate their sexual reproduction.

**anthocyanidin** any member of a group of water-insoluble red, blue, or violet polyhydroxylated 2-phenylbenzopyrylium compounds that occur as glycosides - anthocyanins - in plants. They comprise one class of the widespread group of flavonoids.

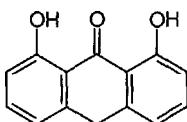

**anthocyanin** any member of a group of intensely coloured soluble glycosides of anthocyanidins that occur in plants. They are responsible for most of the scarlet, purple, mauve, and blue colouring in higher plants, especially of flowers.

**antho-K amide** L-3-phenyllactyl-Phe-Lys-Ala-NH<sub>2</sub>; a neuropeptide from the sea anemone *Anthopleura elegansissima*.

**anthracene** a tricyclic aromatic compound, C<sub>14</sub>H<sub>10</sub>; it is a component of a number of scintillation cocktails.

**anthralin** 1,8-dihydroxyanthrone; a substance that inhibits leukotriene biosynthesis. It is used as an antipsoriatic drug.

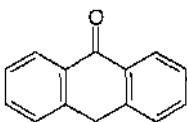

anthralin

**anthranilate** 2-aminobenzoate (anion, salt, or ester); an intermediate in the biosynthesis of tryptophan.

**anthranilate synthase** EC 4.1.3.27; *systematic name*: chorismate pyruvate-lyase (amino-accepting). An enzyme that catalyses the first step in tryptophan biosynthesis, in which chorismate and L-glutamine react to form anthranilate, pyruvate, and L-glutamate. It is a tetramer of two components, I and II: in the absence of II, I catalyses the formation of anthranilate using NH<sub>3</sub> rather than glutamine; II provides glutamine amidotransferase activity. Example from yeast: I database code TRPE\_YEAST, 528 amino acids (59.70 kDa); II database code TRPG\_YEAST, 484 amino acids (53.46 kDa).

**anthrone** 9(IOH)-anthracenone; a compound used in the colorimetric determination of carbohydrates, especially hexoses, with which it gives a green colour.

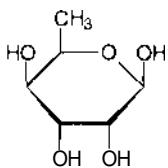

**anti+** or (sometimes before a vowel or h) **ant+** prefix 1 acting against, counteracting, or inhibiting. 2 opposite to (in direction). 3 converse or reverse of; complementary to.

**anti+ prefix (obsolete)** denoting a *cis* isomer.

**antiamoebin** or **antiamebin** see peptaibolophil.

**antiarose** the D isomer, 6-deoxy-D-gulose; occurs in glycosidic linkage in some cardiac glycosides.

D-pyranose form

**antibiotic** 1 any of numerous substances of relatively low M<sub>r</sub> produced by living microorganisms (and also certain plants) that are able selectively and at low concentrations to destroy or inhibit the growth of other organisms, especially microorganisms. Also included are the many semi- or wholly synthetic organic compounds with similar antimicrobial properties. Many are useful chemotherapeutic agents. 2 of or relating to an antibiotic.

**antibody** any glycoprotein of the immunoglobulin family that is capable of combining noncovalently, reversibly, and in a specific manner with a corresponding antigen. Antibodies frequently, but not always, counteract the biological activity of antigens. They are produced in higher animals by cells of the lymphoid cell series, especially plasma cells, in direct response to the introduction of immunogens or autocoupling haptens. Antibodies were originally identified as a class of serum pro-

teins, and most are present in the  $\gamma$ -globulin fraction of the serum. In the ultracentrifuge most antibodies have a sedimentation coefficient of 7S, except for the pentameric IgM at 19S. See also cell-bound antibody.

**antibody-mediated hypersensitivity** or type II hypersensitivity an immune response caused by the presence of antibody to cell-surface antigens and components of the extracellular matrix. These antibodies can sensitize the cells for antibody-dependent cytotoxic attack by K cells or complement-mediated lysis. Type II hypersensitivity is seen in the destruction of red cells in transfusion reactions and in hemolytic disease of the newborn.

**anticholinesterase** any agent, other than an antibody, that inhibits cholinesterase (def. 2). An example is physostigmine, used in the diagnosis and treatment of myasthenia gravis.

**anticircular chromatography** a technique of thin-layer chromatography in which the substances to be separated are applied just inside the perimeter of a circular thin-layer plate and are made to travel radially inwards by subsequent application of the developing solvent at the edge of the plate. It is very fast and is particularly useful for the resolution of substances whose *R<sub>f</sub>* values approach unity. Compare circular chromatography.

**anticlinal** see conformation (def. 2).

**anticoagulant** 1 retarding or preventing coagulation. 2 any substance that retards or prevents coagulation, especially of blood or milk.

**anticoagulate** to treat (esp. blood) so as to prevent coagulation.

**anticodon** a triplet of nucleotides in any particular transfer RNA that is complementary to and therefore pairs with a given codon in messenger RNA. The pairing is antiparallel, 5'→3' in the messenger, 3'→5' in the anticodon. Thus the anticodon of 5'-ACG-3' is 3'-UGC-5'. However, to maintain the convention of writing sequences in the 5'→3' direction, the anticodon is thus written, but with a reverse arrow above: ←CGU. anticodon arm the part in the clover-leaf model of transfer RNA containing a loop bearing the anticodon.

**anticooperativity** negative cooperativity between binding sites on the same (macro)molecule by which binding of a ligand to one site makes the binding of a second ligand more difficult.

**antidiuretic** 1 describing any drug or other agent that decreases the excretion of urine. 2 an antidiuretic substance.

**antidiuretic hormone abbr.:** ADH; *an alternative name (esp. in clinical chemistry) for vasopressin*. It is so named from the hormone's most important biological action, viz. reduction of the rate of urine output by stimulation of the rate of water reabsorption by the kidney(s).

**antidote** a substance or other agent that limits or reverses the effects of a poison.

**antifolate** any of a class of drugs that interfere with the formation of tetrahydrofolate, and are used in the treatment of acute leukemia and choriocarcinoma. One of the best known is methotrexate.

**antifreeze glycoprotein** any of a group of glycoproteins found in the serum of certain cold-water fish, particularly nototheniids and chaenichthyids, which inhabit polar seas; e.g. *Trematomus borchgrevinki* and *Dissostichus mawsoni*. These glycoproteins depress the freezing point of aqueous solutions about 200-500 times as effectively as sodium chloride on a molar basis. They differ only in mass (10.5 kDa, 17 kDa, and 21.5 kDa) and are composed of repeating units of a diglycosyl tripeptide, Ala-Ala-Thr-O-disaccharide, in which the disaccharide consists of a p-galactosyl residue bound to an internal α-N-acetylgalactosaminyl residue.

**antigen** 1 (or complete antigen) any agent that, when introduced into an immunocompetent animal, stimulates the production of a specific antibody or antibodies that can combine with the antigen. It may be a pure substance, a mixture of substances, or particulate material (including cells or cell fragments). In this sense the term includes agglutinogen and

## antigen-antibody complex

allergen and is synonymous with immunogen (def. 1). 2 (*or incomplete antigen*) any substance that can combine with a specific antibody but is not an immunogen (def. 2), i.e. it is not by itself able to stimulate antibody production though it may do so if combined with a carrier (def. 8). In this sense the term includes hapten. -*antigenic adj.*

**antigen-antibody complex** or immune complex any specific macromolecular complex of antigen and antibody. It may be soluble, especially in antigen excess, or insoluble (as a precipitate) when antigen and antibody are present in optimal proportions. Components of complement may bind to antigen-antibody complexes. See also immune complex-mediated hypersensitivity.

**antigen-binding capacity** abbr.: ABC; the total amount of antibody in a preparation, e.g. serum, based on a determination of the amount of antigen bound by unit amount of the preparation.

**antigen excess** the condition when a mixture of antigen and antibody contains sufficient antigen to combine with all the combining sites of the specific antibody molecules, leaving some free uncombined antigenic determinants and resulting in the formation of soluble antigen-antibody complexes. This is the explanation for the type of 'precipitin' curve when increasing amounts of antigen are incubated with a fixed amount of antibody and the amount of precipitate is measured.

**antigenic determinant** any specific chemical structure within, and generally small in relation to, an antigen molecule that is recognizable by a combining site of an antibody, or T-cell or B-cell receptor, and at which combination takes place. It determines the specificity of the antibody-antigen reaction. Several different antigenic determinants may be carried by a single molecule of antigen. See also epitope.

**antigenic drift** any of the minor changes in the antigenicity of influenza virus that result from spontaneous mutation, with corresponding minor changes in the amino-acid sequence of the viral hemagglutinin. Compare antigenic shift.

**antigenicity** the capacity of an agent to stimulate the formation of specific antibodies to itself.

**antigenic shift** any of the major changes in the antigenicity of influenza virus that result from spontaneous mutation, with corresponding major changes in the amino-acid sequence of the viral hemagglutinin. Compare antigenic drift.

**C antigen-independent) mitogenic factor** a lymphokine that acts as a mitogen for lymphocytes.

**antigen-presenting cell** abbr.: APC; a cell, especially a macrophage or dendritic cell, that recognizes an antigen to be targeted for neutralization. It takes up the antigen and processes it, incorporating antigen fragments into its own membrane and presenting them in association with class I major histocompatibility complex molecules to T lymphocytes, which are then stimulated to mount a response.

**antigibberellin** any of the organic compounds that cause plants to grow with thick stems or with an appearance differing from that obtained with gibberellin. The effect can usually be reversed by gibberellin.

**antiglobulin consumption test** a serological method for demonstrating antibody (globulin) attachment to cells. It is based on showing that antiglobulin is removed from solution on addition of the cells in question.

**antiglobulin test** or Coombs test a test for the presence of incomplete antibody against red blood cells. It entails the addition of heteroantibody to immunoglobulin (i.e. antiglobulin) to cause the agglutination of red blood cells previously coated with nonagglutinating incomplete antibody. Compare double-antibody method. [After Robin Royston Amos Coombs (b. 1921), British immunologist and hematologist who (with others) described it in 1945.]

**antihemophilic factor** or **antihemophilic factor A** or **antihemophilic globulin** an alternative name for factor VIII; see blood clotting factors.

## antioxidant

**antihemophilic factor B** an alternative name for factor IX; see blood coagulation.

**antihemophilic factor C** an alternative name for factor XI; see blood coagulation.

**antihemophilic globulin** an alternative name for antihemophilic factor.

**antihistamine** any drug or other agent that antagonizes an action of histamine on the body. Antihistamines are used in the treatment of immediate-type hypersensitivity.

**antihormone** any substance that acts to attenuate hormone-induced responses, regardless of the mechanism involved.

**anti-idiotype** an antibody that reacts with epitopes on the V region of the T-cell receptor.

**anti-inducer** any compound that inhibits operon induction by competing for inducer binding to free repressor and stabilizing the repressor-operator complex.

**antilipolytic** 1 describing any agent that inhibits lipolysis. 2 an antilipolytic agent.

**antilipotropic** 1 describing any agent that is active metabolically in deflecting methyl groups from the synthesis of choline. 2 an antilipotropic agent.

**antilogarithm** abbr.: antilog; symbol: (decadic) Ig-I; (napiерian) In-I; the number that is represented by a logarithm.

**antilymphocyte globulin** the globulin fraction of an anti-lymphocyte serum.

**antilymphocyte serum** abbr.: ALS; any serum containing antibodies to lymphocytes. It is used as a selective immuno-suppressive agent.

**anti-messenger DNA** abbr.: amDNA; an alternative name for complementary DNA.

**antimetabolite** any substance that inhibits the utilization of a metabolite, e.g. by acting antagonistically through competition in a transport system or at a key enzyme site.

**antimicrobial** 1 describing a drug, antibiotic agent, physical process, radiation, etc. that is inimical to microbes. 2 any substance having antimicrobial properties.

**antimicrobial spectrum** a list of the types of microbes against which an antimicrobial agent is effective.

**antimitotic** 1 describing any agent that decreases the rate of mitosis. 2 an antimitotic agent.

**antimonial** 1 of, relating to, or containing antimony. 2 a drug containing antimony.

**antimorph** 1 a mutant gene producing an effect opposite to the wild-type gene at the same locus. Compare allele. 2 obsolete term for an enantiomorph.

**antimutagen** any agent (often a purine nucleoside) that can decrease the rate of induced or spontaneous mutation.

**antimutator gene** any mutant gene that decreases the mutation rate.

**antimycin** any member of a group of antibiotics produced by *Streptomyces* spp. They associate strongly with mitochondria and block the passage of electrons from cytochrome b to cytochrome Cl; as little as 7 pmol antimycin A1 per gram of mitochondrial protein is effective. They are used experimentally to distinguish between events in the earlier and later parts of the electron-transport chain.

**antineoplastic** 1 describing any drug or other treatment that prevents or limits the growth of a neoplasm. 2 an antineoplastic agent.

**antinuclear factor** or **antinuclear antibody** any antibody that reacts with a component of the cell nucleus.

**antioxidant** or **antioxidant** any substance, often an organic compound, that opposes oxidation or inhibits reactions brought about by dioxygen or peroxides. Usually the antioxidant is effective because it can itself be more easily oxidized than the substance protected. The term is often applied to components that can trap free radicals, such as a-tocopherol (see vitamin E), thereby breaking the chain reaction that normally leads to extensive biological damage. The mechanism by which the free-radical scavenger is discharged of its free radical is not clear, but it is likely that ascorbate, glutathione, and,

## antiparallel

## antivitamin

ultimately, NAD<sup>+</sup> and the respiratory chain are involved. Compounds such as *di-tert-butyl-p-cresol* act as antioxidants and are often added to protect labile compounds during storage or incubation. *See also quinhydrone.*

**antiparallel 1** (*in biochemistry*) (describing of a pair of parallel linear structures, such as two polynucleotide or polypeptide chains, having directional polarity or asymmetry in opposite directions. **2** (*in quantum physics*) (of the spins of a pair of electrons occupying the same atomic or molecular orbital) described by different spin quantum numbers. *Compare* parallel (def. 2). -antiparallelism *n.*

**antiperiplanar** *see* conformation.

**antipernicious anemia factor** *former name for* vitamin B<sub>12</sub>.

**antiport** or countertransport the process of coupled solute translocation in which two solutes equilibrate across an osmotic barrier, the translocation of one solute being coupled to the translocation of the other in the opposite direction. *Compare* symport.

**antiporter** any substance or structural feature, but usually a protein, that promotes the exchange diffusion of two specific substances across a membrane by antiport. The convention for denoting such a protein (e.g. a tetracycline-resistance protein) is tetracycline/H<sup>+</sup> antiporter.

**antirachitic 1** describing any agent that opposes or prevents the development of rickets. **2** any agent with antirachitic properties.

**antirachitic factor** or antirachitic vitamin *former term for* any substance with vitamin D activity.

**antirepressor** any gene product that acts to decrease repression by a repressor of gene expression.

**antirestriction** the process whereby a host bacterium is prevented from inactivating foreign duplex DNA; i.e. the prevention of restriction. It is commonly achieved by host-controlled modification of the DNA, but in certain cases a specific bacteriophage-coded antirestriction protein is produced that directly inhibits the host's restriction endonuclease.

**antirestriction protein** *see* antirestriction.

**anti-RNA** single-stranded RNA complementary to mRNA. *See* antisense RNA.

**antiscorbutic 1** describing an agent that opposes or prevents the development of scurvy. **2** any agent with antiscorbutic properties.

**antiscorbutic factor** or antiscorbutic vitamin *former term for* any substance with vitamin C activity.

**antisense DNA** *see* noncoding strand.

**antisense oligonucleotide** an oligoribonucleotide, or an analogue of one, having properties similar to those of antisense RNA.

**antisense RNA** or messenger-RNA-interfering complementary RNA (*abbr.*: miRNA) an artificial single-stranded RNA molecule complementary in sequence to all or part of a molecule of messenger RNA or of some other specific RNA transcript of a gene. It can therefore hybridize with the specific RNA and so interfere with the latter's actions or reactions. *Compare* complementary RNA.

**antisense strand** *see* noncoding strand.

**antisepsis** the elimination of pathogenic and other microorganisms using chemical or physical methods; the promotion of asepsis.

**antiseptic 1** of, relating to, or bringing about antisepsis. **2** any chemical agent used in antisepsis, especially one that can be safely applied to the skin.

**antisera** (*pl.* *antisera* or (*esp.* US) *antisera*) serum that contains a high level of antibodies, usually antibodies against specific antigens.

**antisigma factor** a protein that interferes with the recognition of initiation sites by the sigma factor of DNA-dependent RNA polymerase.

**antistasin** *the generic name for* a family of potent inhibitors of factor Xa. Antistasins are isolated from leeches, and the name

was first given to a 119-amino-acid protein present in salivary gland of the Mexican leech *Haementeria officinalis*; the protein has 20 cysteine residues, all in disulfide bridges (probably characteristic of the family). It appears to present a bait-like structure to factor Xa, which cleaves it at Arg<sup>34</sup>. The 3-D structure has been partially solved, indicating a reactive site in domain I, sequence CRKTC. Antistasins have been considered as possible chemotherapeutic anticoagulants but have strong metastatic activity. Example, ghilanten from the Amazonian leech *H. ghillianii*: database code ANTA\_HAEGH, 119 amino acids (13.30 kDa).

**antistreptolysin-O** *abbr.:* ASO; antibody formed against streptolysin-O. *See* streptolysin.

**antisuppressor** any mutation that diminishes the effects of a suppressor of gene expression.

**antitemplate strand** *see* coding strand.

**antiterminator** (*or* antitermination factor) a protein that prevents the termination of RNA synthesis. It is found as a regulatory device in, e.g., phage lambda, enabling a terminator to be masked from RNA polymerase so that distal genes can be expressed. Antiterminators are associated with switches from early to middle expression following induction (gene N product, database code REGN\_LAMBD, 107 amino acids (12.24 kDa)) and from early to late expression (gene Q product, database code REGQ\_LAMBD, 207 amino acids (22.45 kDa)). The N system is referred to under *nus*. Antitermination is an important mechanism in the reproduction of some bacteriophages, allowing RNA polymerase to read through the terminator to the immediate early genes of the phage and thus initiate production of the mature phage with consequent cell lysis.

**antithrombin''' or heparin cofactor or factor Xa inhibitor** a 62 kDa protein inhibitor of serine proteinases, normally present in plasma, that reacts with factor IIa (thrombin), and also factors IXa, Xa, XIa, and XIIa to form inert 1:1 stoichiometric complexes. The formation of complexes is slow in the absence of heparin but very fast in its presence. Example from *Bos taurus*: ANT3\_BOVIN, 433 amino acids (49.13 kDa).

**antitoxin** any antibody to a toxin of a (micro)organism that neutralizes the toxin both *in vitro* and *in vivo*. **Q'1-antitrypsin ar  $\alpha_1$ -proteinase inhibitor** a major ai-globulin, normally present in human plasma, that inhibits many serine proteinases, including trypsin but especially elastase, and is the archetypal serpin. Its concentration rises dramatically in response to infection or tissue injury (*compare* acute-phase protein). A 51 kDa glycoprotein, its prime physiological role is to inhibit elastase released by neutrophil leukocytes. In humans, its synthesis is controlled by an autosomal allelic system and over 20 different phenotypes have been classified, one of which is associated with emphysema of early onset; in particular, the so-called Z mutant (Glu → Lys at position 342) is associated with a decreased level of a-antitrypsin in the blood. Smoking tends to cause oxidation of Met<sup>358</sup>, by increasing hydrogen peroxide formation by lung neutrophils, and this leads to a less active a1-antitrypsin and hence reduced inhibition of elastase. Excessive activity of elastase may damage lung tissue, resulting in emphysema. Thus smoking is associated with emphysema of early onset. Individuals who are homozygous for the Z mutant and who also smoke suffer decreased levels of a less active anti-elastase and have a high probability of developing emphysema. The protein has two chains; examples (human): chain A, database code NRL\_7APIA, 339 amino acids (38.09 kDa); 3-D structure known; chain B, database code NRL\_7APIB, 36 amino acids (4.13 kDa); 3-D structure known.

**antitussive 1** relieving or suppressing coughing. **2** an agent with antitussive properties.

**antivitamin** any agent that antagonizes a specific vitamin. Sometimes it is a structural analogue of the vitamin and a competitive inhibitor of the vitamin's action.

## antixerophthalmic factor

**antixerophthalmic factor** former term for any substance with vitamin A activity.

**antioxidant** a variant spelling of antioxidant.

**antrin** a decapeptide, isolated from rat gastric antrum. It has the sequence

Ala-Pro-Ser-Asp-Pro-Arg-Leu-Arg-Gln-Phe

and is identical to residues 25-34 of preprosomatostatin (see somatostatin).

**anucleate or anucleated** lacking a nucleus.

**anucleolate** lacking a nucleolus.

**AOX** abbr. for alcohol oxidase.

**AP** see AP endonuclease, AP protein.

**6-APA** abbr. for 6-aminopenicillanic acid.

**apamin** a neurotoxin comprising about 2% of the dry mass of the venom of the honey bee (*Apis mellifera*). It is a highly basic octadapeptide amide, structure

containing two disulfide bridges (between Cys residues I and 11, and 3 and 15), and is the smallest neurotoxic peptide known. Compare melittin.

**APe** abbr. for I activated protein C. 2 antigen-presenting cell.

**APe** the human gene for adenomatous polyposis coli protein. The gene is a tumour suppressor, and mutations are associated with familial adenomatous polyposis, Gardner's syndrome, etc. and contribute to colorectal cancer. The protein product is of unknown function and has serine phosphorylation, glycosylation, and myristylation sites. It is concentrated in the basolateral region of crypt epithelial cells. Product database code: APC\_HUMAN, 2843 amino acids (311.32 kDa).

**Ape** symbol for a residue of the  $\alpha$ -amino acid L-a-aminovaleric acid, L-2-aminopentanoic acid.

**AP endonuclease** abbr. for apyrimidinic or apurinic nuclease; any of various DNA repair enzymes that make breaks at sites generated by DNA glycosylase. There are three types: (1) **deoxribonuclease V**; (2) exodeoxyribonuclease III (endonuclease activity) see deoxribonuclease III; and (3) DNA-(apurinic or apyrimidinic site) lyase, EC 4.2.99.18; other names: AP lyase; AP endonuclease class I; endodeoxyribonuclease (apurinic or apyrimidinic); deoxyribonuclease (apurinic or apyrimidinic); *Escherichia coli* endonuclease III; phage-T4 UV endonuclease; *Micrococcus luteus* UV endonuclease. They catalyse a reaction in which the C-O-P bond 3' to the apurinic or apyrimidinic site in DNA is broken by a p-elimination reaction, leaving a 3'-terminal unsaturated sugar and a product with a terminal 5'-phosphate. Example: endonuclease III from *E. coli*; this binds a Fe4S4 cluster, which is not important for the catalytic activity but which is probably involved in the proper positioning of the enzyme along the DNA: database code END3\_ECOLI, 21 I amino acids (23.53 kDa).

**A peptide** the octadapeptide cleaved from the  $\alpha$  chains of a fibrinogen molecule when it is converted into fibrin by the proteolytic action of thrombin. Compare B peptide.

**aperture** (in physics) 1 an opening in an optical or other similar instrument that controls the amount of radiation entering or leaving it. 2 the diameter of the refracting surface of a lens or reflecting surface of a mirror. See also f-number.

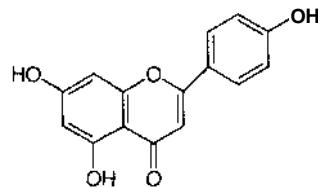

**aphidicolin** a potent antiviral and antimitotic agent, first isolated as an antibiotic from the fungus *Cephalosporium aphidicola*. It inhibits eukaryotic DNA polymerase.

**Api** symbol for  $\alpha$ -apiose.

**apical surface** the surface of an epithelial cell that faces the lumen.

**apigenin** 4',5,7-trihydroxyflavone; the aglycon of apin. It inhibits cyclooxygenase and estrogen synthase. See  $\alpha$ -apiose.

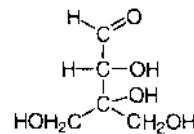

## apolar interaction

apigenin

**apiin** apigenin-7-apiosylglucoside, apioside; the name is derived from *Apium* (celery) from which apiin is isolated. See also apigenin, apiose.

**apiose** symbol: Api; the  $\alpha$  isomer, 3-C-(hydroxymethyl)- $\alpha$ -glycero-aldotetrose is a branched carbon chain sugar that occurs widely in plants either in glycosides or polysaccharides. It is a component of apiin.

D-apiose

**aplasia** incomplete or deficient development of an organ or tissue.

**aplastic** 1 not showing normal growth or change in structure. 2 relating to or showing aplasia.

**Apm** symbol for a residue of the  $\alpha$ -amino acid a-aminopimelic acid, 2-aminoheptanedioic acid.

**Azpm or Dpm** symbol for the di( $\alpha$ -amino acid) a.e-diaminopimelic acid, 2,6-diaminoheptanedioic acid.

**APMSF** p-amidinophenylmethylsulfonylfluoride; a specific irreversible inhibitor of trypsin-like serine endopeptidases, with greater inhibitory activity than phenylmethylsulfonylfluoride.

**apo+** prefix denoting detached, separate. It is used especially of enzymes and other proteins. For example, apocarboxylase is the protein part of the holoenzyme carboxylase, i.e. it lacks the covalently bound biotin residue(s). Apoferritin is a 450 kDa protein with 24 identical subunits, that combines with ferric hydroxide-phosphate to form ferritin. See also apoenzyme.

**Apo(a) or lipoprotein(a)** a serine endopeptidase (EC 3.4.21.-) related to plasminogen, having 37 repeats of plasminogen kringle domains and capable of cleaving fibrinogen. It is covalently linked (by disulfide bond) to apolipoprotein B-100. Its plasma concentration is related to the incidence of atherosclerosis. Example from human: database code APOA\_HUMAN, 4577 amino acids (500.77 kDa).

**apocrine** 1 describing a type of secretion that entails loss of part of the cytoplasm of the secretory cell. 2 describing a gland made up of such cells. Compare eccrine, holocrine, merocrine.

**apoenzyme** the protein part of an enzyme that forms a catalytically active enzyme (holoenzyme) when combined with an activator, a coenzyme, or a prosthetic group. It determines the specificity of the catalytic system.

**apoferritin** see ferritin.

**apolar** 1 lacking poles, especially of nerve cells. 2 nonpolar.

**apolar interaction** any of the entropy-driven interactions between nonpolar parts of molecules when in polar solvents. It is important in maintaining the structure of protein molecules in polar solvents, in antigen-antibody interactions, in virus-protein and enzyme-subunit aggregation and disaggregation, and in determining enzyme specificity.

## apolipoporphin

apolipoporphin a protein component of lipophorin. This protein increases the lipid-carrying capacity of lipophorin by covering the expanding hydrophobic surface resulting from diacylglycerol uptake. Example (precursor) apolipoporphin IIIB from *Locusta migratoria*: database code APL3\_LOCMI, 179 amino acids (19.09 kDa).

apolipoprotein the protein component of any lipoprotein, but especially of plasma lipoproteins. The latter are designated by the abbreviation 'Apo', e.g. ApoA (for apolipoprotein A), ApoB, etc., and are subdivided into subtypes, e.g. ApoA-I for apolipoprotein A, subtype 1. See following entries for individual types of apolipoprotein.

apolipoprotein A-I abbr.: ApoA-I; the major protein of plasma high-density lipoprotein (HDL), also found in chylomicrons. It is synthesized in the liver and small intestine, and participates in the reverse transport of cholesterol from tissues to the liver by promoting cholesterol efflux from tissues; it acts as a cofactor for lecithin-cholesterol acyltransferase. Deficiency of ApoA-I is associated with Tangier disease. Example (precursor) from human: database code APA1\_HUMAN, 267 amino acids (30.74 kDa).

apolipoprotein A-II abbr.: ApoA-II; an apolipoprotein associated with high-density lipoprotein, which it stabilizes. It is a homodimer (disulfide linked). Example from human: database code APA2\_HUMAN, 100 amino acids (11.62 kDa).

apolipoprotein A-IV abbr.: ApoA-IV; an apolipoprotein that is a major component of high-density lipoprotein and chylomicrons. It is involved in the catabolism of chylomicrons and very-low-density lipoprotein, being required for efficient activation of lipoprotein lipase by apolipoprotein CII. It is a potent activator of lecithin-cholesterol acyltransferase. Example from human: database code APA4\_HUMAN, 396 amino acids (45.32 kDa).

apolipoprotein B abbr.: ApoB; a major protein constituent of chylomicrons, very-low-density lipoprotein, and low-density lipoprotein. It exists in two forms, B-100 (amino acids 28-4563 of the sequence) and B-48 (amino acids 28-2179); the latter is of intestinal origin and derived from editing of mRNA to form an internal stop codon. Excessive plasma levels occur in familial hypercholesterolemia. Example from human: database code APB\_HUMAN, 4563 amino acids (514.97 kDa).

apolipoprotein C-I abbr.: ApoC-I; a component of chylomicrons and very-low-density lipoprotein (VLDL), synthesized mainly in liver. It modulates the interaction of apolipoprotein E with  $\beta$ -migrating VLDL and inhibits binding of  $\beta$ -VLDL to low-density lipoprotein receptor-related protein. Example from human: database code APCLHUMAN, 83 amino acids (9.32 kDa).

apolipoprotein C-II abbr.: ApoC-II; a component of very-low-density lipoprotein (VLDL) and an activator of several triacylglycerol lipases. It has a reversible association with plasma chylomicrons, VLDL, and high-density lipoprotein. Deficiency results in hypertriglyceridemia, xanthomas, and increased risk of pancreatitis and early atherosclerosis (hyperlipoproteinemia, type IB). Example from human: database code APC2\_HUMAN, 101 amino acids (11.27 kDa).

apolipoprotein C-III abbr.: ApoC-III; an apolipoprotein that constitutes 50% of the protein fraction of very-low-density lipoprotein. It binds to sugar and sialic-acid residues and inhibits lipoprotein and hepatic lipases. Example from human: database code APC3\_HUMAN, 99 amino acids (10.84 kDa).

apolipoprotein D abbr.: ApoD; an apolipoprotein that occurs in a macromolecular complex with lecithin-cholesterol acyltransferase and in high-density lipoprotein. It is a lipocalin of known 3-D structure, probably involved in the transport and binding of bilin. The homodimer shows wide tissue distribution. Example from human: database code APD\_HUMAN, 189 amino acids (21.25 kDa).

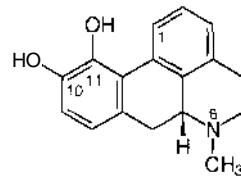

apolipoprotein E abbr.: ApoE; an apolipoprotein that constitutes 10-20% of very-low-density lipoprotein. It mediates

## apple domains

binding, internalization, and catabolism of lipoprotein particles and is a ligand for the low-density lipoprotein (ApoB/E) receptor and for the ApoE receptor (chylomicron remnant) of hepatic tissues. It is present in brain and may have a role in cholesterol transport. O-Glycoside and sialic-acid residues occur, but it is de-sialylated in plasma. It has nine allelic variants and two of these are associated with hyperlipoproteinemia type III. The 3-D structure is known; it contains a heparin-binding motif. Example from human: database code APE\_HUMAN, 317 amino acids (36.11 kDa).

apolipoprotein H abbr.: ApoH; other names:  $\beta_2$ -glycoprotein II precursor; APC inhibitor (see activated protein C). An apolipoprotein that binds to anions such as heparin and phospholipids. It may prevent activation of the intrinsic blood coagulation cascade by binding to phospholipids on the surface of damaged cells. See also amyloid A protein.

apolipoprotein receptor see LDL receptor, VLDL receptor. apomorphine 6ap-aporphine-IO, II-dial; 5,6,6a,7-tetrahydro-6-methyl-4H-dibenzo[de,g]quinoline-IO, II-dial; a synthetic opiate. The (R)-enantiomer is a potent dopamine receptor agonist, noted for its powerful emetic effects.

apoplast the nonliving part of plant tissue, external to the plasmalemma and composed of the cell walls, the intercellular spaces, and the lumen of dead structures such as xylem cells. apoprotein the protein part of a conjugated protein.

apoptosis cell death may occur by accident, by cell necrosis, or by an intracellular controlled process characterized by a condensation and subsequent fragmentation of the cell nucleus during which the plasma membrane remains intact. The term apoptosis may be used broadly to encompass all forms of such normal or pathological cell death or may be confined to those processes involving morphological changes such as occur in normal animal development. A cascade of caspases, (cysteine endopeptidases that cleave at specific aspartic residues hence the name) is involved. In this cascade, caspases cleave pro-caspases to form additional caspases. Some of the caspases thus formed cleave other proteins, including deoxyribonucleases. [From apo+ + Greek *potos*, falling.]

aporepressor the protein component of a complex that can act to inhibit gene expression. See also repressor.

apparent describing a physical quantity, especially an association constant, dissociation constant, equilibrium constant, etc., that has been determined under particular experimental conditions and hence is not the true (i.e. thermodynamic) constant. See equilibrium constant.

apparent exchangeable mass a term used in tracer kinetics in whole animals for a mass obtained by dividing the quantity of administered radioactivity that is retained by the specific activity of the tracer in the (blood) plasma. It equals the total exchangeable mass when the specific activities are equal throughout the system. Compare compartment.

apparent molecular weight former name for apparent relative molecular mass.

apparent relative molecular mass relative molecular mass that has been determined by a method that does not make allowance for any nonideality of the system.

apple domains sequences of 90 or 91 amino-acid residues that contain three highly conserved disulfide bonds linking the first and sixth, second and fifth, and third and fourth cysteine

## applicator

residues present in each repeat. They can be drawn in the shape of an apple. Four are present in human kallikrein and in human coagulation factor XI. *See also* Appendix E.

**applicator** any device or instrument, such as a comb, rod, spatula, or tube, for applying samples in a reproducible manner to a small defined area, e.g. in chromatography, or for applying something to a particular part of the body.

**approach to (sedimentation) equilibrium method** or Archibald method a method for determining the relative molecular masses of (macro)molecules by sedimentation in an ultracentrifuge, by measuring the depletion of the macromolecules from the meniscus and their accumulation at the cell bottom. Its advantage is that only very short periods of sedimentation are required. [After William James Archibald (1912- )]

**AP protein abbr.** for activator protein, one of two transcription factors; API, a product of *c-jun* (see JUN), interacts with Fos (product of *c-fos*) to form a dimer. It harbours two functional domains, one responsible for DNA binding and one for binding to Fos, and includes a leucine zipper. Example from human: database code TAPLHUMAN, 331 amino acids (35.63 kDa). AP2 interacts with inducible viral and cellular enhancer elements to stimulate transcription of selected genes. It contains the consensus binding sequence CCCAGGC and a helix-span-helix motif. Example from human: database code TAP2\_HUMAN, 437 amino acids (48.01 kDa).

**A<sub>2</sub>pr or Dpr symbol** for a residue of the a,p-diamino acid L-a,p-diaminopropionic acid; L-2,3-diaminopropanoic acid.

**aprotic** describing a substance, especially a solvent, that is unable to act as a proton acceptor or donor.

**aprotinin** a proteinase inhibitor derived from animal tissues. It is a basic polypeptide of known sequence of 58 amino-acid residues ( $\approx 6.5$  kDa) that exists as a dimeric aggregate. It is stable in acid or neutral media and at high temperature, and it inhibits kallikrein, trypsin, chymotrypsin, plasmin, and, to a lesser extent, papain. *See also* Trasylol.

**APRT abbr.** for adenine phosphoribosyltransferase.

**APS abbr.** for adenosine 5'-phosphosulfate.

**APT abbr.** for alum-precipitated toxoid.

**aptitude (in microbiology)** the specific physiological state of a lysogenic bacterium that enables it, upon induction, to react so as to produce infectious bacteriophage particles.

**apud or APUD abbr.** for amine precursor uptake and decarboxylation; designating any of a series of cells that produce peptides and/or amines active as hormones or neurotransmitters, share a spectrum of cytochemical qualities, and appear in many cases to have a common embryological origin. They are thought to include the A, B, and D cells of the endocrine pancreas, the C cells of the thyroid, and the various hormone-producing cells of the pituitary and the gut.

**apudoma** any tumour of an apud cell, e.g. a gastrinoma, glucagonoma, insulinoma, or VIPoma.

**apurinic acid** a DNA derivative in which all the purine bases have been removed by selective hydrolysis, leaving the pyrimidine-deoxyribose bonds and the phosphodiester bonds of the backbone intact. It results from the gentle acid hydrolysis of DNA at pH 3.0.

**apurinic endonuclease** see AP endonuclease.

**apyrase** EC 3.6.1.5; *other names:* ATP-diphosphatase; adenosine diphosphatase (*abbr.:* ADPase); a  $\text{Ca}^{2+}$ -requiring enzyme that catalyses the hydrolysis of ATP to AMP and 2 orthophosphate. It also hydrolyses other nucleotides, especially ADP to AMP and orthophosphate. It was originally identified in plants, especially potatoes, but enzymes of this type have also been found in animals, e.g. as a surface enzyme on lymphoid cells identical to CD39, and as a secreted enzyme of the yellow-fever mosquito, *Aedes aegypti*. It is used in platelet incubations to destroy ADP. Example from *A. aegypti*: database code APY\_AEDAE, 562 amino acids (62.73 kDa).

**apyrimidinic acid** a DNA derivative from which the pyrimidine bases have been removed chemically, leaving the

## arabinose

purine-deoxyribose bonds and the phosphodiester bonds of the backbone intact.

**apyrimidinic endonuclease** see AP endonuclease.  
**aq (in chemistry) abbr.** for aqueous.

**aqua+** *comb. form* 1 denoting acting on or reacting with water.

2 denoting presence of water as a neutral ligand in a coordination entity, e.g. aquacobalamin. The number of water molecules per entity is indicated by an approximate multiplying prefix, e.g. hexaquachromium trichloride.

**aquacide** a substance that when added to a mixture removes water molecules, usually by forming a compound with the elements of water. -aquacidal *adj.*

**aquaporin** any of a class of CHIPS that are specific for the transfer of water. Example, specific for erythrocytes and kidney proximal tubule, from human: database code AQP1\_HUMAN, 269 amino acids (28.49 kDa).

**aqueous** 1 of, having the characteristics of, or relating to water. 2 dissolved in or mixed with water. 3 or aqueous humour the fluid occupying the space between the crystalline lens and the cornea of the eye.

**aquo+** *comb. form* 1 containing one or more water molecules in a coordination complex. 2 (*in chemical nomenclature*) derived from water.

**aquo-ion** a complex ion containing one or more water molecules held by coordination.

**Ar symbol** for 1 argon. 2 aryl.

**Ara symbol** for arabinose.

**ara** a plant gene related to fas.

**araBAD** an operon characterized in *Escherichia coli* and encoding L-ribulokinase, L-arabinose isomerase, and L-ribulose 5-phosphate 4-epimerase, three of the enzymes that metabolize arabinose. *See also* arae.

**Arabidopsis fha/iana** a small Cruciferous plant (common wall cress) widely used in plant genetic research because of its small genome and very short generation time.

**arabin+ a variant (before a vowel) of arabin+**.

**arabinan** a branched homopolymer of L-arabinose found in plant pectins.

**arabinarinic acid** see aldaric acid.

**arabino+ or (before a vowel) arabin+ comb. form** indicating arabinose.

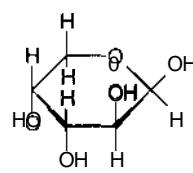

**arabino- prefix** (*in chemical nomenclature*) indicating a chemical compound containing a particular configuration of a set of three (usually) contiguous  $>\text{CHOH}$  groups, as in the acyclic form of D- or L-arabinose. *See* monosaccharide.

**arabinofuranosylcytosine** cytosine arabinoside; *see* cytarabine.

**arabinogalactan** any member of a subgroup of plant hemicelluloses that contain arabinose and galactose and are particularly abundant in larch.

**arabinonucleoside** the 1-p-D-arabinono-N-furanoside of a purine or pyrimidine base. It is a structural analogue of a riboside.

**arabinose** *arabino-pentose*; a monosaccharide. L-Arabinose occurs free, e.g. in the heartwood of many conifers, and in the combined state, in both furanose and pyranose forms, as a constituent of various plant hemicelluloses, bacterial polysaccharides, etc. D-Arabinose occurs to some extent in plant glycosides and is a constituent of the arabinonucleosides.

{L-D-arabinose}

## **o-arabinose isomerase**

**D-arabinose isomerase** EC 5.3.1.3; systematic name: D-arabinose ketol-isomerase. An enzyme that catalyses the reaction:

See also **L-arabinose isomerase**.

**L-arabinose isomerase** EC 5.3.1.4; systematic name: L-arabinose ketol-isomerase. An enzyme that catalyses the reaction:

It initiates the metabolism of L-arabinose. Example from *Escherichia coli*: database code ARAA\_ECOLI, 500 amino acids (55.98 kDa). See also **araBAD**, **D-arabinose isomerase**.

**arabinose-5-phosphate isomerase** EC 5.3.1.13; systematic name: o-arabinose-5-phosphate ketoI-isomerase. An enzyme that catalyses the reaction:

**arabinoside** any glycoside derived from arabinose.

**arabinoxylan** any of various neutral polysaccharides that occur in association with acidic polysaccharides in cereal gums. They consist of a chain of (1→4)-linked P-D-xylan units with single a-L-arabinofuranosyl groups in (1→3) linkage.

**arabitol or arabitol** *araho-pentitol*; the pentitol formally derived by reduction of the aldehyde group of arabinose or xylose. The D enantiomer is present in lichens and mushrooms. **arae** the gene for the AraC protein, which acts as a regulator of expression of the *araBAD* operon and of *araC* itself. AraC acts as both a repressor (when intracellular arabinose levels are low), binding to *araD* operator sites, and an activator (in the presence of arabinose), when bound to the *araI* site, but only in the presence of cyclic AMP-CRP complex. It is a typical helix-turn-helix DNA-binding regulatory protein. Database code ARAC\_ECOLI, 292 amino acids (33.35 kDa).

**ara-C** abbr. for arabinosylfuranosylcytosine.

**arachain** an unclassified proteinase obtained from the peanut, *Arachis hypogaea*.

**arachidic acid** the trivial name for eicosanoic acid;  $\text{CH}_3[\text{CH}_2]_{18}\text{-COOH}$ ; a constituent of arachis oil (from the peanut, *Arachis hypogaea*) and other oils. See also **arachidoyl**.

**arachidonate 5-lipoxygenase** EC 1.13.11.34; other names: 5-lipoxygenase; leukotriene-A<sub>4</sub> synthase; a **lipoxygenase** (def. 2) enzyme that catalyses the reaction of arachidonate with dioxygen to form (6E,8Z,11Z,14Z)-(5S)-5-hydroperoxyeicosanoate. Iron is a cofactor. Example from human: database code LOX5\_HUMAN, 673 amino acids (77.76 kDa).

**arachidonate 12-lipoxygenase** EC 1.13.11.31; other name: 12-lipoxygenase; a **lipoxygenase** (def. 2) enzyme that catalyses the reaction of arachidonate with dioxygen to form (5Z,8Z,10E,14Z)-(12S)-12-hydroperoxyeicosanoate. Iron is a cofactor. Example from human: database code LOX2\_HUMAN, 662 amino acids (75.45 kDa).

**arachidonate 15-lipoxygenase** EC 1.13.11.33; other names: arachidonate w-6 lipoxygenase; 6-lipoxygenase; a **lipoxygenase** (def. 2) enzyme that catalyses the reaction of arachidonate with dioxygen to form (5Z,8Z,11Z,13E)-(15S)-15-hydroperoxyeicosanoate. Iron is a cofactor. Example from human: database code LOXL\_HUMAN, 661 amino acids (74.59 kDa).

**arachidonic acid** see **eicosatetraenoic acid**.

**arachidonoyl symbol:**  $\Delta_4\text{Ach}$ ; the trivial name for (all-Z)-eicosanoate;  $\text{CH}_3[\text{CH}_2]_3[\text{CH}_2-\text{CH}=\text{CH}]_4-\text{[CH}_2\text{h-CO-}$  (all-Z isomer); the acyl group derived from arachidonic (*i.e.*(all-Z)-eicosanoate, **II**, 14-tetraenoic) acid, a polyunsaturated, unbranched, acyclic, aliphatic acid. It occurs naturally in membrane phospholipids, and is a biochemical precursor of **prostaglandins** and **leukotrienes**. It is also present in mosses, algae, and ferns, but not in higher plants. Distinguish from **arachidonyl** and **arachidoyl**.

**arachidonyl** the trivial name for the alkyl group,  $\text{CH}_3[\text{CH}_2\text{h}-\text{[CH}_2-\text{CH}=\text{CH}]_4-\text{[CH}_2]_3-\text{CH}_2-$ , derived from the alkenol analogue of arachidonic acid. Distinguish from **arachidonoyl**.

## **argentaffin cell**

**arachidoyl** or (formerly) **arachidyl** or **arachyl** symbol: Ach; the trivial name for eicosanoate;  $\text{CH}_3[\text{CH}_2]_{18}\text{-CO-}$ ; the acyl group derived from arachidic (or eicosanoic or (formerly) arachic) acid, a saturated, unbranched, acyclic, aliphatic acid. It occurs naturally as triarachin in certain seeds, oils, and butter fat. Arachidyl is now the name for the alkyl group,  $\text{CH}_3[\text{CH}_2]_{18}\text{-CH}_2-$ . Distinguish from **arachidonyl**.

**arachidyl** the trivial name for the alkyl group,  $\text{CH}_3[\text{CH}_2]_{18}\text{-CH}_2-$ , the alkanol analogue of arachidic acid. See also **arachidoyl**.

**arachin** the major protein of the groundnut, *Arachis hypogaea*, comprising a 345 kDa globulin with 12 subunits. Not all groundnuts contain the same arachin; there exist at least two forms, designated A and B, having similar amino-acid compositions and general properties but differing in their subunit composition. Examples of subunits: database code ARA1\_ARAHY, 176 amino acids (20.86 kDa); ARA5\_ARAHY, 201 amino acids (22.22 kDa). See also **conarachin**.

**Arber, Werner** (1929- ), Swiss microbiologist; Nobel Laureate in Physiology or Medicine (1978) jointly with D. Nathans and H. O. Smith 'for the discovery of restriction enzymes and their application to problems of molecular genetics'.

**arbovirus** abbr. for arthropod-borne virus (a term formerly used for **togavirus**).

**arc** a continuous curved line, as part of a circle or ellipse; e.g. the line of antigen-antibody precipitate obtained in **immuno-diffusion** or **immunoelectrophoresis**.

**Archaea** one of three primary kingdoms of cells, together with **Eukarya** and **Bacteria** (formerly **Eubacteria**), defined when cells are classified on the basis of rRNA sequence homologies. Archaea include all methanogens, extreme halophiles and most extreme thermophiles. Representative genera are: *Halo-bacterium*, *Methanobacterium*, *Sulfolobus*, *Thermoplasma*, and *Picrodictium* (growth optimum = 105°C); about 40 others are known. -archaeal adj.

**Archaeabacteria** former name for **Archaea**.

**Archibald method** see **approach to (sedimentation) equilibrium method**.

**Archimedes' principle** the principle that when a body is partly or wholly immersed in a fluid there is an apparent loss of weight equal to the weight of the fluid displaced. [After Archimedes of Syracuse (?287-212 BC), Greek philosopher and applied mathematician.]

**architectural gene** a gene that determines the site of an enzyme within a cell.

**A-region** the presumptive initial oxidation site of a carcinogenic polycyclic aromatic hydrocarbon, on the terminal ring of the **bay region**, in the metabolic pathway leading to carcinogenesis (corresponding to what has sometimes been called the M-region). Compare **B-region**, **K-region**, **L-region**.

**arenavirus** any of a group of RNA viruses consisting of enveloped pleomorphic particles of 80-120 nm with helical nucleocapsids. The group includes Lassa virus and other viruses that spread to humans from rodents.

**arene** any monocyclic or polycyclic aromatic hydrocarbon.

**arene oxide** any epoxide formed by the addition of an atom of oxygen across any double bond of an **arene**.

**ARF** abbr. for ADP-ribosylation factor; a small monomeric cytosolic **GTPase** that, when bound to GTP, binds to the membranes of cells. It was originally discovered as a factor required for cholera toxin to ribosylate G<sup>n</sup> hence its name. Its structure is known and is highly conserved. It is a member of the **HAS** superfamily. Functions of ARF include regulation of membrane traffic in both endocytic and exocytic pathways, maintenance of organelle integrity, assembly of coat proteins (see **coatomer**), and activation of phospholipase D. See **phospholipase**.

**Arg** symbol for a residue of the a-amino acid L-arginine (alternative to R).

**argentaffin cell** a type of cell of the **apud** class, characterized by taking up silver stains with high affinity, without the addi-

## argentation chromatography

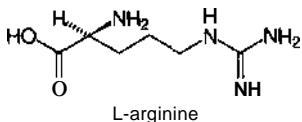

tion of reducing agent. [Named from Latin *argentum*, silver, and affinity.]

**argentation chromatography** any method of chromatography in which an adsorbent impregnated with silver nitrate is used to separate lipid classes according to the degree and geometry of their saturation. The technique may be used with either thin-layer chromatography or column chromatography, or in conjunction with gas-liquid chromatography.

**arginase** abbr. (in clinical biochemistry): ARS; recommended name for EC 3.5.3.1; other names: arginine amidinase; systematic name: L-arginine amidinohydrolase. An enzyme that catalyses the hydrolysis of L-arginine to L-ornithine and urea; it also acts on a-N-substituted L-arginines and canavanine. It is a key enzyme in the **ornithine-urea cycle**, occurring in high concentrations in the liver of ureotelic vertebrates and being absent or nearly so from the liver of uricotelic species. It has a very wide species distribution. In humans it is defective in the inherited disorder argininemia. Examples: from *Bacillus subtilis*, database code ARG1\_BACSU, 296 amino acids (32.15 kDa); from *Rattus norvegicus*, database code ARG1\_RAT, 323 amino acids (34.97 kDa).

**argininate** 1 arginine anion;  $\text{H}_2\text{N}-\text{C}(=\text{NH})-\text{NH}-[\text{CH}_2\text{H}-\text{CH}(\text{NH}_2)-\text{COO}]$ . 2 any salt containing the arginine anion. 3 any ester of arginine.

**arginine** trivial name for N<sup>5</sup>-amidino-ornithine;  $\alpha$ -amino- $\delta$ -guanidinovaleric acid; 2-amino-5-guanidinopentanoic acid;  $\text{H}_2\text{N}-\text{C}(=\text{NH})-\text{NH}-[\text{CH}_2]_3-\text{CH}(\text{NH}_2)-\text{COOH}$ ; a chiral  $\alpha$ -amino acid. L-Arginine (symbol: R or Arg), (S)-2-amino-5-guanidinopentanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: AGA (not in mitochondria of fruit fly or mammals) or AGG (not in mitochondria of mammals); CGA, CGC, CGG, or CGU. It is an essential dietary amino acid in rats and probably in young humans, and is glucogenic in mammals. D-Arginine (symbol: D-Arg or DArg), (R)-2-amino-5-guanidinopentanoic acid, is not known to occur naturally.

**arginine (base)** the ionic form of an arginine residue when the guanidino group is unprotonated.

**arginine carboxypeptidase** see **lysine(arginine) carboxypeptidase**.

**arginine kinase** EC 2.7.3.3; an enzyme that catalyses a reaction between ATP and L-arginine to form ADP and *Nw*-phospho-L-arginine. The latter compound may play a role in invertebrate muscle analogous to that of **creatine phosphate** in vertebrate muscle. Example from *Homarus gammarus* (European lobster): database code KARG\_HOMGA, 355 amino acids (39.81 kDa).

**arginine phosphate** former name (not recommended) for **phosphoarginine**.

**arginine-urea cycle** see **ornithine-urea cycle**.

**[8-arginine]vasopressin** or (less correctly) **argmme vasopressin** abbr.: AVP or [Arg<sup>8</sup>]vasopressin; the molecular form of **vasopressin** in which the variable eighth position in its amino-acid sequence is occupied by an arginine residue. This is the form present in humans and most other mammals.

**arginine vasotocin** or **[Arg<sup>3</sup>]oxytocin** a pituitary peptide found in nonmammalian vertebrates with activity resembling both oxytocin and vasopressin.

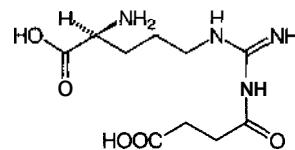

**argininium** 1 argininium(1+); the monocation of arginine. In theory, the term denotes any ion or mixture of ions formed from arginine and having a net charge of plus one, although in practice the predominant species is generally  $\text{H}_2\text{N}-\text{C}(=\text{NH}_2)^+$ .

NH-[CH<sub>2</sub>H-CH(NH<sub>3</sub><sup>+</sup>)-COO]. 2 the systematic name for argininium(2+); the dication of arginine.

**arginino** 1 N<sup>2</sup>-arginino; the alkylamino group,  $\text{H}_2\text{N}-\text{C}(=\text{NH})-\text{NH}-[\text{CH}_2\text{H}-\text{CH}(\text{COOH})-\text{NH}]$ , derived from arginine by loss of a hydrogen atom from its a-amino group. 2 NW-arginino; the alkylguanidino group, HOOC-CH(NH<sub>2</sub>)-[CH<sub>2</sub>]<sub>3</sub>-NH-C(=NH)-NH-, derived from arginine by loss of a hydrogen atom from its w-amino group.

**argininosuccinase** EC 4.3.2.1; systematic name: N-(L-argininosuccinate) arginine lyase; recommended name: argininosuccinate lyase. An enzyme of the **ornithine-urea cycle** that catalyses the hydrolysis of N-(L-arginino)succinate to fumarate and L-arginine. Example (human) homotetramer (deficiency in argininosuccinicaciduria; very strong similarity to bird and reptile I-crystallin): database code ARLY\_HUMAN, 464 amino acids (51.78 kDa).

**argininosuccinate** 2-(NW-arginino)succinate; L-argininosuccinate is an intermediate in the **ornithine-urea cycle**, where it is synthesized by the enzymic condensation of L-citrulline with L-aspartate. See **arginosuccinate synthase**.

**argininosuccinate synthase** EC 6.3.4.5; systematic name: L-citrulline:L-aspartate ligase (AMP-forming); other names: argininosuccinate synthetase; citrulline-aspartate ligase. An enzyme of the **ornithine-urea cycle** that catalyses a reaction between ATP, L-citrulline, and L-aspartate to form L-argininosuccinate with release of AMP and pyrophosphate. A deficiency occurs in citrullinemia. Example (human) homotetramer: database code ASSY\_HUMAN, 412 amino acids (46.37 kDa).

**arginyl** the acyl group,  $\text{H}_2\text{N}-\text{C}(=\text{NH})-\text{NH}-[\text{CH}_2]_3-\text{CH}(\text{NH}_2)-\text{CO}$ , derived from arginine.

**argon detector** a sensitive detector used in gas chromatography that depends on the unique ionization properties of argon whereby its long-lived metastable excited atoms can transfer their energy of excitation by collision to other gas molecules of lower excitation potential. Thus argon can be used as the chromatographic carrier gas, the detector being an ionization chamber containing a source of ionizing radiation. Detectable changes of the level of ionization occur when the argon issuing from the column has another gas mixed with it. The detector was invented by James E. Lovelock. Its great advantage is that it does not depend on the chemical nature of the substances being separated.

**[Arg<sup>2</sup>]va80pressin** abbr. for [8-arginine/vasopressin.

**arithmetic mean** see **mean**.

**arm** a base-paired segment of the clover-leaf model of transfer RNA. There are several such arms: **amino-acid arm**, **anticodon arm**, **dihydrouridine arm**, **extra arm**, and **Tfle arm**.

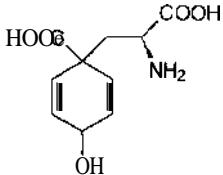

**ARNT** abbr. for aryl-hydrocarbon receptor nuclear translocator; other name: dioxin receptor; a protein that mediates translocation of the **Ah receptor** from the cytoplasm to the nucleus after ligand has been bound. Example from human: ARNT\_HUMAN, 789 amino acids (86.64 kDa).

**A-RNA** abbr. for A form of RNA.

**Br01** a fungal gene for aromatic amino-acid biosynthesis. It encodes a multifunctional protein for, e.g., **3-dehydroquinate synthase**, 3-dehydroquinase, **shikimate 5-dehydrogenase**, **shikimate kinase**, **EPSP synthase**. Example from *Emericella* (*Aspergillus*) *nudulans*: database code AROI\_EMENI, 1603 amino acids (174.89 kDa).

*aroA-H, aroL*

**aroA-H, aroL** *Escherichia coli* genes for chorismate synthesis. arogenate or pretyrosine 3-(1'-carboxylato-4'-hydroxy-2',5'-cyclohexadienyl)alanine; an intermediate in phenylalanine and tyrosine biosynthesis in *Euglena gracilis* and some other microorganisms, and in plants. It is formed by transamination of prephenate and is subsequently decarboxylated and converted to tyrosine, or converted to phenylalanine by dehydration and decarboxylation.

**aromatic** describing any organic compound characterized by one or more planar rings, each of which contains (usually) three conjugated double bonds and  $(4n + 2)$  delocalized pi-electrons, where  $n$  is a small integer. They undergo substitution reactions more readily than addition reactions. The simplest member of the class is benzene. The term was originally used to distinguish fragrant compounds from aliphatic compounds. -aromaticity  $n$ .

**aromatic amino acid** any amino acid containing an aromatic ring. In proteins these are phenylalanine, tryptophan, and tyrosine.

**aromatic-L-amino acid decarboxylase** EC 4.1.1.28; *systematic name*: aromatic-L-amino-acid carboxy-lyase; *other names*: dopa decarboxylase; tryptophan decarboxylase; hydroxytryptophan decarboxylase. An enzyme that catalyses the decarboxylation of L-tryptophan to tryptamine; pyridoxal 5'-phosphate is a coenzyme. The popular name derives from the fact that the enzyme also acts on 5-hydroxyY-L-tryptophan to yield 5-hydroxytryptamine and on dihydroxy-L-phenylalanine (dopa) to yield dopamine. Example from human: database code DCD\_HUMAN, 480 amino acids (53.83 kDa); it is a homodimer, and structurally similar to certain other eukaryotic decarboxylases.

**ARP<sub>a</sub>** *abbr.* for assimilatory regulatory protein a, i.e. ferredoxin-thioredoxin reductase.

**ARP<sub>b</sub>** *abbr.* for assimilatory regulatory protein b, i.e. thioredoxin.

**arrestin or S antigen** any protein of a family that includes the Ca<sup>2+</sup>-binding protein of rod-cell outer segments. It binds to photoactivated-phosphorylated rhodopsin, thereby apparently preventing the transducin-mediated activation of phosphodiesterase. It has been implicated in autoimmune uveitis. Example from human: database code ARRS\_HUMAN, 405 amino acids (45.00 kDa).  $\beta$ -Arrestins are similar in their C-terminal parts to  $\alpha$ -transducin and other purine-nucleotide-binding proteins.  $\beta$ -Arrestins regulate  $\beta$ -adrenergic receptor function; they seem to bind phosphorylated  $\beta$ -adrenergic receptors, thereby significantly impairing their capacity to activate G<sub>s</sub> proteins. Example (I3-arrestin 2) from human: database code ARRC\_HUMAN, 409 amino acids (45.99 kDa).

**Arrhenius, Svante August (1859-1927)**, Swedish chemist and physicist; Nobel Laureate in Chemistry (1903) 'in recognition of the extraordinary services he has rendered to the advancement of chemistry by his electrolytic theory of dissociation'.

**Arrhenius) activation energy symbol:** E<sub>a</sub> or EA; *see Arrhenius equation*.

**Arrhenius equation** an equation representing the effect of temperature on the velocity of a chemical reaction. It may be expressed in the forms:

$$d\ln k/dT = E_a/RT^2 \quad (1)$$

or

$$d \ln k/d(T) = -E_a/RT \quad (2)$$

or

$$k = Ae^{-E_a/RT} \quad (3)$$

where  $k$  is the rate constant for the reaction, E<sub>a</sub> is its IArrhenius) activation energy, R is the gas constant, T is the thermodynamic temperature, and A is a constant termed the frequency factor or the pre-exponential factor. Version 2 may be integrated to:

$$\ln k = \ln A - E_a/RT \quad (4)$$

Version 4 of the equation requires a plot of lnk against  $1/T$ , known as an Arrhenius plot, to be a straight line of slope  $-E_a/R$ , a relationship that has been shown to obtain for a considerable number of chemical reactions. *See also* temperature coefficient of reaction.

**Arrhenius plot** *see* Arrhenius equation.

**ARS** *abbr.* for 1 autonomously replicating sequence; any DNA sequence that can confer upon a plasmid the property of becoming a replicon in a particular host. The term is largely confined to fungal genetics. 2 (*in clinical biochemistry*) *abbr.* for arginase.

**Arsenazo III** 2,2'-(1,8-dihydroxy-3,6-disulfonaphthalene-2,7-bisazo)bisbenzenearsonic acid; an indicator substance used in the determination of low (micromolar) concentrations of free calcium ions. The free acid is purple; the calcium adduct is blue-violet.

**arsenic symbol:** As; a semi-metal element of group 15 of the IUPAC periodic table; atomic number 33; relative atomic mass 79.41. It exists in three forms: yellow, grey, and black. The yellow form, comparable to white phosphorus, is less stable than the other forms and is converted into the grey (metallic) form by heat. The black form is more stable than the yellow form but is metastable with respect to the grey form. Arsenic is required in trace amounts by some organisms, but generally it acts as an antimetabolite.

**arsenical** 1 of or containing arsenic. 2 a drug or other agent (e.g. an insecticide, rodenticide, or nerve gas) containing arsenic as an active principle.

**artemesinin** *see* sesquiterpene lactone.

**arteriosclerosis** a pathological condition in which there is a thickening and loss of elasticity of the walls of the arteries, which may become calcified. This interferes with the blood supply to various organs and tissues, resulting in impaired function. It normally, though not invariably, results from atherosclerosis.

**Arthus reaction** a complement-dependent hypersensitivity reaction caused when antigen reacts with precipitating antibody in the skin or other tissues, forming microprecipitates in and around the small blood vessels and, secondarily, damaging cells. In the passive Arthus reaction antibody is injected intravenously and the antigen applied locally; in the reversed passive Arthus reaction the opposite applies. An active Arthus reaction may occur when antigen is injected locally subsequent to previous injection of the same antigen. The inflammation that results is by type III mechanisms (*see* hypersensitivity (def. 2)). [Described by (Nicholas) Maurice Arthus (1862-1945), French physiologist and bacteriologist, in 1903.]

**articulin** any of a family of cytoskeletal proteins of the epiplasm of flagellate and ciliate organisms. They form filaments and larger sheets or tubes. They contain repeated valine- and proline-rich motifs with the consensus VPVP\_\_V V.

**aryl any** univalent organic radical derived from an arene by loss of one hydrogen atom.

**arylene** any bivalent organic group derived from an arene by loss of two hydrogen atoms.

**arylsulfatase** any of a group of enzymes that catalyse the hydrolysis of a phenol sulfate to a phenol and sulfate. Example from *Escherichia coli*: database code ASLA\_ECOLI, 551 amino acids (60.65 kDa). Arylsulfatases A, B, and Care com-

mon names for **cerebroside-sulfatase**, **N-acetylgalactosamine-4-sulfatase**, and **steryl'sulfatase** respectively.

**As** symbol for arsenic.

**ASA dehydrogenase** see **aspartate-semialdehyde dehydrogenase**.

**ASAT** (in clinical biochemistry) abbr. for aspartate aminotransferase. See **aspartate transaminase**.

**AS-C** abbr. for Achaete-Scute complex. See also **AS-C protein**.

**ascarylose** 3,6-dideoxy-L-mannose; 3,6-dideoxy-L-arabinose; a component of glycolipids found in eggs of the nematode, *Ascaris*, and in the bacterium, *Yersinia pseudotuberculosis*, type V. For the D enantiomer see **tyvelose**.

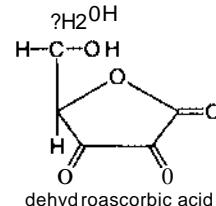

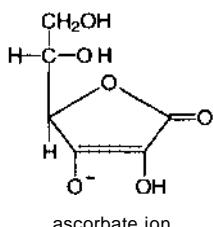

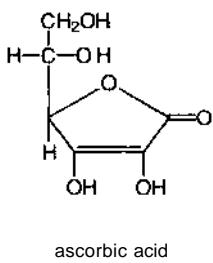

**ascending boundary** the solute boundary that moves upwards in one arm of the cell during electrophoresis in a **Tiselius apparatus**.

**ascending chromatography** any of the techniques of **chromatography** in which the mobile phase moves upwards over the solid phase.

**ascites** the accumulation of serous fluid in the peritoneal cavity. The presence of ascites may be due to the growth of a tumour elsewhere in the body, the ascitic fluid then containing a suspension of single tumour cells. Administration of a **hybridoma** results in the formation of **monoclonal antibodies** which can be recovered from the ascitic fluid. -ascitic adj.

**Ascoli test** a precipitin test used in the serological diagnosis of anthrax. The antigens are extracted with boiling saline and detected by a ring test with immune serum.

**ascorbic acid** a carbohydrate-like compound, containing six carbon atoms per molecule, the L enantiomer of which is found in fruit and vegetables. It has vitamin C activity in humans (most other primates can synthesize ascorbic acid) and guinea pigs. Humans are among the few higher animals that are unable to synthesize L-ascorbic acid, owing to a deficiency of **L-gulonolactone oxidase**, the enzyme catalysing the terminal step in L-ascorbic acid synthesis. The molecule contains an ene-diol group, one hydroxyl group of which is acidic ( $pK_a$  4.04) and ionizes to give an anion ascorbate; the other ene-diol hydroxyl acts as a reducing group ( $E^\circ = +0.058$  V, pH 7), and is oxidized on conversion to dehydroascorbate. Ascorbate is required together with ferric ion as a cofactor in the oxidation of prolyl residues in collagen to hydroxyprolyl residues and in other reactions.

**ascospore** a (usually sexually derived) haploid spore formed within an **ascus**.

**AS-C protein** abbr. for Achaete-Scute complex protein; any of a family of proteins encoded by the Achaete-Scute complex, a gene cluster first discovered in *Drosophila* but with analogues in mammals and other organisms. They are involved in the determination of the neuronal precursors in the peripheral and central nervous systems. The T3, T4, and T5 proteins label strongly in the presumptive stomatogastric nervous system, while T8 is more prominent in the presumptive procephalic lobe. They resemble other members of the **MYC** family of helix-turn-helix transcription factors. Example, AS-C protein T4 (*Drosophila melanogaster*): database code AST4\_DROME, 345 amino acids (38.08 kDa).

**ascus** (pl. *asci*) a sac-like fruiting body formed in ascomycete fungi, e.g. yeasts and *Neurospora*; it contains (typically eight) **ascospores** when mature.

**+ase** suffix denoting an enzyme; it is generally attached to a root indicating the substrate and/or the nature of the reaction catalysed. [From **diasaste**.]

**aematic molecule** any molecule that is not produced by an organism and therefore does not express any of the information that the organism contains. Absorbed molecules, although not derived from information contained within the organism, may nevertheless offer information about the organism relating to its absorption mechanisms. See **semantide**. See also **episematic molecule**.

**asepsis** 1 the state of being **aseptic**. 2 the methods of making or keeping something aseptic. Compare **antisepsis**.

**aseptic** sterile; free from pathogenic microorganisms. Compare **antisepic** (def. 2).

**aseptic technique** any technique incorporating measures that prevent the contamination of cultures, sterile media, etc. and/or the inappropriate infection of persons, animals or plants, by extraneous microorganisms.

**asexual reproduction or agamic reproduction** the development of a new individual from either a single cell or a group of cells without any sexual process. The term includes **agamogeny** and **vegetative reproduction**.

**Ash protein** another name for **Grb2**.

**asialo+** comb. form denoting the absence from a compound of sialic-acid residues, e.g. after their deliberate enzymic removal from a naturally occurring **sialo-** (def. 2) compound.

**A side** the side of the nicotinamide ring of NAD(P)H from which projects the *pro-R* hydrogen atom (known as  $H_A$ ) at the 4 position. Compare **B side**. See also **pro-R,pro-S convention**.

**A site** abbr. for aminoacyl-tRNA site (of a ribosome).

**Asn** symbol for a residue of the α-amino acid L-asparagine (alternative to N).

**AsnC** the asparagine biosynthetic operon regulatory protein, the product of *asnC*. In *Escherichia coli* it is the activator of *asnA* expression, the autogenous regulator of *asnC* expression, and the repressor of *gidA* (a gene of *E. coli* associated with glucose-inhibiting division) at the post-transcriptional level. It is a **helix-turn-helix** (HTH) protein and the prototype for AsnC HTH family of regulatory proteins; database code ASNC\_ECOLI, 152 amino acids (16.87 kDa).

**ASO** abbr. for antistreptolysin-O; see **streptolysin**.

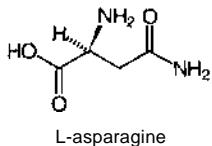

**Asp**

**Asp** symbol for a residue of the a-amino acid L-aspartic acid (alternative to D).

**asparaginase** EC 3.5.1.1; other names: L-asparaginase; systematic name: L-asparagine amidohydrolase; an enzyme that catalyses the hydrolysis of L-asparagine to L-aspartate and NH<sub>3</sub>. It is an effective antileukemic drug when injected into the bloodstream, its action being to deprive fast-growing tumour cells of the exogenous asparagine they require for rapid growth. Its clinical usefulness is limited because it causes damage to tissues with low asparagine synthetase activity. Several isoenzymes are found in several bacteria. Example, L-asparaginase I from *Escherichia coli*, a homotetramer: database code ASGI\_ECOLI, 338 amino acids (37.08 kDa).

**asparaginate** 1 asparagine anion; the anion, H<sub>2</sub>N-CO-CH<sub>2</sub>CH(NH<sub>2</sub>)-COO<sup>-</sup>, derived from asparagine. 2 any salt containing the asparagine anion. 3 any ester of asparagine.

**asparagine** trivial name for the p-amide of aspartic acid: aspartic 4-amide; a-aminosuccinamic acid; 2-amino-3-carbamoylpropanoic acid, H<sub>2</sub>N-CO-CH<sub>2</sub>CH(NH<sub>2</sub>)-COOH; a chiral a-amino acid. L-Asparagine (symbol: A or Asn; (formerly) also Asp(NH<sub>2</sub>), (S)-2-amino-3-carbamoylpropanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: AAC or AAU. It is a nonessential dietary amino acid in mammals and is glucogenic. One residue per molecule of D-asparagine (symbol: D-Asn or oAsn), (R)-2-amino-3-carbamoylpropanoic acid, may occur in the antibiotic bacitracin A as an alternative to one of o-aspartic acid. Compare **isoasparagine**.

**asparagine synthase (glutamine-hydrolysing)** EC 6.3.5.4; other name: asparagine synthetase (glutamine-hydrolysing). An enzyme that catalyses a reaction between ATP, L-aspartate, and L-glutamine to form AMP, pyrophosphate, L-asparagine, and L-glutamate. Example from asparagus: database code ASNLASPOF, 589 amino acids (65.97 kDa); it contains a glutamine amidotransferase motif. Compare **aspartate-ammonia ligase**.

**asparagino** 1 N<sup>2</sup>-asparagino; the alkylamino group, H<sub>2</sub>N-CO-CH<sub>2</sub>-CH(COOH)-NH-, derived from asparagine by loss of a hydrogen atom from its a-amino group. 2 N<sup>4</sup>-asparagino; the acylamino group, H<sub>2</sub>N-CH(COOH)-CH<sub>2</sub>-CO-NH-, derived from asparagine by loss of a hydrogen atom from its amide group.

**asparaginyl** the acyl group, H<sub>2</sub>N-CO-CH<sub>2</sub>-CH(NH<sub>2</sub>)-CO-, derived from asparagine. Compare isoasparaginyl.

**aspartame** N-L-a-aspartyl-L-phenylalanine methyl ester; a low-calorie artificial sweetener, about 160 times sweeter than sucrose in aqueous solution. Its sweetness is lost in cooking due to hydrolysis of the methyl ester. It is to be avoided in patients with phenylketonuria.

**aspartase** EC 4.3.1.1; recommended name: aspartate ammonia-lyase; other name: fumaric aminase. An enzyme that catalyses the hydrolysis of L-aspartate to fumarate and NH<sub>3</sub>. Example from *Escherichia coli*, homotetramer: database code ASPA\_ECOLI, 478 amino acids (52.30 kDa).

**aspartate** 1 aspartate(1-) or hydrogen aspartate; the mono-anion derived from aspartic acid. In theory, the term denotes any ion or mixture of ions formed from aspartic acid and having a net charge of -1, although the species -OOC-CH<sub>2</sub>-CH(NH<sub>3</sub><sup>+</sup>)-COO<sup>-</sup> generally predominates in practice. 2 the systematic name for aspartate(2-); the dianion derived from aspartic acid. 3 any salt containing an anion of aspartic acid. 4 any ester of aspartic acid.

**aspartic acid**

**aspartate aminotransferase** see **aspartate transaminase**.

**aspartate-ammonia ligase** EC 6.3.1.1; other name: asparagine synthetase; an enzyme that catalyses the reaction of ATP with L-aspartate and NH<sub>3</sub> to form AMP, pyrophosphate, and L-asparagine. Example from *Escherichia coli*: database code ASNA\_ECOLI, 330 amino acids (36.61 kDa). Compare **asparagine synthase (glutamine-hydrolysing)**.

**aspartate carbamoyltransferase** see **aspartate transcarbamylase**.

**aspartate kinase** EC 2.7.2.4; other name: aspartokinase; an enzyme that catalyses the formation of 4-phospho-L-aspartate from ATP and L-aspartate with release of ADP. The reaction is the first step in the biosynthesis of lysine, methionine, and threonine in plants and bacteria. In *Escherichia coli*, the pathway for the synthesis of each amino acid is independently controlled by regulation of isoenzymes specific for each pathway. Example from yeast: database code AK\_YEAST, 527 amino acids (58.04 kDa). See **homoserine dehydrogenase** for another example.

**aspartate-semialdehyde dehydrogenase** EC 1.2.1.11; systematic name: L-aspartate-4-semialdehyde:NADP<sup>+</sup> oxidoreductase (phosphorylating); other name: ASA dehydrogenase; an enzyme that, although reversible, normally catalyses the formation of L-aspartate-4-semialdehyde, orthophosphate, and NADP<sup>+</sup> from L-4-aspartylphosphate and NADPH. Its product is a component of a pathway involved in the biosynthesis of lysine and methionine, and can be converted either into dihydropicolinate (a precursor of lysine) or into homoserine (a precursor of methionine). Example from *Escherichia coli*: DHAS\_ECOLI, 367 amino acids (39.97 kDa).

**aspartate transaminase** abbr. (in clinical biochemistry): AST; BC 2.6.1.1; systematic name: L-aspartate:2-oxoglutarate aminotransferase; other names: transaminase A; glutamic-oxaloacetic transaminase; glutamic-aspartic transaminase. An enzyme that catalyses a reaction between L-aspartate and 2-oxoglutarate to form oxaloacetate and L-glutamate. It is a pyridoxal-phosphate enzyme, very widely distributed, performing a pivotal role in amino-acid metabolism. In mammals this includes the transfer of amino groups to aspartate, which then transfers them into the **urea cycle** through **argininosuccinate synthase**. Very high plasma concentrations of AST (more than 100 times normal) are found in cases of severe tissue damage including acute hepatitis, crush injuries, and tissue hypoxemia. In jaundice and myocardial infarction the levels reach 10 to 20 times normal; in myocardial infarction AST starts to rise about 12 h after the infarct, reaching a peak at 24 to 36 h, then declining over 2 to 3 days. The normal level in human plasma is in the range 10–50 IU L<sup>-1</sup> (method-dependent; assumed presence of vitamin B<sub>6</sub> in the assay). Examples: (1) mitochondrial enzyme, homodimer: database code (precursor) AATM\_HUMAN, 430 amino acids (47.42 kDa); (2) cytoplasmic isoform, homodimer: database code AATC\_HUMAN, 412 amino acids (46.08 kDa).

**aspartate transcarbamylase** abbr.: ATCase; EC 2.1.3.2; recommended name: aspartate carbamoyltransferase; other names: carbamylaspartotranskinase. An enzyme that catalyses a reaction between carbamoyl phosphate and L-aspartate to form N-carbamoyl-L-aspartate with release of orthophosphate. In many eukaryotes it is an activity of the **CAD protein**. In *Escherichia coli*, operon *pyrBI* codes for catalytic and regulatory chains; database code ECOPYRBI, catalytic chain 311 amino acids (34.37 kDa). There are six motifs and the 3-D structure of the enzyme in several states is known, e.g. database code NRL\_IATIA. The protein has a very high a-helical content. Carbamoyl aspartate is an important component of the pathway for *de novo* synthesis of pyrimidines.

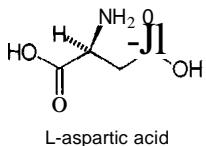

**aspartic** denoting a residue of aspartic acid, whether or not the *p*-carboxyl group is protonated.

**aspartic acid** trivial name for a-aminosuccinic acid; 2-aminobutanedioic acid, HOOC-CH<sub>2</sub>-CH(NH<sub>2</sub>)-COOH; a chiral a-amino acid. L-Aspartic acid (symbol: D or Asp), (S)-

## aspartic amide

## association constant

2-amino butanedioic acid, is a coded amino acid found in peptide linkage in proteins; codon: GAC or GAU. In mammals it is a nonessential dietary amino acid and is glucogenic. Residues of o-aspartic acid (*symbol*: o-Asp or oAsp), (*R*)-2-aminobutanedioic acid, are found in the cell-wall material of bacteria of various species, and one residue per molecule may occur in the antibiotic bacitracin A as an alternative to one of o-asparagine. It is also formed by racemization of L-aspartic acid residues in long-lived proteins such as crystallins, dentine, and myelin.

**aspartic amide** 1 aspartic I-amide; *an alternative name for* isoasparagine. 2 aspartic 4-amide; *an alternative name for* asparagine.

**aspartic endopeptidase or (formerly) acid proteinase or aspartyl protease or carboxyl protease** any enzyme of the sub-subclass EC 3.4.23, comprising endopeptidases having a pH optimum below 5 by virtue of an aspartic residue being involved in the catalytic process. The group includes cathepsin D, chymosin, the pepsins, and renin.

**asparto** the alkylamino group, HOOC-CH<sub>2</sub>-CH(COOH)-NH-, derived from aspartic acid.

**aspartoacylase** *see* aminoacylase.

**aspartokinase** *see* aspartate kinase; *see also* aspartokinase I homoserine dehydrogenase.

**aspartokinase/homoserine dehydrogenase** a multifunction enzyme, characterized in *Escherichia coli*, that catalyses two steps in the pathway from aspartate to diaminopimelate and lysine, to methionine, and to threonine and isoleucine. It is allosterically regulated by threonine. Example from *E. coli*: database code AKIH\_ECOLI, 820 amino acids (89.02 kDa); homotetramer; the first 149 amino acids form the aspartokinase domain, while the last 350 residues form the homoserine dehydrogenase domain.

**aspartoyl** the diacyl group, -CO-CH<sub>2</sub>-CH(NH<sub>2</sub>)-CO-, derived from aspartic acid.

**a-aspartyl aspart-I-yl;** the  $\alpha$ -monoacyl group, HOOC-CH<sub>2</sub>CH(NH<sub>2</sub>)-CO-, derived from aspartic acid.

**J3-aspartyl or (formerly) isoaspartyl aspart-4-yl;** the  $\rho$ -monoacyl group, HOOC-CH(NH<sub>2</sub>)-CH<sub>2</sub>-CO-, derived from aspartic acid.

**J3-aspartyl-N-acetylglucosaminidase** EC 3.2.2.1 I; *systematic name*: I-p-aspartyl-N-acetyl-o-glucosaminylamine L-asparaginohydrolase. An enzyme that catalyses the hydrolysis of I-p-aspartyl-N-acetyl-o-glucosaminylamine to N-acetyl-o-glucosamine and L-asparagine. Example from *Flavobacterium meningosepticum*: database code A42259, 339 amino acids (37.16 kDa). *See also* aspartylglucosaminuria.

**aspartylglucosaminuria** a metabolic disorder with autosomal recessive inheritance; it results in progressive mental retardation due to lysosomal accumulation of aspartylglucosamine (2-acetamido-l-p-L-aspartamido-1,2-dideoxy-p-o-glucose), which is excreted in abnormally high amounts in the urine. This compound is commonly found in several glycoproteins in normal individuals. The first sign of the condition is usually a delay in speech development (1-4 years). The enzymic effect is a deficiency of lysosomal aspartylglucosaminidase (N4-(p-N-acetylglucosaminyl)-L-asparaginase, EC 3.5.1.26).

**aspartylglucosylamine deaspartylase** *see* N<sup>1</sup>-(J3-N-acetylglucosaminyl)-t-asparaginase.

**J3-aspartyl phosphate or 4-phospho-L-aspartate or aspartyl-J3-**

phosphate an intermediate in the biosynthesis of lysine, threonine, and methionine in bacteria and plants. It is formed by aspartate kinase. It is converted to p-aspartyl semi-aldehyde, which is converted by the action of homoserine dehydrogenase to homoserine, a precursor of threonine or methionine. Alternatively addition of pyruvate to p-aspartyl phosphate leads to formation of dihydropicolinate, a precursor of lysine. A p-aspartyl phosphate residue is formed by phosphorylation of an aspartyl residue of Na<sup>+</sup>,K<sup>+</sup>-ATPase during the transport process.

**aspartyl protease** *an older name for* aspartic proteinase.

**J3-aspartyl semi-aldehyde** OHC-CH<sub>2</sub>CH(NH<sub>2</sub>)-COOH; *see also* J3-aspartyl phosphate.

**aspartyl shift or  $\alpha$  → J3-aspartyl shift** an intramolecular rearrangement reaction involving aspartic-acid residues that can occur during chemical synthesis or degradation of peptides. The p-carboxyl group of an aspartic residue displaces the  $\alpha$ -carboxyl of the same residue from its amide (= peptide) linkage to the amino group of the adjacent amino-acid residue, thus forming an acid-sensitive p-amide (= isopeptide) linkage. Conditions must favour ionization of the p-carboxyl group. The reaction may be used to advantage in the partial hydrolysis of polypeptides and proteins by very dilute acid, but may occur to disadvantage during base-catalysed hydrolytic removal of protecting groups in the course of peptide synthesis.

**Aspergillus** a genus of filamentous fungi containing species of industrial and genetic importance. *A. niger* and *A. oryzae* are used in the production of citric acid, industrial enzymes, and fermented foods. The sexual species *A. nidulans* has been an important research tool in both biochemical and mitochondrial genetics. *A. flavus* is a source of aflatoxins.

**asperlicin** a naturally occurring antagonist of the peptide cholecystokinin, produced by various strains of *Aspergillus aliiaceus*.

**aspirin or acetylsalicylic acid** 2-(acetoxy)benzoic acid; an irreversible inhibitor of prostaglandin-endoperoxide synthase, through covalent acetylation of the  $\alpha$ -amino group on the terminal serine active site. It is used as a drug for its antithrombotic activity and nonsteroidal anti-inflammatory and associated actions (antipyrexia, analgesia). *See also* salicylic acid.

**Asp(NH<sub>2</sub>) (formerly symbol for L-asparagine)**

**Asp-NH<sub>2</sub>** symbol for L-isoasparagine, an  $\alpha$ -amino acid.

**Asp(OMe)** symbol for p-methyl aspartate; 04-methyl hydrogen aspartate.

**Asp-OMe** symbol for  $\alpha$ -methyl aspartate; O1-methyl hydrogen aspartate.

**assay** 1 the determination of the activity, potency, strength, etc. of a substance, either on an absolute basis or in comparison with that of a standard preparation. 2 the determination of the relative amount(s) of one or more components of a mixture, or of the degree of purity of a substance. 3 to carry out such a determination. *See also* bioassay, immunoassay, microbiological assay, radioassay.

**assimilation** the absorption of simple foodstuffs (or of the products of their digestion) and their use in the biosynthesis of complex constituents of the organism; sometimes restricted to photosynthesis. *-assimilatory adj.*

**assimilatory nitrate reduction** *see* nitrate reduction.

**assimilatory regulatory protein a** abbr.: ARP<sub>a</sub>; *obsolete name for* ferredoxin-thioredoxin reductase, obtained from chloroplasts.

**assimilatory regulatory protein b** abbr.: ARP<sub>b</sub>; *obsolete name for* thioredoxin, obtained from chloroplasts.

**association** a reversible union between two chemical entities, whether alike or different, to form a more complex substance. *Compare dissociation (def. 1).*

**association constant symbol:**  $K_{ass}$  or  $K_a$ ; the equilibrium constant for the reversible formation of a complex chemical compound from two or more simpler entities; the reciprocal of the dissociation constant,  $K_{diss}$ . Sometimes an apparent association

## assortment

constant,  $K_{\text{ass}}$ , constrained with respect to stated values of certain variables (e.g. pH), is determined (*see* equilibrium constant). For an association of the type: A + B AB the (concentration) association constant is given by;

$$K_{\text{ass}} = [AB]/([A] \times [B]) = 1/K_{\text{diss}}$$

*See also* affinity constant, off-rate, on-rate, stability constant. **assortment** or reassortment during meiosis, the distribution to opposing cell poles of the two members of each pair of chromosomes at anaphase I and of the two members of each pair of chromatids at anaphase II.

**AST** (*in clinical biochemistry*) abbr. for aspartate transaminase. **astacin** EC 3.4.24.21; *other name*: Astacus proteinase; crayfish small-molecule proteinase; an enzyme that catalyses the hydrolysis of peptide bonds in substrates containing five or more amino acids, preferentially with Ala in the P1' and Pro in the P2' positions (*see* peptidase P-sites). Zinc is a cofactor. Example, including 3-D structure, from the European fresh water crayfish: database code NRL\_IAST, 200 amino acids (22.58 kDa).

**astatin** any of a subfamily of zinc metalloendopeptidases of unallocated number within sub-subclass EC 3.4.24, including tollloid (*Drosophila*) and bone morphogenetic protein 1 (human), involved in differentiation.

**astatine symbol:** At; a halogen element of group 17 of the IUPAC periodic table; atomic number 85. It occurs as short-lived isotopes of mass numbers 215, 216, and 218 resulting from  $\beta$ -decay of other radioactive elements. Astatine-211, an a-emitter of half-life 7.5 h, results from a-bombardment of bismuth; it has potential in radiotherapy.

**astaxanthin** 3,3'-dihydroxy-p,p-carotene-4,4'-dione; a carotenoid pigment found mainly in animals (e.g. crustaceans, echinoderms) but also occurring in plants. It can occur free (as a red pigment), as an ester (e.g. the dipalmitate), or as a blue, brown, or green chromoprotein.

**Aston**, Francis William (1877-1945), British experimental physicist; Nobel Laureate in Chemistry (1922) 'for his discovery, by means of his mass spectrograph, of isotopes in a large number of non-radioactive elements, and for his enunciation of the whole-number rule'.

**astral microtubule** *see* prometaphase.

**Astrup technique** a micro technique for the rapid determination of the acid-base status of a sample of blood. The pH of the blood as taken is measured and the remainder of the sample split into two and each part equilibrated with a different  $\text{CO}_2/\text{O}_2$  mixture of known  $p(\text{CO}_2)$  and their pH values measured. These last two pH values and the corresponding  $p(\text{CO}_2)$  values are plotted on a Siggard-Andersen nomogram and the points joined by a straight line. The  $p(\text{CO}_2)$  of the original sample may be obtained from the point on this line corresponding to the pH of the blood as taken. Furthermore, the standard bicarbonate value of the blood may be obtained from the point where the straight line intersects with a scale on the  $p(\text{CO}_2)$  axis at 5.33 kPa (40 mmHg).

**ASV** abbr. for anodic stripping voltammetry.

**Asx symbol** for a residue of either of the a-amino acids L-aspartic acid or L-asparagine when the state of amidation is uncertain (alternative to B).

**asymmetric synthesis** any synthesis of a compound that produces only one of two possible enantiomers of the product. This is usually the case for enzymic but not for nonenzymic reactions.

**asymmetry** absence of symmetry. A particular example of its meaning in biochemistry relates to the different phospholipid composition of the inner and outer leaflets of a lipid bilayer, said to confer asymmetry of composition. -asymmetric *ad*.

**asymmetry potential** the usually small potential across a membrane electrode, such as a glass electrode, when both sides are immersed in identical solutions. It is probably due to slight imperfections in the membrane.

## atomic orbital

**asyneapsis** absence of synapsis (def. I); i.e. the failure of homologous chromosomes to pair during meiosis.

**At symbol** for astatine.

**atactic** characterized by or showing irregularity in the spatial arrangement of the parts of a molecule.

**atactic polymer** any regular polymer in which the molecules display essential randomness with regard to the configurations at all main-chain sites of steric isomerism.

**+ate suffix** 1 designating any anion (including mixtures of anion and free acid), salt, or ester of any oxoacid (def. I) other than an  $\text{+}1$  acid. 2 denoting the product of a process, e.g. distillate, hydrolysate.

**ATF abbr.** for activating (or activator) transcription factor; any of various transcription factors for eukaryotic RNA polymerase II promoters that bind to CRE. Example, ATF-A and ATF-A- $\delta$  (human); these form a dimer; they have different sequences (amino acids 114-134 missing in  $\delta$ ), and possess a leucine zipper; database code ATFA\_HUMAN, 483 amino acids (54.70 kDa).

(A + T)/(G + C) ratio the ratio of the sum of the adenine plus thymine bases to the sum of the guanine plus cytosine bases in a DNA molecule or preparation. The ratio is to some extent a characteristic of an individual type of DNA molecule. *Compare* Chargaff's rules.

**athero-ELAMs** endothelial leukocyte-adhesion molecules, i.e. selectins, expressed in atherosclerotic plaques.

**atheroma** a condition or process affecting blood vessels in which plaques form beneath the intima (i.e. inner lining). These start as infiltration by lipid-containing cells but later become invaded by fibrous tissue or become calcified. It is associated with hypercholesterolemia and defects in the apolipoprotein B receptor -atheromatous *ad*.

**atherosclerosis** a degenerative condition affecting arteries in which there is hyperplasia of the outer coat and fatty degeneration of the middle coat of the arteries due to atheroma.

**aThr symbol** for a residue of the a-amino acid L-allothreonine, (2S,3S)-2-amino-3-hydroxybutanoic acid.

**atmosphere** 1 the envelope of gas surrounding the Earth. 2 any local gaseous environment. 3 symbol: atm; a non-SI unit of pressure equal to 101.325 kPa; the pressure that will support a column of mercury 760 mm high at 273.15 K, sea-level, and latitude 45°.

**atom** a unit of matter consisting of a single nucleus surrounded by one or more orbital electrons. The number of electrons is normally sufficient to make the atom electrically neutral; adding or removing electrons converts the atom into a negative or positive ion, but this is regarded as a state of the same atom since the atom is characterized by its nucleus.

**atomic absorption spectrophotometry** a quantitative version of atomic absorption spectroscopy in which the absorption of electromagnetic radiation by the ground-state atoms in the flame is measured photoelectrically and the concentration of the element in question calculated by reference to the absorption observed with solutions of the elements of known concentration.

**atomic absorption spectroscopy** an analytical technique, based on the observation of the absorption of light energy by atoms, in which an atomic vapour of an element is formed by aspiration of a solution of the element into a flame, or otherwise, so that the large majority of the element's atoms remain in the non-emitting ground state. These ground-state atoms absorb electromagnetic radiation of their own specific resonance frequency, to an extent that is proportional to the density of the elemental atoms in the flame.

**atomic mass constant symbol:**  $m_u$ ; a fundamental constant equal to the mass of a carbon-12 atom divided by 12; it is equal to the unified atomic mass unit.

**atomic mass unit abbr.** (formerly); amu; *see* unified atomic mass unit.

**atomic number** *an older alternative name for* proton number. **atomic orbital** the volume containing all the points within a

## atomic radius

free atom at which the Schrodinger wave-function of an electron is of appreciable magnitude.

**atomic radius** the distance between the centre of the nucleus and the outermost electron shell of an atom. *Compare van der Waals radius.*

**atomic weight** abbr.: at. wt.; former name for **relative atomic mass**.

**atomic weight unit** abbr.: awu; one-twelfth of the mean mass of the neutral atoms of naturally occurring carbon.

**atomizer or atomiser** an instrument for breaking up a solution into a spray of fine droplets.

**atom percent** the proportion of any nuclide in a mixture expressed as a numerical percentage of all the atoms of that element present irrespective of their nuclidic masses.

**atom percent excess** a measure of the abundance of a stable nuclide in a sample expressed in terms of the excess, in **atom percent**, over that naturally present. It is used to express the extent of enrichment or dilution of substances labelled with stable isotopes.

**atopy or atopic allergy** the tendency of some individuals to develop immediate hypersensitivity reactions to **allergens**. It is probably hereditary.

**ATP** abbr. for adenosine 5'-triphosphate.

**ATPase** abbr. for adenosine triphosphatase.

**ATP-diphosphatase** see **apyrase**.

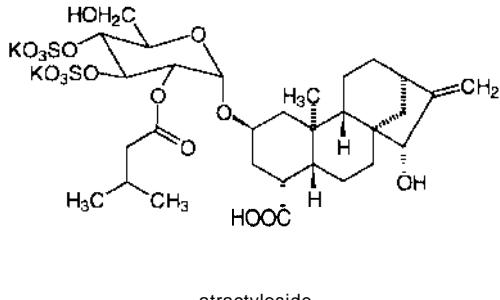

**ATP[ $\alpha,\beta\text{-CH}_2$ ]** abbr. for a,p-methyleneadenosine 5'-triphosphate; i.e. adenosine 5'-(a,p-methylene)triphosphate.

**ATP[ $\beta,\gamma\text{-CH}_2$ ]** abbr. for p,y-methyleneadenosine 5'-triphosphate; i.e. adenosine 5'-(p,y-methylene)triphosphate.

**ATP[ $\beta,\gamma\text{-NH}$ ]** abbr. for p,y-imidoadenosine 5'-triphosphate; i.e. adenosine 5'-(p,y-imido)triphosphate.

**ATP(S)** abbr. for adenosine 5'-y-thiotriphosphate.

**ATP synthetase** see **H<sup>+</sup>-transporting AIP synthase**.

atracyloside

**atractyloside** an extremely toxic glycoside, obtained from the rhizomes of the Mediterranean thistle *Atractylis gummifera*, that produces hypoglycemia and convulsions in animals. It inhibits oxidative phosphorylation, in particular the translocation of mitochondrial adenine nucleotides. Carrier-bound adenine nucleotides are apparently replaced by atractyloside owing to the latter's higher affinity for a common translocation site. *Compare bongrekic acid.*

**A-transferase** EC 2.4.1.40; recommended name: fucosylgalactose a-N-acetylgalactosaminyltransferase; other names: fucosylglycoprotein a-N-acetylgalactosaminyltransferase, [histoblood group] A-transferase; an enzyme that can catalyse a reaction between UDP-N-acetyl- $\alpha$ -galactosamine and glycoprotein a-L-fucosyl-(1,2)- $\alpha$ -galactose to form UDP and glycoprotein N-acetyl- $\alpha$ -D-galactosaminyl-(1,3)-[L-fucosyl-(1,2)]-D-galactose. It thus catalyses the addition of N-acetylgalactosamine to the H antigen of the **ABH antigen** system, forming the A antigen. This and the **B-transferase** protein are products of alleles of the **ABO** gene, differing in only four residues.

**atrial** of or pertaining to an **atrium**.

## atropine

**atrial natriuretic peptide** see **natriuretic peptide**.

**atrial natriuretic peptide receptor** see **natriuretic peptide receptor**.

**atrioactivase** a specific serine protease, present in bovine cardiac atria, that catalyses processing of the precursor of **natriuretic peptide** by selective cleavage at Arg<sup>89</sup>.

**atriopeptins** biologically active peptides isolated from mammalian cardiac atria. Atriopeptin I (I) has 21 amino acids, with the structure

(3-19 disulfide link); atriopeptin II (II) is the same with additional Phe-Arg residues at the C terminus; atriopeptin III is the same as II but with an additional Tyr residue at the C terminus. I relaxes intestinal smooth muscle but not vascular smooth muscle, while II relaxes both. *Compare natriuretic peptide.*

**atrium** (pl. **atria**) or (formerly) **auricle** 1 either of the two chambers of the heart that lie above the ventricles. They receive blood from the afferent veins and pump it into the ventricles. 2 any of various anatomical chambers that receive the openings of other cavities.

**atrolysin B** EC 3.4.24.41; other names: *Crotalus atrox* metalloendopeptidase B; hemorrhagic toxin B (abbr.: HT-B); a snake-venom enzyme that catalyses the cleavage of His<sup>5</sup>-Leu<sup>6</sup>, His<sup>10</sup>-I-Leu<sup>11</sup>, Ala<sup>14</sup>-I-Leu<sup>15</sup>, Tyr<sup>16</sup>-I-Leu<sup>17</sup>, and Gly<sup>23</sup>-Phe<sup>24</sup> of the insulin B-chain. The reaction is identical to the cleavage of insulin B-chain by **atrolysin C**. The enzyme also cleaves Ser-I-Xaa bonds in glucagon. It is a zinc-requiring enzyme.

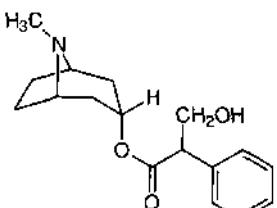

**atrolysin C** EC 3.4.24.42; other names: *Crotalus atrox* metalloendopeptidase C; hemorrhagic toxin C and D; a snake-venom enzyme that catalyses the cleavage of His<sup>5</sup>-I-Leu<sup>6</sup>, His<sup>10</sup>-I-Leu<sup>11</sup>, Ala<sup>14</sup>-I-Leu<sup>15</sup>, Tyr<sup>16</sup>-I-Leu<sup>17</sup>, and Gly<sup>23</sup>-I-Phe<sup>24</sup> of the insulin B-chain. With small-molecule substrates it prefers hydrophobic residues at the P2' position and small residues such as Ala or Gly at the PI position (see **peptidase P-sites**). It is a zinc-requiring enzyme. Example from *C. atrox* (the Western diamondback rattlesnake): database code HRTD\_CROAT, 203 amino acids (23.22 kDa).

**atrolysin E** EC 3.4.24.44; other names: *Crotalus atrox* metalloendopeptidase E; hemorrhagic toxin E; a snake-venom enzyme that catalyses the cleavage of Asn<sup>3</sup>-I-Gln<sup>4</sup>, Ser<sup>9</sup>-I-His<sup>10</sup> and Ala<sup>14</sup>-I-Leu<sup>15</sup> bonds in the insulin B-chain and Tyr<sup>4</sup>-I-Gln<sup>5</sup> and Ala<sup>8</sup>-I-Ser<sup>9</sup> in the A chain. It cleaves type IV collagen at Alaz58-I-Glnz59 in  $\alpha$ -I-collagen and at Gly<sup>191</sup>-I-Leu<sup>192</sup> in  $\alpha$ -II-collagen. It is a zinc-requiring enzyme. Example from *C. atrox* (the Western diamondback rattlesnake): database code HRTE\_CROAT, 478 amino acids (53.58 kDa).

**atrolysin F** EC 3.4.24.45; other names: *Crotalus atrox* metalloendopeptidase F; hemorrhagic toxin F; a snake-venom enzyme that catalyses the cleavage of Val<sup>2</sup>-I-Asn<sup>3</sup>, Gln<sup>4</sup>-I-His<sup>5</sup>, Leu<sup>6</sup>-I-Cys<sup>7</sup>, His<sup>10</sup>-I-Leu<sup>11</sup>, Ala<sup>14</sup>-I-Leu<sup>15</sup>, and Tyr<sup>16</sup>-I-Leu<sup>17</sup> bonds in the insulin B-chain. It is a zinc-requiring enzyme.

**atrophy** diminution in the size of a tissue or organ after full normal development has been attained. It is often a result of nutritional deficiency and/or decreased functional activity.

**atropine** ( $\pm$ )-hyoscyamine; tropyl DL-tropate; *IaH,5aH-tropan-3-ol* ( $\pm$ )-tropate a tropane alkaloid obtained from deadly nightshade, *Atropa belladonna*; and other Solanaceae. The racemic mixture is a tertiary ammonium compound that acts as a **muscarinic receptor** antagonist. It is used as an anticholinergic, mydriatic, etc. See also **hyoscine**.

atropine

**attachment proteins** general term for proteins that are involved in binding other proteins to cell structures, e.g. vinculin, or  $\alpha$ -actinin (see actinin), which bind actin to the plasma membrane.

**attachment site** see active site (def. 2).

**A-T tailing** homopolymer tailing of two types of duplex DNA molecule or fragment by the successive addition of adenine deoxynucleotide residues (A) to the 3' ends of molecules of one type and the complementary addition of thymine deoxynucleotide residues (T) to the 3' ends of molecules of the second type.

**attenuance symbol:**  $D$ ; the logarithm to the base 10 of the ratio of the radiant powers of the incident radiation,  $P_0$ , and the transmitted radiation,  $P$ ; thus:

$$D = \lg(P_0/P) = \lg T^{-1},$$

where  $T$  is the transmittance. Attenuance reduces to absorbance if the incident beam is only either transmitted or absorbed, but not reflected or scattered.

**attenuated virus** a virus that has become less pathogenic following passage in culture outside its natural host, or by the use of physical or chemical means.

**attenuator** a sequence in DNA that is located between the operator and the gene for the first protein in an operon. It can cause transcription termination. The operon for the synthesis of tryptophan in bacteria is an example of an operon that contains an attenuator.

**atto+** symbol: a; prefix used with SI units denoting  $10^{-18}$  times. **attractant** or **chemoattractant** a substance that a motile cell or organism tends to move towards; i.e. one that elicits positive chemotaxis. For a responsive bacterium, attractants can be either nutritive or nonmetabolizable. An example is cytotoxin.

**Au symbol** for gold.

**AUA** 1 a codon in mRNA, excluding that of mammalian mitochondria, for L-isoleucine. 2 a codon in mammalian mitochondrial mRNA for L-methionine (and for N-formyl-L-methionine, chain initiation, in some species).

**AUC** a codon in mRNA for L-isoleucine.

**AUG** a codon in mammalian mitochondrial mRNA, and in non-mitochondrial mRNA the only codon for L-methionine and usually for N-formyl-L-methionine, chain initiation.

**Auger effect** a process by which an orbital electron in an atom passes from an excited to a lower energy level. The X-ray so produced collides with, and ejects, another orbital electron, known as an Auger electron, with energy in the X-ray range. [After Pierre Victor Auger (1899-1993), French physicist.]

**auracyanin** a small blue copper-containing bacterial outer membrane glycoprotein (one Cu<sup>2+</sup> ion per protein) that donates electrons to cytochrome c<sub>554</sub>. Example from *Chloroflexus aurantiacus*: database code AUBI\_CHLAU, 154 amino acids (15.53 kDa).

**aureomycin** 7-chlortetracycline. See tetracycline.

**auriculin** either of two fragments of atrial natriuretic peptide; auriculin A is the 4-27 and B the 4-28 fragment.

**Auriculin** a proprietary name for atrial natriuretic peptide.

**auosome** an artificially induced organelle occurring in animal

cells cultured in the presence of gold. It is an electron-dense lysosomal body containing gold particles.

**Australia antigen** an alternative name for hepatitis B antigen. See hepatitis.

**aut+** a variant form of **auto+**.

**autacoid** any druglike principle that is produced in or can be extracted from the organs of internal secretion. Autacoids include both excitatory substances (hormones) and inhibitory substances (chalone).

**auto+** or (before a vowel) **aut+** comb. form 1 self; one's own. 2 occurring within oneself or itself. 3 acting by itself; automatic; spontaneous.

**autoagglutination** the tendency of a suspension of bacteria or other cells to agglutinate spontaneously in a simple medium not containing an agglutinin or other similar reagent.

**autoallergy** an alternative term for autoimmunity.

**autoanalyser** or (esp. US) **autoanalyzer** any instrument for effecting analyses automatically.

**autoantibody** an antibody produced in an animal that reacts with a constituent of the animal's own tissues, which thus acts as a 'self' antigen or autoantigen.

**autoantigen** an antigen that is a normal constituent of an individual and has the capacity to produce an immune response in the same individual in certain circumstances.

**autocatalysis** the catalysis of a chemical or biochemical reaction by one of the reaction products. -autocatalytic adj.

**autochthonous** derived from that part of the body where found; native. Compare autologous.

**autoclave** an instrument, used for sterilizing culture media, instruments, etc., that consists of an airtight chamber which can be filled with, or surrounded by, steam at high pressure.

**autocoupling** hapten a reactive compound of low molecular mass that, when injected into an animal, reacts with tissue antigens to form hapten-antigen compounds. These then lead to the formation of antibodies to the hapten.

**autocrine** describing an agent that acts on the cell in which it is produced.

**autofluorogram** an alternative name for fluorogram (when produced by fluorography (def. 2)).

**autofluorography** an alternative term for fluorography (def. 2). **autogenesis** or **autogeny** an alternative term for abiogenesis. -autogenetic adj.

**autogenous** 1 self-produced. 2 originating within, especially within one's own body.

**autogenous regulation** the mechanism by which a protein directly controls the expression of its own structural gene.

**autograft** any graft or transplant of the subject's own tissue(s). **autoimmunity** or **autoallergy** a state of immunological reactivity against constituents of the subject's own tissues.

**autoimmunization** or **autoimmunisation** the process of inducing autoimmunity.

**autologous** derived from the same organism. Compare autochthonous.

**autolysate** or (esp. US) **autolyzate** a product of autolysis, e.g. a suspension of broken cells.

**autolysin** EC 3.5.1.28; other name: N-acetylmuramoyl-L-alanine amidase; an enzyme that catalyses the hydrolysis of the link between N-acetylmuramoyl residues and L-amino-acid residues in certain bacterial cell-wall glycopeptides. The enzyme is required for cell separation, cell-wall turnover, etc. Example from *Staphylococcus aureus*: database code ALYS\_STAAB, 481 amino acids (53.76 kDa). See also lysostaphin.

**autolysis** the process of self-digestion that occurs in plant and animal tissues after death of the organism or following separation of tissue from the rest of the organism. It is due to the action of the tissue's own enzymes. -autolytic adj.

**autolysosome** an autophagic vacuole.

**automutagen** any mutagen formed in an organism as a normal or abnormal metabolic product that is mutagenic in the same organism.

## autonomic nervous system

autonomic nervous system *abbr.*: ANS; those parts of the peripheral nervous system and central nervous system that govern homeostasis in vertebrates and are generally independent of voluntary control.

autonomous existing or able to exist independently; used, e.g., of a tumour cell that is free of host control or of an episome or plasmid that replicates independently of the chromosome.

autophagic vacuole an enlarged lysosome containing subcellular structures such as mitochondria; a secondary lysosome.

autophagosome a phagosome containing endogenous cellular debris. *Compare* heterophagosome.

autophagy a process, apparently ubiquitous among eukaryotes, by which cells digest parts of their own cytoplasm. *Compare* heterophagy. -autophagic *adj.*

autophosphorylation the phosphorylation by a protein of one of its own residues. It is important in signal transduction by growth hormone receptors (*see*, e.g., epidermal growth factor receptor), but occurs in the case of other proteins, e.g. caldesmon.

autoprothrombin I *an alternative name for* factor VII; *see* blood coagulation.

autoprothrombin II *an alternative name for* factor IX; *see* blood coagulation.

autoprothrombin IIA *an alternative name for* protein C.

autopsy or necropsy the examination of a dead body, commonly to determine the cause of death or the presence of disease processes; a post-mortem (examination). *Compare* biopsy.

autoradiogram an autoradiograph, especially of a chromatogram or electrophoretogram.

autoradiograph or autoradiogram the image produced by autoradiography.

autoradiography a method by which radioactive material can be localized in, e.g., a tissue, cell, a cell part, or molecule, or in a chromatogram or electrophoretogram. The sample containing a radioactive substance is put in direct contact with a thick layer of specially prepared photographic emulsion. The radiation emitted in the decay of the radionuclide(s) activates individual silver halide grains in the emulsion rendering them susceptible to conversion to metallic silver grains by a photographic developer. After fixation the silver grains may be located either visually or by microscopy.

autosomal of, relating to, or being an autosome.

autosomal disease disease that results from an abnormality affecting the autosomes.

autosome any chromosome except the sex chromosomes. Hence the genes carried by the autosomes show autosomal linkage (or autosomal inheritance) according to the assortment of their respective autosomes to gamete cells during meiosis. Humans have 22 pairs of autosomes in addition to a pair of sex chromosomes.

autosteric effector any effector that binds to, and exerts its effect at, part of or immediately adjacent to the active site of an allosteric protein. It is distinguished from an allosteric effector operating at a distant site.

autotroph or lithotroph any organism that requires only simple inorganic substances to fulfil its nutritional requirements and for which gaseous or dissolved carbon dioxide is the sole source of carbon for the synthesis of cellular constituents. The term often includes any microorganism for which trace amounts of certain substances, e.g. vitamins, must also be supplied. Autotrophs may be subdivided into chemoautotrophs (*or* chemolithotrophs) and photoautotrophs (*or* photolithotrophs) according, respectively, to whether they are chemotrophs or phototrophs. *Compare* heterotroph. -autotrophic *adj.*; autotrophy *n.*

AUU a codon in mRNA for L-isoleucine.

auxiliary amino acid any amino-acid residue in the active site

## Avogadro constant

(def. I) of an enzyme that is more than one bond distance removed from the substrate molecule in the enzyme-substrate complex. *Compare* contact amino acid.

auxin any of a group of plant hormones, produced by regions of actively dividing and enlarging cells, that regulate aspects of plant growth. They include indole-3-acetic acid and indole-3-acetonitrile.

auxochrome any saturated atomic grouping (e.g. -OH, -CH<sub>3</sub>, -NH<sub>2</sub>, -Cl, -SH) that, when attached directly to a chromophore, shifts the selective absorption of light in the direction of longer wavelengths and enhances the intensity of absorption.

auxostat in industrial fermentation, a chemostat in which the dilution rate can be varied, normally in response to some parameter such as growth rate or pH, so that growth rate is more readily maximized.

auxotroph any strain of microorganism (alga, bacterium, or fungus) that differs from the wild-type by requiring a supply of one or more growth factors. *Compare* prototroph. -auxotrophic *adj.*

auxotrophy the condition of being an auxotroph.

average *an alternative term for* (arithmetic) mean.

average life *see* mean life.

average molar mass or (*formerly*) average molecular weight any of a series of numeric characteristics of a macromolecular system that are useful for assessing the extent of its polydispersity. The three most important are the number-average molar mass,  $M_n$ , the mass-average molar mass,  $M_m$ , and the Z-average molar mass,  $M_z$ . These three characteristics are given by the expressions:

$$M_n = \frac{\sum n_i M_i}{\sum n_i} \text{ (kg mol}^{-1}\text{)}$$

$$M_m = \frac{\sum n_i M_i^2 / \sum n_i M_i}{\sum n_i} \text{ (kg mol}^{-1}\text{)}$$

$$M_z = \frac{\sum n_i M_i^3 / \sum n_i M_i^2}{\sum n_i} \text{ (kg mol}^{-1}\text{)}$$

where  $n_i$  is the amount of substance of species  $i$  and  $M_i$  is the molar mass of species  $i$ . Measurement of a colligative property, e.g. osmotic pressure, or end-group analysis, gives  $M_n$ ; light scattering, dielectric dispersion, or fluorescence depolarization measurements give  $M_m$ ; and data obtained by equilibrium ultracentrifugation will yield either  $M_m$  or  $M_z$  depending on how they are treated. For polydisperse or heterogeneous systems,  $M_z > M_m > M_n$ , whereas for monodisperse systems these three characteristics are equal (i.e. equal to the relative molecular mass,  $M_r$ , of the single species).

average molecular weight *former name for* average molar mass.

average radius of gyration *an alternative term for* mean radius of gyration.

average relative molecular mass *former name for* average molar mass.

avermeetin B, *an alternative name for* abamectin.

avidin a 66 kDa glycoprotein comprising four essentially identical subunits, each of which consists of a single polypeptide chain of 128 amino-acid residues. Isolated from the white of the eggs of birds and amphibia, it binds extremely strongly to biotin and produces biotin deficiency when fed to experimental animals. Example from *Gallus gallus* (precursor): database code AVID\_CHICK, 152 amino acids (16.77 kDa); residues 1-24 form the signal.

avidity 1 the tendency of an antibody to form more-or-less stable complexes with a (macromolecular) antigen; a measure of this tendency. 2 *an alternative term for* affinity.

avirulent lacking virulence.

avitaminosis a condition resulting from deficiency of one or more vitamins. The deficient vitamin may be specified, as in avitaminosis A, B, etc.

Avogadro constant or (*formerly*) Avogadro's number symbol:

## avogram

*L or  $N_A$ :* the number of molecular entities in one mole of any chemical species. It is a fundamental physical constant, of value  $6.0221367(36) \times 10^{23}$  mol $^{-1}$ . Compare Loschmidtconstant. **Avogadro number** or Avogadro's number the numerical value of the Avogadro constant.

**Avogadro's hypothesis** or Avogadro's law the principle that equal volumes of all ideal gases, at the same temperature and pressure, contain equal numbers of molecules. [After Lorenzo Romano Amadeo Carlo Avogadro, Count of Quaregna and Cerreto (1776-1836), Italian physicist and chemist who formulated it in 1811.]

**avogram** see dalton.

**AVP** abbr. for arginine vasopressin.

**axenic** pertaining to the growth of organisms of a single species in the absence of living organisms or living cells of any other species (also, strictly, in the absence of living cells of the organism itself except those in the intact living organism and its gametes). -axenity *n.*; axenically *adj.*

**axenate** or axenise to render axenic.

**axenite** an organism grown axenically.

**axial** 1 of, relating to, or being an axis (def. 1 or 2); located on or close to such an axis. 2 (*in stereochemistry*) *Symbol:* a. See conformation.

**axial ratio** the ratio of the length of the major axis to that of the minor axis of a prolate ellipsoid of rotation, a model often used for a protein or other macromolecule in solution.

**axis** 1 a straight line about which a body or three-dimensional figure, e.g. a crystal, is considered to rotate. 2 one of the reference lines of a co-ordinate system. 3 the second vertebra of the neck in higher vertebrates.

**axis of rotation** see rotation axis.

**axis of symmetry** see symmetry, axis of.

**axokinin** a heat-stable phosphoprotein,  $M_r$  56 000, present in flagella and cilia of vertebrate and invertebrate species. Its cyclic AMP-dependent phosphorylation is required for initiation and maintenance of flagellar motility.

**axon** the long process of a neuron that conducts nerve impulses, usually away from the cell body to the terminals which are the site of storage and release of neurotransmitter. Compare dendrite.

**axonal transport** the directed transport of organelles and molecules along the axon of a neuron. It can be anterograde (i.e. outwards from the cell body) or retrograde (i.e. towards the cell body).

**axoneme** the bundle of microtubules and associated proteins that forms the core of cilia and flagella in eukaryotic cells and is responsible for their movements.

**axoplasm** the cytoplasm of the axon of a neuron, especially after it has been extruded from the axon.

**aza+ prefix** 1 (*in systematic chemical nomenclature*) denoting the replacement of a designated carbon atom (together with one associated hydrogen atom) by a nitrogen atom. 2 (*in trivial chemical names*) denoting presence of one or more nitrogen atoms.

**azaserine** *trivial name for* serine diazoacetate; O-diazoacetyl-L-serine,  $Nz=CH-CO-O-CH_2-CH(NH_2)-COOH$ ; an antibiotic substance produced by *Streptomyces* spp. It is an inhibitor of amidotransferase enzymes and interferes with purine synthesis; it also retards the growth of transplantable animal neoplasms and is a specific inhibitor of L-glutamate ferredoxin oxidoreductase (transaminating), EC 1.4.7.1, in ammonium assimilation in plants.

**azathioprine** 6(1-methyl-4-nitro-5-imidazolyl) mercaptopurine; 6-[1-methyl-4-nitroimidazol-5-yl]thiopurine; a derivative of mercaptopurine, into which it is converted *in vivo*. It is useful as an immunosuppressive and antimitotic agent. *One proprietary name:* Imuran.

**azelaic acid** 1,7-heptadicarboxylic acid, nonanedioic acid; a substance that acts as a substitute for biotin in the growth of a number of microorganisms and is proposed as an intermediate in biotin biosynthesis from oleic acid.

## azurophil(e) granule

**azeotrope** a mixture of two or more liquids that distils without change in composition and has a constant boiling temperature.

**azide** 1 any organic compound containing the monovalent azido group,  $-N=N^+=N^-$ . 2 the ion  $N_3^-$ , derived from hydrazoic acid,  $HN_3$ . This ion blocks the electron transport chain by reacting with the ferric form of cytochrome aa3 and thus acts as an inhibitor of respiration. 3 any salt or ester of hydrazoic acid.

**azidothymidine** see AZT.

**azo** the bivalent group  $-N=N-$ . It participates in noncyclic covalent linkage in organic molecules forming azo compounds or diazo compounds.

**azocoll** an insoluble bright-red collagen-rich proteinaceous material prepared by dyeing powdered cowhide or kangaroo-tail tendon with a dye prepared from tetrazolized benzidine, disodium 2-naphthol-3,6-disulfonate and sodium acetate. It is digested by most types of proteinase, the consequent solubilization of dye forming the basis of a simple nonspecific technique for the assay of proteolytic activity.

**azo compound** any organic compound with the general formula  $R-N=N-R'$ . Such compounds thus contain the bivalent azo group in covalent linkage, each nitrogen atom being linked to a carbon atom and replacing one hydrogen atom of each of the parent molecules RH and R'H. The latter may be the same or different, aliphatic or aromatic; e.g. azomethane,  $CH_3-N=N-CH_3$ ; naphthalene-2-azobenzene,  $C_{10}H_7-N=N-C_6H_5$ . Compare diazo compound.

**azoferedoxin** or protein II a very oxygen-sensitive iron-sulfur protein that is a component of the nitrogenase enzyme system. It is a dimer of identical  $\approx 30$  kDa peptide chains. Each dimer contains two iron atoms, four S2- groups, and 12 titratable thiol groups. In nitrogenase it is believed to be the electron carrier responsible for the reduction of molybdenum in molybdoferredoxin.

**azomethine** strictly, any imine having the more limited general structure  $RR'C=NR$  where Rand R' are any organyl groups, but often extended to include any compound where R' is H, the term then being considered to be synonymous with Schiff base.

**azoprotein** any of the modified proteins formed by coupling an aromatic diazo compound to one or more of the tyrosine residues of a protein, e.g. azoalbumin, azocasein.

**azotemia** *former term for* the accumulation of abnormally large concentrations of nitrogenous compounds, especially urea, in the blood.

**Azotobacter** a genus of Gram-negative strictly aerobic soil bacteria, all members of which can effect nitrogen fixation.

**azotoflavin** a somewhat larger than normal flavodoxin that is believed to act as a one-electron carrier between ferredoxin and azoferredoxin during nitrogen fixation in some bacteria, e.g. *Azotobacter*.

**AZT** abbr. for azidothymidine; 3'-azido-3'-deoxythymidine; *other names:* zidovudine; Retrovir; an analogue of thymidine, the phosphorylated form of which is an inhibitor of reverse transcriptase in retroviruses; it also terminates DNA synthesis. AZT undergoes phosphorylation in human T-cells to a nucleoside 5'-triphosphate, which competes with thymidine triphosphate and serves as a chain terminating inhibitor of HIV reverse transcriptase. It is used clinically to treat patients with HIV infection and AIDS.

**azurin** any member of a group of brilliant blue copper-containing proteins of low  $M_r$ , found in some bacteria and thought to transfer electrons to cytochrome oxidase. Example from *Pseudomonas j7uorescens* biotype B: database code AZUR\_PSEFB, 128 amino acids (13.78 kDa).

**azurophil(e)** or azurophilic staining readily with blue aniline dyes.

**azurophil(e) granule** or primary granule a blue-staining lysosome of neutrophil leukocytes.

# Bb

**b** symbol for 1 molality. 2 one of two van der Waals coefficients. 3 breadth.

**B** symbol for 1 boron. 2 a residue of either of the a-amino acids L-aspartic acid or L-asparagine when the state of amidation is uncertain (alternative to Asx). 3 a residue of an incompletely specified base in a nucleic acid sequence that may be cytosine or guanine or either thymine (in DNA) or uracil (in RNA). 4 the ribonucleoside (5')-bromouridine (alternative to BrUrd). 5 the B blood group. See ABO system.

**B** symbol for 1 Napierian absorbance (see absorbance). 2 magnetic flux density (bold italic).

-8 conformational descriptor designating the boat conformation of a six-membered ring form of a monosaccharide or monosaccharide derivative. Locants of ring atoms that lie on the side of the structure's reference plane from which the numbering appears clockwise are indicated by superscripts preceding the letter, and those that lie on the other side of the reference plane by subscripts following the letter; e.g. methyl 2,6-anhydro-a-D-altropyranoside-<sup>2,5</sup>B. See also conformation (under cyclic compounds).

**B<sub>max</sub>** symbol for the amount of drug required to saturate a specific population of receptors in a membrane sample and hence an index of the density of receptor binding sites in the sample. It is usually derived from Scatchard analysis (see Scatchard plot) or from nonlinear regression analysis of data from a saturation binding assay,

**Ba** symbol for barium.

**Baa helices** abbr. for basic amphiphilic  $\alpha$  helices;  $\alpha$  helices that contain an array of basic amino-acid residues (His, Lys, or Arg) on one side and hydrophobic residues on the other. They are found, e.g., in the calmodulin-binding regions of many proteins.

**Babes-Ernst body** or Babes-Ernst granule a volutin granule seen in *Corynebacterium diphtheriae*. [After Victor Babes (1854-1926), Romanian bacteriologist, and Paul Ernst (1859-1937), German pathologist.]

**BAC** abbr. for bacterial artificial chromosome, based on the F factor (F plasmid) of *Escherichia coli*. Compare VAC.

**Bacillaceae** a family of eubacteria that includes the genera *Bacillus* and *Clostridium*.

**bacillary** or **bacillar** 1 of, relating to, caused by, or containing bacilli. 2 an alternative term for bacilliform (def. 1).

**bacilliform** 1 rod-shaped. 2 resembling a bacillus.

**bacillus** (*pl.* *bacilli*) any straight rod-shaped bacterial cell.

**Bacillus** a genus of large rod-shaped Gram-positive eubacteria belonging to the family Bacillaceae. Its members are aerobic or facultatively anaerobic, spore-bearing organisms. *B. subtilis* has become widely established as a vehicle for genetic engineering and many cloning vectors are available. *B. thuringiensis* synthesizes a toxin that is active against insects; different strains of the bacterium produce different forms of the toxin specific for different insect species.

**bacitracin** a cyclic antibiotic polypeptide complex produced by *Bacillus subtilis* and *B. licheniformis*. Commercial bacitracin is a mixture of at least nine bacitracins, mostly bacitracin A. Bacitracin A contains, in addition to several L amino acids, a number of D amino acids. Bacitracin inhibits bacterial cell wall synthesis by blocking the dephosphorylation of undecaprenyl diphosphate (undecaprenyl pyrophosphate) to the monophosphate form; it similarly inhibits the dephosphorylation of dolichyl diphosphate thereby blocking the formation of the core oligosaccharides of glycoproteins.

**backbone** 1 (*in biochemistry*) the sequence of bonded atoms of a polymer to which the side groups and/or the side chains are attached. 2 (*in zoology*) the vertebral column or spine.

**backcross** 1 any cross of a first-generation hybrid, *F*<sub>1</sub>, with

one parent or an individual genetically identical to one of the two parents, 2 the offspring of such a mating.

**back-flush** an alternative term for back-wash.

**background** any intrusive sound or electronic signal registered by a detector but not coming from the source being measured, e.g. the radioactivity registered by a counter in the absence of a radioactive sample.

**back mutation** an alternative term for reverse mutation.

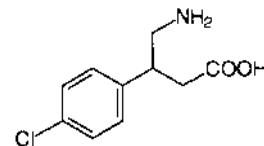

**back scattering** an alternative term for backward scattering.

**back titration** an indirect titration procedure in which a measured excess of the reagent is added and the amount remaining after reaction with the analyte is titrated back to an end-point, the proportion consumed in the reaction being obtained by difference.

**backward scattering** or **back scattering** any scattering of radiation in a direction towards the source of the incident radiation.

**back-wash** or **back-flush** to pass a fluid through a chromatographic column in the direction opposite to that of the eluent flow. It is useful, e.g. to relieve bed-compression and to remove entrained gas.

**baclofen**  $\gamma$ -amino-p-(p-chlorophenyl)butyric acid; 3-(amino-methyl)-3-(4-chlorophenyl)propanoic acid; a 4-chlorophenyl derivative of  $\gamma$ -aminobutyric acid (GABA) that acts as a selective agonist for the GABA<sub>A</sub> receptor and inhibits the release of other neurotransmitters in the central nervous system. It is used for its antispastic (muscle-relaxing) effects.

**bactenecin** any of several highly cationic polypeptides, originally isolated from bovine neutrophil granules but also found in sheep, that exert, *in vitro*, a potent antimicrobial activity, possibly due to inhibition of respiratory chain function. Example, bactenecin 5 (precursor) from *Bos taurus*: database code BCT5\_BOVIN, 176 amino acids (20.03 kDa); residues 131-173 are bactenecin 5.

**bacteremia** or (*esp. Brit.*) **bacteraemia** the presence of live bacteria in the blood.

**bacteria** plural of bacterium.

**Bacteria** one of three superkingdoms (domains) of cellular organisms, the others being Archaea and Eukarya. Bacteria are unicellular and anucleate Le. prokaryotes. They embrace a great diversity of forms, major divisions including the Cyanobacteria, Proteobacteria (which includes Gram-negative bacteria), and Gram-positive bacteria.

**bacterial conjugation** the process whereby genetic material is transferred from one bacterial cell (the donor) to another (the recipient). Material is usually transferred via a tubelike pilus, which extends from the donor cell to the recipient cell. The terms 'donor' and 'recipient' are preferred to 'male' and 'female' since the latter refer only to the presence or absence of Fplasmid,

**bacterial histone** see H-NS,

**bacterial photosynthetic reaction centre** see photosynthetic reaction centre,

**bacterial porin** see porin.

**bacterial recombinant** see transconjugant.

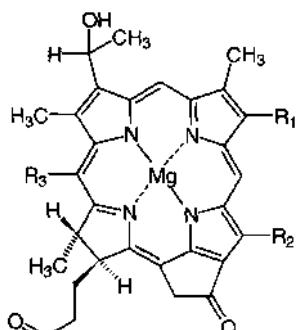

**bacterial virus** see bacteriophage.

**bactericide** or **bacteriocide** any agent (biological, chemical, or

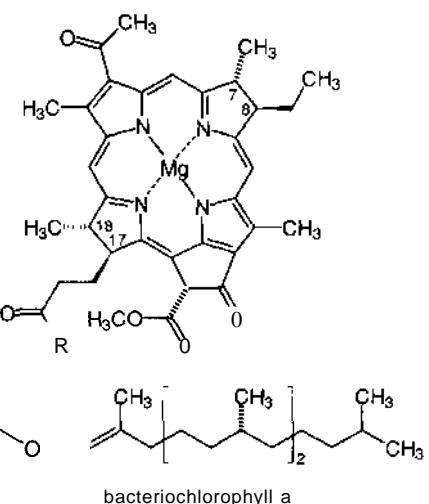

**bactericidin**

physical) that destroys bacteria. -bactericidal or bacteriocidal adj.

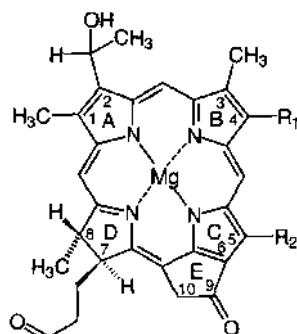

**bactericidin** or bacteriocidin or bacteriolysin any antibody that, with complement, kills bacteria against which it is active. **bacteriochlorophyll** any of the chlorophylls of photosynthetic bacteria. They differ structurally from the chlorophylls of higher plants. Bacteriochlorophylls *a* to *g* are known. Bacteriochlorophylls *a* and *b* are the best known, being the photosynthetic pigments of purple bacteria. Their purple colour results from the fact that they are reduced in both rings B and D, and thus may be regarded as tetrahydropyrroles. Tetrapyrrole carbon atoms and carbon rings are numbered according to the Fischer and IUPAC systems as indicated below. The structure of bacteriochlorophyll *a* is shown. Bacteriochlorophyll *b* has =CH-CH<sub>3</sub> in place of the ethyl group on ring B of bacteriochlorophyll *a*. In some bacteriochlorophylls *a* the phytol group may be replaced by a geranylgeranyl group. Bacteriochlorophylls *c*, *d*, and *e* are antenna pigments of Chlorobiaceae, located in chlorobium vesicles (a core structure is shown). These are dihydropyrrole structures, being reduced in ring D only. The esterifying alcohol is farnesol. In these bacteriochlorophylls, the side chain R<sub>1</sub> (see core structure) on ring B varies, being ethyl, n-propyl, or isobutyl (in bacteriochlorophyll *d* neopentyl is also possible). On ring C the side chain R<sub>2</sub> is ethyl (in bacteriochlorophyll *d* methyl is also possible). R<sub>3</sub> is methyl in bacteriochlorophylls *c* and *e*, and H in bacteriochlorophyll *d*.

Farnesyl 0

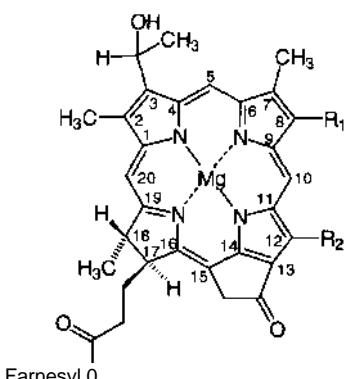

bacteriochlorophyll *c*, *d*, *e* core structure

bacteriochlorophyll a

**bacterioferritin**

Farnesyl 0

tetrapyrrole carbon numbering Fischer system

tetrapyrrole carbon numbering IUPAC system

**bacteriocide** a variant spelling of bactericide.

**bacteriocidin** a variant spelling of bactericidin.

**bacteriocin** any of a heterogeneous group of polypeptide antibiotics that are secreted by certain bacterial strains and are able to kill cells of other susceptible (frequently related) strains after adsorption at specific receptors on the cell surface. They include the colicins, and their mechanisms of action vary. Examples: colicin E1 from *Escherichia coli*: database code CEALECOLI, 522 amino acids (57.21 kDa); this is a channel-forming transmembrane protein that results in membrane depolarization; colicin E3 from *E. coli*: database code CEA3\_ECOLI, 541 amino acids (57.90 kDa); this is an rRNA ribonuclease; plantaricin A from *Lactobacillus plantarum*: database code (of precursor) PLNA\_LACPL; plantaricin A is a channel-forming peptide dimer of α and β chains; the amino-acid sequence of the β chain is:

AYSILQMGATAIKQVKLFKKWGW;

the α chain lacks the N-terminal A. -bacteriocinogenic adj.

**bacteriocinogenic factor** any plasmid that carries genetic information for the production of a bacteriocin. Generally only a small proportion of cells containing the factor actually produce bacteriocin. See also Col plasmid.

**bacterioferritin** a bacterial bl-type cytochrome of 18 kDa sub-unit containing 13-20% wt of iron. It has similar properties to mammalian ferritin. It may be concerned with iron storage in the bacterium. Similar proteins may be present in other species of bacteria. Example from *Azotobacter*

## bacteriology

*vinelandii*: database code BFR\_ECOLI, 158 amino acids (18.49 kDa). These proteins are oligomers of 24 identical sub-units.

bacteriology the branch of science that deals with the study of bacteria.

bacteriolysis *an alternative term for* bactericidin.

bacteriolysis the lysis of bacteria. -bacteriolytic adj.

bacteriopheophytin *a variant spelling of* bacteriopheophytin.

bacteriophage or phage or bacterial virus any virus that can infect and multiply in a bacterium. Phages parasitize almost every group of prokaryotes. Commonly they consist of a core of nucleic acid enclosed within a protein coat, the capsid; additional components, e.g. lipid, occur in some phages. Depending on the type of phage, the nucleic acid may be either DNA (single-stranded or double-stranded) or RNA (single-stranded), and may be either linear or circular. Phages may be filamentous, polyhedral, or polyhedral and tailed; the tubular tails, to which one or more tubular tail fibres are attached in certain circumstances, are involved in attachment of the phages to the bacterial surface and for the injection of the DNA into the host cells. The smallest phages, e.g.  $\phi$ X174, are  $\approx 25$  nm in diameter, whereas tailed polyhedral phages, such as the T-even phages, are 200-250 nm long, while filamentous phages measure roughly 800 nm x 5 nm. In general, a given bacteriophage can infect only one particular species, or strain, or group of closely related strains, though a given strain may be susceptible to infection by a number of different phages. Bacteriophages can bring about transduction (def. I) between bacterial cells. Compare cyanophage. See also (bacterio)phage conversion, lysogeny, phage induction, phage typing, prophage, temperate phage, virulent phage.

(bacteriophage conversion or prophage-mediated conversion or lysogenic conversion the introduction of new properties to a host bacterium by the genome of an infecting lysogenic prophage. Such properties may include resistance to lysis by related phages, changes in antigenic constitution, or the appearance of toxigenicity.

bacteriophage vector *see* cloning vector.

bacteriopheophytin or (*esp. Brit.*) bacteriopheophytin a bacteriochlorophyll in which Mg<sup>2+</sup> is replaced by 2 H<sup>+</sup>.

bacteriorhodopsin a retinal-containing protein, resembling animal rhodopsin, formed by *Halobacterium halobium* and other halophilic Archaea and inserted into patches of purple membrane in the cell surface. The purple membranes serve as light-operated hydrogen-ion pumps to translocate hydrons from the inside to the outside of the cells. Example from *H. halobium* (precursor): database code BACR\_HALHA, 262 amino acids (28.22 kDa); residues 1-13 form the propeptide and the C-terminal Asp is also missing from the mature protein, which is a seven-helix transmembrane protein of known 3-D structure and a model for opsin and related G-protein-linked receptors in eukaryotic cells.

bacteriostatic or bacteristatic describing a drug, antibiotic, or other agent that inhibits the growth and multiplication of bacteria. Compare bactericide. -bacteriostasis n.

bacterium (*pl. bacteria*) any of a vast and ubiquitous group of prokaryotic microorganisms that exist as single cells or in clusters or aggregates of single cells. Most authorities now place them in the exclusively prokaryotic kingdom Monera, along with the cyanobacteria (blue-green algae). The majority of bacteria possess a rigid cell wall; those lacking this feature are termed Archaea. Bacteria, Archaea, and Eukarya constitute the three primary Kingdoms (domains). -bacterial adj.

*Bacteroides* a genus of Gram-negative anaerobic rodlike bacteria. Mostly nonmotile, they are commonly present in the alimentary and urogenital tracts of mammals and may behave as opportunistic pathogens.

bactoprenol *an alternative name for* undecaprenol.

Bactrim *see* sulfamethoxazole.

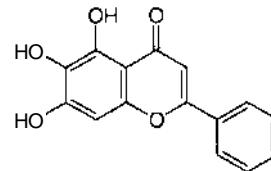

baculovirus any of a group of DNA viruses that are known to multiply only in invertebrates and are now classified in the

## Baltimore

family Baculoviridae. Their genome consists of double-stranded circular DNA of 58-100 MDa. Because of their host range they have potential as pest-control agents. Baculovirus vectors are valuable as a means of expressing certain animal proteins (*see* expression system).

BAF abbr. for B-cell activating factor (*see* interleukin 1).

baicalein 5,6,7-trihydroxyflavone; a pigment (greenish-brown in dilute alkali) found in the root of *Scute/laria baicalensis*. It is a selective 12-lipoxygenase inhibitor. Baicalein inhibits leukotriene biosynthesis and cellular Ca<sup>2+</sup> uptake and mobilization.

bait a hybrid protein containing the GAL4 DNA-binding domain, used in the yeast two-hybrid system. *See also* bait region.

bait region a restricted region in the sequence of IgM-macroglobulin (u2M) that is cleaved by proteinases in the process leading to the conformational changes instrumental in the proteinase inhibitory function of u2M. The bait region occurs in all IgM-macroglobulins but shows great variation in length and amino-acid sequence between different IgM-macroglobulin and animal species. In human u2M, it covers approximately residues 666-706. Outside of the bait region, u2M from different species shows very high sequence homology. *See also* trap hypothesis.

bakers' yeast any of various strains of the yeast *Saccharomyces cerevisiae* that are used in baking.

baking soda *see* soda.

BAL abbr. for British anti-lewisite (*see* dimercaprol).

balance 1 (*in physiology*) the relation between the intake of a particular nutrient and its excretion (or the excretion of its metabolites). 2 any instrument for determining the equality in mass of two objects (or sets of objects). In cases where one (set) is of known mass the mass of the second (set) is thus obtained; e.g. an analytical balance. 3 any instrument designed to measure the weight of an object, e.g. spring balance, torsion balance.

balanced growth a type of growth such that over a time interval (within the exponential phase) every extensive property of the growing system increases by the same factor. Balanced growth for an individual cell requires that each cell after division is an exact replica of the one of the previous cycle.

balanced salt solution any solution designed to provide a normal environment, in terms of ionic composition, pH, and osmotic pressure, for cells in tissue culture.

balance study any study to determine balance (def. I).

balata *see* rubber.

BALB/c a strain of inbred white mice that readily develop experimental myelomatosis.

Balbiani ring a large puff of giant chromosomes present during a greater portion of larval development in members of the Diptera. The structural modification of specific loci is characteristically large and ring-shaped. [After Eduard Gérard Balbiani (1823-99), French entomologist who reported it in 1881.]

Baltimore, David (1938- ), US microbiologist and molecular biologist distinguished for his studies of viral nucleic-acid biosynthesis, particularly his discovery (at the same time as H. M. Temin) of reverse transcription by the enzyme RNA-directed DNA polymerase in the virions of tumour-producing retroviruses, and for the classification of animal viruses named after him; Nobel Laureate in Physiology or Medicine

## Baltimore classification

(1975) jointly with R. Dulbecco and H. M. Temin 'for their discoveries concerning the interaction between tumour viruses and the genetic material of the cell'.

**Baltimore classification** a method of classification of animal viruses based on the nature of the genome and the mechanism for synthesis of mRNA, which is always regarded as the plus strand (def. 2). There are six classes:

**Class I** Viruses having a double-stranded (ds) DNA genome that make mRNA by asymmetric transcription. In many, different mRNA species come from different DNA strands.

**Class II** Viruses having a single-stranded (ss) DNA genome of the same polarity as the mRNA. Some have strands of both polarity in different particles.

**Class III** Viruses having a dsRNA genome that make mRNA by asymmetric transcription. Most have multiple pieces of dsRNA, each of which apparently contains the information for the synthesis of a single protein.

**Class IV** Viruses having an ssRNA genome that make mRNA of base sequence identical to the genomic RNA.

**Class V** Viruses having an ssRNA genome that make mRNA with a base sequence complementary to the genomic RNA.

**Class VI** Retroviruses having an ssRNA genome and a DNA intermediate in their growth.

band 1 an absorption band in an electromagnetic spectrum. 2 a zone of (macro)molecules such as that obtained in density-gradient centrifugation, zone electrophoresis, isoelectric focusing, chromatography, or other similar method. 3 any of the zones readily distinguishable by microscopy in a sarcomere of a muscle. 4 the specific association of a large number of chromomeres at the same level in somatically paired polytenic giant chromosomes of members of the Diptera. *See also* cytochrome absorption bands.

band centrifugation *see* isopycnic centrifugation.

band compression inadequate separation of the bands on a gel electrophoretogram, especially in DNA sequencing gels. It results in poor resolution and difficulties in interpretation.

band electrophoresis *an alternative name for* lone electrophoresis.

banding the formation of distinct bands or zones in density-gradient centrifugation, column chromatography, or other separation techniques.

banding density the density of the suspending medium at which a particular type of particle, e.g. a cell organelle, forms a band during centrifugation in a specified density gradient.

band intensity (*in NMR spectrometry*) the area under the band between the signal trace and the baseline. *See* nuclear magnetic resonance.

band-pass filter 1 an electric circuit or other device that transmits only frequencies within a selected band. 2 an interference filter.

band protein erythrocyte proteins are referred to as bands, numbered according to the position they occupy on electrophoresis gels. Some of the more important bands are: 1 and 2,  $\alpha$  and  $\beta$  spectrin; 3, an anion channel protein; 4.1, always referred to as such, is involved in spectrin junctions; 5, actin.

band width (*in NMR spectrometry*) the distance between the sides of the band at half the band height of a reasonably smooth and symmetrical band. *See* nuclear magnetic resonance.

Bangosome or Bangosome (*colloquially*) *an alternative name for* liposome. [After its inventor, Alec Douglas Bangham (1921-), British biophysicist and medical scientist.]

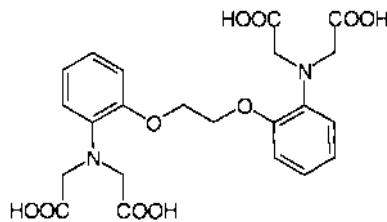

Banting, (Sir) Frederick Grant (1891-1941), Canadian surgeon, physiologist, and endocrinologist distinguished for his discovery (with C. H. Best) of a means of extracting the hormone insulin from pancreatic tissue and for demonstrating its anti-diabetic efficacy; Nobel Laureate in Physiology or Medicine (1923) jointly with J. J. R. Macleod 'for the discovery of insulin'. *See also* Best, Macleod.

Bantu siderosis *see* iron overload.

BAPTA 1,2-bis(o-aminophenoxy)ethane-N,N,N',N'-tetraacetate; a  $\text{Ca}^{2+}$  chelator exhibiting a 105-fold greater affinity (110 nM)

## barometric pressure

than for  $\text{Mg}^{2+}$ . Its UV absorption maximum is at 254 nm which, after  $\text{Ca}^{2+}$  is bound, shifts to 279 nm, a property that can be exploited in its use as an indicator of intracellular  $\text{Ca}^{2+}$  concentration. Its esterified form can enter cells where it is hydrolysed to BAPTA.

bar a unit of pressure temporarily approved for use with SI units. 1 bar =  $10^5 \text{ Pa} = 10^5 \text{ N m}^{-2}$ .

barbed end *see* plus end.

barbital *or* barbitone 5,5-diethylbarbituric acid; 5-diethyl-malonylurea; 5,5-diethyl-2,4,6(IH,3H,5H)-pyrimidinetrione; a long-acting depressant of the central nervous system, widely used as a buffer substance;  $\text{pK}_a = 7.98$  (25 QC), 8.06 (20 QC). *One proprietary name:* Verona!.

barbiturate 1 the tautomeric anion derived from barbituric acid (malonylurea; 2,4,6(IH,3H,5H)-pyrimidinetrione). 2 any mixture of free barbituric acid and its anion. 3 any salt of barbituric acid. 4 any of various pharmacologically active derivatives of barbituric acid, including barbitone, pentobarbitone, phenobarbitone, and thiopentone. Barbiturates are potent CNS depressants that potentiate the actions of GABA by binding to the  $\text{GABA}_A$  receptor. Pentobarbitone and thiopentone are used to induce anesthesia.

Barcroft apparatus *or* Barcroft respirometer a differential respirometer for studying gas exchange of cells, tissue slices, or tissue homogenates, now rarely used. It is a closed system comprising two flasks of equal volume connected by a U-shaped manometer (the Barcroft manometer). In operation, both flasks contain the same volumes of liquid and gas; one, the reaction flask, contains the cells or tissue; the other, the compensation flask, is free from cells or tissue and serves to compensate for changes in temperature and barometric pressure during the course of an experiment. The respirometers are arranged so that they may be shaken with the flasks in a constant-temperature bath. The reading of the apparatus is the difference between the levels of the manometer fluid in the two sides of the manometer. [After Joseph Barcroft (1872-1947), British physiologist, who described it in 1908.]

Barfoed's reagent a solution containing cupric acetate in dilute acetic acid that is reduced when heated with monosaccharides but not with disaccharides or oligosaccharides. [After Christen Thomsen Barfoed (1815-99), Swedish physician.]

barn symbol: b; a non-SI unit of area equal to  $10^{-28} \text{ m}^2$ . It is used as a unit of atomic nuclear cross section.

barnase *or* ribonuclease BA; a small extracellular endoribonuclease from *Bacillus amyloliquefaciens*. Its action involves formation of a 2':3'-cyclic phosphate (*see* ribonuclease). It has been studied as a model for protein folding. The sequence and 3-D structure are known: database code RNBR\_BACAM, 157 amino acids (17.47 kDa).

baroceptor *a variant spelling of* baroreceptor.

barometer an instrument for measuring the pressure of the atmosphere.

barometric pressure the pressure exerted by the atmosphere at a given place and time. It is often expressed in terms of the supported height of a column of mercury, usually measured in millimetres. The SI unit is the pascal. Other non-SI units frequently used in addition to the millimetre of mercury are the atmosphere, the bar, and the torr.

## baroreceptor

**baroreceptor** or **baroceptor** any physiological receptor that is sensitive to changes in pressure, especially the sensory nerve endings in the carotid sinus that set off nerve impulses in response to alterations in blood pressure at that point.

**Barr body** *see* sex chromatin.

**barrier** an extracellular protein, probably a proteinase, excreted by yeast cells of mating type a. Its role may be to act as an antagonist of the a-type mating pheromone and establish optimal pheromone concentration for conjugation. Example (precursor) from *Saccharomyces cerevisiae*: database code BARLYEAST, 587 amino acids (63.66 kDa).

**Barton**, (Sir) Derek Harold Richard (1918-98), British organic chemist; Nobel Laureate in Chemistry (1969), the prize being shared with O. Hassel 'for their contributions to the development of the concept of conformation and its application in chemistry'.

**barwin** a barley seed protein (possibly a lectin) involved in defence mechanisms. It is closely related to the C-terminal domain of proteins encoded by wound-induced plant genes. It gives its name to a family of such proteins. Example, database code BARW\_HORVU, 125 amino acids (13.77 kDa); 3-D structure known.

**basal** 1 at, of, or being a base (def. 4). 2 at, of, or being the minimum level for maintaining the normal or essential functioning of an organism.

**basal body** 1 (*in prokaryotes*) a structure that apparently attaches the flagellum (def. 1) to the cell envelope. The proximal end of the flagellum, the hook, appears curved and thickened and leads into the basal body, which consists of parallel ring-shaped structures, arranged around a rod-shaped core. The rings of the basal body make contact with the layers of the cell envelope. 2 (*in eukaryotes*) a structure at the base of a cilium consisting of spherical granules or short rods arranged in rows below the cell surface. Electron microscopically they are cylindrical bodies, 300-500 nm long and 120-150 nm in diameter, open at one or both ends. They consist of nine sets of triplet microtubules, each triplet containing one complete microtubule fused to two incomplete microtubules.

**basal granule** *an alternative term for* basal body (*esp. in ciliated epithelium*).

**basal lamina** a thin sheet of proteoglycans and glycoproteins, especially laminin, secreted by cells as an extracellular matrix, forming a region between the cells and adjacent connective tissue. The basal lamina has important functions in the organization of tissues including an influence on cell polarity, cell differentiation, and cell migration. The basal lamina is subdivided into the *lamina lucida* (an electron-lucent region) immediately adjacent to the cell layer, and the *lamina densa* (an electron-dense region) external to it. Frequently there is a further outermost layer, the *lamina reticularis*, containing collagen fibrils. The three laminae are often collectively referred to as the basement membrane.

**basal medium** any culture medium that will support the growth of nutritionally undemanding chemoorganotrophs.

**basal metabolic rate abbr.: BMR**; the rate of energy metabolism of an animal at rest but not asleep. It is measured with the animal in a 'comfortable' ambient temperature, and in the postabsorptive state, at least 12 hours after taking food. It may be determined from the oxygen consumption and carbon dioxide (and urinary nitrogen) excretion, or from the heat production of the animal.

**base** 1 (*in chemistry*) a a Brønsted-Lowry base. b a Lewis base. *See also* acid (def. 2). 2 (*in molecular biology*) any purine or pyrimidine that occurs as a component residue in polynucleotides or nucleic acids. Purines and pyrimidines are nitrogen bases, hence the terminology. 3 a unit of length of a polynucleotide or nucleic acid, equal to one nucleotide residue. Large molecules are usually measured in kilobases ( $10^3$  bases; symbol: kb) or megabases ( $10^6$  bases; symbol: Mb). *See also* nitrogenous base. 4 (*in mathematics*) a the number of units in a system of counting that is equivalent to one unit in

## basic dissociation constant

the next higher counting place. b the number that when raised to a specified power, its exponent, has a logarithm equal to the specified power. 5 the bottom or supporting part of anything; the point of attachment of an organ or part to an organism.

**base analogue** or (*esp. US*) **base analog** any unnatural purine or pyrimidine base that can be incorporated *in vivo* into DNA but that, because of its different properties, causes altered base-pairing during incorporation or in subsequent DNA replication. Thus 5-bromouracil, an analogue of thymine, pairs with guanine thereby causing transitions of A-T → G-C. Similarly, 2-aminopurine, an analogue of adenine, pairs with cytosine thereby causing transitions of A-T → G-C. Some base analogues have been used as anticancer and antivirus agents.

**base calling** the automated reading of DNA-sequencing gels using a scanner and appropriate software.

**base composition** the relative amounts of the various purines and pyrimidines occurring in a specimen of polynucleotide or nucleic acid. It is often expressed as moles percent.

**baseline** an imaginary line or a standard or reference value, etc. by means of which measurements may be compared, especially the zero line in the tracing of a chromatogram, spectrum, ultracentrifuge pattern, etc.

**basement membrane** a thin layer of dense material found in various animal tissues interposed between the cells and adjacent connective tissue. It consists of the basal lamina, comprising fine fibrillar material in a glycoprotein matrix, plus an associated layer of reticulin fibres. Occurring in, e.g., capillary linings, kidney tubules, lung alveoli, and renal glomeruli, basement membrane has a supportive function in some tissues and may also act as a passive selective filter for substances diffusing in or out of the cells; e.g. in renal glomeruli it retains protein molecules. It gives a strong periodic acid-Schiff reaction.

**base pair symbol:** bp; any of the possible pairings between two bases in opposing strands of double-stranded DNA or RNA molecules. Adenine forms a base pair with thymine (in DNA) or uracil (in RNA) and guanine with cytosine, hence the number of adenine residues equals the number of thymine (and/or uracil) residues while the number of guanine residues equals that of the cytosine residues. *See also* Chargaff's rules. -base-pair *vb.*; base-pairing *n.*

**base-pair ratio** *see* Chargaff's rules.

**base sequence** the sequential order of nucleotide residues in a polynucleotide or nucleic acid molecule.

**base stacking** the arrangement of base pairs in parallel planes, at an angle to the helix axis, in the interior of a helical double-stranded polynucleotide or nucleic acid molecule.

**base triplet** any sequence of three bases in a nucleic acid that codes for an amino acid, or some other signal, in protein synthesis. *Compare* anticodon; codon.

**basic** 1 of, relating to, containing, or characteristic of a base (def. 1). *Compare* acidic (def. 1). 2 having an alkaline reaction; or of or relating to an aqueous solution having a pH value > 7.0. *Compare* acidic (def. 2).

**basic amino acid** any amino acid possessing a net positive charge at neutral pH.

**basic azo-dye binding protein abbr.: B-ABP**; a 45 kDa (Sephadex) protein, isolated from the soluble cell supernatant fraction from livers of rats given 4-dimethylaminoazobenzene. It was later named ligandin.

**basic dissociation constant** or **basicity constant symbol:**  $K_b$ ; the thermodynamic dissociation constant for the dissociation of a base (def. 1, 2). For a dilute solution of a weak base, B, dissociating in water according to the equilibrium:

where  $a$  is the activity of the species designated by the subscripts. The activity of the water has been omitted from the equation since it may be taken as unity in dilute aqueous solution.  $K_b$  is a measure of the strength of a base, i.e. of its ability to accept hydrons from water (*compare* acid dissociation con-

**basic dye**

stant; see also pK). The concept is no longer used since the conjugate acid, B+, may be considered as an acid and an acid dissociation constant,  $K_a$ , for it defined. Also, in aqueous solutions

$$K_a \times K_b = [H^+][OH^-] = K_w$$

where  $K_w$  is the ion product of water, whence  $K_b$  may be calculated from  $K_a$  or vice versa.

**basic dye** or **basic stain** any cationic dye that binds to, and hence stains, anionic macromolecules or other materials.

**basic salt** any salt containing hydroxyl or oxide groups in partial replacement of, or in addition to, ions or groups derived from an acid, e.g. basic lead acetate,  $(CH_3COO)_2Pb \cdot Pb(OH)_2$ .

**basic stain** an alternative term for basic dye.

**basic zipper** see bZIP.

**basolateral surface** the surface of an epithelial cell that adjoins underlying tissue. Compare apical surface.

**basonuclin** a zinc finger nuclear protein of epidermis, likely to be a transcription factor specific for squamous epithelium and its keratinocytes prior to terminal differentiation. It is present mainly in the nuclei of the basal cell layer. Example from human: database code BASO\_HUMAN, 993 amino acids (110.85 kDa).

**basophil** or **basophil(ic)** leukocyte a polymorphonuclear phagocytic leucocyte of the myeloid series that is distinguished by the presence of coarse cytoplasmic granules that stain with basic dyes. The granules are believed to contain histamine, heparin, and other vasoactive amines. Basophils are closely related to mast cells and constitute <0.5% of blood leukocytes.

**basophilia** 1 the property of being basophilic. 2 an increase in the number of basophils circulating in the blood.

**basophilic** staining readily with basic dyes.

**basotropic** seeking a basic environment; a term used especially in connection with protein kinases that have a requirement for basic residues near the target residue. Compare acidotropic.

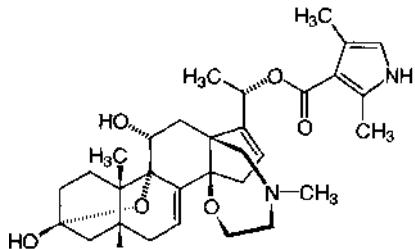

**batch** a quantity of material produced or processed in one operation on a single occasion, as opposed to a continuous operation; hence batch adsorption, batch culture, etc.

**batch elution** a method of column chromatography in which conditions are chosen to ensure complete retention of the material under investigation, using the minimal amount of stationary phase, followed by elution with a solvent or buffer that ensures complete and rapid removal in the minimal possible volume.

**batch process** (in biotechnology) a process in which a bioreactor is loaded with substrates inoculated with microorganisms or enzymes and allowed to run to completion, usually without removing biomass and products during the process.

**bathochromic** (in absorption spectroscopy) describing a shift of an absorption band in the direction of longer wavelengths. Compare hypsochromic.

**batrachotoxin** a steroidal alkaloid neurotoxin from the skin of Colombian arrow-poison frogs of genus *Phylllobates*. It is the most potent known venom. It binds specifically to the voltage-gated sodium channel and renders the membrane permeable to sodium ions. Compare tetrodotoxin, which reverses its depolarizing effect.

**batroxobin** see venombin.

**Batten's disease** see W-transferring ATP synthase.

**batyl alcohol** I-O-octadecyl-sn-glycerol; 3-octadecyloxy-I,2-propanediol; a hydrolysis product of ether lipids.

**bay region** a concave exterior region, bordered by three phenyl rings, of a polycyclic aromatic hydrocarbon when an angularly fused terminal benzo-ring is present. For example, the sterically hindered area between carbon atoms 4 and 5 of phenanthrene, between carbon atoms I and 12 of benz[a]anthracene, or between carbon atoms 10 and II of benz[a]pyrene. It has been suggested that dihydrodiol epoxides in the bay region of such compounds may be responsible for their mutagenicity and carcinogenicity. See also A region, B region, Kregion, Lregion.

**B cell** 1 or (formerly) beta cell the principal cell (60-80%) of the islets of Langerhans of the pancreas. It produces, stores (as B granules), and secretes the hormone insulin. 2 an alternative name for B lymphocyte.

**B-cell activation factor abbr.:** BAF; an alternative term for interleukin 1.

**B-cell antigen receptor complex** a complex consisting of membrane immunoglobulin associated non-covalently with two proteins known as mb-I (other names: Igα, CD79a) and B29 (other names: Igβ, CD79b) that binds antigen and initiates B-cell transformation. mb-I and B29 are often designated α and β respectively, and the complex consists of Ig(αβ)₂. Signalling occurs by activation of tyrosine kinases of the Src family (lyn, blk, fyn, or lck). α and β are themselves phosphorylated on activation. All five immunoglobulin isotypes (IgG, IgM, IgD, IgA, IgE) bind two α/β heterodimers and use a similar signalling pathway, but the glycosylation of the α chain differs according to the isotype with which it associates. Examples (both precursors) from mouse: α chain, database code C79A\_MOUSE, 220 amino acids (24.23 kDa); β chain, database code C79B\_MOUSE, 228 amino acids (25.70 kDa).

**B-cell differentiation factor abbr.:** BDF; an alternative term for interleukin 1.

**BCG abbr. for** bacille Calmette-Guerin; the bacillus from which is made a vaccine composed of live bovine-strain tubercle bacilli, *Mycobacterium bovis*, attenuated by long cultivation on a potato-glycerol-bile medium. [After Léon Charles Albert Calmette (1863-1933), French physician and bacteriologist, and Camille Guérin (1872-1961), French veterinary surgeon and bacteriologist, who described its preparation in 1908.]

**B chain** 1 the longer of the two polypeptide chains of insulin, containing 30 amino-acid residues. 2 the light chain of an immunoglobulin.

**B chromosome** any of a heterogeneous group of accessory, extra, or supernumerary chromosomes found in many species of animals and plants. They differ from normal, or A chromosomes, by being usually smaller and frequently heterochromatic and telocentric, without great effect on the phenotype of their carriers. Both their numbers and their meiotic and mitotic behaviour are highly variable.

**BCKDH abbr. for** branched-chain *a*-keto acid dehydrogenase.

**BCL** any of several genes associated with B-cell leukemia and lymphoma. *BCL1* is identical to the gene for human cyclin D1; its product activates *p34cdc2* kinase and is phosphorylated in G<sub>1</sub> of the cell cycle; database code CGDI\_HUMAN, 295 amino acids (33.73 kDa). *BCL2* is a protooncogene encoding a growth factor that prolongs survival of hematopoietic cells; its product is a mitochondrial inner membrane protein, is able to block apoptosis, and if overexpressed with Myc counteracts the oncogenic action of Myc. Its product exists in two forms, BCL-2 α and β, resulting from differential splicing and expressed in B-cell leukemias and lymphomas. Example α (human): database code BC2A\_HUMAN, 239 amino acids (26.24 kDa). *BCL3* encodes a probable transcription factor of the I-KB family; database code BCL3\_HUMAN, 446 amino acids (46.80 kDa).

**BCR** a human gene named after breakpoint cluster region, a chro-

mosomal region found in humans and other species. It is a member of a small gene family coding for a protein with protein serine/threonine kinase activity, widely expressed in human hematopoietic and nonhematopoietic cell lines; database code BCR\_HUMAN. See also **abl**, Philadelphia chromosome.

**BDF** abbr. for B-cell differentiation factor interleukin (see interleukin).

**B-DNA** abbr. for B form of DNA.

**BDNF** abbr. for brain-derived neurotrophic factor.

Be symbol for beryllium.

**Beadle**, George Wells (1903-89), US geneticist notable in particular for formulating the one gene-one reaction hypothesis; Nobel Laureate in Physiology or Medicine (1958) jointly with E. L. Tatum 'for their discovery that genes act by regulating definite chemical events' [prize shared with J. Lederberg].

**Beckmann thermometer** a sensitive mercury-in-glass thermometer used for measuring small differences or changes of temperature. [After Ernst Otto Beckmann (1853-1923), German chemist.]

**Becquerel**, Antoine Henri (1852-1908), French physicist; Nobel Laureate in Physics (1903) 'in recognition of the extraordinary services he has rendered by his discovery of spontaneous radioactivity' [prize shared with M. Curie and P. Curie]. **becquerel symbol:** Bq; the SI derived unit of (radioactive) activity (def. 2) of a radionuclide; it corresponds to one nuclear transformation per second; i.e.  $1 \text{ Bq} = 1 \text{ disintegration s}^{-1}$ . See also curie:  $1 \text{ Ci} = 3.7 \times 10^{10} \text{ Bq}$  or  $1 \text{ Bq} = 2.70 \times 10^{-11} \text{ Ci}$ .

**bed volume** in column chromatography, the total volume of material, both solid and liquid, in the column; i.e. the volume

of the support particles plus the void volume. It is synonymous with column volume for a packed column.

**Beer-Lambert law** or **Beer-Lambert-Bouguer law** or **Lambert-Beer law** a combination of Beer's law (def. 1) and Lambert's law; put into modern terms, it states that the absorbance,  $A$ , of a beam of collimated monochromatic radiation in a homogeneous isotropic medium is proportional to the absorption pathlength,  $l$ , and to the amount-of-substance concentration,  $c$ , (or, in the gas phase, to the pressure) of the absorbing species. The law may be expressed by the relations

$$A = Ig(\Phi_0/\Phi) = eel \text{ or } \Phi = \Phi_0 = 10^{-cl}$$

where  $\Phi_0$  and  $\Phi$  are respectively the spectral powers of the incident and transmitted radiation beams, and the proportionality constant,  $e$ , is the molar (decadic) absorption coefficient - see absorption coefficient.

**Beer's law 1** or (sometimes) **Bouguer-Beer law**; a physical law extending Bouger's law to solutions: it states that when light passes through a given thickness of an absorbing solution of concentration  $c$ , the intensity of the transmitted light,  $I_{trs}$ , decreases exponentially as  $c$  increases linearly. It may be expressed as  $I_{trs} = I_0 e^{-kc}$ , where  $I_0$  is the intensity of the incident light and  $k$  is a constant. The law applies in practice only to monochromatic light (or other electromagnetic radiation) and when factors such as reflection or scattering are negligible or can be corrected for. See also Beer-Lambert law. [After August Beer (1825-63), German physicist who formulated it in 1857.]

2 name commonly but incorrectly applied to Beer-Lambert law

**beet sugar** an alternative name for sucrose when this has been extracted from sugar beet.

**Beh** symbol for the behenoyl group.

**behenoyl symbol:** Beh; trivial name for docosanoyl,  $\text{CH}_3\text{-}[\text{CH}_2]_{20}\text{-CO-}$ , the acyl group derived from the aliphatic acid behenic acid (= docosanoic acid), which occurs naturally in animal tissues and most seed fats.

**bek** a gene related to that for the fibroblast growth factor (FGF) receptor. Named after bacterial expressed kinase, it encodes a plasma membrane protein tyrosine kinase of class IV with an insert in the kinase region that binds FGFA with high affinity; database code Hsfgfrbe.

**Benacerraf**, Baruj (1920- ), Venezuelan-born US immuno-

logist notable for his discovery of histocompatibility genes and their role in regulation of the immune response; Nobel Laureate in Physiology or Medicine (1980) jointly with J. Dausset and G. D. Snell 'for their discoveries concerning genetically determined structures on the cell surface that regulate immunological reactions'.

**Bence-Jones protein** any of a group of myeloma proteins, occurring in the urine of patients with multiple myelomatosis and related conditions, that precipitate on heating the urine to 60°C, but redissolve at higher temperatures. They consist of light chains of immunoglobulins synthesized by the myeloma cells. Example, a kappa chain: database code KVIK\_HUMAN, 108 amino acids (11.27 kDa). [After Henry Bence-Jones (1813-73), English physician who described them in 1847.]

**Benedict's solution** 1 Benedict's qualitative solution, a reagent used to test for the presence of glucose and other reducing sugars. It contains 0.07 M copper sulfate, 0.67 M sodium citrate, and 0.94 M sodium carbonate. When heated with reducing sugars it is reduced and a red precipitate of cuprous oxide is formed. 2 Benedict's quantitative solution, a reagent used in the estimation of glucose and other reducing sugars. It contains 0.072 M copper sulfate, 0.7 M sodium carbonate, 1.29 M potassium thiocyanate, and a trace of potassium ferrocyanide. On boiling, 25 ml of this solution is reduced by 50 mg glucose. Other reducing sugars may be estimated similarly. [After Stanley Rossiter Benedict (1884-1936), US biochemist.]

**benign** describing a neoplasm that is harmless, localized, and nonmetastasizing, although it may physically impede the function of a nerve or muscle.

**bentonite** a colloidal, native hydrated aluminium silicate clay consisting principally of montmorillonite, a complex aluminosilicate,  $\text{Al}_2\text{O}_3\text{-}4\text{SiO}_2\text{-H}_2\text{O}$ , which has marked adsorptive properties. It is used as an inhibitor of nucleases and also in the bentonite flocculation test, a passive agglutination test in which antigen-coated bentonite particles are used to detect specific antibody.

**benzidine** trivial name for 4,4'-diaminobiphenyl, a substance that is carcinogenic for humans. It was formerly used in a highly sensitive test for the presence of blood, giving a green or blue colour in acetic acid solution on addition of hydrogen peroxide. Another former application was in the chromogenic assay of peroxidases. In view of the carcinogenicity, it has been replaced by 2,7-diaminofluorene and other compounds.

**benzo+** or (sometimes before a vowel) **benz+** comb. form 1 denoting the fusion of a benzene ring to a cyclic organic molecule. 2 indicating derivation from benzene or benzoic acid; compare phenyl.

**benzoate** 1,2-dioxygenase EC 1.14.12.10; systematic name: benzoate,NADH:oxygen oxidoreductase (1,2-hydroxylating, decarboxylating); other name: benzoate hydroxylase. A bacterial dioxygenase that is involved in the utilization of aromatic compounds. It catalyses a reaction between benzoate, NADH, and dioxygen to form catechol,  $\text{CO}_2$ , and  $\text{NAD}^+$ . Iron is a co-factor. Example from *Acinetobacter calcoaceticus*: this comprises three subunits, two of which,  $\alpha$  and  $\beta$ , represent the hydroxylase, while the third,  $\gamma$ , is an electron-transport flavoprotein;  $\alpha$  subunit: database code BENA\_ACICA, 461 amino acids (52.01 kDa);  $\beta$  subunit (probably involved in substrate specificity): database code BENB\_ACICA, 169 amino acids (20.05 kDa);  $\gamma$  subunit (similar to ferredoxin reductase with 2Fe-2S motifs): database code BENC\_ACICA, 348 amino acids (38.74 kDa).

**benzodiazepine** abbr.: BZ; 1 2H-1,4-benzodiazepine; a bicyclic compound consisting of a benzene ring fused to a seven-membered partially unsaturated ring containing two nitrogen atoms. 2 any member of a large class of pharmacologically active substances containing the benzodiazepine ring system. They are CNS depressants of low toxicity, having sedative and anxiolytic effects. A number are useful therapeutically; one of the most widely used is diazepam (one proprietary name: Val-

## betaine

betaine the N-trimethyl derivative of an amino acid; the term originally denoted N-trimethylglycine, now called glycine betaine. Glycine betaine acts as a methyl-group donor in some reactions; *see, e.g.*, betaine-homocysteine 5-methyltransferase. betaine-aldehyde dehydrogenase EC 1.2.1.8; an enzyme involved in the formation of betaine. It catalyses the reaction:

Example from *Escherichia coli*: database code DHAB\_ECOLI, 489 amino acids (52.72 kDa).

betaine-homocysteine 5-methyltransferase EC 2.1.1.5; an enzyme that catalyses the reaction:

beta-lactoglobulin or  $\beta$  lactoglobulin the principal protein of ruminant milk whey, constituting 50–60% of total whey. It is present as a dimer,  $M_r \sim 36000$ , pI 5.2. Of unknown function, it binds retinol and is a member of the Lipocalin family. It occurs in milk of other species (e.g. horse), but not human. Analogues occur in marsupial milk. Example (precursor) from *Bos taurus*: database code LACB\_BOVIN, 178 amino acids (19.88 kDa). *See also* lactalbumin (def. 1).

betalain any of a group of coloured alkaloids occurring widely in plants of the order Centrospermae. They are divided into two groups, betacyanins and betaxanthins, and both occur in plant vacuoles. The former impart a red-violet colour and the latter a yellow colour to the plant organs that contain them.

beta lipoprotein or  $\beta$  lipoprotein any of the plasma lipoproteins that behave electrophoretically as beta globulins, but normally designated low density lipoprotein. *See also* plasma protein.

beta oxidation or  $\beta$  oxidation the metabolic oxidation of a long-chain fatty acid by successive cycles of reactions during each of which the fatty acid is shortened by a two-carbon-atom fragment removed as acetyl coenzyme A. The name derives from the fact that the  $\beta$ -carbon atom is the point of oxidation. *See also* beta-oxidation system, Knoop's hypothesis.

beta-oxidation system a mitochondrial complex that carries out the reactions of beta oxidation. It contains enzymes that fall into the following four categories:

(I) Acyl-CoA dehydrogenases; these include:

(a) long-chain-acyl-CoA dehydrogenase (*abbr.*: LCAD) EC 1.3.99.13; this catalyses a reaction between acyl-CoA and electron transferring flavoprotein (ETF) to form 2,3-dehydroacyl-CoA and reduced ETF; FAD is a cofactor. Examples: a mitochondrial matrix protein and a homotetramer, having three isoenzymes with different substrate specificities; deficiency is associated with nonketotic hypoglycemia; precursor (including transit peptide): database code ACDL\_HUMAN, 430 amino acids (47.62 kDa);

(b) acyl-CoA dehydrogenase is the corresponding medium-chain-specific enzyme, (*abbr.*: MCAD) EC 1.3.99.3; database code ACDM\_HUMAN, 421 amino acids (46.54 kDa); and

(c) butyryl-CoA dehydrogenase is the short-chain enzyme (*abbr.*: SCAD) EC 1.3.99.2; database code ACDS\_HUMAN, 412 amino acids (44.25 kDa).

Both of the latter have corresponding activities and the same subunit composition as LCAD. Deficiencies in MCAD and SCAD are associated with fasting hypoglycemia, hepatic dysfunction, and encephalopathy (often fatal) for the former, and adult lipid storage myopathy and infant acidosis and muscle weakness.

(2) enoyl-CoA hydratase EC 4.2.1.17; this catalyses a reaction forming (3S)-3-hydroxyacyl-CoA from *trans*-2(or 3)-enoyl-CoA, hydrating the double bond introduced by the enzymes in category I. Example (rat, precursor): database code ECHM\_RAT, 290 amino acids (31.48 kDa); it is a homohexamer and a mitochondrial matrix protein.

(3) 3-hydroxyacyl-CoA dehydrogenase EC 1.1.1.35; this catalyses the oxidation of (3S)-3-hydroxyacyl-CoA by NAD<sup>+</sup> to 3-oxoacyl-CoA with formation of NADH. Example from pig:

## bialaphos

database code HCDH\_PIG, 307 amino acids (33.24 kDa); it is a homodimer and mitochondrial matrix protein.

(4) 3-ketoacyl-CoA thiolase (*see* thiolase). Example from rat: database code THIM\_RAT, 397 amino acids (41.82 kDa); a homotetramer and mitochondrial protein.

beta particle or  $\beta$  particle either a (negatively charged) electron or a (positively charged) positron emitted in the transformation (def. 5) of a radionuclide.

beta-pleated sheet or  $\beta$ -pleated sheet *another name for* beta sheet.

beta radiation or  $\beta$  radiation an emission of beta particles.

beta receptor or  $\beta$  receptor *see* adrenoceptor.

beta sheet or  $\beta$  sheet or p-pleated sheet an approximately planar array of two or more beta strands.

beta strand or  $\beta$  strand one of the two basic elements of the secondary structure adopted by a polypeptide chain within the hydrophobic core of a globular protein (*see also* alpha helix). It consists of two chains in a beta configuration. Two or more strands may interact to form a beta sheet.

beta structure or  $\beta$  structure any part of the structure of a protein molecule consisting of one or more  $\beta$  strands.

beta turn or  $\beta$  turn *an alternative name for* beta bend.

betaxanthin *see* betalain.

B form of DNA *abbr.*: B-DNA or DNA-B; the molecular conformation adopted by fibres of the sodium salt of duplex DNA at high relative humidity and in aqueous solution. It consists of a right-handed double helix containing about ten nucleotide residues per turn with the planes of the base pairs normal to the axis of the helix. It is the basis of the Watson-Crick model of DNA, and is thought to resemble the conformation of most of the DNA *in vivo*. *See also* Aform (def. 1), Cform, Zform.

BIF ratio *abbr.* for bound-to-free ratio (in ligand binding). A plot of the B/F ratio versus the concentration of free ligand is known as a Scatchard plot.

BGG *abbr.* for bovine gamma globulin; the component of bovine serum represented by fraction II of a Cohn fractionation.

B granule or beta granule any of very numerous membrane-bound vesicles (granules) containing stored insulin that are found in the B cells of the pancreatic islets. The granules stain a deep bluish purple with Gomori's aldehyde fuchsin and Ponceau stain.

bhang *see* cannabis.

BHK cell *abbr.* for baby hamster kidney cell; a cultured cell derived from this organ.

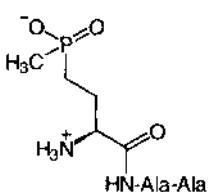

BHT *abbr.* for butylated hydroxytoluene, *di-tert-butyl-p-cresol*, an antioxidant.

bi+ 1 *comb. form* meaning two, twice, or double. 2 *prefix* (in organic chemical nomenclature) indicating two identical groups or rings joined by a link; e.g. biacetyl, biphenyl. 3 *prefix* (in inorganic chemical nomenclature) signifying an acid salt of a dibasic acid; e.g. sodium bicarbonate (though now more correctly termed sodium hydrogen carbonate). 4 (*in enzymology*) denoting two kinetically important substrates and/or products of an enzymic reaction (*see* reactivity of enzymes). *See also* bis+, di+.

Bi *symbol for* bismuth.

BiAcore *proprietary name* of an optical biosensor instrument that measures refractive index changes to record in real-time interactions of macromolecules with ligands immobilized on a dextran-coated gold surface. The resulting 'sensorgrams' can be used to derive kinetic parameters of the interactions.

bialaphos a linear tripeptide produced as a secondary metabolite by *Streptomyces hygroscopicus*. The structure is PT-Ala-Ala, where PT is the glutamate analog, phosphinothricin. After hydrolysis of bialaphos by intracellular nonspecific peptidases, PT acts as an inhibitor of glutamate-ammonia ligase (glutamine synthetase), and thereby derives herbicide and antibiotic activities.

bialaphos

Bial's test a colorimetric test for aldopentoses. *See* orcinol test.

[After Manfred Bial (1870-1908), German physician.]

bibrotoxin a vasoconstrictor peptide of the endothelin/sarafotoxin family, isolated from the venom of the burrowing wasp *Actrastaspis bibroni*. The sequence,

is identical to that of sarafotoxin B except that Ala<sup>4</sup> replaces Lys<sup>4</sup>.

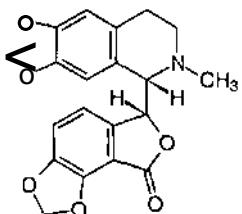

bicarbonate the HC<sub>0</sub><sub>3</sub> ion; now more correctly termed hydrogencarbonate.

bichromatic analysis a term sometimes used to describe any analytical method involving observation at two wavelengths.

Bicine or BICINE abbr. for N,N-bis(2-hydroxyethyl)glycine; a Good buffer substance;  $pK_a$  (20°C) = 8.35.

bicoid protein a segment-polarity protein, discovered in *Drosophila*, that provides positional cues for the development of head and thoracic segments. It regulates the expression of zygotic genes, possibly through its homeodomain, and inhibits the activity of other maternal gene products. It forms an anterior-posterior gradient in the embryo and acts as a transcriptional activator. It binds to *caudal* mRNA. There is similarity to other paired-type homeobox proteins. Example from *Drosophila melanogaster*: database code HMBC-DROME, 494 amino acids (54.43 kDa).

bicuculline 6-(5,6,7,8-tetrahydro-6-methyl-1,3-dioxolo[4,5-g]isoquinolin-5-yl)furo[3,4-e]-1,3-benzodioxol-8(6H)-one; a naturally occurring alkaloid with several sources, including *Dicentra cucullaria* and *Adlumia fungosa*. It is a potent convulsant with effects probably mediated by its GABA antagonist activity at GABA<sub>A</sub> receptors.

bidentate 1 having two teeth or two toothlike processes. 2 describing a ligand molecule that chelates a metal ion by means of two donor atoms.

bifunctional having two functions.

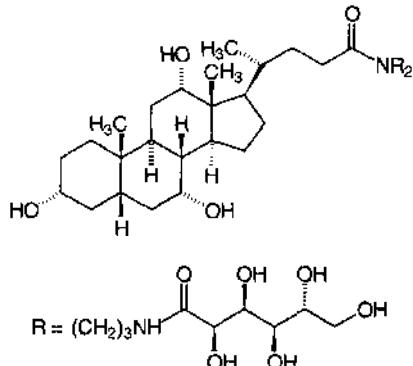

bifunctional antibody an antibody having two combining sites for antigen.

bifunctional catalyst a catalyst that provides both acidic and basic catalytic functions.

bifunctional reagent a compound with two reactive functional groups that can interact with two groups in one molecule or with one group in each of two different molecules.

big-big gastrin or big gastrin *see* gastrin.

BigCHAP N,N-bis(3-D-gluconamidopropyl)cholamide; a non-ionic detergent analogue of CHAPS, but with reduced electrostatic properties; aggregation number 10, CMC 3.4 mM.

big gastrin *see* gastrin.

big glucagon or big plasma glucagon material that is separable from normal human plasma and shows glucagon-like immunoreactivity. It has an estimated  $M_r$  of 160 000.

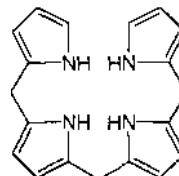

biglycan bone and cartilage proteoglycan I precursor; a connective tissue glycoprotein of the extracellular matrix related to decorin and fibromodulin. Example (precursor) from human: database code PGSLHUMAN, 368 amino acids (41.61 kDa). bijou bottle a small glass screw-capped bottle of 5-7 ml capacity, used especially for liquid and solid cultures.

bikunin a plasma glycoprotein found both in the free state and complexed with the heavy chains of the inter-a-inhibitor family, forming the light chain. It is a serine protease inhibitor having a tandem arrangement of Kunitz domains; it may participate in the control of events such as endothelial cell growth and oocyte cumulus expansion and stabilization. It is synthesized from an al-microglobulin/bikunin precursor. Example from human: database code HC\_HUMAN, 352 amino acids (38.96 kDa); residues 20-203 form al-microglobulin and 206-352 form inter-a-trypsin inhibitor light chain (the inhibitory subunit).

biladiene the semisystematic name for either of two linear tetrapyrroles in which the carbon bridges contain two more double bonds than bilane i.e. two of the three carbon bridges in the molecule are methine groups.

bilamellar having two lamellae; formed of two plates.

bilane the systematic name for a linear tetrapyrrole in which each of the three carbon bridges linking the pyrrole nuclei is saturated, i.e. is a methylene group, and in which, unless otherwise specified, each of the four nitrogen atoms also is saturated. It is the fundamental structure for the naming of linear tetrapyrroles, is defined without oxygen substituents, and is numbered (omitting C<sub>20</sub>) to agree with the numbering of the unsubstituted porphyrin ring system. *Trivial name:* bilinogen.

bilateral hydrophobic zippers putative  $\alpha$ -helical segments of the acidic ribosomal proteins, A1, A2, L44', and L45, of *Saccharomyces cerevisiae*. They have two arrays of 5-7 hydrophobic residues on opposite sides. *Compare* leucine zipper, bZIP.

## bilatriene

**bilatriene** *an alternative (less-favoured) name for bilin.*  
**bilayer** a layer that is two molecules thick, as in some membranes. *See lipid bilayer, unit membrane.*

**bilayer lipid membrane** *see black lipid membrane.*  
**bile** a secretion produced by the vertebrate liver and conveyed through the bile duct to the duodenum. Its alkaline nature helps to neutralize acidic gastric secretions passing from the stomach, and the bile salts it contains are involved in the digestion of fat. Bile also serves as a medium for the excretion of various substances, notably cholesterol (either as such or in the form of bile salts to which it is converted), pigments (from hemoglobin breakdown), heavy metals, and other waste products (usually of >400 Da).

**bile acid** any member of a group of steroid carboxylic acids occurring in bile, where they are present as the sodium salts of their amides with glycine or taurine (*see bile salt*). The C<sub>24</sub> acids are hydroxy or keto derivatives of cholic acid or allocholic acids; some C<sub>27</sub> bile acids are known in eutherian mammals. In mammals, the C<sub>24</sub> acids are found conjugated with glycine (*see glycocholate*) as well as with taurine (*see taurocholate*); in the rest of the animal kingdom only taurine conjugates have been found.

**bile alcohol** any of a group of polyhydroxy derivatives of cholestanone, present as their sulfuric acid esters in the bile of amphibians and some fishes.

**bilene** *the semisystematic name for either of two tetrapyrroles in which the carbon bridges contain one more double bond than bilane; i.e. one of the three bridges in the molecule is a methine group.*

**bile pigment** any bilirubinoid pigment present in bile; i.e. any linear tetrapyrrole derived from a porphyrin (which is a cyclic tetrapyrrole). For physiological reasons certain dipyrroles are also sometimes regarded as bile pigments.

**bile salt** the sodium salt of the conjugate of any bile acid with either glycine or taurine. Bile salts are potent surfactants; in the gut they emulsify ingested lipid, promote its hydrolysis by the activation of lipases, and facilitate its absorption, thereafter being excreted in the feces. *See also* glycocholate, taurocholate.

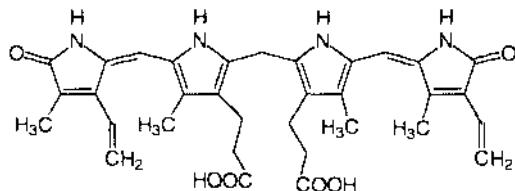

**biliary** of or relating to bile.

**bilin** *the systematic name for the linear tetrapyrrole in which the carbon bridges contain three more double bonds than bilane; i.e. all three bridges are methine groups. This name is preferred to bilatriene.* 2 any coloured bile pigment formed by the oxidation of a colourless bile pigment, or bilinogen (def. 2). Thus the bilinogens urobilinogen and stercobilinogen form urobilin and stercobilin, respectively, on oxidation.

**bilinogen** 1 *trivial name for bilane.* 2 any colourless bile pigment that may be oxidized to a coloured bile pigment (*see bilin* (def. 2)).

**biliprotein** *an alternative name for phycobiliprotein.*

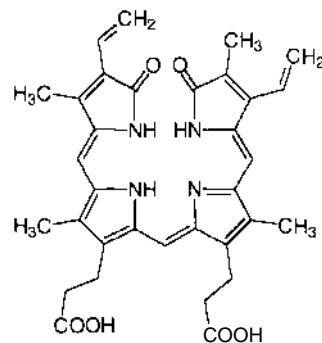

**bilirubin** or (*formerly*) **bilirubin IX $\alpha$**  *the recommended trivial name for the linear tetrapyrrole 8,12-bis(2-carboxyethyl)-2,7,13,17-tetramethyl-3,18-divinylbiladiene-ac-1,19(21H,24H)-dione. It is produced in the reticuloendothelial system by the reduction of biliverdin and transported to the liver as a complex with serum albumin. In the liver, bilirubin is rendered water-soluble by conjugation of the carboxyethyl side-chains to form bilirubin bisglucuronide, most of which is excreted in the bile. Bilirubin accumulates in the blood and tissues in jaundice.*

## binding constant

**bilirubin oxidase** EC 1.3.3.5; an enzyme that catalyses the oxidation by dioxygen of bilirubin to biliverdin and H<sub>2</sub>O. Example from the fungus *Myrothecium verrucaria*: database code B48521, 572 amino acids (63.88 kDa).

**biliverdin** or (*formerly*) **biliverdin IX $\alpha$**  *the recommended trivial name for the linear tetrapyrrole 8,12-bis(2-carboxyethyl)-2,7,13,17-tetramethyl-3,18-divinylbilin-1,19(21H,24H)-dione. It is formed in the reticuloendothelial system by the first step in heme degradation, catalysed by heme oxygenase (decrevelling), EC 1.14.99.3, a reaction in which the a-methene group of heme is oxidized to carbon monoxide. Biliverdin is then reduced by biliverdin reductase, EC 1.3.1.24, to bilirubin.*

**biliverdin reductase** EC 1.3.1.24; an enzyme that catalyses the reaction of bilirubin with NAD(P)+ to form biliverdin and NAD(P)H. Example from human: database code PN0159, 204 amino acids (21.83 kDa).

**bimodal** (*in statistics*) distribution with two modes.

**bimolecular** having a molecularity of two; relating to, consisting of, or involving two molecular entities.

**bimolecular layer** a layer that is two molecules thick.

**bimolecular reaction** any chemical reaction in which there is a transition state composed of the atoms of two separate molecular entities, which may be the same or different.

**binal double**; twofold.

**binary** 1 consisting of or forming two things or parts; dual. 2 describing a number system having the numeral 2 as its base (def. 4b). *See also* bit.

**binary compound** a compound consisting of only two chemical elements; e.g. ammonia, sodium chloride, water.

**binary digit** *see* bit.

**binary fission** the reproduction of a living cell by division into two equal, or near-equal, parts.

**binary operator** any arithmetic or logical operator (e.g. +, AND, OR) that operates on two quantities.

**binary representation** a notation by which alphanumeric symbols are represented by two digits, 0 and 1, in a known sequence. The displacement of one digit position to the left denotes multiplication by a power of 2.

**binder protein** *I see cortisol metabolite binding protein (IgM).*

**bindin** a protein of 285 amino acids, M<sub>r</sub> 35 000, extracted from the insoluble granular material of sea-urchin sperm, responsible for the attachment of the sperm to the vitelline layer of the egg. Bindins may mediate the species-specific recognition of eggs by sperm. *See also* spermadhesin, zona pellucida sperm-binding protein.

**binding** the act or process by which one molecule attaches to another by noncovalent forces; ligation *see* ligate (def. 3). *See* ligand. *See also* binding site.

**binding assay** *an alternative term for saturation analysis.*

**binding capacity** a measure of the quantity of ligand or the number of ligand molecules that can be bound by a given amount of a particular binding agent or system.

**binding constant** *an alternative term for affinity constant.*

**binding curve**

**binding curve** any graphical representation of the extent of binding between two compounds at varying relative concentrations of the reactants.

**binding energy** the free energy change accompanying the binding of *n* ligand molecules to a macromolecule to produce a particular configuration of the liganded macromolecule.

**binding fraction** *an alternative term for saturation fraction.*

**binding potential symbol:** *H*; a concept introduced to clarify the definition of linked functions, linkage groups, and linked sites in ligand binding. It is defined by:  $\nu_i = \delta H / \delta \mu_i$  where  $\nu_i$  is the ratio of component *i* to that of a reference component and  $\mu_i$  is the chemical potential of *i*.

**binding protein abbr.:** BiP; a luminal protein of the endoplasmic reticulum that is a member of the hsp70 family of heat-shock proteins and is a typical molecular chaperone. It recognizes incorrectly folded proteins as well as protein subunits that have not yet assembled into their oligomeric complexes and facilitates their oligomerization of folding. BiP activity requires the participation of ATP, which is hydrolysed to ADP and inorganic phosphate. Example (precursor) from human: database code GR78\_HUMAN, 653 amino acids (72.03 kDa); this is also known as 78 kDa glucose regulated protein.

**binding set** the spatially organized collection of all the groups or residues of *one* protomer that are involved in its binding to *one* other protomer.

**binding site** a specific region in a macromolecule or other molecular entity, or in a membrane, that takes part directly in the combination with a ligand. Binding sites may be independent or interacting, depending on whether or not the binding of one ligand to one site affects the binding of other ligands to other sites on the same macromolecule, or membrane. *See also cooperative ligand binding.*

**binomial** 1 a mathematical expression made up of two terms, e.g.  $2x + 5y$ . 2 a two-part taxonomic name (*see binomial nomenclature*).

**binomial coefficient** the coefficient of any term arising from the expansion of the algebraic binomial  $(a + b)n$ .

**binomial distribution** a statistical function in which the probabilities that an event will or will not occur are given by the successive coefficients of a binomial expansion of the form  $(a + b)^n$ , where *a* and *b* are the probabilities that an event will and will not occur, respectively.

**binomial nomenclature** a system of naming organisms, devised by the Swedish botanist Carolus Linnaeus (1707-78), that employs two Latin names, the first being the genus and the second the species to which the organism belongs.

**bio+ comb. form** denoting life or living organisms, or systems derived from them.

**bioactivation** the activation of a drug or other substance in an organism or by means of a biological or biochemical system.

**bioactive** *an alternative term for biologically active.*

**bioanalytical** of or pertaining to biochemical analysis.

**bioassay** or **biological assay** any quantitative estimation of biologically active substances by measurement of the magnitude of their actions on living organisms or parts of organisms. It is performed under standard conditions and by reference to preparations of defined potency or activity.

**bioautograph** the record obtained in bioautography.

**bioautography** a method for detecting, in a complex mixture, small amounts of substances that are able to act as essential growth factors for a test organism(s). The components of the mixture are first separated by chromatography. The resulting chromatogram is then placed in contact with a culture of the test organism in a solid medium lacking a specific component. Hence, the organism will only grow where the component is present in the chromatogram, thereby establishing its presence in the original mixture.

**bioavailability** 1 the relative amount of the dose of a drug or other substance reaching the systemic circulation. 2 the rate and extent to which the therapeutic moiety of a drug is absorbed and becomes available to the site of drug action.

**biodegradable**

**bioblast** any very small mass of protoplasm having formative powers, formerly considered to be the ultimate elementary living particles; it is now thought the particles seen may have been mitochondria.

**biocatalyst** any agent, present in or obtained from living material, that can increase the rate at which a chemical reaction occurs without itself undergoing permanent change; a biological or biochemical catalyst. Biocatalysts are commonly enzymes. *See also ribozyme. -biocatalysis n.*

**biochemical** 1 of or pertaining to biochemistry. 2 any chemical substance occurring in or isolated from an organism.

**biochemical engineering** or **bioengineering** the scientific discipline underlying the industrial processing of biological materials, e.g. fermentation-based pharmaceuticals, foods, and effluents.

**biochemical evolution** the evolution of the biochemical processes and components of living organisms, such as the structure and function of biologically important molecules, metabolic pathways, subcellular structures, and cells.

**biochemical genetics** the branch of genetics concerned with the chemical nature of hereditary determinants and how they function at the molecular level.

**biochemical imprinting** the adaptive increase in enzyme activities that can occur along specified metabolic pathways when there is a large and sustained traffic through them.

**biochemical lesion** any biochemical change, such as the absence or inactivation of an enzyme, that diminishes the fitness of an organism or leads to a pathological condition.

**biochemical marker** any specific character that may be detected by a biochemical test, e.g. the presence or absence of a particular enzyme.

**biochemical oxygen demand** or **biological oxygen demand abbr.:** BOD; a measure of pollution of water in lakes, rivers, etc. due to the presence of organic matter. Oxidation of the latter by microorganisms removes dissolved oxygen, hence reducing the ability of the water to sustain aquatic life. BOD is the amount of oxygen (mg) taken up by a 1-litre sample of water in 5 days (*BOD<sub>5</sub>*) at 20°C in the dark; it may be necessary to add additional, uncontaminated, water to augment the amount of oxygen available. Sometimes incubation is for a longer time, e.g. 20 days, in which case it is indicated by *BOD<sub>20</sub>*. *Compare chemical oxygen demand.*

**biochemistry** or **biological chemistry** the branch of science dealing with the chemical compounds, reactions, and other processes that occur in living organisms. Lehninger expressed the challenge to the biochemist as follows: 'Living things are composed of lifeless molecules. When these molecules are isolated and examined individually, they conform to all the physical and chemical laws that describe the behaviour of inanimate matter. Yet living organisms possess extraordinary attributes not shown by collections of inanimate molecules.' In this regard Horowitz has proposed a set of criteria for living systems: 'Life possesses the properties of replication, catalysis and mutability.' Biochemists are, therefore, concerned with the manner in which living organisms exhibit these properties. *-biochemist n.*

**biochip** an integrated circuit in which electrical and logical functions are performed by protein molecules appropriately manipulated.

**biocide** any chemical substance that kills living cells or organisms. *-biocidal adj.*

**biocompatible** compatible with life; having no injurious effect on living organisms. *-biocompatibility n.*

**bioconversion** a technique in which the enzymic apparatus of an organism is used to convert or process a chemical substance, not normally present in the organism, into another, (often commercially) useful one.

**biocytin** e-N-biotinyl-L-lysine; a naturally occurring complex of biotin, found especially in autolysates of rapidly growing yeast. It is liberated from biotin holoenzymes by proteolysis.

**biodegradable** capable of being broken down by the action of living organisms. *-biodegradability n.*

## biodegradation

**biodegradation** 1 the processes by which exogenous, usually waste materials are broken down by living organisms. Sometimes this breakdown involves two or more kinds of organisms acting in cooperation. Such degradative abilities are employed to convert waste materials into more acceptable and manageable forms or to produce useful end products. 2 *an alternative term for catabolism. Compare biosynthesis.*

**biodeterioration** any undesirable change in the properties of a material brought about by the activities of organisms.

**bioelectricity** electric current or electric potential produced in living organisms. -*bioelectric adj.*

**bioelectrochemistry** the application of electrochemical models and techniques to biological problems.

**bioelectronics** the application of biomolecular principles to microelectronics, as in biosensors and biochips.

**bioelement** any element that is an essential component of living organisms. Bioelements include: as major elements, C, H, O, N, P, and S, found chiefly in combination in organic compounds, and the elements, Na, K, Mg, Ca, and Cl, found mainly as monatomic ions. Many other 'trace elements' occur in relatively minute amounts.

**bioenergetics** the study of energy transformations in living systems.

**bioengineering** 1 engineering relating to the operation on an industrial scale of biochemical processes, especially fermentation. This is usually now termed biochemical engineering. 2 the application of the physical sciences and engineering to the study of the functioning of the human body and to the treatment and correction of medical conditions.

**biofuel cell** any fuel cell (a cell in which electricity is produced directly by oxidation of fuel) in which one or both electrode reactions are promoted or catalysed by a biological process.

**Bio-Gel** proprietary name for a group of materials used in gel filtration, consisting of either cross-linked agarose (Bio-Gel A) or porous polyacrylamide (Bio-Gel P).

**biogenesis** 1 the synthesis of a substance in a living organism; biosynthesis. 2 the principle that a living organism can originate only from a parent or parents that are similar to itself. *Compare abiogenesis.* -*biogenetic, biogenetical, biogenous adj.*

**biogenic** produced by living organisms.

**biogenic amine** any of various amines, especially those with neurological activity, isolated from plants or animals.

**bioinformatics** see Appendix E.

**biohazard** any organism or material derived from a biological source that is hazardous to health or life.

**bioinorganic chemistry** a branch of inorganic chemistry concerned with the interactions between inorganic substances (especially metallic ions or their complexes) and biological or biochemical systems, and with the properties of related model systems. *Compare inorganic biochemistry.*

**biolistics** descriptive of the administration of DNA in gold particles, using a device known as a 'gun' to deliver the particles to the cell interior. One use has been in the development of vaccines by the administration of suitable genes to foreign cells.

**biolith** a rock or other deposit (e.g. peat, humus) formed from organic material.

**biological adj.** 1 of or pertaining to biology. 2 of or pertaining to life or living organisms. 3 a biological product that is used prophylactically or therapeutically. -*biologically adv.*

**biological activity** any activity of a substance that is demonstrable in living organisms. Biologically active substances are often of biological origin themselves.

**biological clock** any biological mechanism that allows the expression of a certain biological structure (e.g. a gene) or a biological function (e.g. sleep) at periodic intervals. The term is also used colloquially to describe ageing, e.g. in respect to a woman's ability to bear a child.

**biologically active or bioactive** active in a living organism.

**biological value abbr.:** B.V.; a measure of the value of a protein in a foodstuff for the maintenance of growth and normal

## biopterin

functioning of any given animal or species. It is based on the amino-acid composition of the protein, its digestibility, and the availability of its digestion products.

**biology** 1 the scientific study of living organisms, including their structure, functioning, development, distribution, interrelationships, and evolution. 2 the animal and plant life of a particular region considered as a unit. 3 the structure, functioning, etc. of a particular organism or group of organisms. -*biologist n.*

**bioluminescence** the production of light by certain enzyme-catalysed reactions in living organisms. -*bioluminescent adj.*

**biolysis** any decomposition of organic material by biological means. -*biolytic adj.*

**biomass** 1 the total mass of living organisms, of a specified kind, forming a population inhabiting a given region. 2 the material produced by the growth of microorganisms, plants, or animals, especially as a product of or raw material for an industrial process, such as farming or fermentation.

**biomedical science or biomedicine** any branch of science that is relevant to medicine.

**biomembrane** any membrane surrounding a cell or a subcellular organelle, or derived from these structures.

**biometry** the statistical study of biology. -*biometric adj.; biometrically adv.*

**biomimetic chemistry** a branch of organic chemistry that aims to imitate natural reactions and enzymatic processes as a means to improve the power of organic chemistry.

**biomolecular engineering** a term sometimes used to cover those branches of biotechnology dealing with enzyme engineering and genetic engineering.

**biomolecule** any molecule, especially a macromolecule, that occurs in or is formed by living organisms. -*biomolecular adj.*

**bioorganic chemistry** a branch of organic chemistry concerned with the study of organic molecules from living systems.

**biophotolysis** any type of photolysis reaction occurring in a biological system; e.g. the lysis of a water molecule in the reactions of photosystem II during photosynthesis.

**biophysical chemistry** the application of the techniques or methods of physical chemistry to biological systems. It is principally concerned with the conformations, shape, structure, conformational changes, dynamics, and interactions of macromolecules and complexes or arrays of macromolecules. *Compare biophysics, physical chemistry.*

**biophysics** the application of physical techniques and physical methods of analysis to biological problems. Traditionally, the discipline has focused on two main areas: first, the transmission of nerve signals and the maintenance of electrical potentials across membranes; and second, large-molecule crystallography and enzyme structure and mechanisms. For the latter X-ray crystallography has been supplemented by a number of physical techniques, including nuclear magnetic resonance spectrometry, mass spectrometry, fluorescence-depolarization measurements, and circular-dichroism studies. -*biophysical adj.; biophysicist n.*

**biopolymer** any polymer, such as a protein, nucleic acid, or polysaccharide, occurring in, or formed by, living systems.

**biopotency** the extent to which a material (e.g. drug or hormone) influences a biological process.

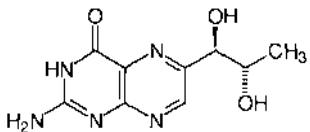

**bioproduct** any (usually) useful product produced by living organisms or by systems derived from living organisms.

**biopsy** examination of (usually) a sample of tissue, cells, or fluid from a living human or animal for diagnostic purposes. The term is also now commonly used for the process of removing such a sample. *Compare necropsy.*

**biopterin** 2-amino-4-hydroxy-6-(1,2-dihydroxypropyl)-pteridine; 1-(2-amino-4-hydroxy-6-pteridinyl)-1,2-propanediol; a growth factor for certain protozoans, e.g. *Crithidia fasciculata* and *Trypanosoma platydactylti*. It is widely distributed in tissues and functions in a reduced form, tetrahydrobiopterin, as a hydroxylation coenzyme, e.g. in the conversion of phenylala-

**bioreactor**

nine to tyrosine. It has been isolated from queen-bee jelly and is considered a growth factor for some insects.

**bioreactor** any reactor containing immobilized enzymes or cells that is used to effect specific chemical reactions in the production of some economically desirable product.

**bioregulator** omnibus term sometimes used for any substance occurring within a cell or organism that has a specific and reversible controlling action on a particular biochemical event within that cell or organism; it may be, e.g., a hormone, an enzyme, an intermediate metabolite, an inorganic ion, or a cyclic nucleotide.

**bioremediation** the use of biological systems to remedy environmental damage.

**bios** *the former name for* various growth factors required by yeast. Originally believed to be a single factor, it was later fractionated into bios I (shown to be **inositol**), bios IIA ( **$\beta$ -alanine**), and bios IIB (**biotin**).

**bioscience(s)** collectively all the individual branches of science that are concerned with biology.

**biose** disaccharide; stem name used in the established trivial names for particular disaccharides whether or not they contain a single type of sugar residue and linkage, as in cellobiose and gentiobiose.

**+biose** suffix used in nomenclature of glycolipids to indicate a compound containing an oligosaccharide moiety composed of two sugar residues (which may be the same or different), as in galabiose.

**biosemiotics** the study of signs, of communication, and of information in living organisms.

**biosensor** a device that uses specific biochemical reactions mediated by isolated enzymes, immunosystems, tissues, organelles, or whole cells to detect chemical compounds, usually by electrical, thermal, or optical signals.

**biospecific** describing: 1 a reagent, e.g. an antibody or hormone, that can recognize and interact only with cells (e.g. within a mixed population of cells) displaying a particular surface characteristic, e.g. a corresponding antigen or receptor. 2 any reagent that, in a similar way, recognizes and interacts with a particular biospecifically occurring substance. 3 any reagent that interacts specifically with a particular biomolecule (e.g. an enzyme). 4 the reaction between two biospecific reagents.

**biospecific-elution chromatography** *an alternative name for affinity-elution chromatography* (when the ligand in the eluting solvent is a biospecific macromolecule).

**biosphere** the parts of the Earth's crust and atmosphere that contain living organisms.

**biosynthesis** the production of substances by processes occurring in living systems; **anabolism**; **biogenesis**. Compare **biodegradation**.

**biosynthetic** 1 of or relating to **biosynthesis**. 2 any substance produced by biosynthesis.

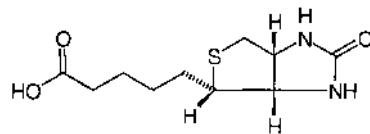

**biosynthetic pathway** any metabolic pathway effecting biosynthesis; an anabolic pathway.

**biotechnology** 'the integration of natural sciences and engineering sciences in order to achieve the application of organisms, cells, parts thereof and molecular analogues for products and services' (European Federation of Biotechnology General Assembly, 1989); a field of technological activity in which biochemical, genetic, microbiological, and engineering techniques are combined for the pursuit of technical and applied aspects of research into biological materials and, in particular, into biological processing. It includes traditional technologies such

**bisalbuminemia**

as fermentation processes, antibiotic production, and sewage treatment, as well as newer ones such as **biomolecular engineering**, and **single-cell protein** production. -**biotechnological** adj.

**biotin** cis-tetrahydro-2-oxothieno[3,4-d]imidazoline-4-valeric acid; hexahydro-2-oxo-1*H*-thieno[3,4-d]imidazole-4-pentanoic acid; vitamin H; formerly known as bios IIB and coenzyme RCO<sub>2</sub>; a substance the (+) enantiomer of which is very widely distributed in cells and serves as a carrier in a number of enzymic p-carboxylation reactions. In biotin-containing enzymes the biotin is covalently bound at the active site through an amide link to the ε-amino group of a lysine residue. It was first found as a growth factor for yeasts. Compare **biocytin**. See also **streptavidin**.

**biotin carboxylase** see **acetyl-CoA carboxylase**.

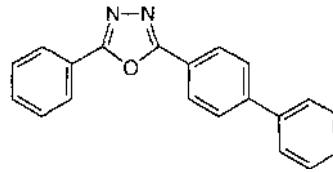

**biotinyl** the acyl group derived from **biotin**.

**biotinylation** the act or process of attaching a biotinyl residue by use of an appropriate reactive derivative, e.g. biotin 4-nitrophenyl ester. It is useful for labelling cell-surface functional groups or biologically active molecules. The presence of the label is subsequently detected, or the labelled material is separated, by means of the specific and high-affinity avidin-biotin reaction, using avidin or **streptavidin** conjugated with, e.g., a fluorochrome, an enzyme, an antibody, or an immobilizing agent. -**biotinylate** vb.; **biotinylated** adj.

**biotransformation** the conversion or conjugation of a foreign compound introduced into an organism or a culture of cells, especially (in biotechnology) with formation of a substance of commercial value. Compare **detoxication**.

**SiP** abbr. for binding protein.

**biphenylphenyloxadiazole** abbr.: PBD; 2-phenyl-S-(4-biphenyl)-1,3,4-oxadiazole; a high-efficiency primary scintillator. The *tert*-butyl derivative, 2-(4-*tert*-butylphenyl)-S-(4-biphenyl)-1,3,4-oxadiazole (abbr.: butyl-PBD) has greater solubility and only a slightly lower photon yield. See also **scintillation cocktail**.

**biphosphate** *an obsolete name for the anion H<sub>2</sub>P<sub>2</sub>O<sub>7</sub> or PO<sub>2</sub>(OH)<sub>2</sub>, now correctly termed dihydrogenphosphate*.

**biradical** or **diradical** any molecular entity in an electronic state (described by a formula or by a combination of contributing structures) that contains two unpaired electrons in atomic orbitals on different atoms (compare **carbene**). Both singlet and triplet species are embraced.

**birefringence** *an alternative term for double refraction*. -**birefringent** adj.

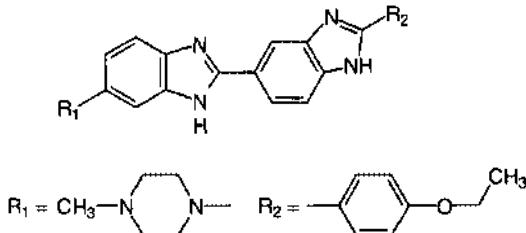

**bis+** comb. form 1 denoting two, twice, doubled; see also **bi-** (def. I), **di-** (def. 1).2 (in chemical nomenclature) a indicating the presence in a molecule of two identical organic groups each substituted in the same way, e.g. **bis(2-chloroethyl)sulfide**. b indicating the presence in a molecule of two separate inorganic oxoacid residues, e.g. fructose 1,6-bisphosphate (formerly known as fructose 1,6-diphosphate). Compare **di-** (def. I).

**bisalbuminemia** or (esp. Brit.) **bisalbuminaemia** a symptom-

**bisbenzimide**

less human condition in which the presence of a variant serum albumin leads to a double albumin band on electrophoresis of serum proteins.

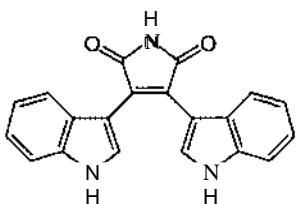

**bisbenzimide** 4-{[5-(4-methyl-1-piperazinyl)-2-benzimidazolyl]-2-benzimidazolyl} phenol (Hoechst 33258) or its ethyl ether (Hoechst 33342); a substance that is useful as a DNA-binding fluorochrome for staining chromosomes within cell nuclei. It is believed to be specific for A-T base pairs.

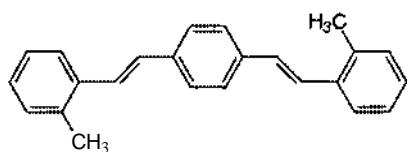

**bis(2-chloroethyl)sulfide** or (formerly) **mustard gas** ( $\text{ClCH}_2\text{CH}_2\text{S}_2$ ; a bifunctional alkylating agent that causes lethal cross-linking of DNA chains.

**Bishop, John Michael** (1936- ), US microbiologist; Nobel Laureate in Physiology or Medicine (1989) jointly with H. E. Varmus 'for their discovery of the cellular origin of retroviral oncogenes'.

**bisindolylmaleimide** GF I09203X; a protein kinase inhibitor, structurally similar to **staurosporine**, that is highly selective for **protein kinase C** (PKC), though not between isotypes  $\alpha$ ,  $\beta\text{I}$ ,  $\beta\text{II}$ , or  $\gamma$ . It acts as a competitive inhibitor at the ATP-binding site on PKC. It exhibits a  $K_i$  of 14 nM for the purified enzyme, but its potency on whole cells is much lower ( $K_i$  1-2  $\mu\text{M}$ ), possibly owing to high cellular ATP levels.

**bismethylstyrylbenzene** abbr.: bis-MSB; 1,4-bis(2-methylstyryl)-benzene; a secondary scintillator with good resistance to quenching and low reactivity with compounds in samples. See also **scintillation cocktail**.

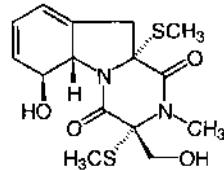

**bis(methylthio)gliotoxin** a naturally occurring analogue of **gliotoxin**. It inhibits platelet activating factor (PAF)-induced platelet aggregation ( $\text{IC}_{50} = 84 \mu\text{M}$ ) (but not platelet aggregation induced by arachidonic acid or ADP) and *in vivo* PAF-induced bronchoconstriction; it lacks the antiviral and immunomodulating effect of gliotoxin. (Illustrated top right.)

**bis-MSB** abbr. for bismethylstyrylbenzene.

**bisphosphate** any compound containing two independent phosphoric residues in ester linkages, at positions indicated by locants. Compare **diphosphate** (def. 3,4).

**bisphospho+** prefix to a chemical name indicating the presence of two independent phosphoric residues in ester linkages, at positions indicated by locants. Compare **diphospho+**.

**2,5-bis(3,4,5-trimethoxyphenyl)-1,3-dioxolane**

bis(methylthio)gliotoxin

**2,3-bisphospho-D-glycerate** a recommended name for (R)-[2,3-dihydroxypropanoate 2,3-bis(dihydrogenphosphate)] (formerly termed 2,3-diphosphoglycerate); abbr.: BPG; it decreases the dioxygen affinity of hemoglobin, its concentration in the erythrocyte being regulated by **bisphosphoglycerate mutase** (synthesis) and **bisphosphoglycerate phosphatase** (degradation). It does not pass through the erythrocyte membrane. See also **bisphosphoglycerate pocket**.

**bisphosphoglycerate mutase** abbr.: BPGM; EC 5.4.2.4; systematic name: 3-phospho-D-glycerate 1,2-phosphomutase; other names: 2,3-bisphosphoglycerate mutase; 2,3-bisphosphoglycerate synthase; diphosphoglycerate mutase; glycerate phosphomutase; bisphosphoglycerate synthase. An enzyme that catalyses the reaction:

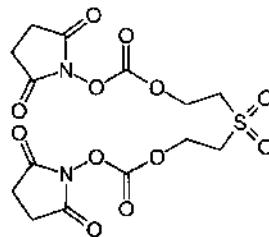

The enzyme plays a major role in regulating the dioxygen affinity of hemoglobin by controlling 2,3-bisphosphoglycerate concentration in the erythrocyte, but with a reduced activity. Example from human: database code PGME\_HUMAN, 258 amino acids (29.84 kDa).

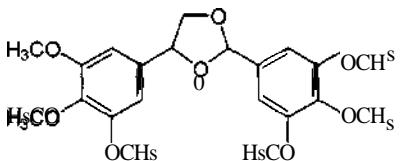

**bisphosphoglycerate phosphatase** EC 3.1.3.13; systematic name: 2,3-bisphospho-n-glycerate 2-phosphohydrolase; an enzyme that catalyses the hydrolysis of 2,3-bisphosphoglycerate to 3-phosphoglycerate and orthophosphate; it thereby assists regulation of the concentration of 2,3-bisphosphoglycerate.

**bisphosphoglycerate pocket** abbr.: BPG pocket; the cavity (pocket) between the two  $\beta$  chains of deoxyhemoglobin in which a single molecule of 2,3-bisphospho-D-glycerate (BPG) binds; the binding of this molecule reduces the affinity of hemoglobin for dioxygen. Residues Val<sup>1</sup> (terminal- $\text{NH}_3^+$ ), His<sup>2</sup>, Lys<sup>82</sup>, and His<sup>143</sup> of each  $\beta$  chain participate in this binding. It plays an important part in establishing the difference in oxygen affinity that is found between maternal and fetal hemoglobin; in fetal hemoglobin, the  $\gamma$  chain has a serine in the position occupied by His<sup>143</sup> of the  $\beta$  chain of the adult hemoglobin, which weakens the affinity of fetal hemoglobin for BPG and thus results in a higher affinity for dioxygen than adult hemoglobin.

**bis[2-succinimidooxycarbonyloxyethyl]sulfone** a non cytotoxic, homobifunctional, lysine-specific cross-linking agent that reacts at 0 °C; the cross-links can be reversed at pH 11.6 at 37°C.

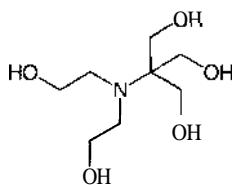

**2,5-bis(3,4,5-trimethoxyphenyl)-1,3-dioxolane** a substance, the *trans*-isomer of which inhibits platelet activating factor-induced platelet aggregation. The *cis*-isomer is inactive.

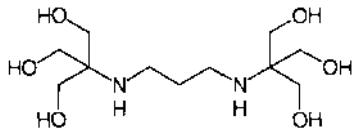

2,5-bis(3,4,5-trimethoxyphenyl)-1,3-dioxolane

**Bistris** or **bis-tris** abbr. for bis(2-hydroxyethyl)imino-tris(hydroxymethyl)methane; 2-[bis(2-hydroxyethyl)amino]-2-(hydroxymethyl)-propane-I,3-diol. A buffer substance useful for the calibration of glass electrodes and for the preparation of biochemical and biological buffer solutions;  $pK_a$  ( $25^\circ\text{C}$ ) = 6.5. It is inexpensive, stable, and readily crystallizable.

**bis-tris propane** abbr. for 1,3-bis[tris(hydroxymethyl)methylamino]propane; a water-soluble buffer substance used for the preparation of biochemical and biological buffer solutions;  $pK_a$  ( $20^\circ\text{C}$ ) = 6.8.

bit a single binary digit having the value of either 0 or 1; the smallest unit of information in a binary system. A group of (usually) eight bits comprises a byte, which can represent numbers between 0 and 11111111 in binary (equal to 0 and 255 in decimal). [abbr. for binary digit.]

**bithorax complex** see BX-C.

**Bittner factor** or **Bittner particle** former name for murine mammary tumour virus. [After John Joseph Bittner (1904-61), US biologist.]

**biuret reaction** the formation of a characteristic purple colour when biuret (carbamoylurea) or compounds containing two or more adjacent peptide bonds (e.g. proteins) react with copper sulfate in alkaline solution. It forms the basis of the biuret test, a colorimetric method for the qualitative or quantitative determination of proteins.

**Bjerrum formation function** a function used in studies of the binding of  $n$  ligand atoms, ions, or molecules to an acceptor atom, ion, or molecule. It is:

$$\nu = \frac{(K_1[L] + 2K_1K_2[L]z + \dots + nK_1K_2\dots K_n[L]n)(1 + K_1[L])}{+ 2K_1K_2[L]z + \dots + nK_1K_2\dots K_n[L]n},$$

where  $\nu$  is the average number of ligand molecules bound per molecule of acceptor;  $K_1, K_2, \dots K_n$  are the stepwise formation (stability) constants of the  $n$  complexes; and  $[L]$  is the free ligand concentration. This function expresses an unambiguous connection between the quantity  $\nu$  and  $[L]$ . It is a generalized form of the Adair equation. [After Jannik Bjerrum (1909- ), Danish chemist who described it in 1941.]

**Bjerrum plot** a plot of  $\nu$ , the average number of ligand molecules bound per molecule of acceptor, versus  $-\log[L]$ , where  $[L]$  is the free ligand concentration. It is used for evaluating the association constants in a Bjerrum formation function.

**Bk symbol** for berkelium.

**BK abbr.** for bradykinin.

**BK<sub>1-8</sub>** abbr. for des-Arg<sup>9</sup>-bradykinin (see bradykinin).

**bla symbol** for p-lactamase gene.

**Black**, (Sir) James Whyte (1924- ), British pharmacologist distinguished for his discoveries of blockade of  $\beta$ -adrenoceptors and of  $H_2$ -receptors by novel drugs; Nobel Laureate in Physiology or Medicine (1988) jointly with G. B. Elion and G. H. Hitchings 'for their discoveries of important principles for drug treatment'.

**black lipid membrane** abbr.: BLM; other names: black lipid film; bimolecular lipid membrane; bilayer lipid membrane; lipid bilayer. An experimental membrane formed by introducing a small amount of suitable lipid solution on to an opening in the wall of a hydrophobic support immersed in an aqueous solution. The thickness of the black membrane does not differ greatly from the length of two of the lipid molecules used and is often about 4.5 nm.

**blank** (determination) any analytical mixture from which analyte is deliberately omitted and which undergoes the same procedures as the complete mixture. It is used to ascertain the contribution of extraneous factors, e.g. reagent impurities or photometric absorption by the reagents, to the analytical result.

**blast+** a variant form of **blasto+**.

**+blast** suffix denoting a formative cell, e.g. erythroblast, fibroblast, osteoblast.

**blast cell** or **blastocyte** any undifferentiated embryonic cell. Such cells characteristically have a cytoplasm rich in RNA, and are actively synthesizing DNA.

**blast crisis** the appearance of heterogeneity in the cell surface characteristics of white blood cells when chronic myeloid leukemia evolves into acute leukemia. This process is virtually inevitable and often rapid.

**blasto+** or (before a vowel) **blast+** prefix denoting 1 an embryo in its early stages; e.g. blastocyst, blastula. 2 a germ cell; e.g. blastocyte.

**blastokinin** see **uteroglobin**.

**blast transformation** see **transformation** (def. 3).

**bleb** 1 a spherical vesicle, about 10  $\mu\text{m}$  in diameter, formed when a chloroplast swells on suspension in very hypotonic medium. It is bounded by a single membrane, on the surface of which a part of the thylakoid system remains concentrated in a few patches. 2 animal membranes are said to form blebs under special conditions that cause small vesicles to pinch off.

**blender** or (sometimes, US) **blendor** a device for disrupting tissue or any aggregate. It consists of blades rotating at the bottom of a glass or stainless-steel vessel (originally named a Waring blender, from a trade name); in an alternative design, known as a top-drive blender, the blades rotate on a spindle from the top of the vessel. The method is indiscriminating and may damage organelle membranes through excessive force or generation of heat. For more precise work, a Potter-Elvehjem homogenizer or a Dounce homogenizer preserves organelle structure.

**bleomycin** any of a group of related glycopeptide antibiotics isolated from *Streptomyces verticillatus*. Bleomycin acts to stop the cell cycle in the  $G_2$  phase (see **cell-division cycle**). It is used to induce synchrony in cell cultures and as an antineoplastic agent, especially in lymphomas.

**blepharoplast** an alternative term for basal body of a flagellate.

**BLK** a gene encoding a protein tyrosine kinase of the Src family, specifically expressed in the B-cell lineage.

**BLM abbr.** for black lipid membrane.

**Bloch** Felix Bloch (1905-83), Swiss-born US physicist notable for his extensive studies in solid-state physics, for his measurement (with L. W. Alvarez) of the magnetic moment of the neutron, and for his discovery (independently of E. M. Purcell) of

**block**

the phenomenon of nuclear magnetic resonance of certain atomic nuclei; Nobel Laureate in Physics (1952) jointly with E. M. Purcell 'for their development of new methods for nuclear magnetic precision measurements and discoveries in connection therewith'. 2 Konrad Emil Bloch (1912– ), German-born US biochemist distinguished for his extensive studies by isotope techniques of the biosynthesis of cholesterol, creatine, and protoporphyrin; Nobel Laureate in Physiology or Medicine (1964) jointly with F. Lynen 'for their discoveries concerning the mechanism and regulation of the cholesterol and fatty acid metabolism'.

**block 1** (*in chemistry*) a portion of a polymer molecule comprising many constitutional base units; such a portion has a constitutional or configurational feature not present in the adjacent multiple-unit portions. 2 (*in physiology*) an interference in the normal metabolic or physiological functioning of an organ or tissue; e.g. metabolic block, heart block. 3 to impede, retard, or prevent an action or activity, e.g. of an agonist, antigen, chemical reagent, enzyme, or receptor.

**blockade 1** (*in pharmacology*) the saturation of a specific type of receptor with an antagonist to its normal agonist. 2 (*in immunology*) the overloading or saturation of the reticuloendothelial system with inert particles, such as carbon particles. 3 to impose any such blockade.

**blocker** something that blocks an action or activity; an antagonist or inhibitor.

**blocking agent** 1 a chemical reagent that introduces a blocking group. 2 a specific pharmacological antagonist.

**blocking antibody** 1 an incomplete antibody that does not agglutinate its antigen but attaches to it and so prevents its agglutination by normal, complete antibody. 2 antibody formed during specific desensitization in atopy.

**blocking group** I or protecting group a chemical group, often easily removable, that is substituted into a reactive part of a molecule to prevent its participation in subsequent chemical or enzymic reactions occurring at another part of the molecule. 2 a chemical group, not easily removable, that is substituted into the active site of an enzyme to prevent its action.

**block polymer** a polymer whose molecules contain two or more species of block (def. 1) attached linearly.

**blood** a fluid tissue in animals that acts primarily as a transport medium. It is contained in vessels or spaces lined with endothelial cells. Metabolites, nutrients, and excretory substances are carried in solution or suspension from one part of the body to another. Respiratory pigments are often present to assist in the transport of dioxygen. It may also contain suspended cells.

**blood-brain barrier** the semipermeable membranous barrier that regulates the passage of dissolved materials from the blood into the cerebrospinal fluid that bathes the brain and spinal cord.

**blood coagulation** or **blood clotting** a mechanism that prevents blood loss at the site of an injury. It involves the formation of a semisolid mass of material, the blood clot, which plugs the wound. The clot consists of aggregated platelets and a mesh of fibrin molecules. The fibrin components include 13 or 14 plasma proteins, at least one tissue protein, phospholipid membrane surfaces, Ca<sup>2+</sup> ions, and platelets. The current concept of the mechanism has changed from one involving a linear sequence of activations of proenzymes to one involving protein-protein and protein-lipid-Ca<sup>2+</sup> interactions between proteinase, protein substrates, and protein cofactors to give discrete complexes and reaction steps. The following factors are involved in coagulation:

Factor I (*or* fibrinogen) concn. =2-4 g L<sup>-1</sup> human plasma; a soluble fibrous protein of 330 kDa, it has an axial ratio of ≈5 and is made up of six disulfide-linked polypeptide chains; two A $\alpha$  chains (66 kDa); two B/J chains (52 kDa); and two  $\gamma$  chains (47 kDa). After proteolysis by thrombin it polymerizes to form an insoluble fibrin clot.

**blood coagulation**

Factor II (*or* prothrombin) concn. 200 mg L<sup>-1</sup> human plasma, 72.5 kDa; a vitamin K-dependent single-polypeptide-chain glycoprotein containing ten  $\gamma$ -carboxyglutamate residues. It is converted to thrombin (*or* fibrinogenase), EC 3.4.21.5, by the proteinase factor Xa.

Factor III (*or* thromboplastin *or* tissue factor) a factor that, when added to blood plasma, markedly shortens the time required for clot formation. Example from human (precursor): database code TF\_HUMAN, 295 amino acids (33.07 kDa).

Factor IV (*or* calcium ion) calcium ions form bridges between vitamin K-dependent proteins and acid phospholipids of cell membranes. They also stabilize factor V and fibrinogen, and are involved in activation of factor XIII.

Factor V (*or* accelerator globulin *or* proaccelerin) a glycoprotein of ≈330 kDa. After activation to factor Va (accelerin) it acts with the proteinase factor Xa in activating prothrombin. Example from human (precursor): database code FA5\_HUMAN, 2224 amino acids (251.70 kDa).

Factor VI an obsolete term (originally named accelerin).

Factor VII (*or* proconvertin) concn. 2 mg L<sup>-1</sup> human plasma; 50 kDa; a vitamin K-dependent single-polypeptide-chain glycoprotein containing  $\gamma$ -carboxyglutamate residues. It is the precursor of factor VIIa, convertin, a Ca<sup>2+</sup>-dependent proteinase, EC 3.4.21.21, that activates factor X and is the first component of the extrinsic pathway of coagulation. Example from rabbit (precursor): database code FA7\_RABBIT, 443 amino acids (48.85 kDa).

Factor VIII (*or* antihemophilic factor); an accessory protein that participates with proteinase factor IXa in the activation of factor X in the intrinsic pathway of coagulation. Example from mouse (precursor): database code FA8\_MOUSE, 2319 amino acids (266.15 kDa).

Factor IX (*or* Christmas factor) concn. 3-4 mg L<sup>-1</sup> human plasma; 57 kDa (human), 55.4 kDa (bovine); a vitamin K-dependent single-polypeptide-chain glycoprotein containing 17% carbohydrate (human; 25% in bovine) and  $\gamma$ -carboxyglutamate residues. After proteolytic activation it consists of two chains: factor IXa, a serine proteinase, EC 3.4.21.22, of 27 kDa that activates factor X in the intrinsic pathway of coagulation; and a light chain of 16 kDa that contains the  $\gamma$ -carboxyglutamate residues. Example from dog (precursor): database code FA9\_CANFA, 452 amino acids (50.83 kDa).

Factor X (*or* Stuart-Prower factor; *other names*: Stuart factor; thrombokinase; prothrombase; prothrombinase) concn. 6-8 mg L<sup>-1</sup> human plasma; a vitamin K-dependent two-polypeptide-chain glycoprotein, containing 15% carbohydrate (human; 10% in bovine). The 40 kDa chain is a serine proteinase while the 15 kDa chain contains 12  $\gamma$ -carboxyglutamate residues. Example (precursor) from human: database code FA10\_HUMAN, 488 amino-acid residues (54.67 kDa). It is the circulating precursor to the proteinase factor Xa, EC 3.4.21.6, that converts prothrombin into thrombin by selective cleavage of Arg-I-Thr then Arg-j-Ile bonds.

Factor XI (*or* plasma thromboplastin antecedent) 160 kDa (human), 124 kDa (bovine); a protein of two disulfide-linked chains of apparently equal molecular mass. Example from human: database code FA11\_HUMAN, 625 amino acids (70.03 kDa). It is the circulating precursor of the serine proteinase factor XIa, EC 3.4.21.27, to which it is converted by proteolysis: selective cleavage of Arg-I-Ala and Arg-I-Val bonds in factor IX to form factor IXa triggers the middle phase of the intrinsic pathway of blood coagulation by activating factor IX. Factor XIa converts factor IX into factor IXa.

Factor XII (*or* Hageman factor) 80 kDa (human), 74 kDa (bovine); a single-polypeptide-chain glycoprotein. It is the circulating precursor of the proteinase factor XIIa, which activates factor XI. Example from human (precursor): database code FA12\_HUMAN, 615 amino acids (67.82 kDa).

## blood group

**Factor XIII (or plasma transglutaminase)** 320 kDa (plasma, tetrameric), 160 kDa (platelets, dimeric). An enzyme precursor whose subunits are proteolytically cleaved by thrombin to form the transglutaminase, factor XIIIa, EC 2.3.2.13, which covalently cross-links fibrin monomers into the fibrin polymer.

**Prekallikrein** a plasma protein, 88 kDa (bovine), that is the precursor of the proteinase kallikrein. This consists of a heavy chain (52 kDa) and a light chain (33-38 kDa) and cleaves factor XII to form factor XIIa.

**High-molecular-weight kininogen** a single-polypeptide-chain glycoprotein of  $\approx$ 150 kDa (human), 76 kDa (bovine). It is the source of bradykinin, which is released from it by kallikrein, and acts as an accessory protein in the activation of factor XI by factor XIIa. Example from *Bos taurus* (precursor): database code KNHI\_BOVIN, 621 amino acids (68.89 kDa).

**Plasminogen** 86 kDa (human); a single-polypeptide-chain protein that, on proteolysis, is converted into the protease plasmin, which degrades the fibrin clot.

There are two pathways of coagulation: in the intrinsic pathway, which occurs during the clotting of platelet-poor plasma, activation of factor X to factor Xa is effected by the combination of factor IXa + factor VIIIa + Ca<sup>2+</sup> + phospholipid; in the extrinsic pathway the earlier stages of the cascade are bypassed and the activation of factor X to factor Xa is effected by the combination of factor VIIa + thromboplastin; this second pathway occurs when tissue extracts are present in optimal amounts and is much more rapid than the intrinsic pathway.

**blood group** any of various systems of classifying erythrocytes according to their surface isoantigens. In humans 14 different, genetically independent blood-group systems are known. They arise from naturally occurring antibodies and from the blood-group substances, antigenic substances present on the surface of the erythrocytes of only certain members of a species. These antigens are also found in a wide variety of other tissues, including endothelial and epithelial cells, and in certain body fluids. The specificities of the blood-group antigens arise in some cases from oligosaccharide chains linked to protein or lipid (ceramide); antigens that fall into this category are those associated with the ABH system, Lewis system, Ii system, and PIIP-related system. In other cases, antigenicity arises directly from the polypeptide chain composition of a surface protein; antigens that fall into this category are associated with the MN system, Ss system, Gerbich system, Rhesus system, Kell system, Duffy system, and Cromer-related system. The blood-group substances were discovered because of the presence in human blood of naturally occurring antibodies (Le. not resulting from infection or other external cause) that react with these antigens on red blood cells causing them to agglutinate. Only the presence of a blood-group antigen during fetal life ensures that no antibody against it will be produced. Hence if blood from an individual (the donor) who lacks a particular antigen is transfused into an individual (the recipient) who possesses the same antigen, a transfusion reaction will result in the recipient owing to the presence in the donor's blood of antibody against the antigen in question. The blood-group substances have therefore been of interest largely in relation to blood transfusion, and in most cases the true physiological function of these substances is unknown.

**blood-group substance** any of numerous antigenic substances present on the surface of erythrocytes of certain members of a species but absent from those of other members of the same species. These same antigens are also found in a wide variety of tissues and in certain body fluids, e.g. saliva, milk, gastric juice, seminal fluid, urine, and ovarian-cyst fluid. The specificities of the A, B, and H antigens of the ABO system are determined by structures present at the nonreducing ends of oligosaccharides of both glycoproteins and glycolipids. The Lewis antigens, Lea and Leb, are associated with glycosphingolipids adsorbed from plasma lipoproteins on to adult

## blue shift

cells and are not synthesized in the developing erythrocyte. Antigenic determinants of the MN system are associated with glycoproteins rich in sialic acid.

**blood plasma** 1 the fluid portion of blood in which the red blood cells and other cellular components (the 'formed elements') are suspended. Clotting may be prevented by the addition of disodium hydrogen citrate which removes ionized Ca<sup>2+</sup> by the formation of an un-ionized complex. Fluoride or oxalate may also be used to precipitate the Ca as an insoluble salt. Heparin is often used. When whole blood containing such an anticoagulant is centrifuged, the formed elements sediment in a volume equal to about 45% of the total volume of blood. The supernatant is known as the plasma. In vertebrates it is clear and almost colourless and clots as easily as whole blood. See also anticoagulant. Compare serum.

**blood sugar** old term for the glucose concentration in the blood; when estimated by older methods it included small amounts of other reducing substances. See also glycemia.

**blotting** or blot transfer a technique useful for identifying similar macromolecules, e.g. sets of DNA or RNA fragments, or mixtures of intact proteins, that are separable by gel electrophoresis. The separated components are then transferred from the gel to a sheet of an appropriate medium while preserving their two-dimensional relationships. This can be achieved either by capillary flow between an underlying wick loaded with buffer solution and an overlay of dry blotting paper, or by applying an electric potential to move separated components on to the medium, to which they bind firmly. Once on the transfer medium the substances may be detected with specific radioactive or fluorescent probes, e.g. complementary polynucleotides or antibodies. The original version of the technique, used for DNA fragments and often referred to as Southern blotting, has been extensively developed and adapted for other applications, e.g. dot hybridization (or dot blotting), colony hybridization, electrophoretic transfer, Northern blotting, and Western blotting.

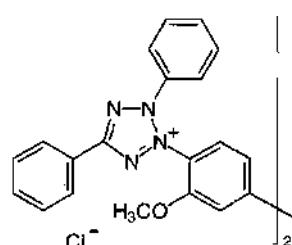

**blue agarose** any insoluble beaded form of agarose gel that is artificially cross-linked between the individual polysaccharide chains and conjugated with the dye Reactive Blue 2. Carboxymethyl (CM) or diethylaminoethyl (DEAE) groups may also have been introduced. It is useful in triazine-dye affinity chromatography.

**blue dextran** a soluble dextran, of average M<sub>r</sub> 10<sup>6</sup>, conjugated with the dye Reactive Blue 2. It is useful in gel filtration for checking column packing and determining the void volume.

**blue-green algae** an alternative name for cyanobacteria.

**blue oxidase** any of a small number of copper-containing oxidase enzymes in which the product of enzyme action in the reduction of dioxygen is water. Blue oxidases are the most complicated of copper proteins; the blue colour is due to a strong absorption band around 600 nm. Among the blue oxidases are laccase (EC 1.10.3.2), L-ascorbate oxidase (EC 1.10.3.3), and the weak oxidase ceruloplasmin.

**blue shift** any shift of the peaks of absorption or emission of a spectrum of electromagnetic radiation to shorter wavelengths, including from the visible to the ultraviolet region.

Blue Tetrazolium

## Blue Tetrazolium

**Blue Tetrazolium or Tetrazolium Blue** 3,3'-dianisole bis[4,4'-(3,5-diphenyl)tetrazolium chloride]; a dye that yields a dark-blue diformazan pigment on reduction; it has a redox potential of approximately -0.08 V. It is useful as a stain for bacteria and moulds, in histochemical studies to demonstrate oxidoreductase activity, and in the colorimetric assay of some dehydrogenases.

**blunt end (of DNA)** an alternative term for flush end (of DNA). **B lymphocyte or B cell or (archaic) bursacyte** any 'bursa-dependent' lymphocyte concerned in the synthesis of circulating antibody. B lymphocytes arise from primitive lymphoid cells of the bone marrow and develop into the plasma cell series. Their maturation is determined by processing within the bursa of Fabricius in birds, or equivalent hematopoietic tissue in other vertebrates. B lymphocytes may be differentiated from T lymphocytes by their surface markers which contain immunoglobulins. In humans the majority of B lymphocytes are derived from bone marrow stem cells, but a minor population, distinguished by the CD5 marker, appears to form a self-renewing set. Cells in this set respond to a number of common microbial antigens and sometimes generate autoantibodies.

**8mi-1** a murine gene encoding a protein that is probably a transcriptional regulator. It is named from B-cell-specific Moloney murine leukemia virus integration site. The protein contains putative zinc finger and helix-loop-helix domains, as well as C-terminal PEST sequences. See PEST hypothesis.

**BMP abbr.** for bone morphogenetic protein.

**BMR abbr.** for basal metabolic rate.

**BNP abbr.** for brain natriuretic peptide (see natriuretic peptide).

**boat conformation** any conformation of a nonplanar six-membered saturated ring compound when ring atoms in relative positions 1, 2, 4, and 5 lie in one plane, and those in relative positions 3 and 6 lie on the same side of that plane. Boat conformations of a monosaccharide or monosaccharide derivative may be designated by the conformational descriptor -E. See also cyclic compounds at conformation.

**Boc or ,BOC symbol** for the tert-butoxycarbonyl group,  $(\text{CH}_3)_3\text{C}-\text{O}-\text{CO}-$ , a protecting group used in polypeptide chemistry. It can be introduced using reagents such as *di-tert-butyl dicarbonate* (Boc anhydride).

**BOD abbr.** for biochemical oxygen demand.

**body water** the water content of the body of an organism. The total body water (abbr. TBW) of a man of average build (70 kg) has a volume of approximately 42 L and represents  $\approx 60\%$  of the body weight. It may be divided functionally into two parts: intracellular fluid and extracellular fluid.

**Bohr 1** Christian Bohr (1855-1911), father of N. H. D. Bohr (see def. 2). Danish physiologist noted for his researches on the binding of dioxygen to hemoglobin (see Bohr coefficient, Bohr effect). **2** Niels Henrik David Bohr (1885-1962), son of C. Bohr (see def. 1), Danish physicist distinguished for his theories of atomic and nuclear structure and their applications; Nobel Laureate in Physics (1922) 'for his services in the investigation of the structure of atoms and of the radiation emanating from them'.

**Bohr coefficient** (for hemoglobin) the ratio of the change in the logarithm of the partial pressure of oxygen when there is half-saturation of the hemoglobin to the change in pH; i.e.  $\Delta \log P_{50} / \Delta \text{pH}$ . See also Bohr effect. [After C. Bohr; see Bohr (def.2).]

**Bohr effect** the variation of oxygen affinity of hemoglobin with pH (the oxygen affinity increases with increasing pH). It is one of the effects arising from oxygen-linked acid groups in hemoglobin and similar oxygen-carrying proteins, and also encompasses similar effects involving other acid-linked functions, e.g. oxidation loss of protons causing increased dioxygen binding. The effect was discovered by C. Bohr *et al.* following observations that changes in the partial pressure of  $\text{CO}_2$  influence the oxygen equilibrium of the blood.

**Bohr magneton symbol:**  $\mu_B$ ; the intrinsic magnetic moment of an electron given by  $\mu_B = eh/4Im_e$ , where  $e$  is the elementary charge,  $h$  is the Planck constant, and  $m_e$  is the rest mass of an

## bombyxin

electron. It is a fundamental physical constant, of value  $9.2740154(31) \times 10^{-24} \text{ J T-l}$ . Compare nuclear magneton. [After N. H. D. Bohr; see Bohr (def. 2).] **boivinose** the  $\alpha$ -enantiomer, 2,6-dideoxy- $\alpha$ -xylo-hexose, is a component of some cardiac glycosides.

**Bollum's enzyme** DNA nucleotidylexotransferase, EC 2.7.7.31. See terminal transferase. [After Frederick James Bollum (1927- ), who described it in 1971.]

**Bolton and Hunter reagent or Bolton-Hunter reagent** 3-(4-hydroxyphenyl) propionic acid N-hydroxysuccinamide ester, iodinated with  $^{125}\text{I}$ . This may be the di-iodo derivative, or the commercially available mono-iodo N-succinimidyl 3-(4-hydroxy-5-[ $^{125}\text{I}$ ]iodophenyl)propionate; a reagent for conjugation labelling of polypeptides or proteins with iodine-125. It is specific for free amino groups, which under mild conditions become acylated to form (4-hydroxy-5-[ $^{125}\text{I}$ ]iodophenyl)propionylamino groups. [After Anthony E. Bolton and William M. Hunter who described its use in 1972.]

**Boltzmann constant symbol:**  $k$ ; the ratio of the gas constant,  $R$ , to the Avogadro constant,  $N_A$ . It is given by  $k = R/N_A = 1.380658(12) \times 10^{-23} \text{ J K}^{-1}$  [After Ludwig Boltzmann (1844-1906), Austrian physicist.]

**Boltzmann distribution law** a law describing the population distribution of a system of particles in different energy states but at thermal equilibrium, given by:  $n_j/n_0 = e^{-(E_j-E_0)/kT}$ , where  $n_j$  is the number of particles in energy state  $j$ ,  $n_0$  is the number in the lowest energy state,  $E_j$  and  $E_0$  are the energies of states of  $j$  and 0 respectively,  $T$  is the thermodynamic temperature, and  $k$  is the Boltzmann constant.

**bolus** 1 a soft, rounded mass, especially of chewed food. 2 a large pill, as used in veterinary or clinical medicine.

**bomb calorimeter** an apparatus with which the heat of combustion of a substance may be determined. The substance is placed in a metal bomb with dioxygen under pressure, and then ignited electrically. The heat evolved is measured by the rise in temperature of the water in a surrounding jacket.

**bombesin** a tetradecapeptide amide isolated from frog skin. It has an N-terminal 5-oxoprolyl residue and shows striking sequence homology with other peptides isolated from amphibian skin, all of which have a C-terminal methioninamide residue. The sequence is (toad):

database code (for precursor) BOMB\_BOMOR, 119 amino acids (13.86 kDa). In mammals it is a potent releaser of, *inter alia*, gastrin and cholecystokinin, and bombesin-like immunoreactivity has been detected in mammalian gut and brain. It is mitogenic in a number of cell types and stimulates smooth muscle contraction. The peptide is said to occur in gastrointestinal nerves of mammals, while in frogs and birds it occurs in endocrine cells.

**bombesin receptor** any of several membrane proteins that bind bombesin and mediate its intracellular effects. Binding studies have indicated two receptor subtypes: on gastrin releasing peptide (GRP)-preferring receptors (e.g. rat pancreas), GRP is more potent than neuromedin B; on other receptors (e.g. rat esophagus) neuromedin B is more potent than GRP. All receptors are of the seven-transmembrane-helix, G-protein-coupled type. The effector pathway involves the phosphoinositide/ $\text{Ca}^{2+}$  second messenger system (see phosphatidylinositol cycle). Example from human: database code BRS3\_HUMAN, 399 amino acids (44.41 kDa).

**bombolitin** any of five structurally related peptides from the venom of the bumblebee, *Megabombus pennsylvanicus*, that are rich in hydrophobic amino-acid residues. They all lyse erythrocytes and liposomes, release histamine from mast cells, and stimulate phospholipase A<sub>2</sub>; their properties are similar to those of melittin. Example, bombolitin I: database code BOL1\_MEGPE, sequence IKTTITMLAKLGKVLAHV (1.836 kDa).

**bombyxin** any of a family of brain secretory peptides of the silkworm that activate prothoracic glands to produce

bond

ecdysone. They contain an A and B chain joined by disulfide bonds, and are homologous to vertebrate insulins. Example, bombyxin A-9 (precursor): database code BXA9\_BOMMO, 92 amino acids (10.29 kDa); residues 20-47 are the B chain, 73-92 the A chain.

bond 1 or covalent bond a region of high electron density between atoms that arises, at least partly, from sharing of electrons and gives rise to an attractive force and a characteristic internuclear distance between the atoms. See coordination, dipolar bond, hydrogen bond. 2 the representation of a covalent bond in an extended chemical formula. 3 to join or link together (esp. chemical entities); to ligate (def. I).

bond angle the angle formed between two bonds at a given polyvalent atom.

bond-dissociation energy see dissociation energy.

bond energy 1 the average value of the gas-phase bond dissociation energies (usually at 298 K) of a given type of bond in the same chemical species: mean bond energy. 2 loosely, the free energy change occurring on hydrolysis of a hydrolysable chemical bond.

bonding the act or process of forming a covalent bond (def. I); the state of being so linked. See also domain of bonding.

bond length the distance between the centres of the nuclei of two bonded atoms.

bone the hard, dense connective tissue that constitutes the skeleton of many animals. It consists of an organic matrix impregnated with bone mineral salts. The matrix is made up of 90-95% type I collagen, a small amount of proteoglycan, and a 49-residue protein containing three  $\gamma$ -carboxyglutamate residues, the formation of which is vitamin K-dependent. This protein binds strongly to the hydroxyapatite crystals of the bone mineral. The inorganic part of the bone consists largely of basic calcium phosphate, which is organized into small crystals of hydroxyapatite, 0.8-1.5 nm thick, 2-4 nm wide, and 20-40 nm long, of approximate composition  $\text{Ca}_10(\text{PO}_4)_6(\text{OH})_2$ . Other anions present are carbonate, fluoride, hydroxide, and citrate. Most of the body's  $\text{Mg}^{2+}$ , about 25% of its  $\text{Na}^+$ , and a smaller proportion of its  $\text{K}^+$  is found in bone.

bone GLA-protein (BGPI see osteocalcin).

bone marrow the soft tissue contained within the internal cavities of bones. Red marrow (or myeloid tissue), found in developing bone, ribs, vertebrae, and in parts of the long bones, is actively hemopoietic and contains all the cells of the circulating blood and their precursors together with megakaryocytes, reticulum cells, macrophages, and plasma cells. In adult animals the marrow of many bones, particularly limb bones, becomes filled with fatty tissue known as yellow marrow. In adult mammals, B lymphocytes develop and differentiate in the bone marrow.

bone-marrow-derived cell any cell derived from bone marrow tissue, including erythrocytes, lymphocytes, granulocytes, etc. The term is often used misleadingly to refer to the B lymphocytes.

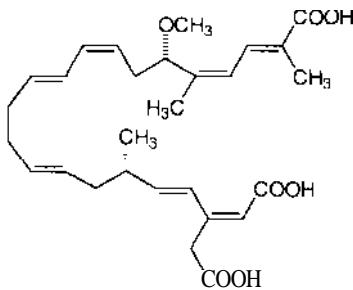

bone morphogenetic protein any of several zinc metallo-endopeptidases enzyme belonging to the sub-subclass EC 3.4.24 and having an EGF motif repeat; they are members of the astacin subfamily. BMP enzymes are disulfide-linked homodimers of the transforming growth factor- $\beta$  family and are related to tolloid. They are involved in induction of bone and cartilage formation. Example BMP-I precursor from human: database code BMPLHUMAN, 730 amino acids (82.81 kDa).

bone sialoprotein 1 see osteopontin.

bongkrekic acid 3-carboxymethyl-17-methoxy-6,18,21-trimethylcyclohexa-2,4,8,12,14,18,20-heptaenoic acid; a toxic antibiotic formed by *Pseudomonas cocovenenans* grown on partially defatted coconut. It is named after 'bongkrek', a product of mouldy Indonesian coconut that becomes highly toxic when the *Pseudomonas* outgrows the mould. It is an inhibitor of oxidative phosphorylation, an effect ascribable to its inhibitory action on mitochondrial adenine nucleotide

botulinus toxin

translocation, apparently by fixing the adenine nucleotides to the translocation sites thus rendering dissociation of the nucleotides from the translocator rate-limiting in the overall transport process. Compare atrocytolside.

booster dose a second or subsequent dose of antigen, especially in the form of a vaccine, given after the priming dose with the object of stimulating rapid production of large amounts of antibody.

Born, Max (1882-1970), German-born British physicist; Nobel Laureate in Physics (1954) 'for his fundamental research in quantum mechanics, especially for his statistical interpretation of the wavefunction' [prize shared with W. W. G. F. Bothe].

Born equation an equation for the free energy change,  $\Delta G$ , when a sphere of charge  $e$  and radius  $r$  is brought into a uniform medium of unvarying dielectric constant  $D$ :

$$-\Delta G = (1 - 1/D)(e^2/2r).$$

borohydride any member of a group of compounds with the structure  $\text{MBH}_4$ , where M is an alkali metal. These compounds will reduce aldehydes, ketones, and Schiff bases in nonaqueous solvents, and also acids, esters, acid chlorides, and nitriles. 3H-labelled borohydrides are useful for the facile reductive tritiation of the aforementioned compounds.

boronyl the group  $-\text{B}(\text{OH})_2$ ; it is used attached to a matrix to complex with cis-diols (as in some saccharides).

borosilicate (glass) a silicate glass containing at least 5% boric oxide. Such a material has a high melting point and a low coefficient of thermal expansion, and hence is useful for the manufacture of heat-resistant glassware.

*boss* symbol for bride-of-sevenless gene (see Sevenless protein).

Bothe, Walther Wilhelm Georg Franz (1891-1957), German experimental physicist noted for his development (with H. Geiger) of the coincidence method of particle counting and for his discovery of the particle later identified as the neutron; Nobel Laureate in Physics (1954) 'for the coincidence method and his discoveries made therewith' [prize shared with M. Born].

bottom yeast the popular name for any of various strains of brewers' yeast that effect fermentation at a comparatively low temperature and tend to sediment to the bottom of the fermentation vessel. It is used for the manufacture of light beers, e.g. lager. Bottom yeast is generally distinguishable from top yeast by its ability to produce extracellular p-galactosidase, EC 3.2.1.23.

botulinus toxin a mixture of exotoxins formed by *Clostridium botulinum*, the causal agent of botulism, that is a potent inhibitor of acetylcholine release from cholinergic neurons, possibly by inactivation of actin involved in transmitter exocytosis. There are several types, depending on the strain of the producing organism; all comprise a disulfide-linked heterodimer of heavy (H) and light (L) chains. The L chain has the pharmacological activity and the B chain has domains that mediate channel formation (N terminus) and toxin binding (C terminus). Example, type A precursor: database code

## Bouguer-Beer law

BXA\_CLOBO, 1295 amino acids (149.15 kDa): amino acids 1-447 form the L chain and 448-1295 form the H chain.

**Bouguer-Beer law** another name for Beer's law (def. 1).

**Bouguer's law** a physical law stating the relation between the amount of light transmitted by an absorbing medium and its thickness, based upon the finding that successive equal thicknesses of sheets of glass absorbed equal fractions of the light incident upon them. It may be expressed in the form  $I_{trs} = I_0 e^{-kd}$ , where  $I_0$  is the intensity of the incident light,  $I_{trs}$  is the intensity of the transmitted light,  $d$  is the thickness of the absorbing medium, and  $k$  is a constant. The law was later restated by Lambert — see Lambert's law (of absorption) — and extended to solutions by Beer — see Beer's law (def. 1). [After Pierre B. Bouguer (1698-1758), French astronomer and mathematician who discovered it in 1728.]

**boundary** any zone of transition, either between solvent and solution or between two solutions; i.e. a zone in which the composition of a solution changes.

**boundary spreading** the broadening of a boundary during ultracentrifugation of macromolecules due to the effects of diffusion.

**bound-to-free ratio abbr.:** B/F ratio; the ratio of the amount of a ligand bound by a specific macromolecule or receptor to the amount of ligand free in solution, in a specified system. Plotting  $[B]/[F]$  versus  $[F]$  yields a Scatchard plot.

**bouvardin** a cyclic hexapeptide isolated from the plant *Bouvardia ternifolia*, used as a drug against dysentery. It has anti-tumour properties and inhibits eukaryotic protein synthesis.

**bovine** of, belonging to, or characteristic of the ox tribe Bovini, which includes cattle, especially of the genus *Bos*.

**bovine albumin** or bovine serum albumin see serum albumin.

**bovine pancreatic inhibitor** or bovine pancreatic trypsin inhibitor or basic protease inhibitor a protein from cattle pancreas that inhibits trypsin, kallikrein, chymotrypsin, and plasmin. A popular molecule for studies on protein folding, etc., it contains three disulfide bonds. Database code: NRL\_5PTI and others (e.g. NRL\_ITGSZ with bound proteinase). The sequence is:

RPDFCLEPPYTGPCKARIIRYFYNAKAGLCQT-  
FVYGGCRAKRNNFKSAEDCMRTCAGGA.

(10.903 kDa). The 3-D structure is also known.

**bovine spongiform encephalopathy abbr.:** BSE; a transmissible dementia in cattle, sometimes also known as 'mad cow disease', characterized by a spongy degeneration of neuronal cells in the brain and also enlargement of the astrocytes therein. It appears to be caused by a prion, and original outbreaks were thought to be the result of feeding cattle on offal derived from sheep infected with scrapie.

**Bowman-Birk inhibitor** see soybean trypsin inhibitor.

**Bowman's capsule** or glomerular capsule the dilated, cup-shaped vesicle at the proximal end of a nephron that encloses a knot of blood capillaries constituting the glomerulus. It is the site of primary filtration of blood into the nephron. [After William Paget Bowman (1816-92), British histologist and ophthalmic surgeon.]

**Boyden chamber** an apparatus, consisting of two small chambers separated by a micropore filter, used in the study of chemotaxis.

**Boyle's law** see gas laws. [After Robert Boyle (1627-91), Irish chemist and physicist.]

**bp** symbol for base pair(s).

**b.p.** abbr. for boiling point.

**BP** abbr. for 1 blood pressure. 2 British Pharmacopoeia.

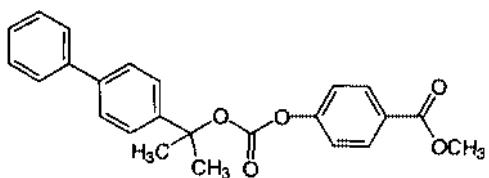

**BPC** abbr. for British Pharmaceutical Codex.

**B peptide** or fibrinopeptide B the 20-residue peptide cleaved from the  $\beta$  chains of a fibrinogen molecule when it is converted into fibrin by the proteolytic action of thrombin.

**BPG** abbr. for 2,3-bis(phospho)-D-glycerate.

**BPOC** abbr. for biphenylisopropylloxycarbonyl-; an acid-labelling

group for amino acids, introduced using, e.g., 2-(4-biphenyl)-prop-2-yl 4'-methoxycarbonylphenylcarbonate (reagent structure shown).

**Bq** symbol for becquerel.

**Br** symbol for 1 bromine. 2 the butyryl group.

**brachyurin** EC 3.4.21.32; other name: collagenolytic proteinase; a serine proteinase that catalyses the hydrolysis of proteins with broad specificity for peptide bonds. It degrades native collagen at about 75% of the length of the molecule from the N terminus; it also shows low activity on small-molecule substrates of both trypsin and chymotrypsin. Example from *Uca pugilator* (fiddler crab); database code COGS\_UCAPU, 226 amino acids (23.47 kDa).

**bradykinin** or kinin-9 abbr.: BK; a vasoactive nonapeptide, H-Arg-Pro-Pro-Gly-Phe-Ser-Pro-Phe-Arg-OH, formed by the action of plasma kallikrein, which hydrolyses the sequence out of the plasma globulin kininogen. Glandular kallikrein cleaves kininogen one residue earlier to give the decapeptide Lys-bradykinin (kallidin, abbr.: Lys-BK). Met-Lys-bradykinin is also formed, perhaps by the action of leukocyte kallikrein. Pharmacologically important analogues include des-Arg<sup>9</sup> or BK<sub>1-8</sub> and Ile-Ser-bradykinin (or T-kinin), [Hyp3]bradykinin, and [Hyp4]bradykinin. Bradykinin is formed in a variety of inflammatory conditions and in experimental anaphylactic shock. It is a powerful blood-vessel dilator, increasing vascular permeability and causing a fall in blood pressure; it is also a constrictor of smooth muscle. See also Lysine(arginine) carboxypeptidase.

**bradykinin receptor** any membrane protein that binds bradykinin (BK) and mediates its intracellular effects. Two types of receptor are recognized: B<sub>1</sub> (previously BK<sub>1</sub>), on which order of potency is des-Arg<sup>9</sup>-bradykinin (abbr.: BK<sub>1-8</sub>) = kallidin (Lys-BK) > BK; and B<sub>2</sub> (previously BK<sub>2</sub>), with order of potency kallidin > BK > BK<sub>1-8</sub>. Hence, BK<sub>1-8</sub> is a powerful discriminator. B<sub>1</sub> receptors are considerably less common than B<sub>2</sub> receptors, which are present in most tissues. The rat B<sub>2</sub> receptor is a seven-transmembrane-domain protein which has been shown on activation to stimulate phosphoinositide turnover. Examples: B<sub>1</sub>, database code BRB1\_HUMAN, 353 amino acids (40.44 kDa); B<sub>2</sub>, database code BRB2\_HUMAN, 364 amino acids (41.44 kDa).

**Bragg** 1 (Sir) William Henry Bragg (1862-1942), father of W. L. Bragg (see def. 2), British experimental physicist remembered for his invention of the X-ray spectrometer named after him and particularly for his use of it in collaboration with his son in solving many problems of concerning the arrangement of atoms in crystals; Nobel Laureate in Physics (1915) jointly with W. L. Bragg 'for their services in the analysis of crystal structure by means of X-rays'. 2 (Sir) William Lawrence Bragg (1890-1971), son of W. H. Bragg (see def. 1) British experimental physicist, born in Australia, remembered for his formulation of Bragg's law of X-ray diffraction and for the X-ray crystallographic studies in collaboration with his father that were thus made possible, for his subsequent concern with the application of X-ray crystallography to biological macromolecules, and for playing an important part in establishing molecular biology as an independent discipline; Nobel Laureate in Physics (1915) jointly with W. H. Bragg (see def. 1).

Bragg

**Bragg's law**

**Bragg's law** a law stating that when a crystal is pictured as a set of reflecting planes uniformly spaced at a distance  $d$  and a beam of X-rays of wavelength  $\lambda$  strikes the crystal at an angle  $\theta$ , reinforcement of the reflected waves occurs when  $\sin \theta = n\lambda/2d$ , where  $n$  is an integer known as the **order of reflection**. [After W. L. Bragg; see Bragg (see deL 2).]

**brain-derived neurotrophic factor** abbr.: BDNF; a protein that promotes the survival of neuronal populations located either in the central nervous system or directly connected to it. Example (precursor) from chicken: database code BDNF\_CHICK, 246 amino acids (27.68 kDa).

**brain natriuretic peptide** see **natriuretic peptide**.

**branch** 1 a subdivision of the stem or the root of a plant; any smaller structure growing or arising from a larger one. 2 a side chain attached to the main chain of a molecular entity. 3 to form a branch; to bifurcate; to divide into offshoots. -branched adj.; branching n.

**branched-chain** describing any molecular entity with one or more **branches** (def. 2).

**branched-chain a-keto-acid dehydrogenase** abbr.: BCKDH; EC 1.2.4.4; recommended name: 3-methyl-2-oxobutanoate dehydrogenase (lipoamide); other name: 2-oxoisovalerate dehydrogenase. An enzyme that catalyses the conversion of a-oxo acids to acyl-CoA and CO<sub>2</sub>. Thiamine diphosphate is a coenzyme. The enzyme consists of a multi-enzyme complex of branched chain a-keto-acid dehydrogenase (E1), lipoamide acyltransferase (E2), and lipoamide dehydrogenase (E3). Human enzyme details: E1 is a dimer of  $\alpha$  and  $\beta$  subunits; precursor database code ODBA\_HUMAN, 444 amino acids (50.16 kDa) and ODBB\_HUMAN, 392 amino acids (43.07 kDa); E2 database code (precursor) ODB2\_HUMAN, 482 amino acids (53.43 kDa).

**branched-chain a-keto-acid dehydrogenase kinase** see **[3-methyl-2-oxobutanoate dehydrogenase (lipoamidell kinase)]**.

**branched-chain oxo-acid dehydrogenase phosphatase** see **[3-methyl-2-oxobutanoate dehydrogenase (lipoamidell-phosphatase)]**.

**branched polymer** any polymer in which there are side chains attached to a main chain.

**brancher-deficiency** amylopectinosis *an alternative name for type IV glycogen disease*.

**branching** (in nuclear physics) the simultaneous existence of more than one disintegration pathway for a particular radionuclide.

**branching enzyme** EC 2.4.1.18; recommended name: 1,4-a-glucan branching enzyme; systematic name: 1,4-a-D-glucan: 1,4-a-D-glucan 6-a-v-(1,4-a-D-glucano)-transferase; other names: amylo-(1,4-1,6)-transglycosylase; corn starch branching enzyme II; amylo-transglycosylase; glucanotransferase; starch branching enzyme II; any 1,4-a-glucan branching enzyme that catalyses the transfer of a segment of 1,4-a-glucan chain to a primary C-6 hydroxyl group in a similar glucan chain. Branching enzymes fall into two types: the plant Q-enzymes and the mammalian enzymes, which are able to produce glycogen, a more highly branched molecule than the amylopectin produced in plants by Q-enzymes. The name should always be qualified, e.g. glycogen branching enzyme, amylopectin branching enzyme. Example from *Zea mays*: database code MZEGLUCTR, 799 amino acids (90.42 kDa).

**branch migration** a proposed model to explain the occurrence of apparently branched DNA structures, as seen by electron microscopy, and their conversion into linear duplex DNA. The branched structures may form by association over parts of their lengths of three or more polynucleotide strands. The migration of the branch point is presumed to occur by displacement of a strand from its fellow in one branch by a strand in another. Such a process may occur in transcription or in recombination.

**BRCA** *BRCA1* and *BRCA2* either of two genes implicated in susceptibility to breast cancer. Up to 80% of women who in-

**bridge**

herit mutated forms of either gene develop breast cancer, and *BRCA1* mutations imply a high risk of ovarian cancer.

**brdU or BrdU** abbr. for bromodeoxyuridine (the symbol BrdUrd is recommended).

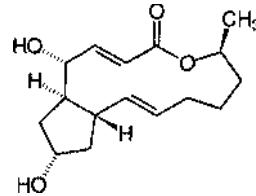

**BrdUrd** symbol for bromodeoxyuridine. Compare **BrUrd**.

**breakage and reunion model** the classical and generally accepted model of chromosomal crossing-over; it involves breakage of the chromatids and reunion of the alternative fragments.

**breakpoint cluster region** term originally suggested for a limited region of 5-6 kb in the base sequence of chromosome 22, in which breakpoints involved in formation of the **Philadelphia chromosome** were found to cluster. Molecular cloning of specific areas of DNA (e.g. band 22q11) gave a probe specific for the breakpoint translocation domain. Subsequent work led to this region being identified as the **BCR** gene.

**breathing** a colloquial term for transient dynamic changes in the structure of macromolecules involving expansion and contraction of the 3-D structure.

**brefeldin A** a fungal metabolite, isolated from *Penicillium brefeldianum*, that inhibits a wide variety of membrane transformations of importance in intracellular transport. It effects a rapid increase in the volume of Golgi cisternae and loss of recognizable Golgi apparatus in treated cells. There is a rapid reversible dissociation of a Golgi-associated peripheral protein identical with a coat protein subunit of non-clathrin-coated vesicles ( $\beta$ -COP). See **coatomer**.

**B region** the site of final epoxidation of carcinogenic polycyclic aromatic hydrocarbons. It is located on the terminal ring of the **bay region** on a bond adjacent to the bay region. Compare **A region**, **Kregion**, **Lregion**.

**brei** a finely and uniformly ground tissue suspension containing all the enzymes of the original material but with the normal spatial relationships between them disrupted. Compare **homogenate**.

**bremsstrahlung** the **X-rays** produced when an electrically charged particle, usually a  $\beta$  particle or an accelerated electron, is decelerated by the electric field of an atomic nucleus. The yield is directly dependent upon the magnitude of the atomic number of the target element. [German: braking radiation.]

**brevetoxin** any of the highly toxic lipid-soluble polyether compounds isolated from *Ptychodiscus brevis* (*Gymnodinium breve*), the red-tide organism. They cause the death of fish and are responsible for shellfish poisoning in humans. They are activators of voltage-dependent Na<sup>+</sup> channels.

**brevin** an alternative term for **gelsolin**.

**brevinin** a secreted amphibian peptide with antibacterial and hemolytic activities. Example, brevinin-1 from *Rana brevipoda porsa*: database code BR LRANBP, sequence

FLPVLAGIAAKVVPAFLCKITKKC.

**brewers' yeast** the common name for strains of the yeast *Saccharomyces cerevisiae* that are used in brewing. In addition to their ability to produce, and remain viable under, appreciable levels of ethanol, such strains are able to ferment maltose, maltotriose, and other sugars in the wort, and to withstand its relatively high osmotic pressure. See also **bottom yeast**.

**bridge** (in chemistry) a valence bond, atom, or unbranched chain of atoms connecting two different parts of a molecule.

## bridgehead

bridgehead (in *chemistry*) either of the two atoms, e.g. tertiary carbon atoms, that are connected by a bridge.

bridge-receptor any molecular entity with two or more specific binding sites able to interact with and join a corresponding number of complementary ligands, which may or may not be the same.

**Briggs-Haldane theory** an alternative to the Michaelis-Menten theory of the kinetics of enzyme reactions for cases where breakdown of the enzyme-substrate complex to products is not slow in comparison with its dissociation to enzyme and substrate. Compare Michaelis kinetics. [After George Edward Briggs (1893-1985), British plant physiologist, and John Burdon Sanderson Haldane (1892-1964), British enzymologist, geneticist, philosopher, and popularizer of science, who put forward their theory in 1925.]

Brij proprietary name for any of a series of polyethylene ethers of higher fatty alcohols. They are surfactants useful for the solubilization of membrane fractions. Brij 35 is polyoxyethylene (23) lauryl ether, aggregation number 40, CMC 92 µM.

British antilewisite abbr.: BAL; another name for dimercaprol. British thermal unit abbr.: Btu; a non-SI unit given by the energy required to raise the temperature of 1 pound of water through 1°F. Since this depends on the temperature of the water, the temperature range should be specified. The Btu(mean), defined as the 1/180 part of the energy required to raise the temperature of 1 pound of water from 32 to 212 OF, is equal to 1055.06 J.

**Srk** abbr. for Bek-related kinase; an alternative name for Cek2. See Cek.

SRN a family of neurally expressed genes encoding brain-specific transcription factors. They contain a POU domain. Brn-3.1 and Brn-3.2 modulate the terminal differentiation of auditory and visual system development respectively. Example, Brn-I from *Mus musculus*: database code BRNI\_MOUSE, 495 amino acids (50.01 kDa).

broad host range relating to the ability of a plasmid to be subjugated as a vector in a broad range of hosts, especially Gram-negative bacteria. Such plasmids are also termed promiscuous.

broad-spectrum antibiotic any antibiotic that is active against a wide range of bacterial species.

Brockmann body a discrete organ, occurring in fish, that contains tissue corresponding to that found in the islets of Langerhans of mammals. One or more Brockmann bodies occur in various teleost species. They are free of pancreatic acinar tissue, which makes them particularly suitable for biochemical studies and a good source of fish insulin. The principal islet weighs in the region of 1-50 mg; smaller secondary islets may also occur.

Brodie's fluid a manometer fluid containing 23 g NaCl!, 5 g sodium tauroglycerate, 100 mg Evan's Blue, and a few drops of an ethanolic thymol solution, in 1000 mL of water; D = 1.033. The standard pressure (760 mmHg) in mm of manometer fluid is 10 000.

bromo+ a variant form of bromo+.

bromelain or bromelin either of two similar cysteine proteinases: stem bromelain, EC 3.4.22.32, isolated from the stem of the pineapple, *Ananas comosus*; and fruit bromelain, EC 3.4.22.33, from the same plant. They are broad-specificity proteinases, similar to other cysteine proteinases but with so far unique geometry and reactivity at the active site. The two types of enzyme are distinguished by the substrate Z-Arg-Arg-NHMec, which is hydrolysed by stem bromelain but not by fruit bromelain. Stem enzyme: database code BROM\_ANACO, 212 amino acids (22.81 kDa).

bromination the introduction of one or more bromine atoms (bromo residues) into an organic molecule, whether by addition or substitution. -brominate vb.

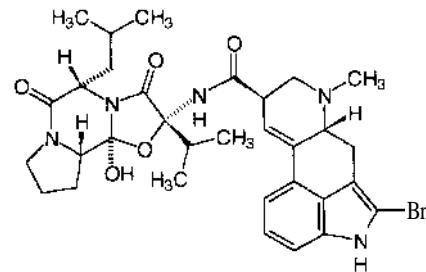

bromine symbol: Br; a halogen element of group 17 of the IUPAC periodic table; atomic number 35; relative atomic mass 79.909. Natural bromine consists of the two isotopes  $^{79}\text{Br}$  and  $^{81}\text{Br}$  at almost equal relative abundances.

## Bromothymol Blue

bromine-82 the radioactive nuclide  $^{82}\text{Br}$ ; half-life 35.3 h; it emits beta radiation (0.444 MeV) and gamma radiation of various energies.

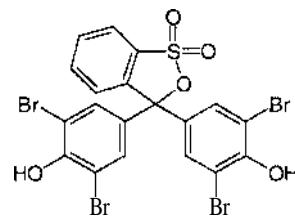

bromo+ or (sometimes before a vowel) brom+ prefix denoting a bromine atom in organic linkage.

bromocriptine or bromoergocriptine 2-bromoergocryptine; an ergotoxin ergot alkaloid derivative that acts as a dopamine ( $D_2$ ) receptor agonist. It inhibits the secretion of prolactin and somatotropin by the pituitary gland, and has potential applications in the treatment of Parkinson's disease.

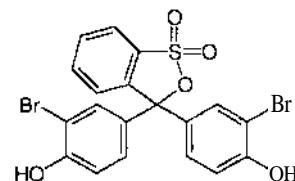

bromodeoxyuridine symbol: BrdUrd; 5-bromo-2'-deoxyuridine; 5-bromouracil 2'-deoxyriboside; a synthetic analogue of thymidine. It acts as an inhibitor of cell differentiation, and also has antiviral properties. See bromouracil.

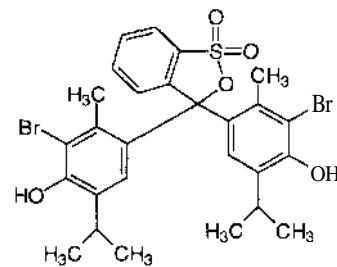

Bromophenol Blue a dye used as a pH indicator, changing from yellow to blue over the pH range 3.0-4.6

Bromophenol Red a dye used as a pH indicator, changing from yellow to red over the pH range 5.2-6.8

Bromothymol Blue a dye used as a pH indicator, changing from yellow to blue over the pH range 6.0-7.6

**bromouracil**

**bromouracil** symbol: BrUra; 5-bromouracil; 5-bromo-2,4(1H,3H)-pyrimidine-dione; a synthetic analogue of thymine with mutagenic activity. It is incorporated into DNA as **bromodeoxyuridine**, which replaces thymidine and induces transitions of G-C base-pairing to A-T pairing. It can be used as a density marker for DNA. The free compound is an inhibitor of dihydrouracil dehydrogenase.

**bromouridine** symbol: B or BrUrd; 5-bromouridine; 5-bromouracil riboside; a synthetic analogue of ribothymidine.

**Brønsted catalysis law** an expression of the relation between the rate constant,  $k$ , of a catalysed reaction, and the  $pK$  of the catalyst:  $\log k = c + bpK$ , where band  $c$  are constants and the value of  $b$  provides a measure of the balance between nucleophilic and general base character of the catalysis. [After Johannes Nicolaus Brønsted (1879-1947), Danish physical chemist.]

**Brønsted-Lowry acid** any chemical species capable of donating a hydron to a base. Examples are  $H_2O$ ,  $H_3O^+$ ,  $CH_3COOH$ ,  $H_2PO_4^-$ ,  $NH_4^+$ . [After J. N. Brønsted (see **Brønsted catalysis law**) and Thomas Martin Lowry (1874-1936), British chemist.]

**Brønsted-Lowry base** any chemical species capable of accepting a hydron from an acid. Examples are  $OH^-$ ,  $H_2O$ ,  $CH_3COO^-$ ,  $HPO_4^{2-}$ ,  $NH_3$ .

**Brookhaven database** see PDB.

**broth** (in bacteriology) any liquid culture medium, especially nutrient broth.

**Brown, Michael Stuart** (1941– ), US physician and molecular geneticist notable for his discovery (in collaboration with J. L. Goldstein) of cellular receptors for low-density lipoproteins and their role in the removal of cholesterol from the bloodstream; Nobel Laureate in Physiology or Medicine (1985) jointly with J. L. Goldstein 'for their discoveries concerning the regulation of cholesterol metabolism'.

**brown adipose tissue** a highly specialized tissue with a high content of lipid and cytochromes found in some animals, particularly hibernating animals and the newborn of some species. It is highly vascular and consists of small polygonal cells, each containing many separate lipid droplets and many mitochondria. Its function is thermogenesis during the arousal period after hibernation or, in the young, to provide heat before shivering has developed. It is active also in normal but not in obese humans. The colour is due to the high cytochrome content. Heat is generated by lipid oxidation through electron transport not coupled to oxidative phosphorylation. The uncoupling is mediated by **brown fat uncoupling protein**. Compare **white adipose tissue**.

**brown fat uncoupling protein** abbr.: UCP; other names: mitochondrial UCP; thermogenin; a dimeric integral mitochondrial inner membrane protein that forms an  $H^+$ -channel, is unique to brown adipose tissue mitochondria, and is important for thermogenesis of this tissue. By causing the membrane to leak protons, it abolishes the proton gradient that drives oxidative phosphorylation, so that electron transport results solely in heat production. Example from mouse: database code UCP\_MOUSE, 306 amino acids (33.08 kDa).

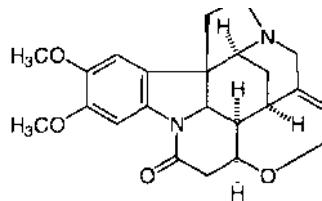

**Brownian movement** the peculiar random movements shown by microscopic particles in a disperse phase, i.e. when suspended in a liquid or gas. It is caused by the continuous irregular bombardment by the molecules of the surrounding

**B-transferase**

medium. [After Robert Brown (1773-1858), British botanist who first observed it in 1827.]

**browning reaction** any of a group of complex reactions, both enzymic and nonenzymic, that occur in some foods during processing and/or storage and cause a brownish discoloration. Members of this group include the oxidation of phenolic compounds (which is believed to be enzymic) together with caramelization, ascorbate decomposition, and the **Mailard reaction** (all of which are believed to be nonenzymic).

**brucine** 2,3-dimethoxstrychnidin-10-one; a highly toxic bitter-tasting alkaloid obtained from *Strychnos* seeds. It is used as a resolving agent for some racemates. Compare **strychnine**.

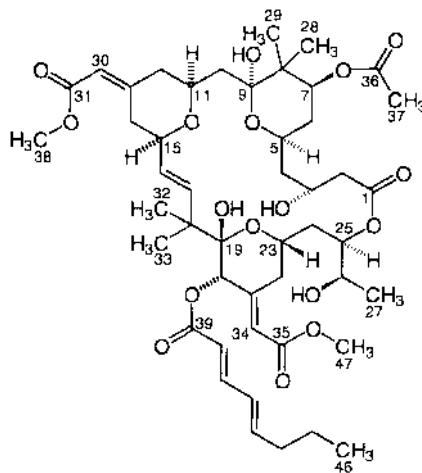

**BrUra** symbol for bromouracil.

**BrUrd** symbol for bromouridine (alternative to B). Compare **BrdUrd**.

**brush border** the dense covering of **microvilli** on the apical surface of epithelial cells in the intestine and kidney. The microvilli aid absorption by increasing the surface area of the cell.

**bryostatin** any of a number of highly potent activators of protein kinase C found in bryozoans, especially *Bugula neritina*. They were isolated as the active anti-leukemic agent of bryozoan extracts. They block phorbol ester-induced differentiation of human promyelocytic leukemia cells and other actions of phorbol esters.

bryostatin 1

**BSA** abbr. for bovine serum albumin. See **serum albumin**.

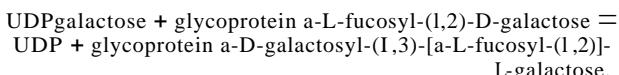

**BSE** abbr. for bovine spongiform encephalopathy.

**B side** the side of the nicotinamide ring of NADH or NADPH at which projects the *pro-S* hydrogen atom (known as  $H_B$ ) at the 4 position. Compare **A side**.

**TTEE** abbr. for N-benzoyl-L-tyrosine ethyl ester (a substrate for the assay of chymotrypsin).

**B-transferase** EC 2.4.1.37; recommended name: fucosylglyco-

protein 3-a-galactosyltransferase; *other name*: [histo-blood group] B transferase; an enzyme that catalyses the reaction:

thus adding galactose to the H antigen of the ABH antigen system, leading to formation of the B antigen. The protein is a product of one allele of the *ABO* gene. It has virtual identity of sequence with that catalysing A-transferase activity, differing only at residues 176 (A has Arg, B has Gly), 235 (A Gly, B Ser), 266 (A Leu, B Met), and 268 (A Gly, B Ala). Database code BGAT\_HUMAN, 354 amino acids (40.89 kDa).

**Btu** abbr. for British thermal unit.

**Bu symbol** for the butyl group.

**BU** (sometimes) abbr. for bromouracil (BrUra is recommended).

**bubble column** a column-shaped bioreactor in which the reaction medium is kept mixed and aerated by the introduction of air at the bottom.

**Buchner**, Eduard (1860-1917), German chemist and biochemist renowned for his seminal discovery that alcoholic fermentation could be initiated with a cell-free press juice from brewers' yeast, the active principle of which he considered to be a protein denoted zymase; Nobel Laureate in Chemistry (1907) 'for his biochemical researches and his discovery of cell-free fermentation'.

**Buchner funnel** a cylindrical funnel for filtration, usually of porcelain or plastic, that includes a perforated plate on which a filter paper is placed. It is generally used with a vacuum. See also Hartley fiber funnel.

**bud** 1 a small lateral or terminal protuberance on the stem of a plant that contains undeveloped foliage or floral leaves. 2 a budlike protuberance on the surface of a yeast cell or other simple organism. 3 to form a bud. 4 to reproduce asexually, as in yeasts, by the process of budding.

**Buddha** suite of computer programs for structure refinement and energy minimization.

**budding** 1 the production of a bud or buds. 2 a form of asexual reproduction, occurring in certain bacteria and fungi (e.g. yeasts) and some primitive animals in which an individual arises from a daughter cell formed by pinching off a part of the parent cell. The budlike outgrowths so formed may sometimes remain attached to the parent cell.

**BUDR or BUDR (sometimes) abbr.** for bromodeoxyuridine (the symbol BrdUrd is preferred).

**bufadienolide** any of various naturally occurring doubly unsaturated lactones of certain steroids with important pharmacological effects on heart muscle (*see* cardiac glycoside). They are so named because they were originally found in the venomous secretion of the skin glands of some toads (*Bufo*), and are hence also known as toad poisons. They also occur in certain plants, e.g. *Digitalis*. See also bufogenin B.

**buffer** 1 any substance or mixture of substances that, when dissolved (usually in water), will maintain its solution at approximately constant pH despite small additions of acid or base. The commonest examples are moderately strong solutions containing both a weak acid and its conjugate base (or a weak base and its conjugate acid). A substance is useful as a buffer over a range of about one pH unit either side of its *pK*, but is most effective at or near the *pK*. Buffer substances used for biochemical or biological purposes include: acetate, bicarbonate, bis-tris propane, borate, citrate, dimethylmalonate, glyciamide, glycylglycine, imidazole, phosphate, succinate, and Tris together with any Good buffer substances. By extension, the term may be applied to agents controlling the activities of various other specified entities, e.g. redox buffer, carbon-dioxide buffer, metal-ion buffer. Also used attributively: e.g. buffer action; buffer salt; buffer solution. 2 a solution of a buffer (def. 1). 3 a short-term storage facility (e.g. as part of the memory of a computer), especially one whose patterns or rates

of input and output can differ. 4 to treat with or to incorporate a buffer (def. 1); to act as a buffer. *See also* buffering capacity, buffer value. -buffered adj.; buffering n.

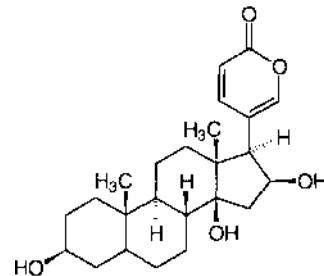

**buffering capacity** or **buffering power** 1 the number of gram-equivalents of either hydrogen ions or hydroxide ions required to change the pH of 1 litre of 1 M buffer solution by one unit. Buffering capacity =  $(1/m)(dn/dpH)$ , where *m* is the number of moles of buffer, and *dpH* is the pH change produced by addition of *dn* equivalents of hydrogen ions or hydroxide ions. 2 an alternative term for buffer value.

**buffer solution** see buffer (def. 2).

**buffer value** or **Van Slyke buffer value** or **buffering capacity symbol**: *f*; the amount of acid or base, in gram-equivalents, needed to change the pH of 1 litre of a buffer solution by one unit at any pH; i.e.  $\beta = db/dpH$ , where *b* is the molar concentration of base in the solution. [After Donald Dexter Van Slyke (1883-1971), US biochemist, who described it in 1922.]

**buffy coat** the layer of white cells that forms between the layer of red cells and the plasma when unclotted blood is centrifuged or allowed to stand.

**bufogenin B**  $3P,14,16P$ -trihydroxy-5p-bufa-20,22-dienolide; a bufadienolide found in the Chinese drug Ch'an Su, prepared from Chinese toads (*Bufo asiaticus*).

**bulge loop** a structure in a polynucleotide duplex in which one strand contains a nonterminal extra sequence that is not able to base-pair with the second strand, thereby forming a bulge on one side of the duplex.

**BUN** abbr. for blood urea nitrogen, an index of the blood-urea concentration.

**bundle sheath** a parenchymal sheath surrounding a vascular bundle in plants.

**bungarotoxin** any of various neurotoxins derived from the venom of the elapid snake, *Bungarus multicinctus*. The chief components are: (1)  $\alpha$  bungarotoxin, a single polypeptide chain of 74 amino-acid residues; it is an irreversible antagonist of nicotinic cholinergic receptors and causes paralysis; (2)  $\beta$  bungarotoxin, a multicomponent protein composed of two polypeptide chains: a long chain (120 amino-acid residues) and a short chain (60 residues); it prevents the release of acetylcholine from cholinergic neurons.

**Bunsen coefficient symbol**: *a*; the absorption coefficient of a gas in a solution. It is defined as the volume of gas in litres, reduced to 273.15 K and 1 atm (101 325 Pa) pressure, that dissolves in 1 litre of liquid when the partial pressure of the gas in the gas phase is 1 atm. [After Robert Wilhelm Bunsen (1811-99), German chemist.]

**bunyavirus** any of a group of RNA animal viruses consisting of enveloped particles, 90-100 nm in diameter with helical nucleocapsids, and containing segmented RNA (minus strand) of 3-4 MDa. The group has been recognized as different from togaviruses and includes arthropod-borne viruses that can cause encephalitis.

**buoyant density** the density of a solute molecule as determined by density-gradient ultracentrifugation. It is the density of the solution, *p*, at the point in the gradient where:  $p = Hy$ , where *y* is the partial specific volume of the solute in question.

## buoyant force

**buoyant force symbol:**  $F_B$ ; the force acting on an object suspended in a liquid due to the liquid displaced by the object. It is given by:  $F_B = VPMg$ , where  $V_p$  is the volume of the object,  $PM$  is the density of the displaced liquid M, and g is the acceleration due to gravity.

**burette or (US) buret** a graduated (often glass) tube with a pinch-clamp, stopcock, or valve at one end used for measuring or dispensing known volumes of fluids, especially liquids. A graduated syringe used for the same purpose may also be termed a burette.

**Burkitt's lymphoma** a malignant tumour of the lymphatic system, most commonly affecting children in tropical Africa within 15° north and south of the Equator. Epstein-Barr virus can be demonstrated in a proportion of cultured tumour cells though it is unlikely that the virus is the sole cause of the malignancy. [After Denis Parsons Burkitt (1911-93), British surgeon.]

**Burnet, (Sir) Frank Macfarlane (1899-1985)**, Australian physician, virologist, and immunologist notable in particular for formulation of the clonal selection theory of acquired immunity; Nobel Laureate in Physiology or Medicine (1960) jointly with P. B. Medawar 'for discovery of acquired immunological tolerance'.

**Burnet's theory of immunity** see clonal selection theory.

**bursacyte** an alternative name (archaic) for B lymphocyte.

**bursa of Fabricius** or cloacal bursa a saclike lymphoepithelial structure opening into the dorsal part of the cloaca in young birds. It usually degenerates as the birds reach maturity. It is associated with humoral immunity and the lymphocytes processed by it are termed B lymphocytes. In mammals it is likely that hemopoietic tissue itself fulfils the equivalent role, providing the appropriate microenvironment for the maturation of B lymphocytes from precursor stem cells.

**bursectomy** removal of the bursa of Fabricius, either by surgery *in ovo* or shortly after hatching, or by destruction *in ovo* by application of, e.g., testosterone. Bursectomy inhibits the formation of B lymphocytes and hence circulating antibody.

**bursin** the tripeptide Lys-His-Gly-NH<sub>2</sub>; a selective B-cell differentiating hormone from the bursa of Fabricius of chickens.

**burst 1** the initial pre-steady-state liberation of the first product, B, in an enzymic reaction of the type:  $E + AB \rightarrow EA + B$  and  $EA \rightarrow E + A$ , where E is the enzyme and A is the second product. 2 the sudden release of phage particles accompanying lysis of a phage-infected bacterial cell. See also burst size, respiratory burst.

**burst size** the mean number of bacteriophage particles set free per infected bacterium upon lysis of phage-infected cells.

**butanediol fermentation** a type of fermentation effected by some members of the Enterobacteriaceae, e.g. *Enterobacter*, *Erwinia*, *Klebsiella*, and *Serratia*, in which glucose is fermented with the production of 2,3-butanediol and other substances.

**butanoyl** another name for butyryl.

**Butenandt, Adolf Friedrich Johann (1903-95)**, German organic chemist and biochemist renowned for his pioneering studies of steroid hormones and pheromones, especially for his isolation and determination of the structures of the first sex hormones (androsterone, estrone, and progesterone) and the first insect hormone (ecdysone), and for the isolation of the first pheromone ( bombykol); Nobel Laureate in Chemistry (1939) 'for his work on sex hormones' [prize shared with L. Ružička].

**butyl symbol:** Bu; the alkyl group, CH<sub>3</sub>-[CH<sub>2</sub>h-CH<sub>2</sub>-], derived from butane.

**butyl-PBD** see biphenylphenyloxadiazole.

**butyrate 1** trivial and preferred name for butanoate; the anion CH<sub>3</sub>-[CH<sub>2</sub>h-COO-], derived from butyric acid (butanoic acid), a saturated, unbranched, aliphatic acid. 2 any mixture of free butyric acid and its anion. 3 any salt or ester of butyric acid.

**butyric acid fermentation** a type of fermentation effected by some saccharolytic species of *Clostridium*, e.g. *C. butyricum*, in which glucose is fermented, with the production of acetic acid, butyric acid, carbon dioxide, and dihydrogen.

**butyrophenone** any of a group of antipsychotic drugs, e.g. haloperidol, that are more selective than the phenothiazine group. Butyrophenones interact rather more specifically with dopamine D<sub>2</sub> receptors and reduce the firing of dopaminergic neurons.

**butyrophilin** a type I membrane protein of mammary gland, probably involved in stimulating the secretion of droplets of fat in milk. Example (bovine, precursor): database code BUTY\_BOVIN, 526 amino acids (59.20 kDa).

**butyryl symbol:** Br; trivial and preferred name for butanoyl; the acyl group, CH<sub>3</sub>-[CH<sub>2</sub>h-CO-], derived from butyric acid (butanoic acid).

**BX-C** abbr. for the bithorax complex, one of two (see ANT-C) major families of homeotic genes in *Drosophila*, mutations in which affect thoracic and abdominal segments.

**byte** a single unit of information handled by a computer; the binary unit required for storage of a character, usually comprising eight bits.

**Bz symbol** for the benzoyl group.

**BZIP** abbr. for basic zipper; a fingerprint of a family of proteins, named after their two main features: a basic region (b) and a leucine zipper domain (ZIP). The basic region harbours a DNA-contact surface, and the leucine zipper domain is essential for homodimer formation or formation of heterodimers with other leucine zipper proteins. The family includes the AP, ATF, and CREB protein transcription factors.

**Bzl symbol** for the benzyl group.

**BZLF1** one of a group of transcription factors related to the *jun* and *fos* gene products. It is involved in the switch from latency to virus-particle production following infection by Epstein-Barr virus. Database code BZLF\_EBV, 245 amino acids (26.83 kDa).

# Cc

c I symbol for a centi+ (SI prefix denoting  $10^{-2}$ ). b cyclic (def. 3) or cyclo+ (denoting cyclic compounds, as in cAMP for cyclic AMP or H<sub>x</sub>c for cyclohexyl. c (*obsolete*) curie (use Ci). 2 abbr. for a complementary (as in eDNA). b *cis* (not recommended). c (*obsolete*) cubic (i.e. to the third power).

c- (in genetics) prefix denoting cellular, as in *c-myc*, the cellular as opposed to viral (v-) version of a (proto)oncogene; see, e.g., MYC.

C symbol for 1 amount-of-substance concentration; that for a particular substance may be denoted by adding a subscript, e.g. C<sub>B</sub> for amount concentration of a substance B. 2 speed (alternative to v, u, or w). 3 (bold italic) velocity (alternative to v, u, or w).

c-abbr. for *cis*.

Co symbol for speed of light *in vacuo*. The subscript may be omitted when there is no risk of ambiguity.

C I symbol for a carbon; see carbon-11, carbon-12, carbon-13, carbon-14. b designating a specific carbon atom, e.g. Col, C-2. c a residue of the a-amino acid L-cysteine (or L-half-cysteine) (alternative to Cys). d a residue of the base cytosine in a nucleic acid sequence. e a residue of the ribonucleoside cytidine (alternative to Cyd). f coulomb. g or (formerly) C' complement (the main components of complement are designated C1-C9). 2 a high-level computer language based on function evaluation and much used in the development of computer software for molecular biology.

·C symbol for degree Celsius (formerly degree centigrade). See Celsius temperature.

C<sub>H</sub> symbol for the constant region of an immunoglobulin heavy chain. The particular constant domain in question may be indicated as CHI, C<sub>H2</sub>, C<sub>H3</sub>.

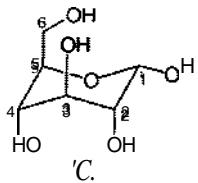

C<sub>L</sub> symbol for the constant region of an immunoglobulin light chain.

C symbol for 1 capacitance. 2 heat capacity (C<sub>p</sub> at constant pressure, C<sub>v</sub> at constant volume, C<sub>m</sub> molar heat capacity). 3 number concentration (C<sub>B</sub> for a substance B).

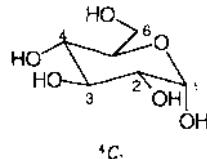

C- (in chemical nomenclature) a locant indicating substitution on carbon; a particular carbon atom may be specified by a right superscript.

-C a conformational descriptor designating the chair conformation of a six-membered ring form of a monosaccharide or monosaccharide derivative. Locants of ring atoms that lie on the side of the structure's reference plane from which the numbering appears clockwise are indicated by left superscripts and those that lie on the other side of the reference plane by right subscripts; e.g. *\_1C*, *.C\_*. See also conformation (def. 2).

*-1C<sub>4</sub>* or (formerly) *-1E* conformational descriptor for an aldopyranose in the chair conformation, with C<sub>2</sub>, C<sub>3</sub>, C<sub>5</sub>, and O<sub>5</sub> in the structure's reference plane, and with C<sub>1</sub> above and C<sub>4</sub> below the plane; e.g. a-D-glucopyranose-*-1C<sub>4</sub>*.

*-4C*, or (formerly) -ct a conformational descriptor for an aldopyranose in the chair conformation, with C<sub>2</sub>, C<sub>3</sub>, C<sub>5</sub>, and O<sub>5</sub> in the structure's reference plane, and with C<sub>1</sub> below and C<sub>4</sub> above the plane; e.g. a-D-glucopyranose-*-4C<sub>1</sub>*.

Ca symbol for calcium.

CAA a codon in mRNA for L-glutamine.

CAAT box or CAT box a conserved sequence in DNA found within the promoter region of the protein-encoding genes of many eukaryotes. It has the consensus sequence GGC-CAATCT and is believed to determine the efficiency of transcription from the promoter.

Cab-O-Sil proprietary name for fumed silica supplied by Cabot Carbon Ltd.

CaBP3 see calreticulin.

CAC a codon in mRNA for L-histidine.

cachectic factor a 24 kDa proteoglycan isolated from the murine adenocarcinoma MAC16 that has been implicated in the production of cachexia. The peptide has the N-terminal sequence YDPEAASAPGSGDPSHEA and has N- and O-glycans. Intravenous injection of the proteoglycan produces rapid weight loss.

cachectin see cachexia, tumour necrosis factor-a.

cachexia a condition caused by chronic disease, such as cancer, and characterized by wasting, emaciation, feebleness, and inanition. It led to the name 'cachectin' for the protein now known as tumour necrosis factor but a 24 kDa proteoglycan has more probably been implicated in this. See cachectic factor.

cacodylate I dimethyl arsenite, the anion (CH<sub>3</sub>)<sub>2</sub>-AsOO<sup>-</sup> derived from cacodylic acid. It is useful as a buffer substance (*pK<sub>a</sub>* = 6.2). 2 any salt of cacodylic acid.

cadaverine 1,5-pentanediamine; a substance formed by microorganisms in decaying meat and fish by the decarboxylation of lysine. It also occurs as an intermediate in the biosynthesis, via lysine, of some quinolizidine alkaloids (e.g. lupinine) in plants.

cadherin any member of a family of calcium-dependent cell adhesion proteins that preferentially interact in a homophilic manner in cell-cell interactions. Cadherins may thus contribute to the sorting of heterogeneous cell types; they are type I membrane proteins. The names of different classes indicate the tissues in which they were first found: E-cadherin is present on many types of epithelial cells; N-cadherin is present on nerve, muscle, and lens cells; and P-cadherin is present on placental and epidermal cells. Typically, cadherins have five similar extracellular domains, the outermost three of which have Ca<sup>2+</sup>-binding sites, and an intracellular C-terminal domain that interacts with the actin cytoskeleton. Examples (all human) E-cadherin precursor: database code CADE\_HUMAN, 882 amino acids (97.35 kDa); N-cadherin precursor: database code CADN\_HUMAN, 906 amino acids (99.75 kDa); P-cadherin precursor: database code CADP\_HUMAN, 829 amino acids (91.32 kDa); three motifs.

cadmium mycophosphat in a cadmium-binding phosphoglycoprotein, M, 12 000; it lacks sulfur-containing amino acids, but is rich in aspartic and glutamic acids and phosphoserine.

CAD protein a multifunctional protein found in many eukaryotes and containing domains for three enzymes of pyrimidine biosynthesis: carbamoyl phosphate synthase (glutamine-hydrolysing); aspartate transcarbamylase; and dihydroorotase. Ex-

## caerulein

ample from *Drosophila melanogaster*: database code PYRI\_DRDOME, 2236 amino acids (248.95 kDa).

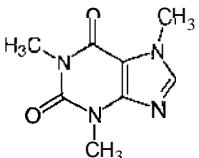

*CaeRorhabditis elegans* a nematode (roundworm), with a genome of about 97 million base pairs. Its cellular anatomy has been fully described, and the nucleotide sequence of the genome determined, revealing over 19 000 genes, 40% of the predicted protein products having significant matches in other organisms.

caerulein the Brit. spelling of cerulein.

caeruloplasmin the Brit. spelling of ceruloplasmin.

caesium alternative spelling (esp. Brit.) for cesium.

caffeine 1,3,7-trimethylxanthine, 3,7-dihydro-1,3,7-trimethyl-IH-purine-2,6-dione; a substance found in certain plants, notably in tea and coffee and the beverages derived from them. It is an adenosine (A<sub>1</sub> and A<sub>2</sub>) receptor antagonist and phosphodiesterase inhibitor, and a stimulant of the central nervous system, affecting the cardiovascular system and causing diuresis. Its actions are similar to those of theophylline but less potent.

caffetannic acid an alternative name for chlorogenic acid.

CAG a codon in mRNA for L-glutamine.

cage carrier see ionophore.

cage compound 1 an alternative name for clathrate (def. 1).2 any compound possessing a nonplanar bicyclic or polycyclic molecular structure that encloses a cavity.

caged ATP a type of protected ATP analogue, e.g. adenosine-5'-triphospho-1-(2-nitrophenyl)ethanol (or the methanol-containing equivalent), that releases ATP in good yield when photolysed by a short pulse of light of 360 nm wavelength. Similarly, guanosine-5'-triphospho-1-(2-nitrophenyl)ethanol is used as caged GTP. These compounds can be introduced into cells prior to photolysis. Caged ATP has been used, e.g., to study muscle contraction on the millisecond timescale.

caged GTP see caged AIP.

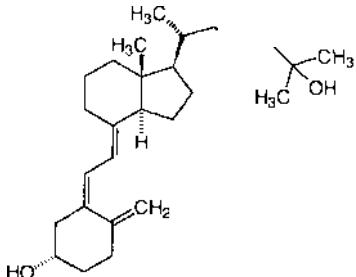

Cahn-Ingold-Prelog rule or Cahn-Ingold-Prelog system an alternative name for sequence rule.

cal symbol for calorie.

calbindin other names: cholecalcin; calbindin D9K; CABP; vitamin D-dependent calcium-binding protein; an EF-hand Ca<sup>2+</sup>-binding protein from intestine. It is present in a variety of cells, including absorptive cells of the duodenum (in which its synthesis is vitamin D<sub>3</sub>-dependent), in hippocampal cells, and in kidney. Example from *Rattus norvegicus*: database code CABI\_RAT, 78 amino acids (8.90 kDa). Example from human: database code CABI\_HUMAN, 78 amino acids (8.88 kDa).

calcemic factor or (esp. Brit.) calcaemic factor the prohormone of parathyroid.

calcidiol the recommended trivial name for calcifediol, 25-hydroxycholecalciferol. It is formed in liver from cholecalciferol, and is the major store of the vitamin in the body, being present largely in plasma. It is the precursor of the hormonal form of the vitamin, calcitriol. See also vitamin D.

## calcitonin

calciductin a name proposed for a 23 kDa sarcolemmal protein that, when phosphorylated by a cAMP-dependent protein kinase, causes an approximately two-fold stimulation of the slow Ca<sup>2+</sup> inward current.

calcifediol 25-hydroxyvitamin D<sub>3</sub>; another name for calcidiol. See also vitamin D.

calciferol an alternative (older) name for ergocalciferol, also known as vitamin D<sub>2</sub>. See also vitamin D.

calcification the deposition of calcium salts in the tissues. It is part of the normal process of bone formation in which hydroxyapatite crystals are deposited, in the neighbourhood of osteoblast cells, in a pre-existing collagen-containing matrix.

calcified describing a tissue that has been solidified by deposition of calcium; having undergone calcification.

calcimedin see annexin.

calcimycin see A23187.

calcineurin or protein phosphatase 2B (abbr.: PP-2B) or CaM-BP<sub>50</sub> a major heat-labile calmodulin-binding protein isolated from bovine brain but later found in all cells from yeast to mammals. It has protein serine/threonine phosphatase activity, and is classified as a protein phosphatase 2B (EC 3.1.3.16). It plays an important role in terminating synaptic transmission, and in T-cell activation. It is only weakly inhibited by okadaic acid, but potently inhibited by certain pyrethrin compounds. It consists of two subunits, A and B, the A subunit having the catalytic activity and the B subunit conferring calcium sensitivity. Examples, from human, A subunit: database code P2BI\_HUMAN, 514 amino acids (58.01 kDa); B subunit: database code CALB\_HUMAN, 169 amino acids (19.17 kDa). The B subunit has a myristylation site at the N terminus.

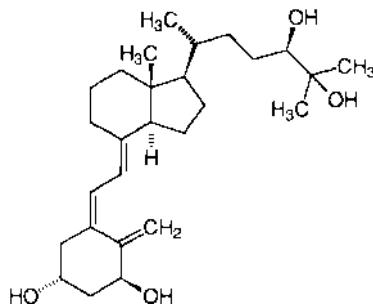

calciof an alternative trivial name for cholecalciferol.

calciosome a discrete cytoplasmic organelle in non-muscle cells, and a candidate for the inositol 1,4,5-trisphosphate-sensitive Ca<sup>2+</sup> store. It has a high content of a calsequestrin-like protein.

calciotropic describing any hormone or other agonist acting on calcium metabolism.

calciphorin a calcium ionophore polypeptide, M, 3000, isolated from the inner membrane of calf mitochondria.

calcitretol the recommended trivial name for 1a,24R,25-trihydroxycholecalciferol. It is the inactivation product of calcitriol, from which it is formed by calcitriol 24-hydroxylase. See also vitamin D.

calcitonin or thyrocalcitonin a 3.4 kDa polypeptide hormone, that regulates the levels of calcium and phosphate in blood. In all species studied it consists of a single polypeptide chain of 32 amino-acid residues with a C-terminal prolinamide residue and an N-terminal seven-membered ring formed by a disulfide bridge between hemicysteine residues at positions 1 and 7. The single letter code structure for the polypeptide is

CGNLSTCMLGTYTQDFNKFH-  
TFPQTAIGVGAP-NH<sub>2</sub>

## calcitonin gene-related peptide

Calcitonin is secreted by the **Ccells**, which in mammals occur primarily in the thyroid gland; in more primitive vertebrates they are found mainly in the ultimobranchial bodies and the lung. The hormone is also found to be concentrated in the hypothalamus of humans and some other vertebrates, and in the primitive brain of the chordate organism *Ciona intestinalis*. Calcitonin causes a rapid but short-lived drop in the level of calcium and phosphate in blood by promoting the incorporation of these ions in the bones. Overall its action is antihypercalcemic, opposing that of **parathyrin**. The response of plasma calcitonin to stimulation by administered **pentagastrin** or calcium may be used to screen for medullary cell carcinoma of the thyroid; the level rises to abnormally high values after stimulation, though normal in its absence. The precursor (human example below) and **calcitonin gene-related peptide** precursor are formed by alternative splicing of the same gene: database code CALO\_HUMAN, 141 amino acids (15.45 kDa); calcitonins have three motifs.

**calcitonin gene-related peptide** abbr.: CGRP; a pleiotropic 3.8 kDa polypeptide of 37 amino-acid residues, found in parts of the nervous system and endocrine system, and in some other organs. It is a potent vasodilator and hypotensive agent, and is regarded as a neuromodulatory peptide. The mRNA is formed by **alternative splicing** of the transcript of the **calcitonin** gene, which has exons coding for a region common to both CGRP and calcitonin precursors together with specific calcitonin and CGRP exons. CGRP was the first peptide to be identified by a molecular approach in the absence of biological information; its existence was predicted, in 1983, on the evidence of a second, structurally distinct transcript resulting from calcitonin gene transcription. Initially a 12.5 kDa pro-CGRP is formed, from which a 55-residue 'amino terminal flanking peptide' is generated. The mature polypeptide has the structure (rat)

a form known as  $\alpha$ -CGRP. Another form, known as  $\beta$ -CGRP, is identical except for Lys instead of Glu at position 35, and is encoded by a separate gene related to the calcitonin/CGRP gene but lacking any exon encoding calcitonin.  $\alpha$ -CGRP is found in the central nervous system in a distribution distinct from that of any other known neuropeptide; it is present in trigeminal and spinal sensory ganglion cells, in olfactory and gustatory systems, and at neuromuscular junctions. CGRP is also found in the endocrine system – in a subset of adrenal medullary cells and in small amounts in thyroid C cells – in bronchiolar cells, and in intestinal cells. Administration of synthetic rat CGRP causes a drop in blood pressure (CGRP is the most potent known hypotensive gene peptide), and increase in heart rate. *In vitro* it can relax arteries from many vascular beds taken from a variety of species, and is one of the most potent vasodilators known. It also inhibits gastrointestinal motility and causes catecholamine release and gastric hypoacidity. See also **amylin**.

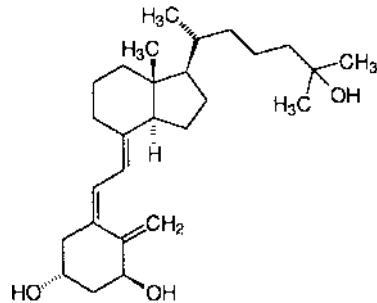

**calcitonin gene-related peptide receptor** any of several membrane proteins that bind calcitonin gene-related peptide (CGRP) and mediate its effects. CGRPI and  $\text{CGRP}_\zeta$  subtypes have been proposed; the antagonist CGRP<sub>8-37</sub> is selective for CGRPI receptors, and [Cys(Acm)Z,7]CGRP for  $\text{CGRP}_\zeta$  receptor types. CGRP receptors are widely distributed in the nervous system, following the pattern of distribution of CGRP, except that receptor numbers are high in cerebellum. They are also widespread in the cardiovascular system, as well as in adrenal, pituitary, exocrine pancreas, kidney, and bone. CGRP receptor stimulation leads to cyclic AMP accumulation in a number of tissues (heart, liver, muscle, pancreatic acinar cells) indicating coupling to one or more G-proteins.

**calcitonin receptor** any of the membrane proteins that bind calcitonin and mediate its effects. They are seven-transmembrane-helix receptors, normally coupled to G-proteins. In

## calcium channel

many systems they can activate both adenylate cyclase and the phosphatidylinositol cycle. In some systems, which second messenger system is activated depends entirely on conditions. For example in synchronized cells of a kidney cell line calcitonin activates adenylate cyclase during the  $G_2$  phase, but activates the phosphoinositide cycle during S phase. Activation of the phosphatidylinositol cycle also causes activation of protein kinase C. In other systems, e.g. in brain, adenylate kinase is inhibited, but not through a G-protein. Example (precursor) from human ovarian small cell carcinoma: database code CALT\_HUMAN, 490 amino acids (57.3 kDa).

**calcitriol**\* the recommended trivial name for 1a,25-dihydroxycholecalciferol. See **cholecalciferol**, **vitamin D**.

**calcium symbol:** Ca; an alkaline-earth metal of group 2 of the IUPAC **periodic table**; relative atomic mass 40.08, atomic number 20; it occurs naturally only in an ionized ( $\text{Ca}^{2+}$ ) or combined state, and is a mixture of stable nuclides of relative mass 40 (96.97 atom percent) and 44 (2.06 atom percent) with small proportions of nuclides of relative mass 43, 46, and 48. Calcium is the fifth most abundant element of the Earth's crust and is an essential component of all living material. It occurs in bone, shell, and teeth and low concentrations of ionic calcium play many important roles in the regulation of diverse cellular processes. The most abundant mineral in the human body, most of it is in the skeleton. It has especially important functions in bone, in the control of nervous, muscle, and other excitable tissue, and as a **second messenger** and regulator of enzyme activity. Calcium homeostasis depends on the action of: (1) **parathyroid hormone**, which increases tubular reabsorption of calcium, and releases calcium from bone, thereby having overall a hypercalcemic action; (2) **vitamin D** (calcitriol), which causes absorption of calcium from the gut and its release from bone, and also therefore has a hypercalcemic action; and (3) **calcitonin**, which reduces calcium resorption from bone. The range of plasma calcium in normal human adults is 2.2–2.6 mmol L<sup>-1</sup>. See also **hypercalcemia**, **hypocalcemia**.

**calcium-45 symbol:**  $^{45}\text{Ca}$ ; an artificial radioactive nuclide of calcium, with a half-life of 165 days. It emits  $\beta$ -particles (i.e. electrons) of 0.252 MeV max. and no  $\gamma$ -radiation.

**calcium-47 symbol:**  $^{47}\text{Ca}$ ; an artificial radioactive nuclide of calcium, with a half-life of 4.54 days. It emits  $\beta$ -particles (i.e. electrons) of two energy ranges (1.98 and 0.67 MeV max.) and  $\gamma$ -radiation of three energies (1.31, 0.815, and 0.49 MeV).

**calcium channel** any of several proteins that permit the controlled (gated) passage of calcium ions through membranes. There are several types. L-type channels are involved in excitation-contraction coupling in muscle; they bind 1,4-dihydropyridine (DHP). The DHP receptor is a protein located in transverse (T-) tubules that specifically binds DHP compounds such as **nifedipine**. This modulates the slow L-type channel in skeletal muscle, neurons, and cardiac cells. N-type channels, identified only in neurons, participate in neurotransmitter release and are blocked by **ro-conotoxin**. T-type channels influence pacemaker activity in the heart and repeti-

## calcium-dependent regulator protein

tive spike activity in neurons; they are blocked by octanol. P-type channels, identified in some CNS neurons and prominent in Purkinje cells, are blocked by co-agatoxin, much less so by co-conotoxin. The L-type channel from skeletal muscle is hetero-oligomeric, consisting of five subunits: α<sub>1</sub>, database code CICLRABIT, 1873 amino acids (211.78 kDa); α<sub>2</sub>, database code CIC2\_RABIT, 1106 amino acids (124.90 kDa); β, database code CICB\_RABIT, 524 amino acids (57.76 kDa); γ, database code CICG\_RABIT, 222 amino acids (25.03 kDa); and δ ( $M_r \approx 27\,000$ ). The largest subunit (α<sub>1</sub>) is responsible for many of the functional features, including DHP binding and the voltage-gated pore. It is structurally similar to the Na<sup>+</sup> channel α subunit, with four internal repeats of 200–300 amino acids exhibiting sequence homology. Each of these repeats contains six putative transmembrane segments, S1 to S6; segment S4 in all repeats has positively charged groups in -(K/R)XX- repeats (four to six K or R residues per segment), that have been implicated in sensing voltage changes; potential N-glycosylation sites (N residues 79 and 257, rabbit skeletal muscle) and seven potential cAMP-dependent phosphorylation sites (S residues 687, 1502, 1575, 1757, 1772, 1854, T residue 1552) have been identified on the α<sub>1</sub> protein. See also verapamil.

**calcium-dependent regulator protein** or **calcium-dependent modulator protein abbr.: CDR**; former name for calmodulin.

**calcium ion ICa<sup>2+</sup>-release channel** another name for the ryanodine receptor.

**calcium pump** any system that transports calcium ions across a biological membrane from a lower to a higher concentration with the consumption of energy. The term is used especially of the pump in the sarcoplasmic reticulum of muscle of which a transmembrane calcium-transporting ATPase is an integral part.

**calcium-regulated actin bundling protein** a protein that is

probably involved in the formation of filopodia. Example from *Dictyostelium discoideum*: database code ACTB\_DICDI,

295 amino acids (33.31 kDa).

**calcium-transferring ATPase** EC 3.6.1.38; an integral membrane protein that forms an essential component of the calcium pump in sarcoplasmic reticulum. It catalyses the hydrolysis of ATP to ADP and orthophosphate, simultaneously transporting two calcium ions from the cytosol into the sarcoplasmic reticulum for each ATP hydrolysed. Probably comprising 10 transmembrane domains, it is related to other metal-ion-transporting ATPases. A number of types exist. Example, SR/ER type from *Drosophila melanogaster*: database code ATCB\_DROME, 1002 amino acids (109.47 kDa).

**calcium-trigger protein** any of a group of small calcium-binding trigger proteins, including calmodulin, troponin C (see troponin), and parvalbumin.

**calculus** (*pl.* calculi) a concretion of material that forms within the body. It often resembles a small pebble, hence is called a 'stone'. Calculi are most common in the gall bladder or kidney, and are composed variously of organic or inorganic salts, frequently of calcium; cholesterol calculi are gallstones of pure cholesterol.

**calcyclin** other names: prolactin receptor associated protein, growth factor-inducible protein 2A9, S100 calcium-binding protein A6; a small protein that copurifies with prolactin receptor. It is induced in fibroblasts by growth factors and is overexpressed in acute myeloid leukemia. It binds specifically annexin XI. Example from human fibroblasts: database code SI06\_HUMAN, 90 amino acids (10.18 kDa).

**caldecrin** a pancreatic protein that lowers serum calcium. It also has chymotrypsin-like activity, which is not needed for the calcium-lowering effect.

**caldesmon** an F-actin crosslinking protein in thin filaments in smooth muscle and in stress fibres in (nonmuscle) fibroblasts. It also binds myosin and tropomyosin. It appears to be a homodimer comprising two polypeptide chains each with a single actin-binding site and a single self-association site. It controls actin-myosin interactions and inhibits the actin-activated

## calmodulin

ATPase of myosin. Its action is attenuated by calcium-calmodulin and potentiated by tropomyosin. Caldesmon will interact with Ca<sup>2+</sup>-calmodulin (but not with calmodulin alone), an interaction that causes caldesmon to dissociate from F-actin. Example from *Gallus gallus*: database code CALD\_CHICK, 756 amino acids (86.96 kDa). See also caldesmon kinase, caldesmon phosphatase.

**caldesmon kinase** EC 2.7.1.120; the name given to a reaction now known to result from the autoprophosphorylation of caldesmon (by ATP) in the presence of calcium. This autoprophosphorylation abolishes the ability of caldesmon to bind actin.

**caldesmon-phosphatase** EC 3.1.3.55; an enzyme that hydrolyses the phosphate from caldesmon phosphate.

**caldolysin** an extracellular protease isolated from *Thermus aquaticus* strain T-351, an extreme thermophile. It contains 13% carbohydrate by weight, and one atom of zinc;  $M_r$  21000.

**calelectrin** see annexin IV, annexin V, annexin VI.

**calgizzarin** an EF-hand Ca<sup>2+</sup>-binding protein isolated from chicken gizzard smooth muscle. It is also abundant in rabbit lung and is found in other tissues. It has homology with annexin II light chain and is a homodimer (disulfide-linked). It is overexpressed in human colorectal tumours. Example from pig: database code ICAL\_PIG, 713 amino acids (77.04 kDa).

**callose** a linear (1,3)-fi-D-glucan insoluble in water but which dissolves in dilute alkali. The glucan chains form stable triple helices. Callose is a ubiquitous higher plant polysaccharide occurring as a component of specialized, and often transient, cell walls, especially in reproductive tissues and is a component of the cell plate. Callose is rapidly deposited on plasma membranes as drops, plugs, or plates on wounding or physiological stress. Callose deposits on cell walls stain specifically with Aniline Blue or its fluorochrome. Specific hydrolases, e.g. glucan endo-1,3-fi-D-glucosidase (EC 3.2.1.39) for callose and membrane-bound callose synthetase (EC 2.4.1.34) are found in plants. Functionally callose may act as a temporary wall matrix, as a special permeability barrier or as a wall strengthening agent. Other (1,3)-fi-D-glucans include yeast glucan, pachyman, lamarin, scleroglucan, curdlan, leucosin, mycolamarin, paramylon, chrysotamarin, and lentinan.

**callus** 1 a mass of relatively unspecialized tissue that develops at wound sites in plants, forming a protective covering. Callus cells are used in tissue culture as the starting material for the propagation of plant clones. 2 tissue formed during the healing of broken bone.

**calmitine** a mitochondrial Ca<sup>2+</sup>-binding protein of fast-twitch muscle fibres with a characteristic 28-residue signal. The mature protein is identical to calsequestrin of the sarcoplasmic reticulum.

**calmodulin abbr.: CAM**; a small, heat-stable, acidic, calcium-dependent modulator protein that binds four calcium ions per molecule and is then able to stimulate a variety of eukaryotic enzymes or enzyme systems. These include brain adenylate cyclase, cytosolic cyclic nucleotide phosphodiesterase, myosin light-chain kinase, erythrocyte Ca<sup>2+</sup>, Mg<sup>2+</sup>-ATPase, plant NAD<sup>+</sup> kinase, and a number of calcium-dependent protein kinases including phosphorylase kinase (to which it contributes the δ subunits); various other cellular processes such as membrane phosphorylation and microtubule disassembly also are stimulated. Calmodulin consists of a single-chain polypeptide of known sequence, aspartic or glutamic accounting together for about 30% of the total residues; it contains one residue of N<sup>6</sup>-trimethyllysine per mole but no cysteine, hydroxyproline, or tryptophan residues. Calmodulin appears to be ubiquitous within the animal and plant kingdoms, to be without species or tissue specificity, and to be almost invariant in structure, being conserved nearly perfectly throughout evolution; it has EF-hand domains and is similar to, but not identical with, troponin C from muscle. It was known previously by a variety of provisional names including modulator protein, phosphodiesterase activator protein, troponin C-like (modulator) pro-

## calmodulin-dependent protein kinase II

tein, and calcium- (or  $\text{Ca}^{2+}$ )-dependent regulator (or modulator) protein (CDR protein). Examples (1) from black rat: database code NRL\_3CLN, 143 amino acids (16.13 kDa); 3-D structure known; (2) from human, rabbit, other rat species, *Xenopus laevis*, chicken, the sea urchin *Arbacia punctulata*, and *Bos taurus*: database code CALM\_HUMAN, 148 amino acids (16.13 kDa).

**calmodulin-dependent protein kinase II recommended name:**  $\text{Ca}^{2+}$ /calmodulin-dependent protein kinase, EC 2.7.1.123; **other names:**  $\text{Ca}^{2+}$ -CAM kinase II; microtubule-associated protein 2 kinase; multifunctional  $\text{Ca}^{2+}$ -CAM kinase. An enzyme with broad specificity and activated by  $\text{Ca}^{2+}$  that catalyses the phosphorylation of Ser and Thr residues in proteins by ATP. It is involved in cell regulation. An oligomeric polypeptide, it is composed of various combinations of a ( $M_r$ , 60 000) and  $\beta$  ( $M_r$ , 55 000) subunits in a dodecahedral structure. On activation by  $\text{Ca}^{2+}$ -CAM, autophosphorylation occurs as a result of which the enzyme converts to a  $\text{Ca}^{2+}$ -CAM-independent form. Substrates include synapsin I, tryptophan hydroxylase, skeletal muscle glycogen synthetase, and microtubule-associated proteins tau and MAP-2. A synthetic peptide substrate is PLSRTLSVSS. Examples from yeast: type I, database code KCC1\_YEAST, 445 amino acids (50.08 kDa); type II (potentially autophosphorylation enzyme), database code KCC2\_YEAST, 447 amino acids (50.36 kDa).

**calmodulin-like domain protein kinase abbr.:** CDPK; EC 2.7.1.-; **other name:**  $\text{Ca}^{2+}$ -binding Ser/Thr protein kinase. An enzyme that is subject to autophosphorylation and resembles calmodulin-dependent protein kinases. Example from soybean: database code CDPK\_SOYBN, 508 amino acids (57.10 kDa).

**calnexin** a calcium-binding protein of the endoplasmic reticulum. It appears to play a role in the processing of endoplasmic reticulum proteins, in monitoring assembly, and in retaining unassembled or incorrectly folded proteins. It has a single transmembrane helical region. Example from human (precursor): database code CALX\_HUMAN, 592 amino acids (67.57 kDa); residues 1-20 are the signal, 21-592 calnexin.

**calomel electrode** the mercury-mercurous chloride (mercury-calomel) ( $\text{Hg}/\text{Hg}_2\text{Cl}_2, \text{Cl}^-$ ) half-cell that is reversible to chloride ions. Because of its stability and simplicity, it is frequently used in conjunction with a saturated-KCl bridge as a reference electrode in pH meters, etc.

**calorie or (sometimes) gram calorie or small calorie symbol:** cal; any of several units of heat or energy in the CGS system. A calorie originally represented the quantity of heat required to raise one gram of water through one degree centigrade (i.e. Celsius). However, the energy represented by a calorie varies slightly according to the initial temperature of the water. Hence, the International Table calorie (symbol: calIT) is now taken to equal 4.1868 J exactly, while the 15 °C calorie (symbol: calIS) is equal approximately to 4.1855 J. Thermochemical calculations have often used a slightly different value; one thermochemical calorie (symbol: Calth) is now taken to equal 4.184 J exactly. In nutrition and physiology, the term 'calorie' is often used to mean the kilocalorie or Calorie (initial capital), equal to  $10^3$  cain. Use of all these units is now deprecated, the joule now being preferred.

**Calorie or (sometimes) kilogram calorie or large calorie** the name used, especially in nutrition, for the kilocalorie, i.e.  $10^3$  cain. *Compare* calorie.

**calorific** of, relating to, or generating heat.

**calorific value** the amount of heat produced by the complete combustion of a given mass of a substance, such as a fuel or foodstuff. It is usually expressed in  $\text{J kg}^{-1}$ .

**calorigenesis** the production or increased production of heat in an organism. -calorigenic adj.

**calorimeter** an instrument for determining quantities of heat evolved, transferred, or absorbed.

## calsequestrin

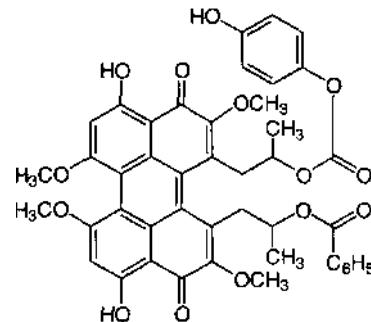

calorimetry the measurement of the amount of heat evolved, transferred, or absorbed by a system. -calorimetric adj.

**calpastatin** see annexin.

**calpain** EC 3.4.22.17; a  $\text{Ca}^{2+}$ -activated, neutral, thiol protease enzyme that preferentially cleaves the bonds: Tyr-I-Xaa, Met-I-Xaa, or Arg-I-Xaa with Leu or Val as the P2 residue. Calpains are cytoplasmic mammalian enzymes, of three main types; these have an identical small regulatory EF-hand subunit and large catalytic subunit but differ in their sensitivity to  $\text{Ca}^{2+}$ . Example (human) calpain II large subunit (responds to millimolar  $\text{Ca}^{2+}$ ): database code CAP2\_HUMAN, 700 amino acids (79.92 kDa).

**calpastatin** a protein, found in liver and erythrocytes of several mammals, that is a specific calpain inhibitor. There are four characteristic domains involved in the inhibitory action. Example (precursor) from pig: database code ICAL\_PIG, 713 amino acids (77.04 kDa).

**calphostin C** one of a group of compounds isolated from *Cladosporium cladosporioides* having a unique structural feature in possessing a perylene quinone. It was identified in a search for inhibition of protein kinases. It inhibits protein kinase C by action on the regulatory domain and has a relatively high degree of specificity, but acts equally on all isoforms having the common regulatory domain. It is a highly potent and specific inhibitor ( $\text{IC}_{50} = 50 \text{ nM}$ ) of protein kinase C. At higher concentrations it inhibits other kinases, including myosin light chain kinase, and cyclic GMP- and cyclic AMP-dependent kinases.

**calphotin** a  $\text{Ca}^{2+}$ -binding protein found in the cytoplasm of photoreceptor cells of *Drosophila melanogaster*. The C-terminal region contains a leucine zipper uninterrupted by prolines. The protein contains >50% proline, alanine, and valine. Database code CPN\_DROME, 865 amino acids (84.78 kDa).

**calponin** a thin filament-associated protein implicated in regulation and modulation of smooth muscle contraction. It is found as an actin-, calmodulin-, and tropomyosin-binding protein present in many vertebrate smooth muscles, and is related to troponin T in immunological and biochemical characteristics. Examples from rat: calponin HI: database code CLPI\_RAT, 297 amino acids (33.31 kDa); acidic isoform: database code CLPA\_RAT, 330 amino acids (36.39 kDa).

**calpromotin** a cytoplasmic protein of red cells that activates  $\text{Ca}^{2+}$ -dependent potassium transport.

**calregulin** see calreticulin.

**calreticulin** **other names:** calregulin; Crp55; CaBP3; HACBP; erp60; a  $\text{Ca}^{2+}$ -binding protein of the endoplasmic reticulum lumen. Example (precursor) from human: database code CRTG\_HUMAN, 417 amino acids (48.09 kDa); amino acids 1-17 constitute the signal; the C terminus contains the KDEL sequence.

**calsequestrin** a 44 kDa calcium-binding protein of low isoelectric point, found on the interior surface of the membrane of the sarcoplasmic reticulum of muscle. It acts as an internal calcium store in muscle and releases  $\text{Ca}^{2+}$  at calcium channels. It has only a moderate affinity for calcium ions, but a high ca-

## calspectin

pacity ( $>40$   $\text{Ca}^{2+}$  ions per molecule); selective binding of  $\text{Ca}^{2+}$  in preference to other cations is promoted by ATP; it also exhibits protein kinase activity. Calsequestrin makes up some 19% of the protein of isolated sarcoplasmic vesicles, and is thought to assist in depleting the sarcoplasm of free calcium ions during relaxation. Example, human muscle isoform: database code CAQS\_HUMAN, 390 amino acids (44.53 kDa), very acidic (47 Asp, 56 Glu; has a sequence of eight aspartic-acid residues at the C terminus).

calspectin *an alternative name for* fodrin.

calstordin a calcium-binding protein of the microsomal lumen of rat brain, similar to calsequestrin.

caltractin *or* centrin an EF-hand  $\text{Ca}^{2+}$ -binding protein of the centrosome of interphase and mitotic cells that plays a fundamental role in microtubule-organizing centre structure. It is present in the centrosome/basal body apparatus of the green alga *Chlamydomonas reinhardtii*. It contains four EF-hands, and belongs to the calmodulin/parvalbumin/tropomodulin superfamily. Example from the salt bush *Atriplex nummularia*: database code CATR\_ATRNU, 167 amino acids (19.22 kDa).

caltrin *abbr. for* calcium transport inhibitor; *other name:* seminalplasmin; a small basic protein of male seminal vesicle fluids. It binds to calmodulin and inhibits  $\text{Ca}^{2+}$  uptake by epididymal spermatozoa. It has antimicrobial properties. Example (precursor, bovine): database code CALT\_BOVIN, 80 amino acids (8.97 kDa).

Calvin, Melvin (1911-97), US chemist and biochemist distinguished for pioneering the use of radioactive isotopes, especially carbon-14, as tracers in metabolism; Nobel Laureate in Chemistry (1961) for his research on the carbon dioxide assimilation in plants'.

Calvin cycle *see* reductive pentose phosphate cycle.

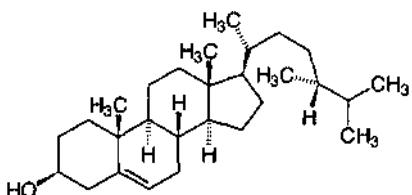

Cam symbol *for* the carbamoylmethyl group.

CAM *abbr. for* 1 calmodulin, 2 crassulacean acid metabolism.

CaM-BP<sub>50</sub> *an alternative name for* calcineurin.

cAMP *abbr. for* cyclic AMP; *see* adenosine 3',5'-phosphate.

campesterol (24R)-ergost-5-en-3 $\beta$ -ol; a sterol found in small amounts in rapeseed and other vegetable oils.

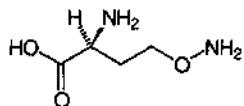

camphor 1,7,7-trimethylbicyclo[2.2.1]heptan-2-one; a compound obtained from the camphor tree, *Cinnamomum camphora*, which is indigenous to Taiwan. It is widely used in ointments and liniments. It is also used as a starting material in organic chemistry.

cAMP receptor protein *see* catabolite (gene) activator protein.

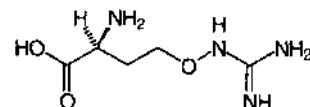

cAMP-regulatory protein *see* catabolite (gene) activator protein.

canaline 04-aminohomoserine; 2-amino-4-(aminoxy)-butanoic acid; HzN-O-[CH<sub>2</sub>-CH(NHz)-COOH]; a basic a-amino acid found as the L-enantiomer in the jack bean, *Canavalia ensiformis*, and in some other legumes containing L-canavanine. It is formed from canavanine by deamidination or transamidination. It inhibits pyridoxal-dependent enzymes.

canavalin a globular protein isolated from ripe seeds of the jack bean, *Canavalia ensiformis*. It is a storage protein, with sequence similarity to phaseolin, vicilin, and related proteins. See also concanavalin A. Example from *Canavalia gladiata*: database code CANA\_CANGL, 445 amino acids (50.29 kDa). canavanase *see* arginase.

canavanine d-guanidino-N-methylethanolamine; 2-amino-4-(guanidinoxy)butanoic acid; a basic a-amino acid, occurring as the L-enantiomer in certain legumes esp. the jack bean, *Canavalia ensiformis*; an arginine antagonist. In seeds of the jack bean it constitutes up to 8% of their dry mass and forms their main storage compound for nitrogen. On germination of the seeds the nitrogen is released for synthetic purposes by hydrolysis of L-canavanine to L-canagine and urea, from each of which ammonium is then formed by further hydrolysis. See also cananine.

cancellate *or* cancellated *or* cancellous having a porous or spongy structure; meshlike or lattice-like.

cancer any malignant neoplasm. Cancers are usually divided into carcinomas, derived from epithelial tissue, and sarcomas, derived from connective tissue.

cancer-associated retinopathy protein *see* recoverin.

candela symbol: cd; the SI base unit of luminous intensity, defined as the luminous intensity, in a given direction, of a source that emits monochromatic radiation of frequency  $540 \times 10^{12}$  hertz and that has a radiant intensity in that direction of  $1/683$  watt per steradian.

*Candida* a genus of (in many cases) dimorphic yeasts containing species of medical (*C. albicans*) and industrial importance: *C. cylindrica* is a source of lipases and is a rare example of a eukaryote with a non-standard genetic code for nuclear/cytoplasmic gene expression.

cane sugar *an old and common name for* sucrose.

cannabinoid any of about 30 derivatives of 2-(2-isopropyl-5-methylphenyl)-5-pentylresorcinol found in the Indian hemp, *Cannabis sativa*, among which are those responsible for the narcotic actions of the plant and its extracts. The most important cannabinoids are cannabidiol, cannabinol, *trans*- $\Delta^9$ -tetrahydrocannabinol, *trans*-L18-tetrahydrocannabinol, and L19-tetrahydrocannabinolic acid. See also cannabis.

cannabinoid receptor any of several membrane proteins that bind cannabinol and structurally similar compounds and mediate their intracellular action. Two types have been characterized, both of which are seven-transmembrane-domain G-protein-coupled receptors. CB1 receptors are found in brain and testis. CB2 receptors are found in spleen and not in brain. For both types arachidonylethanolamide (anandamide) is a putative endogenous ligand and both types are negatively coupled to adenylate cyclase decreasing intracellular cyclic AMP levels. Examples from *Mus musculus*: CB1, database code CBIR\_MOUSE, 473 amino acids (52.94 kDa); CB2, database code CB2R\_MOUSE, 347 amino acids (38.21 kDa).

cannabinol *see* cannabinoid.

cannabis the dried flowering or fruiting tops of Indian hemp, *Cannabis sativa*; numerous synonyms exist, including marijuana, bhang, and maconha. A resin, known variously as cannabinol, hashish, or charas, is also obtained from the plant. Both preparations contain active principles, cannabinoids, and are used as recreational drugs, producing relaxation, euphoria, and enhanced awareness. Occasionally, anxiety or mental disturbance may result, and, rarely, loss of consciousness or even death. The major active ingredients are tetrahydrocannabinols. Cannabis is a controlled substance in the US Code of Federal Regulations.

## cannabis

## Cannizzaro reaction

**Cannizzaro reaction** the base-catalysed dismutation of aldehydes with no  $\alpha$  hydrogen atoms into the corresponding acids and alcohols:

[After Stanislo Cannizzaro (1826–1910).]

**canonical form** or **canonical structure** *an older name for contributing structure.*

**canonical sequence** a nucleotide or amino-acid sequence regarded as the archetype with which variants are compared.

**cap** 1 or **cap structure** a structural feature present at the 5' end of most eukaryotic (cellular or viral) mRNA molecules and also of some virion mRNA molecules but not of bacterial mRNA molecules. It consists of a residue of 7-methylguanosine and a triphosphate bridge linking it 5'-5' to the end of the polynucleotide chain; in addition, the first one or two nucleotide residues in the chain may possess a 2'-O-methyl group and the first, if adenylyl, a 6-N-methyl group. The cap structure is thought to protect the 5' end of the mRNA from degradation by phosphatases or nucleases and to facilitate initiation of translation of mRNA by the eukaryotic (but not by the bacterial) ribosome. 2 a cluster or patch of aggregated proteins at one site on the surface of a cell, e.g. a lymphocyte. Surface components of the cell membrane are aggregated, e.g., by the action of polyvalent ligands, and may be swept to the posterior area of the cell when the cell moves, forming a cap at that site. 3 to form or place a cap on a molecule (or structure).

**CAP** *abbr. for* 1 catabolite (gene) activator protein. 2 chloramphenicol (use deprecated, full name preferred). 3 *Clostridium (histolyticum)* aminopeptidase, EC 3.4.11.13. 4 cyclic AMP receptor protein; *see CRP.*

**capacitance** or **electric capacitance symbol:** C; the ability of a system to store electric charge or a measure of this capacity for a particular system.  $C = Q/U$  where Q is the quantity of charge stored to raise the system's potential by U volts. The SI derived unit of capacitance is the farad.

**capacitance minimization method** a simple method for the determination of asymmetric surface potentials in lipid bilayers, based on the dependence of bilayer capacitance on transmembrane voltage. The capacitance is measured by rectifying the 90° component of an applied a.c. current signal. A superimposed slow triangular wave results in a hysteresis-like time course of capacitance. The centre of the hysteresis figure is shifted along the voltage axis by an amount equal to the capacitance minimization potential, the difference between the dipole plus surface-charge potentials on the two sides of the membrane.

**CAPB** *see calbindin.*

**cap-binding protein** any protein (e.g. a 24 kDa protein obtainable from rabbit reticulocytes) that specifically binds to the cap (def. 1) of eukaryotic capped mRNA. Such proteins may facilitate the translation of capped mRNA molecules.

**CAP factor** *see catabolite (gene) activator protein.*

**capillarity** the phenomenon, resulting from surface tension, in which liquids rise up capillary tubes and which also causes them to form a concave or convex meniscus at their surface where it contacts a solid.

**capillary** 1 of, or relating to, a hair or hairlike structure. 2 of, or relating to, a tube with a very fine bore. 3 any of the very fine blood vessels that form a network between the arterioles and the venules throughout the body. 4 a capillary tube.

**capillary column** a chromatography column that has a very fine bore (0.1–0.25 mm), the inner surface of which may be coated with stationary phase or other support. Such columns are used in gas chromatography, supercritical fluid chromatography, or capillary electrophoresis. The column may be up to a few metres in length, coiled, and made of glass or fused silica. In high-performance liquid chromatography, columns of somewhat wider bore and shorter length are referred to as capillary columns.

**capillary electrophoresis** *abbr.: CE;* a very-high-resolution

## capsaicin

method of electrophoresis, also known as capillary zone electrophoresis (*abbr.: CZE*) or high-performance electrophoresis. It is based on the use of long (up to 100 cm), narrow (<100  $\mu\text{m}$ ) silica columns for separation of peptides, etc. by electroosmotic flow. By using sensitive detectors (e.g. laser-induced fluorescence), sensitivity in the attomole range can be achieved. **capillary filtration** a technique for membrane filtration in which the membrane is supported inside porous capillary tubes (capillary membranes). Bundles of such tubes make up a larger filtration unit. *Compare hollow-fibre technique.*

**capillary viscometer** an instrument for measuring the viscosity of a liquid by determining the rate of flow of the liquid through a capillary tube of known dimensions. An Ostwald viscometer is a simple capillary viscometer; an Ubbelohde viscometer is a viscometer with several different capillary tubes, so that measurements may be made at different shear values.

**capped mRNA** an mRNA molecule that has a cap (def. 1).

**capping** the act or process of forming or placing a cap on a molecule or structure.

**capping enzyme** any guanylyltransferase enzyme concerned in the formation of a cap (def. 1) on an RNA molecule.

**caprate** or **caprinate** *a trivial name for* decanoate, or for any salt or ester of decanoic acid.

**capric acid** or **caprinic acid** *a trivial name for* decanoic acid; *see decanoate.*

**caprin** *a trivial name for* any of the glyceryl esters of decanoic acid (*see decanoate*); these often occur in milk fat, especially the triester tricaprin,  $(\text{CH}_3\text{-}[\text{CH}_2]_8\text{-COO})_3\text{C}_3\text{H}_5$ .

**caprinate** *see caprate.*

**caprynyl** (*formerly*) *an alternative name for* caproyl (def. 1).

**caproate** *a trivial name for* hexanoate, or any salt or ester of hexanoic acid.

**caproic acid** *a trivial name for* hexanoic acid (*see hexanoate*).

**caproin** *a trivial name for* any of the glyceryl esters of hexanoic acid (*see hexanoate*); these often occur in milk fat, especially the triester tricaproin,  $(\text{CH}_3\text{-}[\text{CH}_2]_4\text{-COO})_3\text{C}_3\text{H}_5$ .

**caproyl** 1 or (*formerly*) **caprynyl**; *symbol:* Dco; *trivial name for* decanoyl,  $\text{CH}_3\text{-}[\text{CH}_2]_8\text{-COO}$ , the univalent acyl radical derived from decanoic acid (*formerly* capric acid or caprinic acid). Use of the term caproyl is disfavoured because of confusion with caproyl (def. 2) and capryloyl. 2 *an old trivial name for* hexanoyl, the univalent group derived from hexanoic acid (*formerly* caproic acid), a saturated unbranched, acyclic, aliphatic acid (i.e. fatty acid). It occurs naturally in acylglycerols in, e.g., coconut and palm nut oils, and milk fat. Use abandoned (*see caproyl* (def. 1)).

**capryl** 1 *an old trivial name for* octyl. 2 *an old trivial name for* sec-octyl. 3 *symbol:* Dec; *a trivial name sometimes used for* decyl.

**caprylate** *former name for* octanoate or for any salt or ester of octanoic acid.

**caprylic acid** *a former name for* octanoic acid; *see capryloyl.*

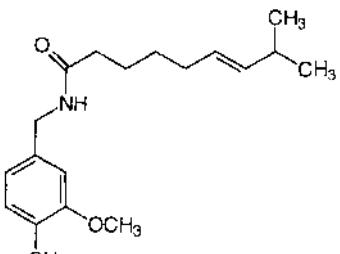

**caprylic alcohol** 1 or **n-caprylic alcohol** *a former name for* (n-) octyl alcohol (octan-1-ol). 2 or **sec-caprylic acid** *a former name for* sec-octyl alcohol (octan-2-ol). *See also* caprylic acid.

**caprylin** *a former name for* any of the glyceryl esters of octanoic acid; these occur in milk fat, especially the triester tricaprylin,  $(\text{CH}_3\text{-}[\text{CH}_2]_6\text{-COO})_3\text{C}_3\text{H}_5$ .

**capryloyl** or **caprylyl** *an old trivial name for* octanoyl.

**Caps** or **CAPS** *abbr. for* 3-(cyclohexylamino)propanesulfonic acid; a compound with properties similar to a Good butler substance,  $\text{pK}_a$  ( $20^\circ\text{C}$ ) = 10.4.

**capsaicin** (*E*)-N-(4-hydroxy-3-methoxybenzyl)-8-methyl-non-6-enamide; the active principle in chilli pepper (*Capsicum*), paprika, and cayenne that causes a burning sensation by stimulation of nociceptive (pain sensory) neurons followed by desensitization of nociceptive responses and neuronal depletion of substance P.

**capsanthin**

capsaicin

**capsanthin** (*3R,3'S,5'R*)-*3,3'*-dihydroxy-*p,K*-caroten-6'-one; the main carotenoid pigment of red pepper (*Capsicum annuum*).

**capsid** the protein coat that surrounds the infective nucleic acid in some virus particles. It comprises numerous regularly arranged subunits, or capsomeres.

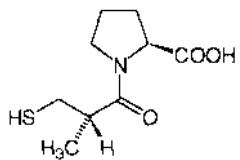

**capsomere** or capsomere any of the (protein) subunits that comprise the closed shell or coat (capsid) of certain viruses.

**cap structure** see cap (def. 1).

**capsular antigen** or capsular polysaccharide or capsular substance any of the antigens, usually polysaccharide in nature, that are carried on the surface of bacterial capsules. The term K antigen is used for those that mask somatic (O) antigens.

**capsule** 1 an outer layer, rich in polysaccharides, that is present in certain types of bacteria. Presence of a capsule is often linked with virulence and the capsular material is often immunogenic. 2 a membrane or sheath of connective tissue that encloses an organ or tissue.

**captopril** D-3-mercaptopethylpropanoyl-L-proline, (*S*)-I-(3-mercaptop-2-methyl-1-oxopropyl)-L-proline; an antihypertensive drug that acts as an inhibitor of angiotensin converting enzyme. It was designed to fit the known active site of carboxypeptidase A; the mercapto group binds to the enzyme zinc ion, the amide carbonyl to a hydrogen-bonding site, and the proline carboxylate to an electrophilic centre. A related compound, enalapril, is more potent when administered orally and has fewer side effects.

captopril

**capture cross-section** the probability of a particle that impinges on an atomic nucleus being captured by that nucleus multiplied by the cross-sectional area of the nucleus (measured in barns).

**carba+** comb. form (in chemical nomenclature) indicating the replacement of a heteroatom by a carbon atom.

**carbamide** former name for ureido.

**carbamino** the chemical group -NH-COO<sup>-</sup>, which is stable only in the salt form. Carbamino compounds are formed by spontaneous reversible reaction of CO<sub>2</sub> with unprotonated primary aliphatic amino groups; e.g. with α-amino acids to form carbamino acids, or with the N termini of proteins, as in

**carbohydrate**

the formation of carbamino hemoglobin from hemoglobin. Compare carbamoyl.

**carbamoyl** or (formerly) carbamyl or carboxamido symbol: Cbm; the acyl group, -CO-NH<sub>2</sub>, corresponding to carbamic acid (an acid unknown in the free state). See also carboxamide.

**carbamoylmethyl** symbol: Cam; the chemical group 2-amino-2-oxoethyl, -CH<sub>2</sub>-CO-NH<sub>2</sub>.

**carbamoyl-phosphate synthase** 1 or carbamoyl-phosphate synthase (glutamine-hydrolysing) EC 6.3.5.5; other names: carbamoyl-phosphate synthetase (glutamine-hydrolysing); GD-CPSase. A glutamine-dependent enzyme that is the first step in the pathway for pyrimidine biosynthesis. It catalyses a reaction between 2 ATP, glutamine, CO<sub>2</sub>, and H<sub>2</sub>O to form 2 ADP, orthophosphate, glutamate, and carbamoyl phosphate; this enzyme is part of the CAD protein in many eukaryotes. 2 or carbamoyl-phosphate synthase (ammonia) EC 6.3.4.16; other names: carbamoyl-phosphate synthetase (ammonia); carbamoyl-phosphate synthetase I, carbon-dioxide-ammonia ligase. An enzyme that incorporates free ammonium ion into carbamoyl phosphate, which then enters the ornithine-urea cycle. It catalyses a reaction between 2 ATP, NH<sub>3</sub>, CO<sub>2</sub>, and H<sub>2</sub>O to form 2 ADP, orthophosphate, and carbamoyl phosphate. Example of latter type from human mitochondria: database code CPSM\_HUMAN, 1500 amino acids (164.6 kDa).

**carbamyl** former name for carbamoyl.

**carbanion** any anion containing an even number of electrons in which a significant part of the excess negative charge is located on one or more carbon atoms.

**carbapenem antibiotic** any of various broad-spectrum *p*-lactam antibiotics, such as thienamycin derived from *Streptomyces cattleya*, that inhibit peptidoglycan synthesis. Semi-synthetic derivatives include imipenem.

**carbene** 1 any chemical species of the type RzC: containing an electrically neutral, bivalent carbon atom with two nonbonding electrons. The spins of such electrons may be either anti-parallel (in the singlet state) or parallel (in the triplet state). Carbenes are highly reactive short-lived groups formed as intermediates in the course of certain organic reactions. 2 or (formerly) methylene the chemical group HzC:, the simplest of the carbenes.

**carbenium ion** any real or hypothetical carbocation with one important contributing structure containing a tervalent carbon with a vacant p-orbital. These structures have often been described as carbonium ions.

**carbenoxolone** glycyrrhetic acid hydrogen succinate, a 3-(3-carboxy-1-oxopropoxy)-II-oxoolean-12-en-29-oic acid, steroid agent with anti-ulcerative effects, the mechanism of which is unresolved.

**carbobenzyloxy** or carbobenoxy former name for benzyloxy-carbonyl.

**carbocation** a cation with an even number of electrons with a significant portion of the excess positive charge located on one or more carbons. This general term includes carbenium ions, carbonium ions, etc.

**carbocycle** any compound or molecular structure that is carboncyclic (def. 1); a carbocyclic (def. 2).

**carbocyclic** 1 describing any cyclic molecular structure containing only carbon atoms in the ring or rings; describing any compound having such a structure. See also homocyclic (def. 1). Compare heterocyclic (def. 1). 2 or carbocycle any such compound.

**carbodiimide** any organic compound of general structure R-N=C=N-R, widely used for forming amide (peptide) or phosphodiester linkages in the laboratory. Water-soluble carbodiimides, e.g. 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide, are used to couple carboxylic acid residues to *N,N'*-dicyclohexylcarbodiimide is much used.

**carbohydrase** former name for glycosidase.

**carbohydrate** any of a group of organic compounds based on

## carbon

the general formula  $C_x(H_2O)_y$ . The group comprises the monosaccharides, oligosaccharides, and polysaccharides, and is usually extended to include their derivatives and, sometimes, the cyclitols. Some of the simplest members of the group may, notionally, be considered as hydrates of carbon. However, note that the very important carbohydrate, 2-deoxy-D-ribose ( $C_5H_{10}O_4$ ), does not fit the empirical formulation.

**carbon symbol:** C; a nonmetallic element of group 14 of the IUPAC periodic table; atomic number 6; relative atomic mass 12.011. It exists in two main allotropic forms, diamond and graphite, and as a third allotrope, fullerene; there are also several amorphous forms, such as carbon black and charcoal. Carbon also forms a vast array of compounds, the organic compounds, based on chains and rings of covalently bonded carbon atoms. There are two stable nuclides, the predominant one being carbon-12. This has a relative abundance in natural carbon of 98.89 atom percent. Its mass is used as the reference standard for all relative atomic masses of nuclides. The other stable nuclide is carbon-13. There are also four radioactive nuclides: carbon-10, carbon-11, carbon-14, and carbon-15.

**carbon-11** a radioactive nuclide of carbon,  $^{11}C$ . It emits a positron ( $\beta^+$ -particle) (0.97 Mev), no  $\gamma$ -ray, and has a half-life of 20.3 min.

**carbon-13 or heavy carbon** the stable nuclide  $^{13}C$ . Relative abundance in natural carbon 1.108 atom percent. It is used as a tracer in studies of reaction mechanisms and of carbon metabolism; now often replaced by carbon-14 unless double labelling is required. Carbon-13 was/is used when a non-radioactive isotope is essential. See also carbon-13 nuclear magnetic resonance spectroscopy.

**carbon-14** a radioactive nuclide of carbon,  $^{14}C$ . It emits an electron ( $\beta^-$ -particle) (0.156 Mev), no  $\gamma$ -radiation, and has a half-life of 5730 years, decaying to  $^{14}N$ . A minute proportion occurs in atmospheric  $CO_2$  due to the action of cosmic rays, and it forms the basis of carbon dating. It is used very widely as a radioactive tracer, for which it is produced artificially.

**carbonate dehydratase** EC 4.2.1.1; systematic name: carbonic anhydrolase; other names: carbonic dehydratase; carbonic anhydrase; an enzyme that catalyses the reversible hydration of carbon dioxide to carbonic acid (or to bicarbonate ion at certain pH values) in a wide range of species. Zinc is a cofactor. It is an intracellular enzyme, present in erythrocytes, and is needed to accelerate the reaction, which, although it occurs spontaneously, would not be sufficiently rapid for the needs of higher animals.  $CO_2$  entering the blood from tissues is taken up by the erythrocytes and released as bicarbonate. At least seven enzymatic forms are known, designated carbonic anhydrases I to VII (abbr.: CA-I to CA-VII). Example of CA-I from *Chlamydomonas reinhardtii* (precursor): database code CAHI\_CHLRE, 377 amino acids (41.63 kDa). Example from human (type I): database code CAHI\_HUMAN, 260 amino acids (28.71 kDa). See also dehydratase.

**carbon cycle** the sum total of chemical and biochemical processes whereby carbon is cycled between carbon dioxide in the atmosphere (and oceans) and organic compounds in organisms and their remains. Atmospheric carbon dioxide is fixed during photosynthesis by green plants and other photoautotrophic organisms, using solar energy to split water molecules and liberate  $O_2$ . The carbon dioxide is thus converted into glucose and other organic compounds, which are used as metabolic fuel and building blocks by the majority of organisms. Aerobic organisms, in particular, are able fully to oxidize organic compounds during respiration to release carbon dioxide to the atmosphere. The carbon stored in the remains of dead organisms is liberated by the respiration of decomposers or, especially that in fossil fuels, by combustion. Hence, photosynthetic organisms and aerobic heterotrophic organisms exist in a state of syntropy. However, green plants and other aerobic autotrophs also liberate carbon dioxide during respiration. Compare oxygen cycle.

**carbon dating or radiocarbon dating** a technique for determin-

## Carbowax

ing the age of specimens of biological origin, e.g. wood. It is based on determining the amount of carbon-14 remaining in the specimen, the known half-life of carbon-14, and the assumption that the abundance of this radionuclide in the atmosphere has remained constant since its incorporation into the material from atmospheric  $CO_2$ .

**carbon-dioxide buffer** any aqueous solution of a water-soluble salt,  $pK_a$  9-10, that, when equilibrated with  $CO_2$ , is capable of maintaining a constant partial pressure of  $CO_2$  ( $pCO_2$ ) in the gas phase in a closed vessel. Carbon-dioxide buffers are used especially in maintaining a constant  $pCO_2$  in manometric experiments on reactions involving the steady production of that gas.

**carbon-dioxide electrode** an electrode system for determining  $CO_2$  tension in a gas or a liquid. It consists of a combination pH electrode bathed in a thin layer of a dilute bicarbonate solution, the whole being separated from the sample by a rubber or silicone-rubber membrane permeable to  $CO_2$  but not to water or ionizable solutes. The pH of the layer of bicarbonate solution, and hence the electrode's response, varies logarithmically with the  $CO_2$  tension in the sample.

**carbon-dioxide fixation** the process whereby the carbon atoms of carbon dioxide are incorporated into hexoses by the reductive pentose phosphate cycle.

**carbon-dioxide snow** solid carbon dioxide in powder form. See also dry ice.

**carbonic anhydrase** common name for carbonate dehydratase. **carbonium ion** any real or hypothetical cation, containing an even number of electrons and at least one penta-coordinate carbon atom, in which a significant part of the excess positive charge is located on one or more carbon atoms. See also carbonium ion, carbocation.

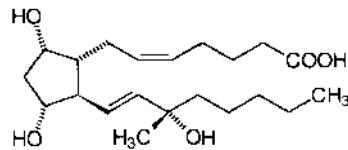

**carbon monoxide** CO; a colourless, odourless, toxic gas that combines with hemoglobin to form carboxyhemoglobin; it also combines with and inhibits cytochrome oxidase. In very small amounts it functions as a neurotransmitter.

**carbon-13 nuclear magnetic resonance spectroscopy or  $^{13}C$ -NMR spectroscopy** a variant of nuclear magnetic resonance spectroscopy in which resonances in carbon-13 nuclei in natural carbon of organic molecules are examined instead of proton responses. Carbon-12 has no NMR spectrum, and with a natural abundance of carbon-13 of 1.11%, a carbon-13 NMR spectrum has a several thousandfold disadvantage in signal-to-noise ratio compared with a proton NMR spectrum. However, the carbon-13 spectrum is much simpler and therefore has a particular advantage in large molecules. Since  $^{13}C$ - $^{13}C$  coupling can be observed, a double labelling tracer technique is possible, using e.g.  $^{13}CH_3$ - $^{13}COOH$  as a precursor in studies of polyketide biosynthesis.

**carbon skeleton** the arrangement of the carbon atoms in an organic molecule.

**carbonyl** the bivalent group =C=O (often written =CO); it is a characteristic group in aldehydes, ketones, and carboxylic acids.

**carboprost** (15S)-15-methylprostaglandin F2<sub>1</sub>; an oxytocic agent used to terminate pregnancy. See also prostaglandins.

**Carbowax** proprietary name for a group of polyethylene glycols of general formula  $H[OCHrCH_2]_n-OH$  and of average  $M_r$  400 to 20 000.

## carboxamide

carboxamide an amide derived from a carboxylic acid. The carboxamide group is  $-\text{CO}-\text{NH}_2$ . See also carbamoyl.

carboxamido *former name for carbamoyl*.

carboxy+ *prefix (in chemical nomenclature) denoting the presence of a carboxyl group.*

carboxyethyl *symbol: Cet; the  $-\text{CH}_2-\text{CH}_2-\text{COOH}$  group.*

4-carboxyglutamic acid or  $\gamma$ -carboxyglutamic acid *symbol: Gla; 1-aminopropane-1,3,3-tricarboxylic acid; a noncoded amino acid, one or more residues of which are present in a number of calcium-binding proteins, e.g. osteocalcin and blood coagulation factors II, VII, IX, and X. It is formed subsequent to biosynthesis of the proteins by vitamin K-dependent carboxylation of glutamic acid residues.*

carboxyhemoglobin a form of hemoglobin in which carbon monoxide has displaced oxygen from the heme group of hemoglobin, to which it binds with much greater affinity and thus less reversibly than oxygen. The formation of carboxyhemoglobin thus reduces the oxygen-carrying capacity of the blood and deprives tissues of oxygen. It is the basis of carbon monoxide poisoning.

carboxyl the chemical group  $-\text{COOH}$  in an organic molecule; it is acidic in character.

carboxylate 1 the anionic group  $-\text{COO}^-$ , formed by dissociation of a carboxyl group. 2 any salt, anion, or ester formed from a carboxylic acid. 3 to perform or undergo carboxylation.

carboxylation the introduction of a molecule of  $\text{CO}_2$  into an organic compound.

carboxylic acid any organic acid containing one or more carboxyl ( $-\text{COOH}$ ) groups.

carboxyl protease *see aspartic proteinase.*

carboxyl proteinase or acid proteinase or aspartic proteinase any enzyme of the sub-subclass EC 3.4.23 (aspartic endopeptidases), a common feature of which is a low pH optimum and an aspartic acid residue in the active centre. It includes pepsins, rennins, and cathepsin D.

carboxyl terminus or carboxyl terminal *an alternative name for the C terminus of a polypeptide chain (also called, less correctly, carboxy terminus or carboxy terminal). -carboxy-terminal adj.*

carboxy-lyase any enzyme of sub-subclass EC 4.1.1 that catalyses a decarboxylation reaction.

carboxymethyl *symbol: Cm; the  $-\text{CH}_2-\text{COOH}$  group.*

carboxymethylation the process of introducing carboxymethyl groups into a substance; e.g. cellulose may be carboxymethylated to produce a cation-exchanger.

carboxypeptidase any enzyme of the sub-subclasses serine carboxypeptidases (EC 3.4.16) or metallo-carboxypeptidases (EC 3.4.17). Both types hydrolyse C-terminal amino-acid residues from oligopeptides or polypeptides. See carboxypeptidase A, carboxypeptidase B, carboxypeptidase H.

carboxypeptidase A EC 3.4.17.1; *other name: carboxy-polypeptidase.* A carboxypeptidase enzyme that catalyses the hydrolysis of peptidyl-L-amino acid to peptide and L-amino acid; zinc is a cofactor.

carboxypeptidase B EC 3.4.17.2; *other name: protaminase.* A carboxypeptidase enzyme that catalyses the hydrolysis of peptidyl-L-lysine (or L-arginine) to peptide and L-lysine (or L-arginine); zinc is a cofactor.

carboxypeptidase E *see carboxypeptidase H.*

carboxypeptidase H EC 3.4.17.10; *other names: carboxypeptidase E; enkephalin convertase; (wrongly) enkephalinase.* A carboxypeptidase enzyme involved in prohormone processing. It catalyses the hydrolysis of peptidyl-L-lysine (or L-arginine) to peptide and L-lysine (or L-arginine); zinc is a cofactor. Example from human: database code CBPH\_HUMAN, 476 amino acids (53.09 kDa).

carboxypeptidase-tubulin *see tubulinyl-Tyr carboxypeptidase.*

carboxy-terminal *see carboxyl terminus.*

carboxy terminus *a less correct alternative term for the C terminus of a polypeptide chain. See also carboxyl terminus.*

carcinoembryonic antigen *abbr.: CEA;* any member of a

## cardioid

subfamily of immunoglobulin-like proteins on the outer cell surface and grouped in the cluster CD66 (*see CD markers*). CD66e, *other name: meconium antigen 100, mass 180-200 kDa,* was first found in extracts of tumour tissue and of normal fetal colon. It is a glycoprotein, attached to the membrane by a GPI-anchor. It is present in elevated concentrations in many patients with colorectal cancer, but its presence is too variable in this and other diseases for screening for the condition. However, it can be used for monitoring therapy. Example, human (precursor): database code CCEM\_HUMAN, 702 amino acids (76.8 kDa). CD66d, *other names: CGM1, CEA gene member 1,* is present on leukocytes and granulocytes, but not lymphocytes, monocytes, or tumours. Several forms are produced by alternative splicing. Example, human (precursor): database code CGMLHUMAN, 252 amino acids (27.08 kDa). CD66b (*formerly CD67*), *other names: CGM6, CEA gene member 6,* is expressed in leukocytes of chronic myeloid leukemia patients and bone marrow. It is attached to the membrane by a GPI-anchor. Example, human (precursor): database code CGM6\_HUMAN, 349 amino acids (38.13 kDa).

carcinogen any agent that directly or indirectly induces the transformation of a normal cell into a neoplastic cell. Such agents include various substances of small *Me* (often termed chemical carcinogens), oncogenic viruses, ionizing radiations, and ultraviolet light. *See also precarcinogen, proximate carcinogen, -carcinogenic adj.*

carcinogenesis the process(es) involved in the production of cancers, including the action of carcinogens on living cells. *See also oncogenesis.*

carcinogenicity the measure or extent of the potency of a chemical carcinogen.

carcinoid (tumour) or argentaffin carcinoma or argentafinoma any tumour arising from argentaffin cells. Carcinoids arise from any site of such cells, notably in the ileocecal region, and produce large amounts of 5-hydroxytryptophan and 5-hydroxytryptamine, the former mainly by bronchial tumours and the latter by the decarboxylase-containing intestinal tumours. Histamine, kinins, and substance P may also be produced.

carcinoma any cancer that arises from epithelial tissue. Carcinomas form malignant tumours that tend to invade lymph spaces in surrounding connective tissue and to spread by lymphatic permeation and embolism; they also enter the bloodstream to form metastases. *-carcinomatous adj.*

cardenolide any of a group of  $C_{23}$  cardiotonic steroids characterized by a 14P-hydroxyl group and an unsaturated  $\gamma$ -lactone ring on C-17. They occur free or as the aglycons of cardiac glycosides in plants and insects.

cardiac 1 of, relating to, or affecting the heart. 2 of, or relating to, the upper part of the stomach.

cardiac glycoside any of a group of toxic steroid glycosides, derived from plants, that in pharmacological doses increase the power of the contractions of the mammalian heart; some are inhibitors of  $\text{Na}^+,\text{K}^+$ -ATPase. The steroid aglycon carries a  $17\beta$  unsaturated pentenyl lactone ring and a 3P-hydroxyl group to which the carbohydrate moiety is attached. Examples are digitoxin from *Digitalis purpurea*, ouabain from *Strophantus gratus*, and strophanthin from *Strophanthus kombe*.

cardiac muscle the specialized muscle of which the walls of the vertebrate heart are made. It is composed of a network (syncytium) of branching elongated cells (fibres) with cross striations, and undergoes spontaneous rhythmical contractions.

cardiac puncture a convenient and quick method for obtaining reasonable volumes of blood from an animal by inserting a syringe needle directly into the heart.

Cardice *proprietary name for solid carbon dioxide. See dry ice.*

cardio+ or (*before a vowel*) cardi+ *comb. form denoting heart.*

cardioid (*in mathematics*) a type of expression that yields a heart-shaped curve.

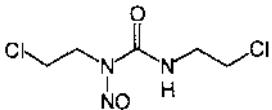

## cardiolipin

cardiolipin an immunogenic 1,3-bis(3-phosphatidyl)glycerol, extracted from beef heart, that is used as an active antigen in the Wassermann reaction and other serological tests for syphilis. It may carry antigenic determinants similar to *Treponema pallidum* or be similar to products of tissue necrosis formed when the spirochaete attacks human tissues.

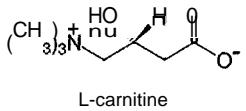

cardiotonic having the effect of improving the tone of heart muscle. Cardiotonic steroids (cardiac glycosides) act directly on heart muscle to restore the power of the heart's contractions.

cardiovascular of, or relating to, the heart and the system of blood vessels.

carmustine 1,3-bis(2-chloroethyl)-1-nitrosourea; an anti-neoplastic derivative of chloroethylnitrosourea with immunosuppressive and antifungal activity.

carnitine  $\gamma$ -amino-p-hydroxybutyric acid trimethylbetaine, 3-carboxy-2-hydroxy-*N,N,N*-trimethyl-*I*-propanaminium hydroxide, inner salt;  $(\text{CH}_3)_3\text{N}^+ \text{---} \text{CH}_2 \text{---} \text{CH}(\text{OH}) \text{---} \text{CH}_2 \text{---} \text{COO}^-$ ; a compound that is found in striated muscle, liver, and other tissues and participates in the transfer of acyl groups across the inner mitochondrial membrane. Carnitine acyltransferases catalyse the transfer of acyl groups to and from acyl-CoA molecules to form O-acylcarnitine, which can exchange across the inner mitochondrial membrane with unacylated carnitine. This cyclic movement of carnitine is sometimes referred to as the carnitine shuttle.

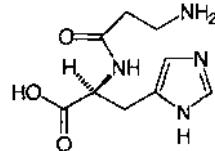

L-carnitine

carnitine acyltransferase or (sometimes) carnitine acylase, any of various enzymes that catalyse a reaction between acyl-CoA and carnitine to form CoA and O-acylcarnitine. Carnitine O-acetyl transferase, EC 2.3.1.7, is a soluble enzyme found (in eukaryotes) in the mitochondrial matrix, peroxisomes, and the lumen of the endoplasmic reticulum. It is specific for short-chain fatty acyl-CoA ( $\text{C}_2 \text{---} \text{C}_{14}$ ), having no activity with palmitoyl-CoA. In transferring acyl groups to carnitine, it maintains the concentration of free coenzyme A, and also provides a mechanism for the transport of acetyl groups, as acetylcarnitine, through the mitochondrial membrane. Example from yeast: database code CACP\_YEAST, 670 amino acids (77.19 kDa). Mitochondrial carnitine palmitoyltransferase, EC 2.3.1.21, exists as two isoforms. One isoform, CPT<sup>I</sup> or CPT-I, is a mitochondrial outer membrane protein involved in regulating fatty acid  $\beta$ -oxidation by controlling the rate of formation of carnitine acyl esters; database code CPT1\_RAT, 773 amino acids (88.04 kDa); another isoform, CPT<sup>II</sup> or CPT-II, is located in the mitochondrial inner membrane and reforms acyl-CoA esters in the mitochondrial matrix after the carnitine esters have been transported through the inner membrane by acylcarnitine:carnitine antiporter.

carnosine N-p-alanyl-L-histidine; a substance that occurs in the skeletal muscle of some animals, including humans (up to 30 mmol kg<sup>-1</sup>). Compare anserine.

## carrier

carnosine

carotene see carotenoid.

carotenoid any of a group of naturally occurring tetraterpenes that are widely distributed in plants and animals but only synthesized by higher plants, algae, fungi, and bacteria. They may be represented formally as consisting of eight isoprenoid (ip) residues and formed by the joining tail to tail of two units each comprising four ip residues joined head to tail: ip.ip.ip.ip.pi.pLpLpi. There are two groups of carotenoids: carotenes, which are hydrocarbons, and xanthophylls, which contain oxygen in various forms. They occur in all photosynthetic tissues, where they function as protectors against photo-sensitization and as antenna pigments in photosynthesis.

carrageenan or carrageen or carrageenin a mixture of sulfated galactans, also known as Irish moss, extracted from red seaweeds (class Rhodophyceae), particularly *Chondrus crispus* and *Gigartina stellata*. It shows blood anticoagulant activity and is used as a gelling and stabilizing agent in foods and pharmaceuticals. Three major types are known: I-carrageenan is the most highly sulfated and contains alternate units of 3-linked p-D-galactopyranose 4-sulfate and 4-linked 3,6-anhydro-a-D-galactopyranose 2-sulfate; K-carrageenan is precipitated by potassium chloride and contains only one sulfate per disaccharide unit;  $\lambda$ -carrageenan is largely devoid of the 3,6-anhydro component. I-Carrageenan forms a kinked double-helical structure. [After Carragheen, near Waterford, Republic of Ireland.]

K-carrageenase EC 3.2.1.83; an enzyme that catalyses the hydrolysis of 1,4-p-D-linkages between D-galactose 4-sulfate and 3,6-anhydro-D-galactose in various carrageenans.

carrier 1 any known or putative component of a biological membrane that effects the transfer of a specific substance or group of related substances from one side of the membrane to the other. The mechanism is supposedly a cyclic process, involving combination of the carrier with the substance(s) on one side of the membrane, diffusion of the combined form across the membrane, release of the substance(s) on the far side, and diffusion of the carrier back across the membrane in uncombined form. See also facilitated diffusion, permease, translocation, transport. 2 any component of a biological fluid (e.g. a blood protein) that can combine with a specific substance (e.g. a hormone or metabolite) and transport it from one part of the organism to another. 3 (in enzymology) any substance undergoing reversible combination with a metabolite or reversible oxidation-reduction and thereby carrying the metabolite, electron(s), or hydrogen atom(s) between enzymes or cellular organelles, or into cells. Some coenzymes may act as carriers. See electron carrier, hydrogen carrier. 4 a substance that is mixed with a reagent or other substance to facilitate the chemical or physical manipulation of the latter. The carrier is commonly of similar constitution and/or properties to the reagent, and present at relatively high concentration. The term is used especially for the nonradioactive chemical counterpart of a radionuclide or of a compound containing a radionuclide, whether deliberately added or present from the time of initial preparation of the radioactive substance. Compare carrier-free. 5 (in chromatography) the mobile phase or a component thereof. See carrier ampholyte, carrier displacement chromatography, carrier gas. 6 or matrix the inert support material to which a small molecule, biopolymer, cell fragment, or intact

## carrier ampholyte

cell is artificially linked to form an immobilized or insolubilized derivative. *See also* microcarrier. 7 any vesiculated structure within which a biologically active substance (e.g. a drug or enzyme) is artificially incorporated, commonly to protect the substance from degradation and/or to direct it to a target organ upon injection into the bloodstream. Such a carrier may be either artificial (e.g. a liposome) or of natural origin (e.g. an erythrocyte ghost). 8 (*in immunochemistry*) any substance of high  $M_r$  (e.g. a protein) to which a non- or poorly immunogenic substance (e.g. a hapten) is naturally or artificially linked to enhance its immunogenicity. 9 (*in genetics*) any individual who is heterozygous for a specified recessive allele and who thus does not normally display any characteristic (e.g. a disease) associated with that allele but who may, with appropriate mating, produce homozygous offspring that exhibit the recessive characteristic. 10 (*in pathology*) any individual who harbours a specified infectious microorganism without showing signs of disease, and is capable of transmitting the microorganism to others. *Compare* vector (def. 2). *See also* vehicle.

**carrier ampholyte** a mixture of amphoteric electrolytes used in isoelectric focusing to generate a linear and stable pH gradient, and in isotachophoresis and ampholyte displacement chromatography. The component electrolytes are commonly of similar constitution, low molecular mass, and closely spaced isoelectric points. *See also* Ampholine.

**carrier displacement chromatography** a variant of displacement chromatography in which substance(s), either related or unrelated, are added to the mixture being chromatographed to assist in the manipulation of the components separated.

**carrier-free** describing a preparation of a radionuclide, or of a radionuclide-labelled compound, to which no carrier has been added, and for which precautions have been taken to minimize contamination with other isotopic nuclides. It does not necessarily imply, however, 100% isotopic abundance. Material of high specific activity is often wrongly referred to as 'carrier-free'; more correctly it would be of high isotope abundance.

**carrier gas** the inert gas that forms the mobile phase in gas-liquid chromatography or gas-solid chromatography and that carries the eluted substances in gaseous form into the detector.

**carrier lipid** *see* undecaprenol.

**carrier protein** any protein that functions as a carrier (def. 8), e.g. acyl carrier protein. The term has been applied more specifically to describe cytochrome  $b_5$ , ADP,ATP carrier protein, and GDC (Graves' disease carrier protein).

**Carr-Price reaction** the reaction of an anhydrous solution of antimony trichloride in chloroform with retinol (vitamin A) to produce a transient blue colour, maximal at about 10 s. It can be used to estimate retinol.

**CARS abbr.** for coherent anti-Stokes Raman spectroscopy.

**Cartesian of, or relating to,** Descartes or his works.

**Cartesian coordinates** a system of coordinates that defines the location of a point in a plane (two dimensions) or in a space (three dimensions) in terms of its perpendicular distance from each of a set (two or three) of mutually perpendicular axes.

**Cartesian diver or** Cartesian devil a device, devised as a toy, adapted as an ultramicrorespirometer, consisting of a small piece of capillary glass tubing open at one end and closed and slightly expanded at the other. A sample of tissue, in approximately 2  $\mu\text{L}$  buffer, is placed in the vessel which is then filled with gas and the neck sealed with a drop of oil. The diver is placed in a constant-temperature vessel filled with a solution in which the diver just floats. If the pressure in the vessel is reduced the diver will rise and if the pressure is increased the diver will fall. The buoyancy of the diver is determined by the gas volume within it, and changes in the latter may be measured by adjusting the pressure in the vessel so that the diver floats in the same position.

**cartilage** a tough, elastic type of connective tissue, found in most vertebrates. It is a major component of the embryonic skeleton, but in higher vertebrates it is mostly converted to

## casomorphin

bone during development. In adult humans, it is largely confined to the ears, nose, trachea, the anterior ends of the ribs, and the articular surfaces of bones. Cartilage consists of a firm resilient matrix, formed by chondroblasts (which become enclosed as chondrocytes), and composed of glycosaminoglycans including chondroitin sulfate A and C, hyaluronic acid, and keratosulfate II, together with varying amounts of collagen. The entire skeleton of some lower vertebrates, notably the cartilaginous fishes (class Chondrichthyes), consists of cartilage. -cartilaginous *adj.*

**cartilage link protein** a protein that stabilizes the aggregates of proteoglycan monomers with hyaluronic acid in the extracellular cartilage matrix. Example (precursor) from human: database code PLK\_HUMAN, 354 amino acids (40.12 kDa).

**cartilage oligomeric matrix protein abbr.:** COMP; a pentameric disulfide-linked  $\text{Ca}^{2+}$ -binding EF-hand protein of the cartilage matrix. Example (precursor) from *Rattus norvegicus*: database code COMP\_RAT, 755 amino acids (82.57 kDa).

**cartilage-specific proteoglycan core protein** a major proteoglycan of the extracellular matrix of cartilaginous tissues. The N-terminal region binds hyaluronic acid. Chondroitin sulfate is the main glycan component, but keratan sulfate and O-linked and N-linked oligosaccharides are also present. It also has an epidermal growth factor-like domain and a Sushi domain. Example (precursor) from human: database code PGCA\_HUMAN, 2415 amino acids (250.19 kDa).

**caryon** a variant spelling of karyon.

**caryopsis** *see* grain.

**CAS abbr.** for carbonic anhydrase.

**cascade sequence or waterfall sequence** a sequence of successive activation reactions involving either enzymes (enzyme cascade) or hormones (hormone cascade), or both. There are various examples: (1) the series of transformations of proteolytic enzymes in blood coagulation in which each enzyme activates the next until the final substrate, fibrinogen, is reached; (2) the series of reactions involved in the formation of, and mediation of the action of second messengers, e.g. in the activation of glycogen phosphorylase; (3) the process of activation of steroidogenesis in the adrenal gland by hypothalamic and pituitary hormones. The term has also been applied to other sequential phenomena, e.g. DNA  $\rightarrow$  RNA  $\rightarrow$  protein. Cascade sequences are characterized by a series of amplifications of a weak initial stimulus, and may be activated at more than one point along the sequence.

**cascara** the dried bark of the small tree *Rhamnus purshiana*. It is a potent purgative due to its constituent hydroxyanthracene derivatives (anthroglycosides), including cascariosides and related glycosides. These yield active anthracene derivatives after metabolism by colonic bacteria.

**casein 1 or** (esp. Brit.) caseinogen the principal protein fraction of milk; it is present as a colloidal suspension and may be precipitated by acidification. It is a mixture of several related proteins -  $\alpha_1$ -,  $\beta$ -,  $\gamma$ -, and  $\kappa$ -caseins - which differ in amino-acid composition and which may be separated electrophoretically. The  $\alpha_1$ - and  $\beta$ -caseins are rich in phosphate, present mainly as O-phosphoserine residues, which bind calcium ions. Casein is easily prepared and is valuable as a dietary supplement. 2 or (esp. US) paracasein the product formed by coagulation of milk (or casein (def. 1)) by treatment with chymosin (rennin). This enzyme removes a 64-residue carbohydrate-rich hydrophilic C-terminal moiety of K-casein, thereby destroying the latter's protective action on the casein micelles and thus allowing them to be precipitated by the calcium ions present. Examples from *Bos taurus*,  $\beta$ -casein (precursor): database code CASB\_BOVIN, 224 amino acids (25.11 kDa); K-casein (precursor): database code CASK\_BOVIN, 190 amino acids (21.27 kDa).

**caseinogen** an alternative name (esp. Brit.) for casein (def. 1). **casomorphin** or exomorphin any of a number of opioid peptides isolated from an enzymatic digest of bovine casein; activ-

## castor oil

ity corresponds to residues 60–66 of bovine  $\beta$ -casein. See also morphiceptin.

caspase see apoptosis.

castor oil an oil derived from seeds of the plant *Ricinus communis*. It contains triglycerides of ricinoleic, oleic, linoleic, palmitic, and stearic acids.

CAT abbr. for 1 computer of average transients. 2 chloramphenicol O-acetyltransferase. 3 computer-assisted tomography. catabolic dead-end a point in a catabolic pathway where, in a particular organism, a metabolite is neither catabolized further nor excreted but accumulates intracellularly. Consequently the pathway is unable to function as an energy-yielding process. The enzyme that can form the metabolite thus lacks an obvious role in that organism.

catabolic pathway any degradative, usually exergonic, sequence of reactions. Compare anabolic pathway. See also amphibolic.

catabolism or katabolism any metabolic process involving the breakdown of complex substances into smaller products, including the breakdown of carbon compounds with the liberation of energy for use by the cell or organism. Compare anabolism. -catabolize or catabolise vb.; catabolic adj.

catabolite any product of a catabolic pathway.

catabolite (gene) activator protein abbr.: CAP; other names cAMP receptor protein, cAMP-regulatory protein (abbr.: CRP); a protein that binds to and is activated by cAMP. It then acts as a transcription-initiation factor, binding near the operator of bacterial operons that are subject to catabolite repression and being necessary for their efficient transcription. It belongs to the CRP family of transcription factors. Example from *Haemophilus influenzae*: database code CRP\_HAEIN, 224 amino acids (25.15 kDa).

catabolite inhibition a general regulatory mechanism, found in *Escherichia coli*, that controls the activity of an early reaction in carbohydrate metabolism. For instance when *E. coli* is grown in synthetic medium with radioactive galactose or lactose as the carbon source, the addition of glucose rapidly inhibits utilization of the radioactive substrate. Subsequent removal of the glucose rapidly reverses the inhibition.

catabolite repression a mechanism of genetic regulation in bacteria in which the accumulation of catabolites in the cell represses the formation of enzymes that contribute to the formation of the catabolites.

catalase EC 1.11.1.6; a widely distributed hemoprotein enzyme that catalyses the formation of  $O_2 + 2 H_2O$  from two molecules of  $H_2O_2$ ; heme and manganese are cofactors. It plays an important role in removing  $H_2O_2$  formed in peroxisomes in animals and plants and in glyoxysomes in plants. The molecule has seven motifs. Examples: (1) homotetramer from tomato: database code CAT1\_LYCES, 492 amino acids (56.44 kDa); (2) bovine enzyme: database code NRL\_7CATA, 498 amino acids (56.61 kDa); 3-D structure is known; a helical and  $\beta$  barrel regions are present.

catalytic of, or pertaining to, catalase.

catalyse or (esp. US) catalyze to influence a reaction through catalysis.

catalysis an increase in the rate of a chemical reaction brought about by a catalyst. -catalytic adj.; catalytically adv.

catalysome 1 an enzyme-containing cap found on lipid droplets in the fat body of some insects. 2 a mitochondrion-like organelle specialized for lipid metabolism, found in adipose tissue.

catalyst any substance that increases the rate of a chemical reaction but is itself unchanged at the end of the reaction. Catalysts are usually present in very low concentrations relative to those of the substances whose reaction they are catalysing.

catalytic activity an index of the actual or potential activity of a catalyst. The catalytic activity of an enzyme or an enzyme-containing preparation is defined as the property measured by the increase in the rate of conversion of a specified chemical reaction that the enzyme produces in a specifiedt

## catalytic intermediate

assay system. [This word, in one or other position, has been misprinted as 'specific' in certain published versions of this definition.] Catalytic activity is an extensive quantity (see extensive property) and is a property of the enzyme, not of the reaction mixture; it is thus conceptually different from rate of conversion although measured by and equidimensional with it. The unit for catalytic activity is the katal; it may also be expressed in mol s<sup>-1</sup>. Dimensions: NT-I. Former terms such as catalytic ability, catalytic amount, and enzymic activity are no longer recommended. Derived quantities are molar catalytic activity, specific catalytic activity, and catalytic activity concentration. catalytic activity concentration or catalytic concentration the catalytic activity of an enzyme per unit volume, where volume refers to that of the original enzyme-containing preparation, not that of the assay system. It may be expressed in katals per litre.

catalytic amount the amount of a substance used in a chemical reaction as a catalyst, primer, or sparker. It is generally much smaller than the stoichiometric amounts of either reactants or products. For an enzyme the term is now obsolete and replaced by catalytic activity.

catalytic assay technique for measuring low concentrations ( $\approx 1 \mu M$ ) of substrates in certain enzyme-catalysed reactions (e.g. NAD(P)+ or coenzyme A), where simple kinetic methods are not feasible because too-rapid consumption makes reaction rates impossible to measure reliably. Conditions are arranged so that the concentration of the substrate in question is kept constant by a regeneration reaction, the substance being made to behave as an intermediate catalyst. The regeneration reaction may act also as the indicator reaction. For example, NAD+ may be determined by coupling the reaction catalysed by alcohol dehydrogenase (EC 1.1.1.1) to the combined regeneration/indicator reaction catalysed by cytochrome c reductase (EC 1.6.99.3), according to the equations:

and

The rate of increase in absorbance of Cyt  $c^{2+}$  at 550 nm is measured. If the coupled regeneration reaction does not act as an indicator reaction, the technique is known as enzymic cycling. Compare coupled assay.

catalytic concentration an alternative term for catalytic activity concentration.

catalytic constant symbol:  $k_{\text{cat}}$  or  $k'_0$ ; a measure of the catalytic potential of an enzyme, customary unit S-I. In general it is the value of the velocity of the reaction,  $v$ , divided by the stoichiometric concentration of active sites,  $[E]_0$ , obtained by extrapolating all substrate concentrations to infinity; alternatively it can be expressed as  $V_{\text{max}}/[E]_0$ , where  $V_{\text{max}}$  is the limiting rate.  $k_{\text{cat}}$  is also known as the turnover number, because it represents the number of reactions catalysed per unit time by each active site.

catalytic domain see domain (def. 3).

catalytic exchange method a method for randomly labelling a compound with tritium. A solution of the compound in a tritiated hydroxylic solvent is allowed to stand in the presence of metal catalysts and either acid or base.

catalytic facilitation a process whereby the product formed by one enzyme in a complex is passed directly to the catalytic site of the next enzyme in a reaction sequence more efficiently than when the second substrate is supplied from the environment.

catalytic factor a term sometimes used of a specified enzyme to define the quantitative ratio between the rates of a chemical reaction in the presence and the absence of the enzyme but otherwise under the same conditions.

catalytic intermediate a chemical species produced during the course of a catalytic reaction, intermediate between reactants and products.

## catalytic power

**catalytic power** a measure of the ability of an enzyme to accelerate a chemical reaction.

**catalytic residue** any of the amino-acid residues in an enzyme that are directly involved in making or breaking covalent bonds while the enzyme is acting on a substrate.

**catalytic site** the site on a catalyst that is concerned with catalysis, especially as part of the active site of an enzyme.

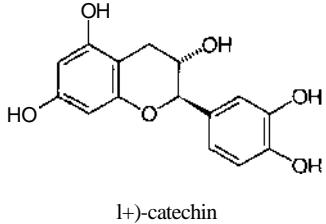

**catalyze** *the US spelling of catalyse.*

**CAT assay** assay of chloramphenicol O-acetyltransferase, frequently employed to detect expression of its gene in cDNA technology.

**catastrophe theory** see error catastrophe hypothesis.

**CAT box** see CAAT box.

**catechin** the type compound for one of the 12 classes of flavonoids. It is characterized by oxidation state (OH at C-3) of the central pyran ring. Some 70 catechins are known; e.g. (+)-catechin is (2R,2S)-3,3',4',5,7-flavanpentol. Catechins are among the polyphenols widely distributed in vegetable foods, arising biosynthetically from the shikimate pathway. (+)-Catechin produces artificial cross-links in collagen *in vitro* and has anti-tumour activity. Catechin and curcumin have been found to be non-toxic, non-mutagenic, non-teratogenic and excellent anti-mutagens and anti-carcinogens which are being clinically tested by the National Cancer Institute.

**catechol** 1 *former name for* pyrocatechol. 2 any aromatic o-diol; any compound containing a pyrocatechol nucleus or substituent. *Compare* hydroquinone (def. 2), quinone (def. 2).

**catecholamine** any of a group of physiologically important biogenic amines that possess a catechol (def. 2) (i.e. 3,4-dihydroxyphenyl) nucleus and are derivatives of 3,4-dihydroxyphenylethylamine. They include adrenaline, (epinephrine) noradrenaline (norepinephrine), and dopamine. Catecholamines have various physiological roles, particularly as neurotransmitters, and produce effects in the brain, the cardiovascular system, and other organs; they also help to regulate carbohydrate and fat metabolism.

**catechol melanin** any of various deep-brown or black plant pigments, so called because they yield catechol on alkali fusion. *See also* melanin.

**catechol-D-methyltransferase** EC 2.1.1.6; *systematic name:* S-adenosyl-L-methionine:catechol O-methyltransferase. An enzyme found primarily in non-neuronal tissues and catecholamine-releasing neurons, especially in the periphery; it effects O-methylation of catecholamines and their deaminated metabolites, but is less active against catechols. It catalyses the reaction between S-adenosyl-L-methionine and catechol to form S-adenosyl-L-homocysteine and guaiacol; in catecholamines it methylates the phenolic group at position 4. This inactivates catecholamine neurotransmitters and catechol hormones. Example from human: database code COMT\_HUMAN, 271 amino acids (30.00 kDa), is the membrane-bound form; a cytosolic form (residues 52-271) lacks the transmembrane signal anchor.

**catechol oxidase** see polyphenol oxidase. *See also* monophenol monooxygenase.

**catenane** any type of compound containing two or more rings that are interlocked but not covalently joined; i.e. resembling the links of a chain. An example is an interlocked circular

## cathode-ray tube

**duplex DNA molecule** found in mitochondria. *Compare* concatemer.

**catenate** 1 to interlock, without covalent bonding, two or more circular structures, e.g. cyclic molecules. 2 linked as the interlocked rings of a chain. *Compare* concatenate. -catenated *adj.*; catenation *n.*

**cathepsin** any of a group of intracellular peptide hydrolases.

**cathepsin B** EC 3.4.22.1; *other name:* lysosomal cysteine endopeptidase. An enzyme that catalyses the hydrolysis of proteins with broad specificity for peptide bonds; preferentially it cleaves -Arg-Arg-I-Xaa- bonds in small substrates. It is a glycoprotein dimer comprising a heavy chain and a light chain cross-linked by a disulfide bond. Example (human) precursor: database code CATB\_HUMAN, 339 amino acids (37.76 kDa).

**cathepsin C** EC 3.4.14.1; *recommended name:* dipeptidyl peptidase I. An enzyme that catalyses the hydrolysis of dipeptides from the N terminus of a polypeptide, except where the N-terminal residue is Arg or Lys, or where the adjacent amino acid is Pro. It also catalyses the transfer of dipeptide residues.

**cathepsin D** EC 3.4.23.5; a lysosomal aspartic endopeptidase that is active in intracellular protein breakdown. It has a specificity similar to, but narrower than, that of pepsin A. The molecule comprises a light chain and a heavy chain. Example (human) precursor: database code CATD\_HUMAN, 412 amino acids (44.50 kDa).

**cathepsin E** EC 3.4.23.34; an aspartic endopeptidase with similar activity to cathepsin D, but found in lymphoid-associated tissue. It may have a role in immune function. Example (human) precursor: database code CATE\_HUMAN, 396 amino acids (42.74 kDa).

**cathepsin G** EC 3.4.21.20; a glycoprotein serine endopeptidase with a specificity similar to that of chymotrypsin. It is found in the lysosomes of polymorphonuclear leukocytes. Example (human) precursor: database code CATG\_HUMAN, 255 amino acids (28.80 kDa).

**cathepsin H** EC 3.4.22.16; a lysosomal cysteine endopeptidase that also acts as an aminopeptidase on peptide substrates with a free N terminus. It is composed of a minichain and a large chain; the large chain may be split into heavy and light chains; all chains are held together by disulfide bonds. Example (human) precursor: database code CATH\_HUMAN, 335 amino acids (37.36 kDa).

**cathepsin L** EC 3.4.22.15; *other name:* major excreted protease (*abbr.:* MEP). A lysosomal cysteine endopeptidase that hydrolyses proteins but not acylamino acid esters, and has no peptidyl-dipeptidase activity - the activity is similar to that of papain. It is found in rat-liver and other mammalian lysosomes, and is inhibited by leupeptin. The molecule is a dimer of a heavy and a light chain linked by disulfide bonds. Example (human) precursor: database code CATL\_HUMAN, 333 amino acids (37.52 kDa).

**cathepsin S** EC 3.4.22.27; a lysosomal single-subunit cysteine endopeptidase with similar activity to cathepsin L but more activity for -Val-Val-Arg-I-Xaa-. Example (human) precursor: database code CATS\_HUMAN, 331 amino acids (37.44 kDa).

**cathode** or (*formerly*) kathode 1 the electrode of an electrolysis cell or electrophoresis apparatus towards which cations of the electrolyte migrate under the influence of an electric field applied between the electrodes. 2 negative electrode: the electrode, pole, or terminal of a discharge tube, solid-state rectifier, thermionic valve, or other apparatus by which conventional electric current returns to an external source; i.e. the electrode through which electrons flow into such a device. 3 the positive pole or terminal of an electric (primary or secondary) cell or battery (of cells); i.e. the pole from which electrons emerge from such a device. *Compare* anode. -cathodal, cathodic, or cathodical *adj.*; cathodally or cathodically *adv.*

**cathode-ray tube** a vacuum tube in which a beam of electrons is emitted and focused by an electron gun onto a fluorescent screen. The beam can be deflected by horizontal and vertical electrostatic or magnetic fields to produce a visual display of

**catholyte**

electric signals, as in a television tube or cathode-ray oscilloscope.

**catholyte** in isoelectric focusing, the electrolyte that is in immediate contact with the cathode.

**cation** or (*formerly*) **katioD** any ion with a net positive charge. In a solution being electrolysed, a cation migrates towards the cathode. *Compare anion. -cationic ad.*

**cation exchange** the process of ion exchange in which one cation is exchanged for another cation.

**cation exchanger** any ion exchanger that is able to exchange cations with the surrounding solution. *See also* ion-exchange resin.

**cationic acid** any acid that carries a positive charge, i.e. is a cation.

**cationic detergent** any detergent in which the polar part of the molecule carries one or more positive charges.

**cationized ferritin** a polycationic derivative of ferritin prepared by coupling horse-spleen ferritin with N,N-dimethyl-1,3-propanediamine, most of the carboxyl groups on the ferritin molecule thereby being converted into positively charged tertiary amino groups. It is useful for labelling negatively charged groups on cell surfaces, where the ferritin particles may easily be identified by electron microscopy because of their electron-dense iron cores.

**cationmotive** describing any enzyme, enzyme system, or other process that produces the vectorial movement of cations, especially across a biomembrane. The particular cation(s) may be specified, e.g. protonmotive, Na<sup>+</sup>/K<sup>+</sup>-motive.

**CAU** a codon in mRNA for L-histidine.

**caudal** a homeodomain transcription factor which forms a concentration gradient in the opposite direction to that of bicoid protein, possibly as a result of the translation control exerted on the caudal mRNA by bicoid.

**cauliflower mosaic virus** a double-stranded DNA virus that is a potential recombinant vector for plants.

**cau'limovirus** any double-stranded DNA plant virus belonging to the *Caulimovirus* group, the type member of which is the cauliflower mosaic virus.

**caustic soda** *see* soda.

**caveo'a** (*pl.* *caveolae*) a closed plasmalemmal vesicle that is thought to remain attached to the plasma membrane while extruding into the cytoplasm materials taken up from the outside of the cell. It is rich in glycosylphosphatidylinositol (GPI)-anchored proteins. [From Latin *eavea*, a small cavity.]

**caveolin** a protein that lines the cytoplasmic surface of a caveola. Example from dog: database code CAVE\_CANFA, 178 amino acids (20.6 kDa).

**CBF** *abbr.* for centromere binding factor (*see* centromere binding proteins).

**CBG** *abbr.* for cortisol binding globulin. *See* transcortin.

**CBL** a protooncogene related to *v-ebl*, the nuclear oncogene of Cas NS-1 retrovirus, named from Casitas B-lineage lymphoma. The function of the normal protein is unknown, but it may be a transcriptional regulator. *v-ebl* encodes a truncated form of Cbl, which has lost a C-terminal leucine zipper and a 208-residue proline-rich region. Example, human protooncogene product c-Cbl: database code CBL\_HUMAN, 906 amino acids (99.65 kDa).

**Cbm** symbol for carbamoyl.

**CBN** *abbr.* for (IUPAC-IUB) Commission on Biochemical Nomenclature; now succeeded by JCBN.

**Cbz** symbol for the benzylloxycarbonyl group.

**cc** symbol for cubic centimetre (cm<sup>3</sup> is preferred).

**CC** *abbr.* for cholecalciferol (vitamin D<sub>3</sub> is preferred).

**CCA** a codon in mRNA for L-proline.

**C<sub>III</sub>** carrier lipid or C<sub>55</sub> lipid carrier *an alternative name for* undecaprenol.

**CCC** 1 a codon in mRNA for L-proline. 2 *abbr.* for [ $\beta$ ]-chloroethyltrimethylammonium chloride; an inhibitor of gibberellin synthesis in plants.

**cccDNA** *see* DNA.

**CCCP** *abbr.* for carbonyl cyanide m-chlorophenylhydrazone, a powerful uncoupler of oxidative phosphorylation.

**C cell** the distinctive type of apud cell that secretes the polypeptide hormone calcitonin. In mammals C cells are found predominantly in the thyroid gland (when they are also known as parafollicular cells), and in some mammals and birds they also occur in the parathyroid gland and the thymus. In other vertebrates the cell type is present mainly in the discrete ultimobranchial body and the lung. [The name C cell was chosen to signify calcitonin-secreting cell.]

**CCG** a codon in mRNA for L-proline.

**CCK** *abbr.* for cholecystokinin.

**CCK cell** *see* Icell.

**CCK-PZ** *abbr.* for cholecystokinin-pancreozymin. *See* cholecystokinin.

**cCMP** *abbr.* for cyclic CMP.

**C**, compound or one-carbon compound or single-carbon compound any (real or hypothetical) organic compound that consists of a single carbon atom with attached hydrogen atom(s), and sometimes also an oxygen atom or imino group, and that functions as a unit in metabolism. Examples include the methyl group of S-adenosylmethionine or the iminomethyl-formimidoyl- (or formimino-), formyl-, hydroxymethyl-, methyl-, methylene-, and methenyl- groups of tetrahydrofolate coenzymes.

**C3/C5 convertase** *see* complement.

**C5 convertase** *see* complement.

**CCP** *abbr.* for Collaborative Computational Programs; an initiative, started in the UK, for the development and distribution of software for scientific applications. Programs include: CCP4 (crystallographic software), CCP5 (molecular dynamics), and CCPII (sequence analysis).

**CCU** a codon in mRNA for L-proline.

**C<sub>3</sub> cycle** *an alternative name for* reductive pentose phosphate cycle.

**C<sub>4</sub> cycle** *an alternative name for* the Hatch-Slack pathway.

**cd** symbol for candela.

**Cd** symbol for cadmium.

**CD** *abbr.* for 1 circular dichroism. 2 cluster of differentiation or cluster determinant; *see* CD marker. 3 compact disc.

**c-di-GMP** *abbr.* for cyclic diguanylic acid.

**CD4** a CD marker that occurs on T-helper cells and is involved in MHC class II restricted interactions. It is down-regulated by HIV infection. Example, T-cell CD4 antigen (precursor) from human: database code CD4\_HUMAN, 458 amino acids (51.05 kDa); 3-D structure known; a type I membrane glycoprotein of the immunoglobulin superfamily.

**CDS** a CD marker that occurs on human cytotoxic T-cells and suppressor T-cells. It is associated with MHC class I restricted interactions. It is a heterodimer of an  $\alpha$  and  $\beta$  chain and isoforms of the  $\beta$  chain result from alternative splicing. The  $\alpha$  chain binds to the MHC  $\alpha_3$  domain. Examples,  $\alpha$  chain (precursor): database code CD8A\_HUMAN, 235 amino acids (25.73 kDa);  $\beta_1$  chain (precursor): database code C8B1\_HUMAN 210 amino acids (23.72 kDa).

**CD44** *other names:* phagocyte glycoprotein I; lymph node homing receptor; HERMES antigen; extracellular matrix receptor III. A cell adhesion molecule that is constitutively expressed on the surface of Band T cells, monocytes, neutrophils, epithelial cells, fibroblasts, glial cells, and myocytes. It has a molecular mass of 85–90 kDa and plays a general role in cell adhesion, including lymphocyte homing; it binds to collagen and hyaluronate. Example from horse: database code CD44\_HORSE, 359 amino acids (38.99 kDa).

**CD59** a glycoprotein that is a potent inhibitor of complement membrane attack complex (MAC); it acts after C5b8 assembly (*see* complement). It is also involved in signal transduction for T-cell activation, being complexed to a protein tyrosine kinase. It is attached to the membrane by a GPI-anchor. Example (human) precursor: database code CD59\_HUMAN, 128 amino acids (14.16 kDa).

**CD66** *see* carcinoembryonic antigen.

**CD66d** *see* carcinoembryonic antigen.

**CD66e** *see* carcinoembryonic antigen.

**CD79** *see* B cell antigen receptor complex associated protein.

**cdc** gene *abbr.* for cell-division-cycle gene. Many genes are now known that encode proteins essential for cell division. These were initially identified in yeast, using temperature-sensitive mutants that divide at low temperature but which at high temperature arrest at a point in the cell-division cycle at which expression of the mutated gene would normally be required. The yeast genes were named in a series *cde1*, *cdc2*, etc. Homologues of these genes have since been found in many other species, but the *cdc* nomenclature is used specifically for the fission yeast, *Schizosaccharomyces pombe*. The convention Cdc followed by a numeral is used for the protein products of these genes. Many products identified by this method were found not to be directly involved in the control of cell division, being proteins such as DNA polymerases. Some of those that are involved in cell-division control are (all database examples are from yeast):

**Cdc2**, a major cell regulatory protein, with counterparts in all eukaryotic cells. *cdc2* is homologous to *CDC28* in budding yeast. Cdc2 is a Ser/Thr protein kinase, alternatively denoted *p34<sup>cdc2</sup>*, and regulated by cyclin B. *p34<sup>cdc2</sup>* and cyclin B comprise maturation promoting factor (MPF). Cdc2 is the patriarch of a family of cyclin-dependent kinases; Cdc2 is Cdk1. Example from *S. pombe*: database code CC2\_SCHPO, 297 amino acids (34.36 kDa).

**cdc25** encodes a protein phosphatase that positively regulates *p34<sup>cdc2</sup>* by dephosphorylation of Tyr<sup>15</sup>. Entry to mitosis is negatively regulated by *wee1*, a gene in *S. pombe* that encodes a protein tyrosine kinase. Its action on mitosis results from phosphorylation of Tyr<sup>15</sup> of *p34<sup>cdc2</sup>*. Note: *CDC25* from budding yeast encodes a guanine nucleotide exchange protein.

**Cdc28**, a Ser/Thr protein kinase required for completion of both the START transition of the cycle and also the *G<sub>2</sub>/M* transition: database code CC28\_YEAST, 298 amino acids (34.02 kDa);

**Cdc31**, an EF-hand protein involved in microtubular organization: database code CC31\_YEAST, 298 amino acids (18.73 kDa);

**Cdc46**, a protein mobilized from the cytoplasm to the nucleus after mitosis, and a potential ATP-binding protein: database code CC46\_YEAST, 775 amino acids (86.31 kDa);

**Cdc48**, a putative ATP-binding protein involved in spindle formation: database code CC48\_YEAST, 834 amino acids (91.77 kDa).

**CDE** *abbr.* for centromere DNA element; CDE-I is a group of DNA sequences, RTCACRTG, found in centromeres and some promoters. *See also* centromere-binding proteins.

**CD59** glycoprotein precursor *see* membrane attack complex inhibition factor.

**CDH** *abbr.* for ceramide dihexoside (*Cer(Hex)2* is preferred).

**CDI** *abbr.* for *N,N'*-carbonyldiimidazole; I, I'-carbonyl bis-IH-imidazole, a reagent used in the synthesis of nucleotide triphosphates and peptides, and for cross-linking proteins.

**Cdk** *abbr.* for cell division protein kinase.

**CD marker** (*in immunology*) any of a series of antigenically distinct molecules occurring on the surface of leukocytes and other cell types, and used in the characterization of such cells. More than 80 individual CD marker molecules are recognized, as identified by monoclonal antibodies. The most frequently encountered CD molecules are those used to distinguish T cells.

CD2 is present on all T cells and is involved in antigen-non-specific activation. CD3 is also present on all T cells and is an invariant part of the T-cell antigen receptor involved in antigen-specific T-cell activation. C04 occurs on T-helper cells and is involved in MHC class II restricted interactions, COB occurs on cytotoxic T cells and is involved in MHC class I restricted

interactions. *See also* C044, CD59. Other CD markers listed here under other names include CD16 (*see* Fc receptor), CD29 (*see* VLA), CD31 (*see* PECAMj), CD32 (*see* Fc receptor), CD49a and CDS1 (*see* VLA), CDSO and CDS4 (*see* ICAM), CD62 (*see* selectin), CD64 (*see* Fc receptor), CDI02 (*see* ICAM), and CDI06 (*see* VCAM). [From 'cluster of differentiation'.]

**cDNA** *abbr.* for complementary DNA.

**C-DNA** *abbr.* for C form of DNA.

**cDNA clone** any bacterial cell transformed by a plasmid containing a complementary DNA copy of an RNA molecule.

**cDNA library** a collection of cloned recombinant cDNA, usually in bacteria or yeast. The clones represent cDNAs prepared from all the mRNAs in any particular species or organ. **CDP** *abbr.* for 1 cytidine 5'-diphosphate or the group cytidine(5')diphospho. 2 cardiodilatin related peptide; *see* natriuretic peptide.

**CDPCholine** *see* cytidine15'diphosphocholine.

**CDPdiacylglycerol** *see* cytidine(5')diphosphodiacylglycerol.

**CDPdiacylglycerol-inositol** 3-phosphatidyltransferase EC 2.7.8.11; *other names:* phosphatidylinositol synthase; CDPdiacylglyceride-inositol phosphatidyltransferase; an enzyme that catalyses the formation of phosphatidyl-I-D-myoinositol from CDPdiacylglycerol and *myo-inositol* with release of CMP. It is a component of the pathway for the biosynthesis of phosphatidylinositol and also for its resynthesis after activation of the phosphatidylinositol cycle. Example from yeast: database code PIS\_YEAST, 220 amino acids (24.80 kDa).

**CDPdiacylglycerol-serine** o-phosphatidyltransferase EC 2.7.8.8; *systematic name:* CDPdiacylglycerol:L-serine 3-O-phosphatidyltransferase; *other names:* phosphatidylserine synthase; CDPdiglyceride-serine O-phosphatidyltransferase. It is an enzyme of the pathway that effects *de novo* synthesis of phosphatidylserine. It catalyses the formation of *O-sn*-phosphatidyl-L-serine from CDPdiacylglycerol and L-serine with the release of CMP. Example from *Escherichia coli*: database code PSS\_ECOLI, 452 amino acids (52.76 kDa). Example from *Saccharomyces cerevisiae*: database code PSS\_YEAST, 275 amino acids (30.67 kDa).

**CDPethanolamine** *see* cytidine(5'diphosphoethanolamine.

**CDP-glycerol pyrophosphorylase** *see* glycerol-3-phosphate cytidylyltransferase.

**CDPK** *abbr.* for calmodulin-like domain protein kinase.

**CDR** *abbr.* for calcium-dependent regulator protein (i.e. calmodulin).

**CDTA** *abbr.* for trans-cyclohexylene-1,2-diamine-N,N',N'-tetraacetate, the anion of trans-1,2-diaminocyclohexane-N,N',N'-tetraacetic acid. A chelating agent with a high affinity for Mg<sup>2+</sup>; the abbreviation is also used for its partially or fully protonated forms.

**Ce** symbol for cerium.

**C<sub>x</sub>E<sub>y</sub>** a series of non-ionic detergents useful for the solubilization of membrane-bound proteins in their native state. They include C<sub>10</sub>E<sub>6</sub>, hexaethyleneglycol mono-n-decyl ether; C<sub>10</sub>OEs, octaethyleneglycol mono-n-decyl ether; C<sub>12</sub>E<sub>6</sub>, hexaethyleneglycol mono-n-dodecyl ether; C<sub>12</sub>E<sub>8</sub>, octaethyleneglycol mono-n-dodecyl ether; and C<sub>12</sub>E<sub>9</sub>, nonaethyleneglycol mono-n-dodecyl ether; the latter two are constituents of the proprietary detergent Lubrol-PX a detergent useful for the solubilization of membrane-bound proteins in their native state.

**CEA** *abbr.* for carcinoembryonic antigen.

**CEA gene member 1** *see* carcinoembryonic antigen.  
**Cech, Thomas Robert** (1947- ) US chemist, biochemist, and molecular biologist; Nobel Laureate in Chemistry (1989) jointly with S. Altman 'for their discovery of catalytic properties of RNA'.

**cecropin** any of a group of small, basic polypeptides with potent antibacterial activity. Cecropins are active against *Escherichia coli* and several other Gram-negative species, and are isolated from the cecropia moth, *Hyalophora cecropia*, and several other insects.

**CEF10** or **CEF-IO** a secreted protein that is implicated in

growth regulation. It is induced by *v-src* and belongs to a family of growth regulators that includes connective tissue growth factor. Example (precursor) from chicken: database code CEIO\_CHICK, 375 amino acids (40.60 kDa).

Cek a chick gene encoding receptor-type protein tyrosine kinases, and named from chicken embryo kinase. The protein product Cek-1 is the chicken fibroblast growth factor receptor; Cek-2 and Cek-3 are related to *Btl*; Cek-4 and Cek-5 are homologous to *Eph*.

celiac or (*esp. Brit.*) coeliac of, or belonging to, the abdominal cavity.

celiac disease or (*Brit.*) coeliac disease or gluten enteropathy or nontropical sprue a condition caused by sensitivity of the mucosa of the upper small intestine to the  $\alpha$ -gliadin component of gluten in wheat and rye. Characterized by diarrhoea and malabsorption, it can be relieved by elimination of gluten from the diet.

Celite proprietary name for preparations of amorphous diatomaceous silica, used as a filter-aid and in partition chromatography.

cell 1 the basic structural unit of all living organisms; it typically comprises a small, usually microscopic, discrete mass of organelle-containing cytoplasm, bounded externally by a membrane. Each cell is capable of interacting with other cells and performing all the fundamental functions of life. In plants the cell usually also includes the cell wall. Originally the term referred to the bounding wall of a plant cell that had lost its living content. See also +cyte, cyto-. 2 a container for liquid during measurement or separation procedures, such as dialysis, electric conductivity measurement, electrolysis, micro-diffusion, moving boundary electrophoresis, analytical ultracentrifugation, ultrafiltration, and (spectro)photometry; see also cuvette. 3 or electric cell a device for producing electric current by converting chemical energy into electric energy; it consists of two electrodes in contact with an electrolyte. 4 (in crystallography) see unit cell. -cellular adj.

cell-adhesion molecule see adhesion molecules.

cell body an alternative term for perikaryon.

cell-bound antibody or cell-fixed antibody any antibody molecule that is bound to the surface of a cell, e.g. an incomplete antibody (def. 1) or a cytophilic antibody.

cell coat another name for the glycocalyx.

cell cortex the part of the microtrabecular lattice lying just under the outer cell membrane of certain protozoans, e.g. paramecia.

cell counter any device for determining the number of cells in a known volume of a liquid suspension. See Coulter counter, flow cytometer, hemocytometer.

cell culture see tissue culture.

cell cycle the period between the formation of a cell by division of its mother cell and the time when the cell itself divides to form two daughter cells. See also cell-division cycle, DNA cycle.

cell-cycle engine all the biochemical components, and the reactions between them, that cause the periodic activation and inactivation of M-phase-promoting factor during cell maturation. cell differentiation see differentiation.

cell-division cycle the pattern of DNA synthesis in dividing eukaryotic cells. It is divided into four periods:  $G_1$  is the first 'gap' in DNA synthesis between telophase and the period of DNA synthesis, designated S. This S phase is followed by  $G_2$ , the second gap in DNA synthesis. This runs on into the period of mitosis, M, which lasts from early prophase to late telophase. cell division protein kinase abbr.: CDK; any of various protein kinase enzymes involved in the regulation of cyclin activity, such as CDC20. See also cdc.

cell-fixed antibody an alternative name for cell-bound antibody.

cell fractionation the fractionation of disrupted cells into their subcellular components.

cell-free extract a fluid, made by breaking open cells, that

contains most of the constituents of the cells in question but no intact cells.

**cell-free** system any experimental system composed of sub-cellular fractions and/or cell-free extracts. Cell-free systems for amino-acid incorporation (protein synthesis) generally contain ribosomes, natural or synthetic mRNA, tRNAs, enzymes, amino acids, an ATP generating system, GTP, buffer, certain inorganic salts, and some organic compounds.

cell fusion the formation of a single hybrid cell containing the nuclei and cytoplasms from different cells. It may be induced by treatment of a mixed cell population with certain fusogens (e.g. killed Sendai virus or polyethylene glycol). It is an important step in the technique of forming hybridoma cells for the production of monoclonal antibodies.

cell junction a specialized region of connection between two cells or between a cell and the extracellular matrix. See also desmosome, gap junction, hemidesmosome, tight junction.

cell line a population of cells cultured *in vitro* that are descended through one or more generations (and possibly subcultures) from a single primary culture. The cells of such a population share common characteristics.

cell locomotion see cell migration.

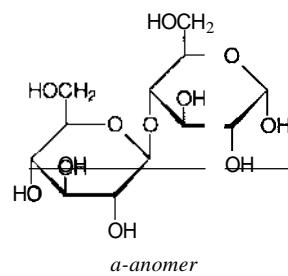

cell matrix see extracellular matrix.

cell-mediated immunity specific immunity that depends on the presence of T lymphocytes. It is responsible for, e.g. allograft rejection, delayed hypersensitivity, and tuberculin test reactions, and is important in the organism's defence against viral and some bacterial infections.

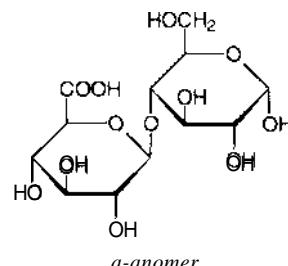

cell membrane any membrane found in a cell. The term is sometimes used loosely to indicate the plasma membrane. See also cytoplasmic membrane.

cell migration the active movement of a cell from one location to another, particularly the migration of a cell over a surface.

13-cellobiose another name for  $\beta$ -D-glucosidase; see glucosidase. cellobiose 4-O-P-D-glucopyranosyl-D-glucose; a disaccharide that represents the basic repeating unit of cellulose; it is liberated by cellulase.

cellobiuronic acid 4-O-P-D-glucopyranuronosyl-D-glucose; condensed form: GlcA( $\beta$ 1-4)Glc. It is a component of, e.g. type III pneumococcal bacterial capsule polysaccharides.

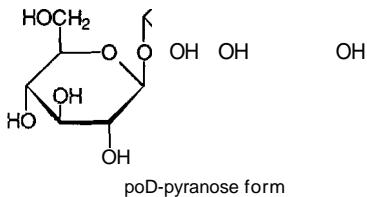

## cellophane

cellophane a form of transparent, flexible sheeting made from regenerated cellulose; originally a proprietary name.

Cellosolve *proprietary name* for a range of ethanediol monoalkyl ethers, especially 2-ethoxyethanol. They are useful as solvents, e.g. in liquid scintillation mixtures, to facilitate the dispersion of aqueous samples in organic solvents.

cellotetraose a tetrasaccharide composed of  $\alpha$ -glucose units in  $1\beta$ - $4$  linkage.

cellotriose the trisaccharide O-f3- $\alpha$ -glucopyranosyl-(1-4)-O-f3- $\alpha$ -glucopyranosyl-(1-4)- $\alpha$ -glucose; *condensed form*: Glc(f3l-4)Glc(f3l-4)Glc.

cell plate the nascent cell membrane and cell wall structure that forms between the two daughter nuclei near the centre of a dividing plant cell. It develops at the equatorial region of the phragmoplast. It grows outwards to join with the lateral walls and form two daughter cells.

cell sorter any flow sorter for sorting cells in liquid suspension, on the basis of some characteristic that is detectable by the sorter.

cell-surface protein *abbr.*: CSP; *an alternative name for fibronectin.*

cellubrevin a synaptobrevin homologue that is involved in membrane traffic as part of a constitutively recycling pathway. With VAMP proteins it is a component of the machinery controlling docking and fusion of secretory vesicles with their target membrane. It is a ubiquitous substrate for tetanus toxin light chain. Example from *Rattus norvegicus*: database code S35077, 103 amino acids (11.47 kDa).

cellular affinity the tendency of cells to adhere specifically to cells of the same type, but not to cells of a different type. This property is lost in cancer cells.

cellular immunity 1 the increased ability of phagocytic cells to destroy parasitic organisms, i.e. macrophage immunity. 2 *an alternative name for cell-mediated immunity.*

cellulase 1 EC 3.2.1.4; *other names*: endoglucanase; endo- $\beta$ -f3-glucanase; carboxymethyl cellulase. An enzyme that catalyses the endohydrolysis of 1,4-f3- $\alpha$ -glucosidic linkages in cellulose, thereby hydrolysing cellulose to cellobiose. It causes abscission in plants, and its synthesis is stimulated by ethylene. Microbial cellulases play an important part in the digestion of cellulose by ruminants. 2 any lytic enzyme whose substrate is cellulose. See cellulose 1,4- $\beta$ -cellobiosidase, glucosidase. Example from *Cellulomonas uda*: database code GUNCELUD, 359 amino acids (40.64 kDa).

cellule 1 (*archaic*) a minute cavity or very small cell. 2 *a former name for a liposome bounded by a single lipid bilayer.*

cellulose a linear  $1\beta$ - $4$  glucan of molecular mass 50-400 kDa with the pyranose units in the  $\beta$ -C<sub>4</sub> conformation. It is predominantly a plant polysaccharide though it also occurs in some tunicates. Cellulose microfibrils are major components of plant cell walls. Cellulose is insoluble in water but will dissolve in ammoniacal solutions of cupric salts. It is often said

## central nervous system

to be the most abundant organic compound in the biosphere, but this distinction has also been accorded to the hemicelluloses.

cellulose **1,4- $\beta$ -cellobiosidase** EC 3.2.1.91; *other names*: exoglucanase; exocellulobiohydrolase; 1,4-f3-cellulobiohydrolase. An enzyme that catalyses the hydrolysis of 1,4-f3- $\alpha$ -glucosidic linkages in cellulose and cellotetraose, releasing cellobiose from the nonreducing ends of the chains. Example (precursor) from *Trichoderma reesei*: database code GUXLTRIRE, 513 amino acids (54.01 kDa); 3-D structure of C-terminal domain: database code NRL\_ICBH, 36 amino-acid fragment (3.74 kDa).

cellulosic 1 of, or pertaining to, cellulose; of the nature of cellulose; composed (primarily) of cellulose; derived from or made by chemical modification of cellulose. 2 a substance made from cellulose or a derivative of cellulose.

**cellulolysis** the process of hydrolysing cellulose. -cellulolytic *adj.*

**cell wall** the rigid or semi-rigid envelope lying outside the cell membrane of plant, fungal, and most prokaryotic cells maintaining their shape and protecting them from osmotic lysis. In prokaryotes it lies inside any capsule and slime layer, usually consists mainly of peptidoglycan, and can be removed by various techniques with retention of its three-dimensional form. In fungi the cell wall is composed largely of polysaccharides, while in plants it is made up of cellulose and, often, lignin.

**Celsius temperature symbol:**  $^{\circ}$  or  $t$ ; a temperature defined as the excess of the thermodynamic temperature,  $T$ , over 273.15 K; i.e.  $^{\circ} = T - 273.15$ , where  $^{\circ}$  is measured in  $^{\circ}\text{C}$  (i.e. degrees Celsius, formerly called degrees centigrade) and  $T$  is measured in kelvins. It is identical with centigrade temperature. [After Anders Celsius (1701-44), Swedish astronomer.]

**centi+** symbol: c; SI prefix denoting  $10^{-2}$ .

**centigrade temperature** *former name for Celsius temperature.*

**centimetre-gram-second system** see cgs system.

**centimorgan** or **centiMorgan** *abbr.*: cM; a unit of map distance used in genetic mapping, equal to 1% crossover found in recombination studies; 1 cM equals 1 map unit. Hence, if two genes are separated by 1 cM, there is a 1% probability of recombination in a single meiotic event.

**central dogma** a fundamental principle of molecular biology, first articulated by Francis Crick in 1958. He wrote that the central dogma states that once 'information' has passed into protein *it cannot get out again*. In more detail, the transfer of information from nucleic acid to nucleic acid, or from nucleic acid to protein may be possible, but transfer from protein to protein, or from protein to nucleic acid is impossible. Information means here the *precise* determination of sequence, either of bases in the nucleic acid or of amino-acid residues in the protein. The dogma has been taken to relate primarily to the following transfers of information that can occur in all cells: DNA  $\rightarrow$  DNA, DNA  $\rightarrow$  RNA, and RNA  $\rightarrow$  protein. However, the transfer of information from RNA to RNA occurs in the replication of RNA viruses. The transfer of information from RNA to DNA occurs following infection of a cell with a retrovirus; the DNA is then incorporated into the host genome. When challenged that the reverse transfer of information from RNA to DNA by retroviruses contradicted the dogma, Crick refuted the challenge by drawing attention to the fact that as originally formulated the dogma permitted the transfer of information from (any) nucleic acid to (any other) nucleic acid (although the action of retroviruses was not known at that time) and that the essential point was that *sequence* information could not be passed from protein to nucleic acid, or from protein to protein.

**central nervous system** *abbr.*: CNS; the part of the nervous system of an animal that contains a high concentration of cell bodies and synapses and is the main site of integration of nervous activity. In higher animals it is isolated from the circulation by the blood-brain barrier. It consists essentially of a brain or cerebral ganglia, and a nerve cord, which may be dorsal or ventral, single or double. *Compare peripheral nervous system.*

**centrifugal**

**centrifugal** 1 moving, acting, or tending to act away from a centre or axis. 2 of, pertaining to, or operated by a **centrifugal force**. 3 (*in botany*) developing outwards from a centre, as the flowers of certain types of inflorescence. 4 (*in physiology*) sending nerve impulses from a central location to parts supplied by that nerve; **afferent**. Compare **centripetal**.

**centrifugal analyser or centrifugal fast analyser** an apparatus widely used in clinical chemical laboratories for the simultaneous and very rapid chemical, biochemical, or immunochemical determination of one particular constituent in each of a large number of samples. Basically it consists of an appropriately designed transfer disk into which reagent(s) and samples are discretely and automatically pipetted. When loaded, the transfer disk is placed in the centre of a cuvette rotor in the centrifuge, and the rotor is accelerated. Reagent(s) and each sample are mixed together as they are radially propelled along specially shaped channels into the cuvettes. Absorbance, fluorescence, or other measurements are then made automatically on the cuvettes as they are rotating. The whole process, including data handling, is controlled by a computer.

**centrifugal elutriation** a technique in which cells or other particles are separated by **elutriation** in a specially constructed centrifuge rotor; the increased gravitational field resulting from centrifugation speeds up separation of the particles.

**centrifugal field** any space in which a **centrifugal force** is operating, as in the spinning rotor of a centrifuge.

**centrifugal force** a force acting radially outwards on any body moving in a curved path, equal and opposite to the **centripetal force**. The centrifugal force on a body of mass  $m$ , moving in a circular path of radius  $r$ , with velocity  $v$ , is:  $mv^2/r$ .

**centrifuge** 1 an apparatus in which fluids may be rotated rapidly so that substances (solutes or dispersed particles) of different densities may be separated by centrifugal force. 2 to rotate rapidly in a centrifuge. **-centrifugation n.**

**centrin** *an alternative name for caltractin.*

**centriole** a cellular organelle, found close to the nucleus in many eukaryotic cells, consisting of a small cylinder with microtubular walls, 300–500 nm long and 120–150 nm in diameter. It contains nine short, parallel, peripheral microtubular fibrils, each fibril consisting of one complete **microtubule** fused to two incomplete microtubules. Cells usually have two centrioles, lying at right angles to each other. At division, each pair of centrioles generates another pair and the twin pairs form the poles of the mitotic spindle. Compare **basal body**.

**centripetal** 1 moving, acting, or tending to act towards a centre or axis. 2 of, pertaining to, or operated by a **centripetal force**. 3 (*in botany*) developing inwards from the outside, as the flowers of certain inflorescences. 4 (*in physiology*) sending nerve impulses towards a central location from peripheral parts supplied by that nerve; **afferent**. Compare **centrifugal**.

**centripetal force** a force acting radially inwards on any body moving in a curved path; it constrains the body to a curved path. It is equal and opposite to the **centrifugal force**.

**centromere** the region of a eukaryotic chromosome that is attached to the spindle during nuclear division. It is defined genetically as the region of the chromosome that always segregates at the first division of meiosis; i.e. the region of the chromosome in which no **crossing over** occurs. At the start of M phase, each chromosome consists of two sister chromatids with a constriction at a point which forms the centromere. During late prophase two **kinetochores** assemble on each centromere, one kinetochore on each sister chromatid.

**centromere-binding proteins** proteins from, e.g., the yeast **kinetochore** that are able to bind centromere DNA; examples from yeast: centromere-binding protein 1: database code CBFI\_YEAST, 351 amino acids (39.40 kDa); a protein that binds to a sequence in centromere DNA known as COE-1; it is a helix-turn-helix protein; (2) centromere-binding protein 2: sequence of the 110 kDa subunit: database code CBF2\_YEAST, 956 amino acids (111.79 kOa); a complex involving a

**cerebroside-sulfatase**

larger (240 kDa) subunit of this protein also binds to CDE-I and is involved in spindle formation.

**centrosome** a structure occurring close to the nucleus during **interphase** in many eukaryotic cells. It comprises a pair of **centrioles**, satellite bodies, and a cytoplasmic zone from which the mitotic microtubule spindle is organized. The structure of the centrosome in animal cells changes continually during the **cell-division cycle**.

**centrosphere** a more or less well delineated part of the cytoplasm at the poles of the spindle (see **mitotic spindle**).

**cephaeline** an alkaloid derived from *Uragoga ipecacuanha*. It is a gastric irritant, inducing emesis. See also **emetine, ipecacuanha**.

**cephalin** *a former name for 1 phosphatidylethanolamine. 2 phosphatidylserine.*

**cephalosporin** any of a heterogeneous group of natural and semisynthetic, often  $\beta$ -lactam, antibiotics. Cephalosporins C, N, and P are obtained from cultures of moulds such as *Cephalosporium acremonium*. Cephalosporins are active against a range of Gram-positive and Gram-negative bacteria.

**cephalosporinase** *an alternative name for  $\beta$ -lactamase II.*

**Cer** symbol for a ceramide residue. See also **Cer(Hex)**.

**ceramidase** EC 3.5.1.23; *other name:* acylsphingosine deacylase; an enzyme involved in the degradation of sphingolipids. It catalyses the hydrolysis of N-acylsphingosine to a fatty acid and sphingosine.

**ceramide** symbol: Cer; any N-acylated **sphingoid**.

**ceramide cholinophotransferase** EC 2.7.8.3; an enzyme involved in the biosynthesis of sphingomyelin by the reaction of COPcholine with N-acylsphingosine with the release of CMP.

**ceramide glucosyltransferase** EC 2.4.1.80; an enzyme that catalyses the formation of glucosylceramides. The reaction involves the formation of D-glucosyl-N-acylsphingosine from UDPglucose and N-acylsphingosine with the release of UDP.

**cercidosome** an atypical mitochondrion or oxidizing body, found, e.g., in trypanosomes, whose function may primarily be to regulate the NAD+/NADH ratio of the cytosol. [From Greek *kerkis, kerkido*, weaver's shuttle, + **+some**.]

**cerebellin** see **precerebellin**.

**cerebral** 1 of, or relating to, the cerebrum. 2 (*loosely*) of, or relating to the brain.

**cerebrodiene** a lipid, resembling **sphingosine**, that is obtained from the brain of sleep-deprived cats.

**cerebroglycan** an integral membrane heparan sulfate proteoglycan unique to the developing nervous system and expressed specifically during neuronal differentiation. Example from neonate rat brain: database code RATCRBGLVC, 579 amino acids (63.28 kDa).

**cerebrone** 2-hydroxytetraacosanoate;  $CH_3(CH_2)^{21}CH(OH)COO^-$ ; it is the 2-hydroxy derivative of lignocerate. It is enriched in brain cerebrosides, the fraction containing this fatty acid being known as **phrenosin**.

**cerebrose** see **galactose**.

**cerebroside** any **glycosphingolipid** that contains a monosaccharide, normally glucose or galactose, in I-O- $\beta$ -J-glycosidic linkage with the primary alcohol of an N-acyl **sphingoid** (ceramide). In plants the monosaccharide is normally glucose; in animals it is normally galactose, though this may vary with the tissue, glucose being present in blood cerebroside. In plants, the sphingoid is usually phytosphingosine, in animals sphingosine or dihydrosphingosine (sphinganine). Cerebrosides frequently contain large amounts of longer-chain fatty acids such as behenic (22:0), lignoceric (24:0), and nervonic (24:1) acids, and 2-hydroxy fatty acids such as cerebronic (a-OH24:0) and 2-hydroxynervonic acids. Cerebroside synthesis may proceed either by acylation of psychosine or transfer of glucose or galactose to ceramide.

**cerebroside-sulfatase** EC 3.1.6.8; *other name:* arylsulfatase A; an enzyme involved in the catabolism of sulfatides. It catalyses the hydrolysis of a cerebroside 3-sulfate to a cerebroside

## cerebrospinal fluid

and sulfate. Example (precursor) from human: database code ARSA\_HUMAN, 507 amino acids (53.53 kDa).

cerebrospinal fluid *abbr.*: CSF; a clear fluid, containing little protein and few cells, that fills the subarachnoid space and ventricles of the brain, and the central canal of the spinal cord.

Cerenkov counter *a variant spelling of Cherenkov counter.*

Cerenkov radiation *a variant spelling of Cherenkov radiation.*

Cer(Hex) symbol for ceramide monohexoside. The di- and tri-hexosides are symbolized by Cer(Hex)<sub>2</sub> and Cer(Hexh) respectively. See also Car.

cerinic acid see cerotoyl.

ceroid an autofluorescent, insoluble lipopigment that accumulates in the livers of rats with nutritional cirrhosis.

cerotoyl symbol: Crt; the trivial name for hexacosanoyl, CH<sub>3</sub>-[CH<sub>2</sub>h4CO-], the univalent acyl group derived from hexacosanoic acid (also called certoic acid or (formerly) cerinic acid), a saturated, unbranched, acyclic, aliphatic acid, which occurs naturally in wool fat.

certoic acid see cerotoyl.

cerulein or (Brit.) caerulein a decapeptide, pGlu-Gln-Asp-Tyr(SO3H)-Thr-Gly-Trp-Met-Asp-PheNH<sub>2</sub>, isolated from the skin of various frogs, e.g. *Hyla caerulea*. It is often accompanied by the nonapeptide phyllocaerulein (or phyllocaerlein). Both have the same C-terminal pentapeptide amide sequence as porcine cholecystokinin. Cerulein-like peptides have been isolated from the antrum and small intestine of amphibians, in which they stimulate strongly the secretion of gastric acid.

cerulenin (2R,3S)-epoxy-4-oxo-7E,10E-dodecadienamide; an antifungal antibiotic isolated from *Cephalosporium caerulens* and other sources. It inhibits fatty-acid biosynthesis by binding with 3-oxoacyl-[acyl carrier protein] synthase (see fatty acid synthase complex) and also interferes with sterol biosynthesis by inhibiting hydroxymethylglutaryl-CoA synthase activity.

cerulin *a variant spelling of cerulein.*

ceruloplasmin or (Brit.) caeruloplasmin a bright-blue copper-containing protein found in blood plasma. It has ferroxidase activity, EC 1.16.3.1, and catalyses the reaction:

It binds six or seven Cu<sup>2+</sup> ions per molecule. It is important in iron metabolism and is abnormally low in hepatolenticular degeneration (Wilson's disease). It is one of the acute phase proteins, its level rising late in the acute phase. Example from human: database code CERU\_HUMAN, 1065 amino acids (122.2 kDa).

ceryl the common name for hexacosyl, CH<sub>3</sub>-[CH<sub>2</sub>]<sub>24</sub>-CH<sub>2</sub>-, a saturated, unbranched, acyclic, alkyl group.

cesium chloride or (esp. Brit.) caesium chloride a salt that forms dense solutions in water and so is used in isopycnic centrifugation to separate DNA molecules of different densities.

Cet symbol for the carboxyethyl group, -CH<sub>2</sub>-CH<sub>2</sub>-COOH.

cetaceum an alternative term for spermaceti.

Cetavlon a proprietary name for cetrimide.

cetoleic acid see docosanoic acid.

cetrimide or cetrimumidum a detergent disinfectant consisting of a mixture of alkylammonium bromides, principally cetyltrimethylammonium bromide. See quaternary ammonium compounds.

cetyl or palmityl the common name for hexadecyl, CH<sub>3</sub>-[CH<sub>2</sub>h4-CH<sub>2</sub>-] a saturated, unbranched, acyclic, alkyl group (hexadecyl is preferred).

cetyltrimethylammonium bromide *abbr.*: CTAB; hexadecyltrimethylammonium bromide; N,N,N-trimethyl-1-hexadecanaminium bromide; a cationic detergent useful in the solubilization of membrane proteins; aggregation number 170, CMC 1 mM. It is the principal component of cetrimide.

Cf symbol for californium.

C form of DNA *abbr.*: C-DNA or DNA-C; the molecular conformation adopted by fibres of the lithium salt of duplex DNA at low relative humidity (below approximately 44%). It consists of a right-handed double helix containing about 9.3

## chalcone

nucleotide residues per turn; otherwise it is similar to the B form. See also Aform (def. I), Zform.

CFTR *abbr.* for cystic fibrosis transmembrane conductance regulator.

CG *abbr.* for chorionic gonadotropin (see choriogonadotropin).

cg clone any crown gall clona (def. 1); see crown gall disease.

CGM1 see carcinoembryonic antigen.

cGMP *abbr.* for cyclic GMP; see guanosineJ'5'-phosphate.

CGRP *abbr.* for calcitonin gene-related peptide.

cgs system or CGS system *abbr.* for centimetre-gram-second system; a metric system of units based on the centimetre (length), gram (mass), and second (time). It has now been superseded by the SI system.

Chaikoff homogenizer a hydraulically operated tissue or cell homogenizer in which the sample is forced through an annulus by a piston. The piston diameter relative to that of the annulus is chosen to suit the size of the component that it is desired to isolate with minimal damage.

Chain, (Sir) Ernst Boris (1906-79), German-born British chemical pathologist and biochemist remembered particularly for his part in the development of penicillin (with H. W. Florey) and semisynthetic variants of penicillin as clinically useful antibacterial agents; Nobel Laureate in Physiology or Medicine (1945) jointly with A. Fleming and H. W. Florey' for the discovery of penicillin and its curative effect in various infectious diseases'.

chain reaction a chemical reaction in which one or more reactive intermediates are continuously regenerated, often through a repetitive cycle of elementary 'propagation' steps.

chain-termination codon an alternative name for termination codon.

chain-termination method or dideoxy method or Sanger method a rapid technique for determining nucleotide sequences in DNA in which the 2',3'-dideoxy (or arabinonucleoside) analogues of the normal deoxynucleoside triphosphates are used as specific chain-terminating inhibitors of DNA polymerase. Single-stranded fragments obtained by nuclease action on the DNA are replicated by DNA polymerase I in the presence of a primer and a mixture of one dideoxynucleoside triphosphate and the four normal nucleoside triphosphates, one of which is labelled with 32p. Separate incubations are carried out using analogous terminators for the other nucleotides. The effect is to yield radioactively-labelled stretches of DNA corresponding in length to the number of bases between the 5' end and the position of the base corresponding to the terminator, which will be incorporated once into each stretch of DNA in such a way that it yields an appropriate stretch of DNA for every position occupied by the base in question. The resulting products from each incubation are separated in parallel by gel electrophoresis; from the pattern of radioactive bands obtained the sequence of the fragment can be read off. The method is reasonably accurate for sequences of 15 to about 200 nucleotides.

chair configuration (of a cyclobutadipyrimidine) see pyrimidine dimer.

chair conformation any conformation of a nonplanar, six-membered, saturated ring compound in which the ring atoms in relative positions 1, 2, 4, and 5 lie in one plane, and those in relative positions 3 and 6 lie on opposite sides of that plane. For a monosaccharide or monosaccharide derivative the conformational descriptor -C may be added to its name, and the reference plane is so chosen that the lowest-numbered carbon atom in the ring is exoplanar. See also C'' C, Compare boat conformation.

chalcone 1 phenyl styryl ketone; 1,3-diphenyl-2-propen-1-one. 2 any of a group of hydroxylated derivatives of chalcone (def. I); they are important intermediates in plants in the biosynthesis of flavanones, flavones, flavonols, and anthocyanidins. The chalcone derivative isoliquiritigenin has anti-platelet activity, inhibiting l2-lipoxygenase. It stimulates soluble

**challenge**

guanylate cyclase. It has anti-tumour activity and potently prevents tumour promotion by phorbol esters.

**challenge 1** (*in immunology*) the act or process of injecting antigenic material into an immunized animal to test for immunity or to provoke a further immune response. 2 (*in endocrinology*) the act or process of administering an agent to evaluate hormonal responses. It is used to test hormonal control and function.

**chalone** any inhibitor affecting the cell cycle before the onset of mitosis that is tissue-specific and present in the tissue of action; it need not be species-specific. [From Greek *khalon*, to make slack.]

**channel 1** a passage, often tubular or trough-shaped, along or through which movement of substances, especially fluids, can occur; e.g. a pore through a membrane. 2 the span between selected settings of two discriminators in a pulse counter, e.g. a scintillation counter, that defines the range of pulse intensities that will be recorded. 3 to guide into or cause to move through a particular channel or along a particular route; e.g. to channel a metabolite along a particular metabolic pathway. 4 descriptive of a membrane protein that transports ions across the membrane in the direction of the concentration gradient. See also calcium channel, potassium channel, sodium channel. - channelled or (US) channeled adj.

**channel carrier** see ionophore.

**channel-forming integral membrane protein 28** abbr.: CHIP 28; other name: aquaporin I; an integral membrane protein that forms a water-specific channel that provides the plasma membranes of red cells and kidney proximal tubules with high permeability to water. It is a homotetramer. Example from human: database code AQPLHUMAN, 269 amino acids (28.49 kDa).

**channelling** or (US) channeling (*in column chromatography*) the uneven flow resulting from inhomogeneous packing of the column.

**channel protein** an integral (cell membrane) protein that permits the controlled (gated) movement of ions through a membrane. See calcium channel, potassium channel, sodium channel.

**channels-ratio method** a method of quench correcting in liquid scintillation counting in which two channels are used to measure the average energies of beta particles both before and after quenching.

**chaoptin** an extracellular membrane glycoprotein required for *Drosophila melanogaster* photoreceptor cell morphogenesis and containing a leucine-rich repeat domain. It is a cell-type specific adhesion molecule, exclusively localized to photoreceptor cells, linked to the outer surface of the membrane by a GPI-anchor. Example (precursor) from *D. melanogaster*: database code CHAO\_DROME, 1134 amino acids (130.57 kDa).

**Chaotropicase** the proprietary name for a mixture of endopeptidases isolated from *Streptomyces griseus*, so named for their stability and activity in the presence of the chaotrope 6 M guanidinium chloride.

**chaotropic** or chaotropic agent any substance that increases the transfer of apolar groups to water because of its ability to decrease the 'ordered' structure of water and to increase its lipophilicity. Chaotropes are usually ions, e.g. SCN<sup>-</sup>, CNS<sup>-</sup>, ClO<sub>4</sub><sup>-</sup>, I<sup>-</sup>, Br<sup>-</sup>, CH<sub>3</sub>-COO<sup>-</sup>. They cause the dissolution of biological membranes, the solubilization of particulate proteins, changes in the secondary, tertiary, and quaternary structure of proteins, and denaturation of nucleic acids.

**chaotropic dissociation assay** a technique used to measure the heterogeneity of antibody affinities in, e.g., serum. Immune complexes are dissociated in buffers of varying strengths and pH or in chaotropic agents (see chaotropic). Low-affinity antibodies dissociate more readily.

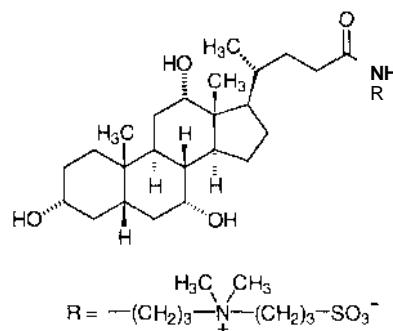

**chaperone** any of a functional class of unrelated families of proteins that assist the correct non-covalent assembly of other polypeptide-containing structures *in vivo*, but are not components of these assembled structures when they are performing

**Chargaff's rules**

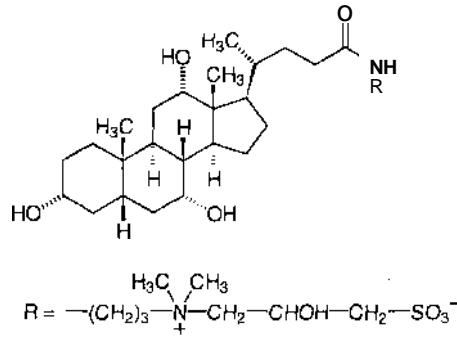

their normal biological functions. See also chaperonin, heat-shock protein.

**chaperonin** any of a ubiquitous subclass of molecular chaperones implicated in the folding of other proteins. They include two kinds of proteins: (1) chaperonin 60 kDa (*also called* chaperonin-60 or cpn 60; the counterpart in other structures of the product of the *groEL* gene of *Escherichia coli*); five motifs identify such chaperonins; example from *Brassica napus*, plastid chaperonin-60: database code BNA60CPNA, 546 amino acids (57.63 kDa); and (2) chaperonin 10 kDa (*also called* chaperonin-10 or cpn 10; the counterpart in, e.g., *Mycobacterium* of the product of the *groES* gene of *E. coli*). See also heat-shock protein.

**CHAPS** 3-[(3-cholamidopropyl)dimethylammonio]-I-propanesulfonate; a zwitterionic detergent combining the properties of sulfobetaine and bile-salt types of detergent. It is used for membrane solubilization. Aggregation number 4-14, CMC 6-10 mM.

**CHAPSO** 3-[(3-cholamidopropyl)dimethylammonio]-2-hydroxy-I-propanesulfonate; zwitterionic detergent combining the properties of sulfobetaine and bile-salt types of detergent; it is more soluble than CHAPS. Aggregation number II, CMC 8 mM.

**characteristic group** (*in chemistry*) any atom or group that is incorporated into a parent compound otherwise than by a direct carbon-carbon linkage, but including the groups -C=N and =C=X where X is O, S, Se, Te, NH, or substituted NH.

**characteristic time** a measure of the time required for a system to change from one state of motion to another, usually taken as the time required for the system to approach within one half of the new state of motion.

**characteristic X-ray** see X-rays.

**Charcot-Marie-Tooth disease** see myelin proteins.

**Chargaff's rules** a set of quantitative rules describing the base composition of duplex DNA: (1) [A] = [T] and (2) [G] = [C], where the square brackets denote the concentrations of the

**charge**

bases in moles per cent; minor bases, if present, are included with the appropriate major base. Three corollaries follow: (1)  $[A]/[T] = [O]/[C]$ ; (2) total purines = total pyrimidines, i.e.  $[A] + [O] = [C] + [T]$ ; and (3) total 6-aminobases = total 6-keto-bases,  $[A] + [C] = [O] + [T]$ . A further consequence of these relationships is that the  $[A + T]/[G + C]$  ratio is a characteristic property of individual DNAs. (After Erwin Chargaff (1905–), US biochemist.)

**charge 1** to load with the proper or appropriate quantity, e.g. to charge a tRNA molecule with an aminoacyl group, or to charge (an accumulator, capacitor, etc.) with electricity. 2 see **electric charge**. 3 the quantity of electricity held in, e.g., an accumulator or a capacitor. 4 a load. Compare **discharge**.

**charge density symbol  $p$** ; SI unit C m<sup>-3</sup> (coulombs m<sup>-3</sup>).

**charged tRNA** any **aminoacyl-tRNA** molecule.

**charge-relay system** a catalytic triad found in the serine proteases comprising, in chymotrypsin, the residues His<sup>57</sup>, Ser<sup>195</sup>, and Asp<sup>102</sup>, the histidine being hydrogen bonded to the carbonylate of the buried aspartate. Spatially, these residues occur in positions such that the electronegativity of the aspartate carboxyl group can be relayed through the histidine nitrogen atoms to the serine hydroxyl group, enhancing its reactivity.

**chargerin II** other names: A61; protein 8 of H<sup>+</sup>-transporting ATP synthase (EC 3.6.1.34); one of the chains of the nonenzymic component (CF<sub>o</sub> subunit) of the mitochondrial ATPase complex (membrane bound). Example from *Rattus norvegicus*: database code ATP8\_RAT, 67 amino acids (7.63 kDa). See also **W-translocating ATP synthase**.

**charge-shift electrophoresis** a method of **electrophoresis** in a detergent solution in which the net charges of the complexes between amphiphilic proteins and the detergent depend on the charge of the latter, while the net charges on hydrophilic proteins are unaffected. This effect is exploited in, e.g., SDS-polyacrylamide gel electrophoresis.

**charge-transfer chromatography** a method of **liquid-gel chromatography** in which separation is due to electronic coupling between molecules being chromatographed and strong electron donor or acceptor groups attached to the supporting gel.

**charge-transfer complex** a complex that may be formed in an oxidation-reduction reaction, corresponding to electronic transition(s) to an excited state in which there is a partial transfer of electronic charge from the electron donor to the electron acceptor.

**charging** the covalent attachment of an aminoacyl group to a tRNA molecule to form an **aminoacyl-tRNA** molecule.

**Charles's law** see **gas laws**. [After Jacques Alexandre Cesar Charles (1746–1823), French physicist.]

**charybdotoxin abbr.**: ChTX; a 37-residue peptide isolated from the venom of the scorpion *Leiurus quinquestriatus hebraeus*. It is a potent inhibitor of some Ca<sup>2+</sup>-activated K<sup>+</sup> channels and voltage-dependent K<sup>+</sup> channels, and probably acts at the outer face of the membrane, blocking the ion conductance channel. It has links between Cys residues 7–28, 13–33, and 17–35; amino-acid sequence:

XFTNVSCTTSKGCWSVCQRLHNTSR-  
OKCMNKKCRCYS

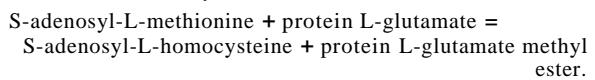

(X = pyroglutamyl).

**chase 1** the effective termination of incorporation of either a (radio)nuclide or a labelled compound into a substance, brought about by the addition of a large excess of an isotope of the (radio)nuclide or the unlabelled compound to the system, used especially after a pulse. 2 the quantity of isotope or unlabelled compound added to stop the incorporation of a (radio)nuclide or a labelled compound.

**ehs** the symbol for any of a class of genes that are implicated in chemotaxis in *Escherichia coli*. For example, *cheA* encodes a chemotaxis protein, protein phosphotransferase (EC 2.7.1.-), that is autophosphorylated and transfers its phosphate to CheB and CheC. Other two-component bacterial regulatory proteins are related. Example: database code CHEA\_ECOLI,

**chemical cleavage method**

654 amino acids (71.24 kDa). *cheB* encodes a chemotaxis protein, **protein-glutamate** methylesterase (EC 3.1.1.61), that catalyses the hydrolysis of protein L-glutamate O-methyl ester to protein L-glutamate and methanol. The protein is a **methyl-accepting chemotaxis protein** (MCP), the methylation state of which is crucial for sensory responses and adaptations. Example: database code CHEB\_ECOLI, 349 amino acids (37.45 kDa). *cheR* encodes the chemotaxis protein methyltransferase (EC 2.1.1.80); it catalyses the reaction:

The protein is an MCP, the methylation state of which is crucial for sensory responses and adaptations. Example: database code CHER\_ECOLI, 286 amino acids (32.71 kDa). *cheW* encodes a purine-binding chemotaxis protein that is involved in the transmission of sensory signals from chemoreceptors to the flagellar motors. Example: database code CHEW\_ECOLI, 167 amino acids (18.06 kDa). *cheY* encodes a chemotaxis protein involved in the transmission of sensory signals from chemoreceptors to flagellar motors and the regulation of clockwise rotation. Example: database code CHEY\_ECOLI, 128 amino acids (13.95 kDa); the 3-D structure (NRL\_3CHY) is known; the structure is largely a-helical, with some β-strands. *cheZ* encodes a chemotaxis protein thought to be involved in generating a regulating signal for bacterial flagellar rotation. Example: database code CHEZ\_ECOLI, 214 amino acids (23.95 kDa).

**checkpoint** a point in the eukaryotic **cell division cycle** where the cycle can be halted until conditions are suitable for the cell to proceed to the next stage.

**chel abbr.** for chelate effect.

**chelate 1** any chemical species in which there is **chelation**. 2 of, or denoting, a chelate (def. I). 3 to form a chelate compound; to effect **chelation**. A chelate compound is a chemical compound in which a metal ion is combined with a substance that contains two or more electron donor groups so that the resulting structure contains one or more rings. -**chelated adj.**

**chelate effect abbr.**: chel; the stability difference between a chelate complex and the corresponding complex with simple ligands. For the displacement reaction:

$$\text{chel} = \log P_m (\text{ML}_m) - \log \beta_n (\text{MA}_n)'$$

where  $\text{ML}_m$  and  $\text{MA}_n$  are complexes containing an equal number of the same donor atoms. Ligand L is multidentate, containing several donor atoms of the same element as the unidentate ligand A, and  $P_m$  and  $\beta_n$  are the overall stability constants.

**chelating agent or chelator** a substance that is able to form a chelate compound with a metal ion.

**chelation** the formation or presence of bonds from two or more atoms within the same ligand to a single central (metal) atom.

**Chelex 100** the proprietary name for a synthetic ion-exchange resin consisting of a styrene divinylbenzene copolymer containing paired iminodiacetate groups that act as chelating groups in binding metal ions, especially transition-metal or other divalent ions.

**chemical adsorption** an alternative term for **chemisorption**.

**chemical antagonism** antagonism resulting from the chemical combination of an **antagonist** with the substance being antagonized.

**chemical carcinogen** any carcinogenic substance of low relative molecular mass. See **carcinogen**.

**chemical cleavage method or Maxam-Gilbert method** a rapid technique for determining nucleotide sequences in DNA (or in restriction fragments) that depends on labelling either end of a DNA strand with <sup>32</sup>P and the subsequent preferential, partial chemical cleavage of the labelled DNA specifically at

## chemical coupling hypothesis

positions occupied by one of the four possible bases. This results in a nested set of radioactive fragments extending from the  $32p$  label to each of the positions occupied by the particular base. The process is then repeated with cleavage, in turn, at each of the other three bases. The four sets of radioactive fragments are then separated, in adjacent lanes, by polyacrylamide gel electrophoresis, which arranges oligonucleotides in ascending order of the number of nucleotide residues contained. The base sequence of the original piece of DNA can be read directly from an autoradiograph of the resultant gel. The method can be used for sequences of 150 or more nucleotide residues. *Compare* chain-termination method. [After Allan M. Maxam and Walter Gilbert (1932-).]

**chemical coupling hypothesis** the hypothesis that the coupling of ATP synthesis to oxidation in oxidative phosphorylation is due to the formation of common 'high-energy' intermediates during electron transport that are subsequently used to phosphorylate ADP to ATP. It has been superseded by the chemiosmotic coupling hypothesis.

**chemical equivalent** the combining proportion of a substance, by mass, relative to a hydrogen standard. The chemical equivalent of an element is the number of grams of that element that will combine with or replace 1 g of hydrogen.

**chemical exchange** the changing magnetic environment of an atomic nucleus in a molecule that is rapidly undergoing reversible chemical or physical changes, which in turn produces changes in the chemical shift of that nucleus.

**chemically induced dynamic nuclear polarization abbr.: CIDNP**; a technique for the direct detection and identification of low concentrations of free radicals by electron spin resonance. It depends on strong polarization of certain nuclear spins by the unpaired electron during the molecule's existence as a free radical.

**chemical messenger** a term sometimes used loosely to mean variously a hormone, a neurocrine or paracrine transmitter, or a rheoseme. *See also* second messenger.

**chemical oxygen demand abbr.: COD**; a measure of the oxygen equivalent of that portion of the organic matter in a sample of water that is susceptible to oxidation by a strong chemical oxidant. Essentially the sample is boiled under a reflux condenser with potassium dichromate in strong sulfuric acid (with silver sulfate as catalyst); part of the dichromate is reduced by the contained organic matter and the remaining dichromate is titrated with ferrous sulfate. The result is expressed as milligrams oxygen absorbed from standard dichromate per litre of sample. *Compare* biochemical oxygen demand.

**chemical pathology** the branch of pathology dealing with the biochemistry of disease processes and the measurement of the amounts of substances present in body fluids and other samples as an aid to diagnosis.

**chemical potential symbol:  $\mu$** ; the partial molar free energy of a chemical entity; the entity in question may be indicated by a subscript. For example,  $\mu_B$  symbolizes the chemical potential of entity B in a mixture of entities B, C, ... etc. It is defined by:

$$\mu_B = (\partial G / \partial n_B)_{T, P, n_C}$$

where  $G$  is the Gibbs energy of the mixture,  $T$  is the thermodynamic temperature,  $P$  is the pressure, and  $n_B, n_C, \dots$  etc. are the amounts of the entities B, C, ... etc. in the mixture.

**chemical quenching** or impurity quenching the quenching that occurs in liquid scintillation counting due to diffusion-controlled collisional interaction between the quencher molecules and the excited solvent and solute molecules. *Compare* colour quenching.

**chemical reaction** any single process or operation involving the interconversion of chemical species through changes in orbital electrons but not in the atomic nuclei.

**chemical score** a measure of the nutritional value of a protein. The limiting essential amino acid in the test protein is expressed as the percentage of the amount of the same amino

acid present in egg albumin, the nutritionally perfect protein. Chemical score is numerically equal to biological value. **chemical shift** the displacement of a resonance signal in NMR spectroscopy along the magnetic field coordinate resulting primarily from the magnetic effects of the chemical environment of the nuclei producing that signal. *See* nuclear magnetic resonance.

**chemical species** any set of chemically identical molecular entities, the members of which have the same composition and can explore the same set of molecular energy levels within the time scale of a particular experiment. Two conformational isomers may interconvert sufficiently slowly to be considered separate chemical species on an NMR time scale, but in a slow chemical reaction they may interconvert sufficiently quickly to be considered as a single chemical species.

**chemical transmitter** (*sometimes*) an alternative term for neurotransmitter.

**chemiluminescence** the production of visible light (luminescence) occurring as a result of a chemical reaction. It occurs, for example, during the respiratory burst in neutrophils and other phagocytic cells. The phenomenon is now exploited in sensitive enzyme assays and labelling methods in nucleic-acid hybridization, etc.

**chemiosmotic coupling hypothesis** a hypothesis proposed in 1961 by the British biochemist Peter Mitchell to explain ATP formation in mitochondria. Essentially it states that the energy-yielding reactions of the respiratory chain are coupled to the energy-requiring reactions of phosphorylation through the creation of a membrane electrochemical potential. An electrochemical gradient of  $H^+$  ions, and a voltage gradient, is established across the mitochondrial inner membrane during electron flow through the respiratory chain. The electron carriers of the respiratory chain serve as an active-transport system or 'pump' to transport  $H^+$  ions from the mitochondrial matrix across the inner membrane, which is an integral part of the coupling mechanism. The electrochemical gradient thus formed drives the synthesis of ATP from ADP and  $P_i$ . A similar mechanism is believed to drive oxidative phosphorylation in the chloroplast during the light reactions of photosynthesis.

**chemism** (*rare*) chemical action, operation, activity, or force. **chemisorption** or chemical adsorption a type of adsorption in which the forces involved are valence forces of the same kind as those operating in the formation of chemical compounds. *Compare* physisorption.

**chemoattractant** an alternative term for attractant.

**chemoautotroph** or chemolithotroph any organism that is both an autotroph and a chemotroph. -chemoautotrophic *adj.*

**chemoceptor** an alternative name for chemoreceptor (esp. in immunology).

**chemography** an artefact in autoradiography due either to the creation of reduced crystals in the photographic emulsion by chemicals present in the specimen (positive chemography), or to the removal of latent images, also by chemicals in the specimen (negative chemography).

**chemoheterotroph** or chemoorganotroph any organism that is both a chemotroph and a heterotroph. -chemoheterotrophic *adj.*

**chemokine** or intercrine any of a subgroup of cytokines acting primarily on hemopoietic cells in acute and inflammatory processes and other immunoregulatory functions. They are chemotactic and related by primary structure, especially conservation of a motif of four cysteines, the first two of which are either adjacent or separated by one other residue.

**chemolithotroph** an alternative term for chemoautotroph.

**chemoorganotroph** an alternative term for chemoheterotroph.

**chemoreceptor** or chemoceptor any receptor on a cell that receives chemical stimuli and reacts to them or binds them. **chemostat** a device for the continuous culture of bacterial (and other) cells. Growth occurs in an aerated fermenter vessel and its rate is controlled by the rate of addition of fresh nutrient from a reservoir (i.e. the dilution rate); this in turn controls the rate of removal of cells (and culture medium). In a

## chemosynthesis

chemostat, as opposed to an auxostat, the dilution rate is constant. At equilibrium, the rate of production of new cells by multiplication is equal to the rate of removal of grown cells. **chemosynthesis** the synthesis of organic chemical compounds by an organism using energy obtained from the oxidation of inorganic chemical compounds rather than from light. *Compare* photosynthesis. -*chemosynthetic adj.*

**chemotactic factor for macrophages** *see* lymphokine.

**chemotaxin (sometimes) an alternative term for cytotoxin.**

**chemotaxis** 1 a movement of a motile cell or organism (*see* taxis) in response to a specific chemical concentration gradient. Movement may be towards a higher concentration (positive chemotaxis) or towards a lower concentration (negative chemotaxis). In *Escherichia coli* the *ehe* family of genes has been implicated in controlling certain aspects of chemotaxis, and galactose/glucose binding protein is also involved. *See also* cytotoxicity. 2 (*in immunology*) the migration of polymorpho-nuclear leukocytes and macrophages towards higher concentrations of certain fragments of complement such as C3a and C5a. *See also* lymphokine. -*chemotactic adj.*

**chemotaxonomy** the classification of organisms on the basis of the nature, content, and/or the distribution of constituent chemical substances, e.g. DNA.

**chemotherapy** the treatment of disease, especially infections and neoplasms, with chemical agents (chemotherapeutic agents) that act specifically on infective organisms or tumours. The term also describes the treatment of psychiatric disease with chemical agents (as opposed to cognitive therapy). -*chemotherapeutic adj.*

**chemotractant** *see* attractant.

**chemotroph** any organism that derives its energy from exogenous chemical sources, independently of light. Chemotrophs may be subdivided into (1) chemoautotrophs (or chemolithotrophs) i.e. organisms that are both chemotrophs and autotrophs and (2) chemoheterotrophs (or chemoorganotrophs) i.e. organisms that are both chemotrophs and heterotrophs. *Compare* phototroph. -*chemotrophic adj.*; *chemotrophy n.*

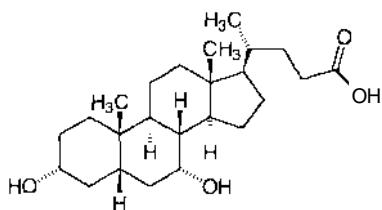

**chemotropism** the orientation of cells or organisms in response to chemical stimuli. The term is used especially of plants or plant organs. *See also* tropism. -*chemotropic adj.*

**Cheng-Prusoff equation** an equation relating the concentration, *I<sub>so</sub>*, of a competitive ligand required to reduce the binding of a substrate to an enzyme by 50%, to the dissociation constant, *K<sub>i</sub>*, of the enzyme-inhibitor complex; it is:

$$I_{so} = K_i (1 + S/K_m)$$

where *S* is the substrate concentration and *K<sub>m</sub>* the Michaelis constant for the enzyme-substrate complex.

**chenodeoxycholate** or **chenodiol** the anion of (3 $\alpha$ ,5 $\beta$ ,7 $\alpha$ )-3,7-dihydroxycholan-24-oic acid; a major component of bile in some species (hens, geese) but a minor component in humans. It is used therapeutically to decrease the synthesis of cholesterol and to help dissolve cholesterol gallstones.

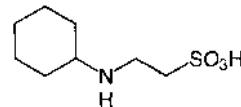

**Cherenkov, Pavel Alekseyevich** (1904-1990), Russian-born Soviet physicist noted for his study of the effects produced by high-energy charged particles; Nobel Laureate in Physics

(1958) jointly with I. M. Frank and I. Y. Tamm 'for the discovery and interpretation of the Cherenkov effect'.

**Cherenkov counter** or **Cerenkov counter** a device for counting charged particles, or radionuclides emitting them, that depends on Cherenkov radiation.

**Cherenkov radiation** or **Cerenkov radiation** a radiation of bluish light, consisting of photons, emitted when charged particles, especially high-energy beta particles, pass through either a solid or liquid medium at velocities greater than that at which light passes through the same medium. The effect is analogous to the creation of a sonic boom that occurs when an object exceeds the speed of sound in a medium.

**Ches** abbr. for 2-(cyclohexylamino)ethanesulfonic acid; a compound with similar properties to a Good buffer substance; pK<sub>a</sub> (25°C) = 9.3.

**chewing gum** *see* chicle.

**chi symbol:** X(lower case) or X(upper case); the twenty-second letter of the Greek alphabet. For uses *see* Appendix A.

**chiasma** (pl. chiasmata) 1 (*in genetics*) a connection formed between chromatids, visible during meiosis, thought to be the point of the interchange involved in crossing-over. 2 or (*esp. US*) **chiasm** (pl. chiasms) (*in anatomy*) a decussation or intersection, as of two nerves; e.g. optic chiasma.

**chicle** a mixture of *cis*- and *trans*-*l,4-polypropenoids* obtained from the evergreen tree, *Achras sapota*; the original chewing gum base.

**chimera** or (*esp. Brit.*) **chimaera** (*in genetics*) an organism comprising tissues of two or more genotypes. Chimeras can occur as a result of mutation, abnormal distribution of chromosomes, or grafting. *See* mosaic, transgenic, chimeric molecule. -*chimeric* or *chimaeric adj.*

**chimeric molecule** 1 any of the hybrid DNA molecules formed when DNAs from different sources are digested with the same restriction endonuclease and the digests are mixed. The DNA fragments in the mixture become associated by hydrogen bonds between complementary sequences to form new arrangements, which may be converted into covalently linked molecules by the action of DNA ligase. This process can produce chimeric plasmids and other chimeric structures. 2 a chimeric protein is a protein obtained by the insertion or substitution of a partial sequence from one protein into another, typically using eDNA technology. The resultant protein thus has elements of both the original proteins. 3 a recombinant antibody that has, e.g., structural characteristics of both human and mouse antibodies.

**chimerin** any of several related proteins that function as GTP-ase-activating proteins, specific for the p21 Ras-related Rac GTPase. They include n-chimerin, and a- and f3-chimerins. n-Chimerin is a cerebellar protein and f3-chimerin is expressed in testis. They are phorbol ester receptors, with an N-terminal domain homologous to the zinc-finger region of protein kinase C, and a C-terminal domain homologous to the product of BeR. Through their action on Rac, they lead to changes in cytoskeletal organization. Example from human: database code A53764, 466 amino acids (53.81 kDa).

**chimyl alcohol glycerol** 1-hexadecyl ether, (+)-3-(hexadecyl-oxy)-1,2-propanediol; a hydrolysis product of ether lipids.

**Chinese restaurant syndrome** *see* monosodium glutamate.

**CHIP 28** abbr. for channel-forming integral membrane protein 28.

**chiral** describing a chemical compound that displays chirality.

**chiral drug** a single pure enantiomer of a specified drug rather than the racemate; the enantiomers may have very different

## chiral drug

## chirality

pharmacological effects, e.g. in the case of propoxyphene and levopropoxyphene.

chirality topological handedness; the property of nonidentity of an object with its mirror image. A chiral chemical compound, i.e. one that possesses chirality, is one that cannot be superimposed on its mirror image, either as a result of simple reflection or after rotation and reflection. If superposition can be achieved then the molecule is said to be achiral. Chirality is most commonly due to the presence of one or more chiral centres (formerly referred to as asymmetric carbon atoms) or the presence of a chiral axis (as in allene structures, some of which are found in natural products). Rarely, chirality may also result from the presence of a chiral plane. See also prochiral. [From Greek *kheir*, hand.]

chiral methyl a carbon atom carrying the three hydrogen isotopes, i.e.  ${}^1\text{H}^2\text{H}^3\text{H}$ .

chiral recognition the differentiation of the enantiomers of a compound. This can be achieved by living organisms, chiral molecules, enzymes, drug receptors, etc.

chiroid (*rare*) any molecule that has chirality.

chiroptical describing any of the phenomena that depend on the ability of chiral and other intrinsically asymmetric molecules to rotate the plane of polarized light, known collectively as optical activity. Such phenomena include optical rotation, optical rotatory dispersion, and circular dichroism. The term is also applied to any of the techniques used for investigating these phenomena.

chi sequence or chi site a sequence of base pairs first discovered in a phage lambda mutant, called *chi*. These mutants were found to have single base pair changes creating sites that stimulate recombination. Characteristic of chi sites is a nonsymmetrical sequence of eight base pairs, consensus sequence:

5' GCTGGTGG 3'.

A recombinational hot spot in *Escherichia coli* and a binding site for Rec A is a chi site.

chi site see chi sequence.

chi-square test a statistical test to determine whether an observed series of values differs from a series of values expected on a hypothesis, to a greater degree than would be expected by chance. If  $m$  is the expected value and  $(m + x)$  is the observed value then  $\chi^2 = \sum(x^2/m)$ . The goodness of fit may be found from available tables of  $\chi^2$  and the number of degrees of freedom,  $n$ , in which the observed series may differ from the hypothetical.

chi structure a structure formed when circular duplex DNA that is undergoing recombination is cut with a restriction enzyme. This yields two strands joined at a site intermediate between the ends, which by electron microscopy can yield a shape with the appearance of the Greek letter  $\chi$ . The structure results from the fact that if two circular duplex DNAs undergo site-specific recombination, a single strand from each duplex will be opened and the two single strands ligated to each other to form a figure of eight. If each of the loops of this figure of eight is cut by the restriction enzyme the chi structure will result. Compare Holliday junction.

chitin a linear polysaccharide consisting of P-I,4-linked *N*-acetyl-*O*-glucosamine residues. It is found in annelid cuticle, arthropod exoskeleton, and in some plants and fungi. In fungi, chitin represents the microfibrillar component of the cell wall. See also chitobiose, chitosan.

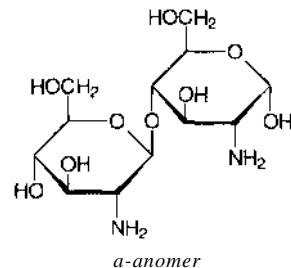

chitinase EC 3.2.1.14; other names: chitodextrinase; 1,4-P-poly-*N*-acetylglucosaminidase; poly-P-glucosaminidase. An enzyme that catalyses the hydrolysis of the 1,4-*P*-linkages of *N*-acetyl-*O*-glucosamine polymers of chitin. Example, endochitinase from *Hordeum vulgare* (barley); database code NRL\_IBAA, 243 amino acids (25.92 kDa); 3-D structure known, largely  $\alpha$  helix.

chitin synthase EC 2.4.1.16; other name: chitin-UDP *N*-acetyl-glucosaminyltransferase; an enzyme that catalyses the reaction between UDP-*N*-acetyl-*O*-glucosamine and *I*,4-(*N*

## chloramphenicol

acetyl-*p*-*O*-glucosaminyl)In to form UDP and [*I*,4-(*N*-acetyl-*p*-*O*-glucosaminyl)]n+1'. Example from *Neurospora crassa*: database code CHS3\_NEUCR, 960 amino acids (106.78 kDa).

chitobiose 4-0-(2-amino-2-deoxy-*p*-*O*-glucopyranosyl)-2-amino-2-deoxy-*O*-glucose; condensed form: GlcN( $\beta$ 1-4)GlcN; a disaccharide found in its acetylated form in chitin. This acetylated form, GlcNAc(PI-4)GlcNAc, is the repeating unit of chitin, and should, logically, have the name chitobiose (by analogy with cellobiose, the repeating unit of cellulose). However, historically the nonacetylated form received the name chitobiose, a convention that has persisted.

chitosamine see glucosamine.

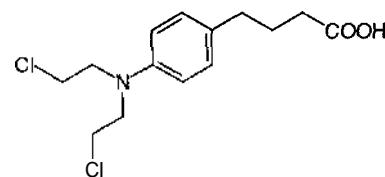

chitosan the cationic polymeric carbohydrate obtained by the deacetylation of chitin.

chitosome a body found in fungi and containing chitin synthase; it synthesizes chitin microfibrils.

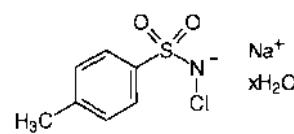

Chi abbr. for chlorophyll.

chlor+ a variant of chloro+ (sometimes before a vowel).

chlorambucil 4-[bis(2-chloroethyl)amino]benzenesbutanoic acid; an alkylating agent that reacts with DNA causing the formation of covalent bonds that cross-link with the two strands of DNA, thereby preventing its replication.

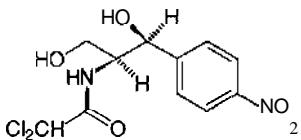

chloramine T N-chloro-4-methylbenzenesulfonamide sodium salt; sodium 4-toluenesulfonchloramide hydrate;  $\text{CH}_3\text{C}_6\text{H}_4\text{SO}_2\text{NCINa}\cdot\text{xH}_2\text{O}$ . A white crystalline solid with a faint odour of chlorine. In aqueous solution it slowly decomposes to sodium hypochlorite and thus is a mild oxidant and antiseptic. It is widely used for the oxidation of radioiodide in the preparation at high specific radioactivity of radioiodine-labelled peptides and proteins for use in radioimmunoassay or other *in vitro* techniques. Microgram quantities of many proteins are labelled efficiently at or near pH 7; however, some proteins may suffer an unacceptable degree of oxidative damage.

chloramphenicol abbr.: CAP; a broad-spectrum, chlorine-containing antibiotic produced by *Streptomyces venezuelae*; it

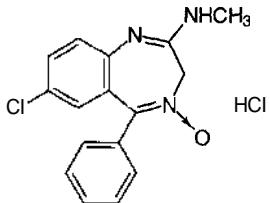

## chloramphenicol o-acetyltransferase

is now produced by chemical synthesis. The configurations at C-1 and C-2 are (*S*), as shown in the structure. It inhibits prokaryotic protein synthesis by attaching to the 50S ribosomal subunit and inhibiting peptidyltransferase (EC 2.3.2.12), thereby preventing the formation of peptide bonds. Chloramphenicol also inhibits protein synthesis in mitochondria, and this accounts for its toxic effect in causing aplastic anemia. It is much used for the treatment of typhoid fever.

**chloramphenicol D-acetyltransferase abbr.: CAT; EC 2.3.1.28;** a bacterial enzyme, not found in eukaryotes, that catalyses the reaction between acetyl-CoA and chloramphenicol to form CoA and chloramphenicol 3-acetate. This reaction forms the basis for acquired chloramphenicol resistance in certain bacterial strains. Also the gene for CAT is used as a reporter because its expression can be detected by a sensitive radiochemical assay. In cDNA technology, for example, the expression of a eukaryotic promoter can be characterized by assay of the enzyme if CAT cDNA is included in the genes to be expressed. Example from *Escherichia coli*: database code CAT2\_ECOLI, 213 amino acids (24.75 kDa).

**chlordiazepoxide 7-chloro-N-methyl-5-phenyl-3H-1,4-benzodiazepin-2-amine 4-oxide;** a CNS depressant noted primarily for its effective anti-anxiety effects at nonsedative doses. It is the prototypical benzodiazepine, used therapeutically as the hydrochloride. It is a controlled substance in the US Code of Federal Regulations. One proprietary name of the hydrochloride is Librium.

**chloride 1 symbol:** Cl<sup>-</sup>; the anion of the element chlorine. 2 any salt of hydrochloric acid. 3 any compound containing a chlorine atom in organic linkage.

**chloride channel** any of a family of proteins that facilitate Cl<sup>-</sup> transport through a membrane. These channels are of two types: (1) ligand-gated Cl<sup>-</sup> channels associated with inhibitory neurotransmitter receptors such as the GABA receptor or the glycine receptor; and (2) voltage-gated Cl<sup>-</sup> channels. These have 13 transmembrane helical regions, the last two being separated by a long (between 130 and 160 residue) cytoplasmic loop. In nerve membranes these channels ensure the high conductance of non-innervated membranes of the electrolyte necessary for efficient current generation caused by Na<sup>+</sup> influx through the acetylcholine receptor at the innervated membrane. Example from *Torpedo californica*: database code CICH\_TORCA, 810 amino acids (89.45 kDa). In muscle cells voltage-gated Cl<sup>-</sup> channels are involved in regulation of cell volume, membrane potential stabilization, and transepithelial transport. Examples: database code CICLHUMAN, 988 amino acids (108.74 kDa). A Cl<sup>-</sup> channel in the kidney proximal tubule is involved in chloride reabsorption. Example

## chloroperoxidase

from *Rattus norvegicus*: database code CICK\_RAT, 686 amino acids (75.63 kDa). See also cystic fibrosis transmembrane conductance regulator.

**chloride shift or Hamberger shift** the phenomenon whereby, because of the isohydric shift, there is a higher concentration of hydrogencarbonate ions in the erythrocytes in blood leaving the tissues (venous blood) than in arterial blood, and hence the hydrogencarbonate/chloride ion ratio is higher in the erythrocytes than in plasma. This results in a movement of hydrogencarbonate ions out of the erythrocytes into the plasma and an equivalent movement of chloride ions from the plasma into the erythrocytes. In the lungs the reverse ion movements occur upon the oxygenation (arterialization) of the blood there.

**chlorin** *a trivial name for 2,3-dihydroporphyrin.*

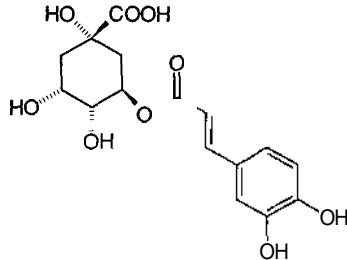

**chlorinate** 1 to treat or react (a substance) with dichlorine. 2 to introduce one or more chloro groups into an organic compound, whether by addition or substitution. 3 to disinfect (especially water) with dichlorine. -chlorination *n.*

**chlorine 1 symbol:** Cl; a halogen element of group 17 of the IUPAC periodic table; atomic number 17; relative atomic mass 35.453. The 15th most abundant element of the Earth's crust, occurring in the combined state, mostly as inorganic chlorides. 2 symbol: Cl<sub>2</sub>; the common name for the yellowish-green gaseous substance, correctly known as dichlorine.

**chloro+ or (sometimes before a vowel) chlor+ comb. form** 1 denoting a chlorine atom in organic linkage. 2 denoting the colour green.

**chlorocruorin** any green, approximately 3 MDa, hemochrome respiratory pigment found in the blood of certain polychaete annelids; it contains 96 heme groups.

**chlorogenic acid** 3-O-(3,4-dihydroxycinnamoyl)-D-quinic acid; a tannin found in tea and coffee.

**chlorolabe** a pigment sensitive to green light (535 nm) found in some retinal cones. It is lacking in subjects with green-blindness but present in those with red-blindness. Compare cyanolabe, erythrolabe.

**p-chloromercuribenzenesulfonate abbr.: PCMBS;** 4-(chloromercu)benzenesulfonate; Cl-Hg-C<sub>6</sub>H<sub>4</sub>-SO<sub>3</sub><sup>-</sup>; a reagent that reacts with thiol groups; it is more soluble than p-chloromercuribenzoate.

**p-chloromercuribenzoate abbr.: PCMB;** 4-(chloromercu)benzoate; Cl-Hg-C<sub>6</sub>H<sub>4</sub>-COO<sup>-</sup>; a reagent that reacts with thiol groups. It is supplied either as p-chloromercuribenzoic acid or as p-hydroxymercuribenzoate sodium salt.

**4-chloromercuriphenylsulfonate** see p-chloromercuribenzene-sulfonate.

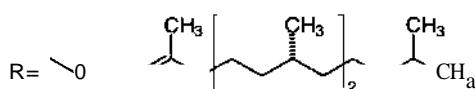

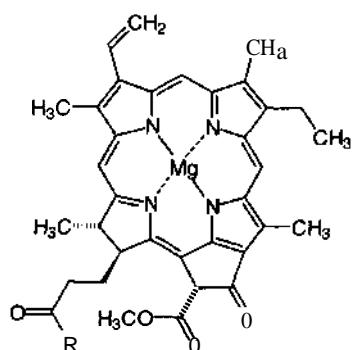

**chloroperoxidase EC 1.11.1.10; other name: chloride peroxidase.** An enzyme that catalyses a reaction between H<sub>2</sub>O<sub>2</sub>, two molecules of Cl<sup>-</sup> ion, and two molecules of an organic compound to form two molecules of an organic chloride and two molecules of H<sub>2</sub>O. It is useful for the introduction of (radioisotopes of) chlorine, bromine, or iodine into tyrosine residues in proteins. It is involved in the synthesis of chlorine-containing compounds such as (*1S-trans*)-2,2-dichloro-1,3-cyclopantanediol (caldariomycin). Example (precursor) from

**p'-chloro-p-phenylaniline**

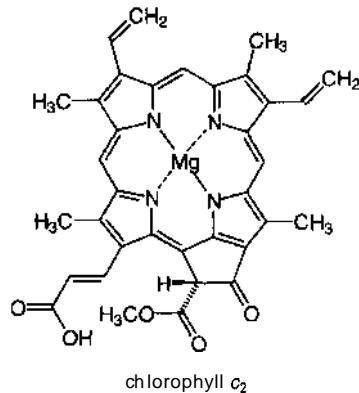

*Caldariomyces fumago*: database code PRXC\_CALFU, 321 amino acids (35.20 kDa).

**p'-chloro-p-phenylaniline** see **4-amino-4'-chlorodiphenyl**.

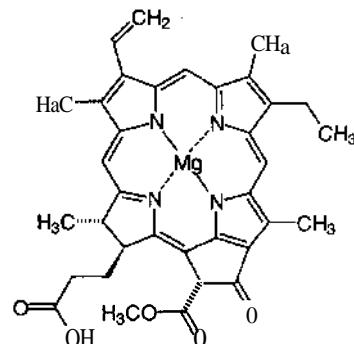

**chlorophyll** any of the several green (or purple, see **bacteriochlorophyll**) pigments, found in plants and photosynthetic bacteria, that function in **photosynthesis** by absorbing light energy mainly in the red and violet-blue parts of the spectrum. Chlorophylls are magnesium complexes of various closely related porphyrins or chlorins. The main chlorophylls of land plants are chlorophylls *a* and *b*, and some algae contain chlorophylls *c*. Chlorophylls *a* and *b* are dihydroporphyrins, having no double bond at position 3 of ring B, while chlorophylls *c* are porphyrins. Photosynthetic bacteria contain various bacteriochlorophylls. The structure of chlorophyll *a* is shown. Chlorophyll *b* differs from chlorophyll *a* only in the presence of a formyl group in place of the methyl group at position 3 on ring B (Fischer system: see **bacteriochlorophyll**). Several chlorophylls *c* are known. They are accessory light-harvesting pigments found in eukaryotic algae that do not contain chlorophyll *b*. The structure of chlorophyll *c<sub>2</sub>* is shown, chlorophyll *c<sub>1</sub>* differing from this in having an ethyl group at position 4 of ring B, and chlorophyll *c<sub>3</sub>* differing from it in having a methylformyl group at position 3 of ring B. Most chlorophylls exist in **antenna complexes**, where their function is to absorb visible light and to transmit the energy so absorbed to a reaction centre in which other chlorophyll molecules are excited by the accumulated energy to transfer an electron to an electron transfer system known as a **photosystem**. Differences in structure have significant effects on the absorption spectrum of the chlorophyll molecule, i.e. on the wavelength of the light absorbed, and thus on the energy available as a result of the absorption (see **Planck constant** for the relationship). To restore its electronic state, the oxidized chlorophyll molecule can accept an electron from a water molecule (or, in photosynthetic sulfur bacteria, from hydrogen sulfide), the transfer being catalysed by a manganese-rich protein complex that is part of the photosystem. This reaction is responsible for the dioxygen (or sulfur) that is formed during photosynthesis, one molecule of dioxygen, four protons, and four electrons being produced from two water molecules. See also P680, P69II, P71I0. [From the Greek *khloros*, yellowish or pale green, and *phyllon*, leaf.]

chlorophyll a

**chlorosorone**

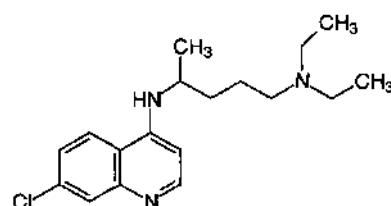

**chlorophyllide a** chlorophyll lacking the terpenoid side chain, usually phytol. The penultimate intermediate in chlorophyll biosynthesis. It is formed by the light-catalysed reduction of protochlorophyllide attached to a protein, protochlorophyllide holochrome.

chlorophyllide a

**chloroplast** or (sometimes) **chloroplastid** a chlorophyll-containing **plastid**, found in cells of algae and higher plants, that is the site of **photosynthesis**. Chloroplasts are characterized by a system of membranes embedded in a hydrophobic proteinaceous matrix, or stroma. The basic unit of the membrane system is a flattened single vesicle called the **thylakoid**; thylakoids stack into grana (*sing.* **granum**). All the thylakoids of a granum are connected with each other, and the grana are connected by intergranal lamellae.

**chloroquine** [*N*<sub>4</sub>(7-chloro-4-quinolinyl)-*N*<sup>1</sup>,*N*<sup>1</sup>-diethyl-1,4-pentanediamine; a widely used synthetic quinoline antimarial drug, with action similar to **quinine**. It accumulates in the cells of the malaria parasites and prevents digestion of their host's hemoglobin; it may also possibly disrupt the parasite's ribonucleotide metabolism. See also **acridine**.

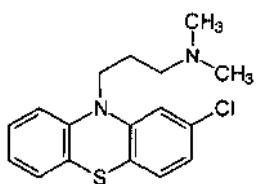

**chlorosome** a small compartment found in photosynthetic

## chlorosulfolipid

Chlorobiaceae bacteria. It contains bacteriochlorophyll *c* and is attached to the cytoplasmic membrane.

**chlorosulfolipid** a class of sulfolipid found in the alga, *Ochromonas danica*. They are based on n-docosane-1,14-diol disulfate; chlorine atoms have been located at C-2, C-13, C-15, and C-16.

**chlorpromazine** 2-chloro-10-(3-dimethylaminopropyl)phenothiazine; a neuroleptic drug with sedative and antiemetic actions. It acts as an antagonist at dopaminergic ( $D_2$ ), a-adrenergic, and many other receptors (see adrenoceptor). It was formerly classed as a major tranquilizer, a term now deprecated. Largactil is one proprietary name of the hydrochloride.

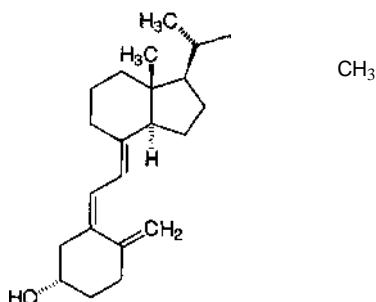

**Cho symbol** for a residue of choline.

**CHO abbr.** for Chinese hamster ovary (applied to cell cultures derived from this organ).

**chole+** or (before a vowel) **chol+** comb. form denoting bile.

**colecalciferol** or **calcidiol** the recommended trivial name for vitamin D<sub>3</sub> (5Z,7E)-(3S)-9,10-seco-5,7,10(19)-cholestatrien-3-ol. It is formed in skin by UV-irradiation of 7-dehydrocholesterol, and is metabolized to 1a,25-dihydroxycolecalciferol (calcitriol). The latter affects the absorption of calcium from the gastrointestinal tract and the metabolism of calcium in bone. See vitamin D.

**cholecalcin** an intracellular calcium-binding protein.

**cholecystokinin** abbr.: CCK; formerly called cholecystokinin-pancreozymin (abbr.: CCK-PZ); gall-bladder emptying peptide hormone from I cells of the duodenum and proximal jejunum of mammals, also present in most parts of the brain and in the nerves of the colon, ileum, and pancreas. It is identical with pancreozymin, the different names relating to the activities by which they were separately identified. The sequence of human cholecystokinin is

KAPSGRMSIVKNLQNLDPHRISDRDY(-S03)-  
MGWMDF-NH<sub>Z</sub>

Sulfation of the tyrosine is essential for activity. Highly heterogeneous, the various species are known by the number of amino-acid residues they contain, e.g. CCK-39, CCK-33 (e.g. human), CCK-12, CCK-8, CCK-4, etc.; all are truncated from the N terminus and thus contain the same C-terminal tetrapeptide amide sequence, which is identical to that of

## cholestanol

gastrin and in which the functional activity of gastrin largely resides. CCK is released when fat, peptones, amino acids, or MgSO<sub>4</sub> are placed on the intestinal mucosa; it causes contraction of the gall bladder and secretion of enzyme precursors from pancreatic acinar tissue, it appears to act as a neurotransmitter in a number of situations, and it elicits the behavioural sequence characteristic of satiety.

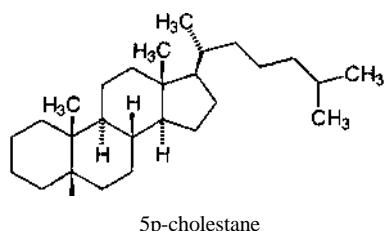

**cholecystokinin receptor** any of several membrane proteins that bind cholecystokinin forms and mediate their intracellular effects. Two types are recognized, designated CCK<sub>A</sub> and CCK<sub>B</sub>. Both types also bind gastrin, but type A binds cholecystokinin with 1000-fold higher affinity than gastrin. When CCK-8 and CCK-4 are used as agonists, CCK-8 is the most potent. Gastrin and CCK-4 are about equipotent, with much greater effect on CCK<sub>B</sub> than CCK<sub>A</sub>. CCK<sub>B</sub> is regarded as the gastrin receptor. Both types of receptor are seven-transmembrane-segment receptors, coupled to G-proteins that stimulate the phosphatidylinositol cycle. Examples, human (precursors), type A: database code CCKR\_HUMAN, 428 amino acids (47.84 kDa); type B: database code GASR\_HUMAN, 447 amino acids (48.42 kDa).

**choleragen (sometimes) an alternative name for cholera toxin.**

**choleragenoid** a 57 kDa protein that occurs naturally in the cell-free culture fluid of *Vibrio cholerae* and is immunologically almost indistinguishable from cholera toxin but is non-toxic. It consists of the pentamer of the B subunit of the toxin without its A subunit.

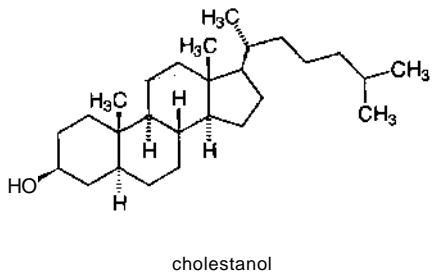

**cholera toxin or choleragen** the antigenic and potently diarrheogenic enterotoxin produced by the cholera bacterium, *Vibrio cholerae*. Pathogenic strains of the bacterium secrete the toxin into their growth medium. The toxin is an 84 kDa multimeric protein of exceptional stability and formed of two dissimilar subunits: the A subunit consists of two polypeptide chains ( $\alpha$ , 22 kDa;  $\gamma$ , 5 kDa) linked by a single disulfide bond; the B subunit consists of four to six noncovalently associated  $\beta$  chains (11.5 kDa each). Binding of the toxin to its receptor ganglioside (G<sub>M1</sub>) in the membranes of sensitive cells occurs via the B subunit; the A subunit then activates cellular adenylate cyclase; together with cellular ADP-ribosylation factor it constitutes an ADP-ribosyltransferase, which transfers ADP-ribose to the G-protein  $\alpha$  subunit, inhibiting its GTPase and converting it to an irreversible activator of adenylate cyclase. Database code CHTA\_VIBCH, 258 amino acids (29.30 kDa), is precursor for chains  $\alpha$  (amino acids 19-211) and  $\gamma$  (amino acids 213-258); database code CHTB\_VIBCH, 124 amino acids (13.94 kDa), is precursor for  $\beta$  chain (signal is amino acids 1-21).

**cholestane** the fully saturated carbon skeleton from which cholesterol is structurally derived; the configuration at C-5 can be *a* or *p*; 5*p*-cholestane is known as coprostanone.

5*p*-cholestane

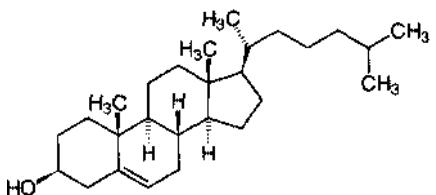

**cholestanol** 3*P*,5*a*-cholestane-3-01; dihydrocholesterol; 3*P*-hydroxycholestanone; a steroid that occurs in human feces, gallstones, and in eggs.

**cholestasis**

**choleataaia** the arrest (stasis) or impairment of bile flow. It may originate intrahepatically, due to hepatocellular defects, or extrahepatically, often due to obstruction of the bile duct by calculi.

**cholesteric** of, relating to, or resembling cholesterol or a derivative of cholesterol. *See also liquid crystal.*

**cholesterol** cholest-5-en-3p-ol; the principal sterol of vertebrates and the precursor of many steroids, including bile acids and steroid hormones. It is found in all animal tissues, especially brain and spinal cord, in the bile, and in gallstones, being a component of the plasma membrane lipid bilayer. It is also a component of the plasma lipoproteins and excessive levels in the plasma have been implicated in atherogenesis. It is synthesized from acetyl-CoA via hydroxymethylglutaryl-CoA and squalene.

**cholesterol acyltransferase** *see sterol O-acyltransferase.*

**cholesterol desmolase** *see cholesterol monooxygenase.*

**cholesterol 7a-hydroxylase** *see cholesterol 7a-mono-oxygenase.*

**cholesterol 7a-monooxygenase** EC 1.14.13.17; *other names:* cholesterol 7a-hydroxylase; cytochrome P450 VII; a cytochrome P450 enzyme that catalyses the hydroxylation of cholesterol to form 7a-cholesterol. NADPH and dioxygen are reactants, NADP<sup>+</sup> and H<sub>2</sub>O being formed. This is the first step in the biosynthesis of bile acids from cholesterol and is rate-limiting. Example from human: database code CP70\_HUMAN, 504 amino acids (57.66 kDa).

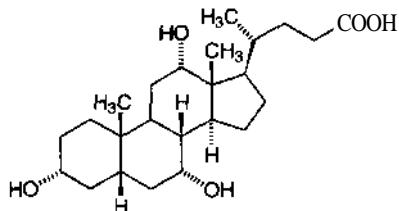

**cholesterol monooxygenase (aide-chain cleaving)** EC 1.14.15.6; *systematic name:* cholesterol-reduced-adrenal-ferredoxin:oxygen oxidoreductase (side-chain-cleaving); *other names:* CYPXIAI cholesterol desmolase; cholesterol side-chain cleavage enzyme; cytochrome P450,cc; a cytochrome P450 enzyme that catalyses the formation of pregnenolone from cholesterol, with release of 4-methylpentanal and H<sub>2</sub>O. It is the first enzyme in the pathway for the biosynthesis of steroid hormones from cholesterol and is a rate-limiting step. It is a target for regulatory systems that stimulate steroid hormone biosynthesis. The reaction involves an oxidation by dioxygen, reduced adrenal ferredoxin being oxidized in the process. This is a heme-thiolate enzyme. Example from human: database code CPMI\_HUMAN, 521 amino acids (60.11 kDa); a theoretical 3-D model for the bovine enzyme has been produced: database code NRL\_ISCC, 482 amino acids (56.46 kDa).

**cholinceptor**

**cholesterol side-chain cleavage enzyme** *see cholesterol monooxygenase (side-chain cleaving).*

**cho••tyramine resin** *see colestyramine resin.*

**cholic acid** 3a,7a,12a-trihydroxy-5p-cholan-24-oic acid; a metabolic derivative of cholesterol, produced in the liver and secreted as a **bile acid**. It is used as a detergent, as the sodium salt; aggregation number 2, CMC 9–15 mM.

**choline** symbol: Cho; abbr.: Ch; N,N,N-trimethylethanolammonium (ion); 2-hydroxyethyltrimethylammonium (ion); 2-hydroxy-N,N,N-trimethylethanaminium; (CH<sub>3</sub>)<sub>3</sub>N<sup>+</sup>·CH<sub>2</sub>CH<sub>2</sub>OH. An amino alcohol that functions as a methyl group donor in metabolism; it also occurs in the neurotransmitter acetylcholine and in some phospholipids.

**choline acetyltransferase** EC 2.3.1.6; *recommended name:* choline O-acetyltransferase; *systematic name:* acetyl-CoA: choline O-acetyltransferase. An enzyme that catalyses the reaction between acetyl-CoA and choline to form O-acetylcholine and CoA. It is instrumental in the synthesis of the neurotransmitter acetylcholine. Example from rat: database code A48319, 644 amino acids (72.32 kDa). *See also cholinceptor.*

**choline kinase** EC 2.7.1.32; an enzyme that catalyses the phosphorylation by ATP of choline to form O-phosphocholine and ADP. Phosphocholine (choline phosphate) is an important intermediate in phospholipid biosynthesis, reacting with CTP to form CDPcholine. Example from human: database code S23104, 456 amino acids (52.01 kDa). *See also choline-phosphate cytidylyltransferase.*

**choline-phosphate cytidylyltransferase** EC 2.7.7.15; *systematic name:* CTP:choline-phosphate cytidylyltransferase; *other name:* phosphorylcholine transferase. An enzyme that catalyses the formation of **cytidine(5'diphosphocholine** (CDP-choline) from CTP and choline phosphate with release of pyrophosphate. Example from yeast: database code CTPT\_YEAST, 424 amino acids (49.33 kDa).

**cholinergic** describing nerve fibres that, when activated, release acetylcholine or an acetylcholine-like substance from their endings. *Compare adrenergic, peptidergic, purinergic.* *See also cholinceptor.*

**cholinesterase** 1 *recommended name for* EC 3.1.1.8; *other names:* choline esterase II, pseudocholinesterase. An enzyme that hydrolyses a variety of choline esters to choline and a carboxylic acid. In mammals, the enzyme is found in the liver, pancreas, heart, serum, and the white matter of brain. Its function is unknown. In humans, individuals with abnormally low activity of cholinesterase fail to hydrolyse succinylcholine, often given as a muscle relaxant in anaesthesia. The gene (E<sub>1</sub>) encoding the enzyme can exist in at least four allelic forms, the normal (E<sub>1</sub>U), and three variants, E<sub>1</sub>a (atypical), E<sub>1</sub>f (fluoride resistant), and E<sub>1</sub>' (silent). Homozygotes for the atypical gene have a dibucaine-resistant enzyme which is weakly active against most enzyme substrates, and homozygotes for the silent gene exhibit minimal enzyme activity. Individuals having low enzyme activity from whatever cause may suffer prolonged respiratory paralysis after succinylcholine has been administered. Example from *Canis familiaris*: database code CHLE\_CANFA, 141 amino acids (15.09 kDa). 2 alternative name for **acetylcholinesterase**.

**cholinceptor** any receptor for acetylcholine on cholinergic or

## cholinomimetic

## chorion

other neurons; such receptors occur on the postjunctional membrane of synaptic clefts or on terminal axons and mediate the neurotransmitter action of acetylcholine. Cholinoreceptors may be divided into two main types: (1) muscarinic cholinoreceptors of smooth muscle, cardiac muscle, endocrine glands, and the central nervous system at which muscarine, but not nicotine, can readily mimic the action of acetylcholine; and (2) nicotinic cholinoreceptors of skeletal muscle, ganglia, and the central nervous system at which nicotine, but not muscarine, can readily mimic the action of acetylcholine.

Muscarinic acetylcholine receptors for which structures are known are all G-protein-coupled and of the single polypeptide chain, seven-transmembrane-helix class. They fall into five types: four are designated M<sub>1</sub>-M<sub>4</sub>; a fifth, which has been cloned, acts through phosphoinositide-specific phospholipase C when expressed in CHO cells, but although mRNA has been isolated from brain, a translation product has not been found *in vivo*; its database code is ACM5\_HUMAN, 532 amino acids (60.00 kDa). Of the remainder, M<sub>1</sub> (database code, human, ACMLHUMAN, 460 amino acids (51.36 kDa)) and M<sub>3</sub> (database code, human, ACM3\_HUMAN, 590 amino acids (66.05 kDa)) activate phosphoinositide-specific phospholipase C; M<sub>2</sub> (database code, human, ACM2\_HUMAN, 466 amino acids (51.65 kDa)) and M<sub>4</sub> (database code, human, ACM4\_HUMAN, 479 amino acids (53.00 kDa)) are negatively coupled to adenylate cyclase; M<sub>2</sub> also increases potassium channel conductance through the action of G-proteins.

Nicotinic acetylcholine receptors are glycosylated multisubunit pentamers with an intrinsic cation-permeable channel with little selectivity among cations; subunit variants include α, β, γ, δ, and ε. After binding acetylcholine, this type of receptor responds by an extensive change in conformation that affects all subunits and leads to opening of an ion-conducting channel across the plasma membrane. *Torpedo* electric organ and embryonic muscle pentamers have α<sub>2</sub>βγδ, adult mammalian muscle α<sub>2</sub>βδε, and mammalian neurons α<sub>2</sub>β<sub>3</sub> stoichiometry; subunits are of the four-transmembrane-helix class (the segments being termed M<sub>1</sub> to M<sub>4</sub>); bungarotoxin is a selective antagonist. Examples (precursors) from mouse: α, database code ACHA\_MOUSE, 457 amino acids (51.88 kDa); β, database code ACHB\_MOUSE, 501 amino acids (56.87 kDa); γ, database code ACHG\_MOUSE, 519 amino acids (58.68 kDa); δ, database code ACHD\_MOUSE, 520 amino acids (59.08 kDa). The neuronal receptor has two subunits (α and non-α); example, precursors α-3 and β-2 (non-α) respectively from human: database code ACH3\_HUMAN, 502 amino acids (57.05 kDa); and database code ACHN\_HUMAN, 502 amino acids (56.95 kDa).

**cholinomimetic** describing a drug with an acetylcholine-like action.

**cholyl** the acyl group derived from colic acid.

**chondrioma** or **chondriome** 1 the entire mitochondrial content of a cell. 2 all the hereditary determinants that are localized in mitochondria.

**chondriosome** a former name for mitochondrion.

**chondroblast** a cell that secretes the matrix of cartilage.

**chondrocalcific** the C-terminal peptide formed from amino acids 1173-1418 of human procollagen α<sub>1</sub>. Database code (of procollagen α<sub>1</sub>) CAI2\_HUMAN, 1418 amino acids (134.34 kDa).

**chondroclast** a large, multinucleate cell that digests the cartilage matrix.

**chondrocyte** a cartilage cell, formed from a chondroblast.

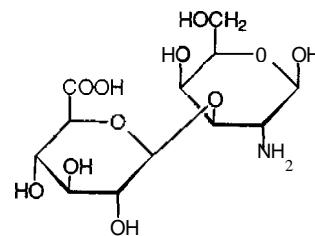

**chondroitinase** see N-acetylgalactosamine-4-sulfatase, N-acetylgalactosamine-&-sulfatase.

**chondroitinsulfatase** see N-acetylgalactosamine-4-sulfatase, N-acetylgalactosamine-&-sulfatase, iduronate-2-sulfatase.

**chondroitin sulfate** any member of a group of 10-60 kDa glycosaminoglycans, widely distributed in cartilage and other mammalian connective tissues, the repeat units of which con-

sist of p(I-4)-linked o-glucuronyl(p-I-3)N-acetyl-o-galactosamine sulfate. They usually occur linked to a protein to form proteoglycans. Two subgroups exist, one in which the sulfate is on the 4-position (chondroitin sulfate A) and the second in which it is in the 6-position (chondroitin sulfate C). They often are polydisperse and often differ in the degree of sulfation from tissue to tissue. The chains of repeating disaccharide are covalently linked to the side chains of serine residues in the polypeptide backbone of a protein by a glycosidic attachment through the trisaccharide unit galactosylgalactosylxylosyl. Chondroitin sulfate B is more usually known as dermatan sulfate.

**chondrosamine** former name for the o-enantiomer of galactosamine, reflecting its presence in chondrosine. **chondrosine** the disaccharide 2-amino-2-deoxy-3-O-*o*-glucopyranuronosyl-*o*-galactopyranose; condensed form: GlcpA(pI-3)GaIN. In sulfated form it is the core unit of chondroitin sulfate.

**chopper** 1 a device for chopping tissue e.g. the McIlwain chopper. 2 (in optics) a device for interrupting a light beam in a regular manner. For example, in a spectrophotometer it consists of a rotating wheel with alternate silvered and cut-out sectors that is placed in the light beam to allow the light to pass alternately through the sample and the reference cells, the photocell thereby generating an alternating current.

**choriocarcinoma** a malignant tumour, typically occurring in the uterus, originating as a proliferation of chorionic villi. It may follow pregnancy or develop from a hydatidiform mole. Choriogonadotropin is an excellent marker for the presence of this tumour.

**choriogonadotropin** or **chorionic gonadotropin** or **choriogonadotrophin abbr.: CG**; the recommended name for a placental glycoprotein hormone that has the gonadotropic activities of both luteinizing hormone (LH) and follicle-stimulating hormone (FSH). It is a member of the family of glycoprotein hormones that includes LH and FSH, the β subunit being specific to choriogonadotropin. It is produced by the corpus luteum after fertilization of the ovum; the blood level rises to a detectable concentration 7-9 days after conception and CG may be detected in urine 1-2 days later, which yields a highly sensitive and specific test for pregnancy. Its administration to males causes increased secretion of testosterone; the lack of such a response indicates testicular failure. It is also a good marker for choriocarcinoma. It is a heterodimer of an α chain (identical with that of LH and FSH) and a β chain that confers specificity. Example from *Equus asinus* β chain (precursor): database code LHSB\_EQUAS, 169 amino acids (17.94 kDa).

**choriomammotropin** or **chorionic mammotropin** or **choriomammotrophin abbr.: CS**; the recommended name for a placental hormone similar in action to somatotropin and prolactin and of similar amino-acid sequence to pituitary gonadotropin. It is also known as chorionic somatomammotropin or placental lactogen (abbr.: PL). Example, human lactogen (precursor): database code PLC\_HUMAN, 217 amino acids (25.02 kDa). **chorion** 1 the highly vascular outermost embryonic membrane of higher vertebrates. In placental animals it has a villous part

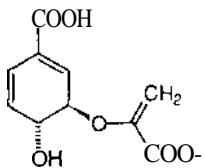

## chorionic gonadotropin

that enters the placenta. 2 membrane of an animal egg, especially the hardened external membrane of an insect's egg.  
**chorionic gonadotropin or chorionic gonadotrophin** *an alternative name for choriogonadotropin.*

**chorionic somatomammotropin or chorionic somatomammotrophin** *an alternative name for choriomammotropin.*

**chorion villus sampling abbr.: CVS**; a technique for a biopsy of the chorion frondosum during pregnancy to obtain fetal tissue for prenatal diagnosis.

**chorismate** the anion of (*3R-trans*)-*3-[(l-carboxyethenyl)oxy]-4-hydroxy-1,5-cyclohexadiene-l-carboxylic acid*; the unsymmetrical ether derived from phosphoenolpyruvate and 5-phosphoshikimic acid (*see shikimate pathway*); it is formed as an intermediate in the biosynthesis of aromatic amino acids and many other compounds. The common pathway to aromatic amino acids bifurcates at chorismate: one branch, the prephenate pathway, leads to phenylalanine and tyrosine; the other branch, the anthranilate pathway, leads to tryptophan. There are many other branchpoints in the shikimate pathway. (Note: the configurations can be stated as *3R,4R*.)

**chorismate mutase** EC 5.4.99.5; an enzyme that catalyses the conversion of chorismate to prephenate. It is the first enzyme in the branch of the shikimate pathway that leads to synthesis of phenylalanine. Isoenzymes are found in cytoplasm and in chloroplasts. The chloroplast isoenzyme is activated by tryptophan and inhibited by phenylalanine and tyrosine. Example from yeast: database code CHMU\_YEAST, 256 amino acids (29.71 kDa). For an example see prephenate dehydratase.

**chorismate synthase** EC 4.6.1.4; *other name: 5-enolpyruvyl-shikimate-3-phosphate phospholyase*; an enzyme that catalyses the formation of chorismate from 5-0-(l-carboxyvinyl)-3-phosphoshikimate with release of orthophosphate. Example from *Escherichia coli*: database code AROC\_ECOLI, 360 amino acids (38.96 kDa). *See also* shikimate pathway.

**Christmas disease** or hemophilia B a sex-linked inherited disorder of blood coagulation due to a deficiency of coagulation factor IX (Christmas factor) activity in the blood. It occurs in humans, dogs, cats, and other species, but is less common than classical hemophilia (hemophilia A) from which it can only be differentiated by laboratory tests.[After S Christmas, the first described sufferer of the disease.]

**Christmas factor** *an alternative name for factor IX. See also blood coagulation, Christmas disease.*

**chrom+** *see chromo+.*

**chromaffin** or **chromaffine** describing a tissue, cell, or subcellular granule that stains deeply with chromium salts.

**chromaffin tissue** a tissue made up of modified neural cells (chromaffin cells) that synthesize, store, and secrete catecholamines. The catecholamines are stored in special subcellular organelles, chromaffin granules, ready for release. Chromaffin tissue is found in all vertebrates, at various bodily locations but especially in the medulla of the adrenal gland.

**chromat+** *see chromat+.*

**chromatic** of, or related to, colour.

**chromatid** one of the two daughter strands of a duplicated chromosome that become apparent between early prophase and metaphase in mitosis and between diplotene and second metaphase in meiosis.

**chromatin** the network of fibres of DNA and protein that make up the chromosomes of the eukaryotic nucleus during

## chromatopile

interphase. It stains strongly with basic dyes. Some parts of the chromosomes are highly dispersed (called euchromatin) and other parts are highly condensed (called heterochromatin). Chromatin is made up of repeating units, each unit consisting of some 200 DNA base pairs and two each of histones H2A, H2B, H3, and H4; most of the DNA is wound around the outside of a core of histones to form nucleosomes. The remainder of the DNA, linker DNA, joins adjacent nucleosomes, thereby contributing flexibility to the chromatin fibre, a flexibly jointed chain of nucleosomes.

**chromatin body** a body, containing ribosomal DNA, that occurs during early oogenesis in some water beetles. It disappears at about the time of vitellogenesis and its contents become dispersed in the nuclear interior.

**chromatin fingerprinting** a two-dimensional electrophoretic technique for simultaneously mapping the total distributions of DNA sizes, protein compositions, and nuclease-mediated precursor-product relationships present in heterogeneous populations of mono- and polynucleosomes. Chromatin, partially digested with micrococcal nuclease, is electrophoretically separated in the first dimension in the presence of inactive DNase I. Subsequently the enzyme is activated by incubating the gel in a magnesium ion-containing buffer and the histones are then separated by electrophoresis in the second dimension.

**chromato+** or (*before a vowel*) **chromat+** *comb. form* 1 denoting colour or coloured. 2 denoting chromatins. 3 indicating chromatogram, chromatograph, or chromatography.

**chromatofocusing** a column-chromatographic technique of high capacity and high selectivity for separating proteins according to their isoelectric points. A pH gradient is formed in a column containing an anion exchanger, by use of a special eluting buffer containing a large number of differently charged species. Proteins emerge from the column as a series of sharply focused zones in descending order of their pI values, with peak widths in the range 0.04–0.05 pH unit.

**chromatogram** the result of a chromatographic separation. It may be directly visible, e.g. in the form of a column or strip of material, or, after processing of data, take the form of a graph.

**chromatograph** 1 to effect a separation by chromatography. 2 an apparatus with which to carry out a particular form of chromatography. -chromatographic *adj.*; chromatographic-ally *adv.*

**chromatography** any technique, analytical or preparative, for separating the components of a mixture by differential adsorption of compounds to adsorbents, partition between stationary and mobile immiscible phases, ion exchange, or a combination of these. *See* individual entries for the many different types of chromatography; these include: adsorption, affinity, affinity-elution, ampholyte-displacement, argentation, ascending, biospecific-elution, charge-transfer, chromatography, circular, countercurrent, covalent, descending, dye-ligand, electro, exclusion, frontal, gas, gas-liquid, gel-filtration, gel-permeation, high-performance liquid-affinity, high-performance liquid, high-pressure liquid, hydrophobic, ion-exchange, ion-exclusion, ionic-interaction, ion-moderated partition, ligand-mediated, liquid, liquid-liquid, metal-chelate affinity, molecular-exclusion, molecular-sieve, negative, paper, partition, permeation, positive, pseudo-affinity, reverse(d)-phase, salting-out, sievorpitive, steric-exclusion, subunit-exchange, thermal-elution, thin-layer, triazine-dye affinity.

**chromatophore** 1 a pigment-containing cell, especially one in the integument of an animal, that is capable of changing the apparent skin colour by contracting or expanding. 2 any of the particles isolated from photosynthetic organisms that contain photosynthetic pigments, e.g. a chromatophore, or membrane fragments from photosynthetic bacteria.

**chromatopile** a stack of filter papers, of the same diameter, that is compressed in a chromatographic column in large-scale separations.

**chromatoplate**

**chromatoplate** the plate that is covered with the support during thin-layer chromatography.

**chromatosome** a nucleosome lacking the linker DNA.

+**chrome** *comb. form* denoting colour, coloured, or pigment.

**chromium symbol:** Cr; the element of proton number 24. It is a paramagnetic, metallic transition element of group 6 of the IUPAC periodic table, with oxidation states of II, III, and IV. Natural chromium has a relative atomic mass of 51.966 and is a mixture of four stable nuclides with nucleon numbers of 50, 52, 53, and 54, the predominant one being chromium-52 (relative abundance 83.789 atom percent). A number of artificial radioactive nuclides are known, of which chromium-51 is the longest lived. Chromium has an abundance of about 0.02% of the igneous rocks of the earth and it occurs in nature exclusively in the combined form, the mixed oxide chromite  $\text{Fe}_2\text{Cr}_2\text{O}_4$  being the chief ore. It is an essential dietary trace metal, but functions in the body primarily as a component of glucose-tolerance factor, the chief symptom of experimental chromium deficiency in animals being impaired glucose tolerance.

**chromium-51** the artificial radioactive nuclide of chromium,  $^{51}\text{Cr}$ . It decays by electron capture, 9.8% of nuclei emitting  $\gamma$ -radiation (0.32 MeV); it also emits X-rays (0.005 MeV, 22%) but no  $\beta$ -particles; it has a half-life of 27.7 days. It is used as chromate for labelling blood cells, and as the I:I complex of  $\text{Cr}^{2+}$  with EDTA for measuring glomerular filtration rate.

**chromo+** or (*before a vowel*) **chrom+** *comb. form* 1 denoting colour, coloured, or pigment. 2 indicating chromium.

**chromobindin** *see annexin I, annexin II, annexin IV, annexin VI.*

**chromogen** 1 the colourless precursor of a dye or pigment, that is converted into the dye or pigment, e.g. by oxidation. 2 a compound containing a chromophore that is not itself coloured but becomes so when an auxochromic group (*see auxochrome*) is introduced into the molecule. 3 any microorganism that produces pigment.

**chromogenic** 1 producing colour. 2 of, or pertaining to, a chromogen.

**chromogenic substrate** a substrate that, when acted on by an enzyme, gives rise to a coloured product.

**chromogranin abbr.:** Cg; either of two soluble proteins, originally discovered in bovine chromaffin granules (*see chromaffin tissue*) but now known to be widely distributed in endocrine (including neuroendocrine) tissues. They are designated chromogranin A (CgA) and chromogranin B (CgB; *also called secretogranin I*). Both proteins are acidic (pI 4.5-5.0), but homology is limited except in the N-terminal and C-terminal regions, and there is a lack of immunological reactivity. Both have been detected immunologically in various mammals, amphibians, birds, and fishes; CgA also occurs in *Drosophila*. CgA is a 430 amino acid  $\text{Ca}^{2+}$ -binding glycoprotein; it is hydrophilic with no hydrophobic stretches, and is co-secreted with many hormones from, e.g., pancreas and thyroid C cells. Both proteins have dibasic cleavage sites for endopeptidases, the action of which leads to the formation of several active peptides: CgA yields parasatin (porcine CgA347-419), an inhibitor of low calcium-stimulated parathyroid cell secretion; pancreasatin (porcine CgA240-2ss), an inhibitor of glucose-induced insulin release from the pancreas; chromosatin (bovine CgA124-143), an inhibitor of catecholamine release by chromaffin cells; vasostatin (bovine CgA<sub>1-76</sub>); beta-granin (bovine CgA<sub>1-114</sub>), an inhibitor of parahormone secretion; and a peptide WE-14. CgB is co-secreted from adrenal medulla with catecholamines, from sympathetic nerve with norepinephrine, and from some cell lines; proteolytic cleavage releases several peptides of unknown function. Example (incomplete but contains entire CgA sequence) from pig: database code CMGA\_PIG, 446 amino acids (48.83 kDa).

**chromomere** any of the beadlike concentrations of chromatin that are arranged linearly along a chromosome.

**chromonema** (*pl. chromonemata*) *cytological term* for 1 all of the threads which make up the nuclear reticulum. 2 any of the

**chylomicron**

smallest strands of DNA in a chromosome or chromatid. 3 a twisted chromatid thread within the chromosome.

**chromophore** any functional grouping within a molecular entity that gives rise to the colour (or characteristic absorption spectrum) of the substance.

**chromoplast** any coloured plastid containing carotenoid pigments but not chlorophyll. Chromoplasts give the yellow to red colours of many flowers (e.g. daffodil), fruits (e.g. tomato), and some roots (e.g. carrot).

**chromoprotein** any of a class of proteins that contain a colour-producing group or chromophore. Both chlorophylls and carotenoids exist in chloroplasts as chromoproteins.

**chromosome** a structure composed of a very long molecule of DNA and associated proteins (e.g. histones) that carries hereditary information. Chromosomes are especially evident in plant or animal cells undergoing mitosis or meiosis, where each chromosome becomes condensed into a compact, readily visible thread. In nondividing cells chromosomes typically assume a more dispersed form called chromatin. The number of chromosomes is characteristic for the species concerned. In a bacterium only one chromosome is evident as the cell is about to divide. After DNA replication, the two new chromosomes attach to a specialized site on the bacterial plasma membrane for segregation to the two daughter cells. -chromosomal *ad.*

**chromosome mutation** a type of mutation (def. 1) involving alteration(s) in chromosome structure.

**chromosome walking** a method used to identify which clone in a gene bank contains a desired gene or sequence that cannot easily be selected for. The gene bank must contain the entire DNA sequence of the chromosome as a series of overlapping fragments. A series of colony hybridizations is carried out, starting with a cloned gene that has already been identified and that is known to be on the same chromosome as the desired gene. This identified gene is used as a probe to pick out clones containing adjacent sequences. These are then used in turn as probes to identify clones carrying sequences adjacent to them, and so on. At each round of hybridization one 'walks' further along the chromosome from the identified gene.

**chromostatin** a 20-amino-acid peptide that can be released *in vitro* by the proteolytic cleavage of chromogranin A. It potently inhibits catecholamine release by chromaffin cells induced by carbamoylcholine or by depolarizing K<sup>+</sup> concentration, and it inhibits secretagogue-induced calcium influx. Its physiological status is uncertain - it is not flanked by dibasic cleavage sites in the precursor.

**chronic** 1 continuing over a long time; repeatedly recurring. 2 (*of a disease*) developing slowly or lasting for a long time.

**chrono+** or (*before a vowel*) **chron+** *comb. form* denoting time. **chronobiocomchemistry** the branch of biochemistry concerned with the biochemical aspects of chronobiology, the study of the inherent rhythmicity or periodicity of living organisms and their activities.

**chrysolamarin** *see callose.*

**chrysotherapy** the use of gold-containing substances in the treatment of disease.

**CHS** (*in clinical biochemistry*) *abbr. for cholinesterase* (def. 1). **ChTX** *abbr. for charybdotoxin.*

**chyle** the white lymph found in the lymph vessels of the intestine (lacteals) during the digestion of fats. It contains globules with a high fat content. *See also chylomicron.*

**chylomicron** a large lipoprotein particle, of molecular mass up to  $10^7$  kDa, measuring up to 100 nm in diameter, and of density < 1.006. The approximate composition (% by weight) of chylomicrons is 2% cholesterol, unesterified; 5% cholesterol, esterified; 7% phospholipid; 84% triacylglycerol; 2% protein. Their apolipoprotein composition (% by weight total apolipoprotein) is 7.4% A-I; 4.2% A-II; 22.5% B-48; 66% C-I + C-II + C-III. Chylomicrons are formed in the mucosa of the small intestine, and contain mostly triacylglycerols re-esterified in the mucosal cells from dietary long-chain fatty acids associated with apolipoproteins. They then enter the lymphatic

## chymase

capillaries (lacteals) of the intestinal villi, and thence the bloodstream. They are the vehicle by which fat is absorbed into the body.

**chymase** EC 3.4.21.39; *other names*: mast cell protease I; skeletal muscle (SK) protease. An enzyme that catalyses preferential cleavage of the bonds: Phe-I-Xaa > Tyr-I-Xaa > Trp-I-Xaa > Leu-I-Xaa. It is a trypsin-like serine proteinase, and a homologue of chymotrypsin; it is found in mast cell granules (heart, lung, etc.). Example, human (precursor): database code MCPI\_HUMAN, 247 amino acids (27.29 kDa).

**chyme** the semifluid mass of partially digested food that passes through the pylorus of the stomach into the small intestine.

**chymopapain** EC 3.4.22.6; *other name*: papaya proteinase II; the major endopeptidase enzyme of papaya (*Carica papaya*) latex; its specificity is similar to that of papain. The protein from that species is: database code PAP2\_CARPA, 218 amino acids (23.66 kDa).

**chymosin or rennin** EC 3.4.23.4; an aspartic proteinase enzyme that cleaves a single bond in  $\kappa$  casein (Ser-Phe<sup>105</sup>-I-Met-Ala) and is responsible for clotting of milk. It is produced from a precursor in the mucosa of the fourth stomach of calves. It is now produced by eDNA technology. Example (bovine): database code NRL\_ICMS, 323 amino acids (35.61 kDa); 3-D structure is known. (*Note*: use of the synonym rennin is now deprecated because of possible confusion with renin.)

**chymotrypsin** a serine endopeptidase, EC 3.4.21.1, formed from the proenzyme chymotrypsinogen by the action of trypsin. In vertebrates, chymotrypsins are contained in pancreatic juice, and hydrolyse protein in the small intestine. Chymotrypsinogen is synthesized in the acinar cells of the exocrine pancreas and stored in zymogen granules until released. Several forms of chymotrypsin are found: Chymotrypsin A is formed from bovine and porcine chymotrypsinogen A. It will hydrolyse peptides, amides, and esters, preferentially at the carbonyl end of Tyr, Trp, Phe, and Leu residues. Chymotrypsin B, formed from chymotrypsinogen B, is homologous with chymotrypsin A. Chymotrypsin C, EC 3.4.21.2, is formed from porcine chymotrypsinogen C and from bovine subunit II of procarboxypeptidase A. It preferentially cleaves at the carbonyl end of Leu, Tyr, Phe, Met, Trp, Gln, and Asn residues. Enzymes homologous to and with similar specificities to chymotrypsin have been isolated from many species. Chymotrypsinogens are synthesized as a single 245-residue polypeptide chain cross-linked by five disulfide bonds. This is fully activated when the bond between Arg<sup>15</sup> and Ile<sup>16</sup> is cleaved by trypsin to yield 1t-chymotrypsin; subsequent autocatalytic cleavage of more peptide bonds (to remove 14-15, 147-148) converts it into a-chymotrypsin. Amino acids 1-13 form chymotrypsin A-chain, 16-146 form chymotrypsin B-chain, and 149-245 form chymotrypsin C-chain, the three chains being covalently linked by disulfide bonds, 1-122, 42-58, 136-201, 168-182, and 191-220. The mechanism involves a charge-relay system of His<sup>57</sup>, Asp<sup>102</sup>, and Ser<sup>195</sup>. Chymotrypsin is more active than trypsin against certain esters, e.g. N-acetyl-L-tyrosine ethyl ester. Chymotrypsin binds  $\alpha_1$ -antitrypsin. Example (bovine): database code CTRA\_BOVIN, 245 amino acids (25.64 kDa). 3-D structure known.

**chymotrypsinogen** *see* chymotrypsin.

**chymotryptic** of, or relating to, chymotrypsin; chymotryptic digestion is the partial hydrolysis of a protein by chymotrypsin.

**Ci symbol** *for* curie.

**e/or cl symbol** *for* lambda repressor.

**CI** abbr. for Colour Index (especially as a prefix to the identifying number for a particular dye or stain).

**CIDNP** abbr. for chemically induced dynamic nuclear polarization.

**CIE** abbr. for counterimmunoelectrophoresis.

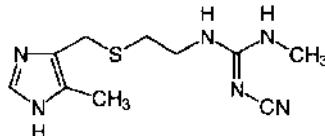

**ciliatine** *see* phosphono-.

**cilium** (*pl. cilia*) a specialized eukaryotic locomotor organelle that consists of a filiform extrusion of the cell surface. Each cilium is bounded by an extrusion of the cytoplasmic mem-

## circular chromosome

brane, and contains a regular longitudinal array of microtubules, anchored basally in a centriole. *Compare* flagellum. -ciliary adj.

**cimetidine** *N-cyano-N'*-methyl-N"-[-2-[(5-methyl-1H-imidazol-4-yl)methyl]thio]ethyl]guanidine; a competitive antagonist of histamine H<sub>2</sub> receptors used clinically as an anti-ulcer drug; it inhibits gastric acid secretion and reduces the output of pepsin. One proprietary name is Tagamet.

**cIMP** abbr. for cyclic IMP; *see* inosine 3'.5'-phosphate.

**ein4** the gene for the enzyme trans-cinnamate 4-monoxygenase found in many plants.

**cinchonine** an alkaloid obtained from cinchona bark and possessing antimalarial properties. *See also* quinine.

**cinnamate** the anion of 3-phenyl-2-propenoic acid; *trans-cinnamate* (3-phenyl-2E-propenoate) is a compound formed from phenylalanine by phenylalanine ammonia-lyase, EC 4.3.1.5; it is the precursor of ferulic and sinapic acids in the pathway for lignin synthesis.

**trans-einnamate 4-monoxygenase** abbr.: CA4H; EC 1.14.13.11; systematic name: trans-cinnamate,NADPH:oxygen oxidoreductase (4-hydroxylating); *other names*: cinnamic acid 4-hydroxylase; cinnamate 4-hydroxylase. An enzyme that catalyses a reaction between *trans-cinnamate*, NADPH, and dioxygen to form 4-hydroxcinnamate, NADP<sup>+</sup>, and H<sub>2</sub>O. It is an endoplasmic reticulum enzyme of high specificity - it does not act on amino acids, phenylacetate, or benzoate - and is the first enzyme in the pathway from cinnamate to lignin. Example from *Catharanthus roseus*: database code CRCIN4HX, 505 amino acids (58.21 kDa).

**cinoxacin** azolinic acid; 1-ethyl-1,4-dihydro-4-oxo[1,3]diox-010[4,5-g]cinnoline-3-carboxylic acid; a 4-quinolone antibiotic with activity against Gram-negative bacteria through the inhibition of DNA gyrase.

**ciprofloxacin** a fluorinated 4-quinolone antibiotic active against both Gram-positive and Gram-negative bacteria although more so against the latter and also active against *Chlamydia* and mycobacteria.

**circadian** describing biological activity (e.g. behavioural, physiological, metabolic) that exhibits an endogenous periodicity of approximately 24 hours independently of any daily variation in the environment. *Compare* diurnal, inhradian, ultradian. [From Latin *circa*, about, + *dies*, day.]

**Circe effect** the phenomenon underlying any physicochemical description of the action of an enzyme upon a substrate. It refers to the strong attractive forces that bind the substrate into the active site of the enzyme, where it undergoes a radical transformation of form and structure. It is named after the sorceress, Circe, who according to Greek mythology transformed the men of Odysseus into beasts.

**circular birefringence** the birefringence produced by left and right circularly polarized light.

**circular chromatography** a technique of paper chromatography in which the substances to be separated are allowed to travel radially from the centre of a filter-paper disk. The material is applied to the centre of the disk from which a small sector is cut out and folded down to allow it to dip into the eluting solvent.

**circular chromosome** a circular DNA duplex, the form taken by the chromosomes of some prokaryotic organisms, e.g. *Escherichia coli*, *Bacillus subtilis*, and *Pseudomonas aeruginosa*.

## circular dichroism

**circular dichroism abbr.:** CD; the difference in absorption of left and right circularly polarized light. The shape and magnitude of the CD curve as a function of wavelength of solutions of proteins (and other macromolecules) are sensitive to changes in conformation of these solutes. *See also* Cotton effect, ellipticity, molecular ellipticity, optical rotatory dispersion.

**circular DNA** any single- or double-stranded DNA molecule with a circular (but not necessarily geometrically circular) structure. If single-stranded, the circle is closed covalently, but if double-stranded, one or both strands may be open. *See also* covalent (closed) circle of DNA.

**circularly polarized light** *see* polarized light.

**cis abbr.:** c; conformational descriptor denoting synperiplanar (use not recommended); *see* conformation.

**cis- abbr.:** C; prefix (in chemical nomenclature) denoting that two specified substituents lie on the same side of a reference plane in the molecule. (*cis* means 'on this side'.) In systematic names it is denoted by the symbol Z. *See cis-trans* isomerism, E/Z convention. *Compare trans-.*

**cis-acting** (in genetics) describing a regulatory genetic element whose effects are sensitive to its position relative to the gene being regulated, i.e. on the same molecule of DNA. Examples include bacterial operators.

**cis-configuration** (in genetics) describing the configuration of two linked heterozygous genes in which both wild-type alleles occur on one of the paired homologous chromosomes while the mutant alleles occur on the other homologue; i.e. (+/ab). *Compare trans configuration.*

**cis isomer** *see* *cis-trans* isomer.

**CISP abbr. for** corticotropin-induced secreted protein; now called thrombospondin-2 (*see* thrombospondin).

**cisplatin** *cis*-diamminoplatinum(IV) dichloride; *cis*-diamine-dichloroplatinum; a substance that interacts with, and forms cross-links between, DNA and proteins. It is used as a neoplasm inhibitor to treat solid tumours, primarily of the testis and ovary.

**cisterna** (pl. *cisternae*) 1 (in cytology) the flattened, saclike space enclosed between paired membranes of the endoplasmic reticulum and the Golgi apparatus. 2 (in anatomy) an enlarged space, such as the cisterna magna in the rear of the brain or the cisterna chyli between the crura of the diaphragm. —*cisternal adj.*

**cis-trans complementation test** a genetic test to determine whether two gene mutations (*a* and *b*) occur in the same functional gene (or cistron). It involves comparison of heterozygotes in which the relevant mutations are in the same chromosome, i.e. in the *cis* configuration (+/ab), with heterozygotes in which the mutations are in separate chromosomes, i.e. the *trans* configuration (a+/b+).

**cis-trans isomer or (sometimes) geometric isomer or geometrical isomer** either of a pair of diastereoisomers that differ only in the positions of atoms relative to a specified reference plane in the molecules, in cases where these atoms are, or are considered as if they were, parts of a rigid structure. The two isomers are designated the *cis* isomer and the *trans* isomer when the two particular atomic groupings lie respectively on the same or on opposite sides of the reference plane. *See also cis-trans isomerism. -cis-trans-isomeric adj.*

**cis-trans isomerism or (sometimes) geometrical isomerism** the phenomenon of the existence of *cis-trans* isomers in general, or the occurrence of paired *cis* and *trans* isomers in a particular molecule. Atoms or groups are termed *cis* or *trans* to one another when they lie respectively on the same or on opposite sides of a reference plane identifiable as common among stereoisomers. For compounds containing only doubly bonded atoms the reference plane contains the double-bonded atoms and is perpendicular to the plane containing these atoms and those directly attached to them. For cyclic compounds the reference plane is that in which the ring skeleton lies or to which it approximates. *See also* E/Z convention.

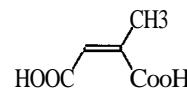

**cistron** a unit of DNA sequence that codes for a single

## citrate cleavage enzyme

polypeptide or protein. It may be a smaller unit than the gene, which contains the unit of DNA determining a single character. Whether or not a cistron is the same as a gene can be determined by the *cis-trans* complementation test, hence the name cistron (*cis* means 'on this side').

**Cit symbol** for a residue of the α-amino acid L-citrulline.

**citraconate** 1 the trivial name for methylmaleate, *cis*-1,2-propylenedicarboxylate, (Z)-2-methyl-2-butenedioate, the dianion of citraconic acid, (Z)-2-methyl-2-butenedioic acid. 2 any mixture of citraconic acid and its mono- and dianions. 3 any salt or ester of citraconic acid.

citraconic acid

**citraconoyl** the bivalent *cis*-acyl group, -CO-CH=C(CH<sub>3</sub>)-CO-, derived from citraconic acid. *Compare citraconyl.*

**citraconyl** either of the isomeric univalent *cis*-acyl groups, HOOC-C(CH)=CH-CO- or HOOC-CH=C(CH<sub>3</sub>)-CO-, derived from citraconic acid. *See also* citraconylation.

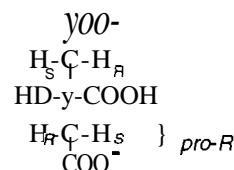

**citraconylation** introduction of one or more citraconyl groups into a substance by acylation. Similarly to maleylation (and succinylation), citraconylation of a protein with citraconic anhydride is used to acylate its free lysine (and other) amino groups in order to change their charge at neutral pH from positive to negative and to render the adjacent peptide bond resistant to hydrolysis by trypsin. Reaction occurs at pH 8 and the citraconyl groups can be removed at pH 3.5 (both operations at 20°C). Introduction of citraconyl groups is slower than is the case with maleyl groups, but their removal is faster and more complete. -citraconylate *vb.*; citraconylated *adj.*

**citratase** *see* citrate Ivase.

**citrate** 1 the trivial name for p-hydroxytricarballylate, 2-hydroxy-1,2,3-propanetricarboxylate,

the trianion of citric acid, 2-hydroxy-1,2,3-propanetricarboxylic acid. 2 any mixture of free citric acid and its anions; the trianion is the predominant form at physiological pH values. It is widely distributed in nature and is an important intermediate in the tricarboxylic-acid cycle and the glyoxylate cycle. Citrate (alone or in mixtures) is useful as a buffer;  $pK_{a1}$  (25°C) = 3.13,  $pK_{a2}$  (25°C) = 4.76,  $pK_{a3}$  (25°C) = 6.40. It is useful also as a component of anticoagulant solutions and has many commercial applications in the chemical, food, pharmaceutical, and other industries. Industrial production of citrate is usually by fermentation of inexpensive sources of glucose or sucrose with selected strains of *Aspergillus niger*; world production in 1992 was 5 x 10<sup>8</sup> tons. 3 any (partial or full) salt or ester of citric acid.

**citrate aldolase** *see* citrate Ivase.

**citrate cleavage enzyme** EC 4.1.3.8; *recommended name:*

## citrate cycle

ATP-citrate (pro-S)-lyase. An enzyme that catalyses a reaction between ATP, citrate, and CoA to form acetyl-CoA, oxaloacetate, ADP and orthophosphate. In mammals it participates in the release of acetyl-CoA in the cytosol, particularly as a precursor for fatty acid synthesis, there being no system for transporting excess acetyl-CoA out of the mitochondrion. The acetyl carbons are thus transported across the mitochondrial membrane as citrate and then released by this enzyme. Example from rat, homotetramer: database code ACLY\_RAT, 1100 amino acids (120.50 kDa).

**citrate cycle** another name for the tricarboxylic-acid cycle.

**citrate (*pro*-3*S*)-lyase** EC 4.1.3.6; other names: citrase; citratase; citritase; citridesmolase; citrate aldolase; a bacterial enzyme that catalyses the formation of acetate and oxaloacetate from citrate. Example from *Klebsiella pneumoniae*: database code CILB\_KLEPN 289 amino acids (31.32 kDa). ATP-citrate lyase is another name for citrate cleavage enzyme.

**citrate (*Re*)-synthase** EC 4.1.3.28; an enzyme from some bacteria that forms citrate with the incoming -CH<sub>2</sub>-COOH group in the *pro-R* position of citrate. The addition is to the *Re*-face of the carbonyl group of oxaloacetate.

**citrate (Si)-synthase** EC 4.1.3.7; other names: citrogenase; oxaloacetate transacetylase; condensing enzyme; citrate condensing enzyme. An enzyme that catalyses a reaction between acetyl-CoA, H<sub>2</sub>O, and oxaloacetate to form citrate and CoA. It synthesizes citrate from oxaloacetate and acetyl-CoA, placing the incoming -CH<sub>2</sub>-COOH in the *pro-S* position in citrate (see oxaloacetate). The addition is to the *Si*-face of the carbonyl group of oxaloacetate. This is the usual mammalian citrate synthase; mitochondrial enzymes are closely related homodimers (six motifs). Example from chicken: database code CISY\_CHICK, 433 amino acids (46.88 kDa); 3-D structure known.

**citric acid** see citrate.

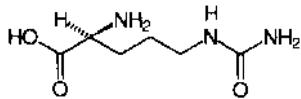

**citric-acid cycle** an alternative name for tricarboxylic-acid cycle.

**citrildasmolase** see citrate lyase.

**citrilatase** see citrate lyase.

**citrovorum factor** (formerly) an alternative name for folinic acid.

**citrulline N<sup>5</sup>-carbamoyl-L-ornithine**; 2-amino-5-ureidovaleric acid; an α-amino acid, not found in proteins. L-Citrulline is an intermediate in the urea cycle in animals and in a modified urea cycle in plants. It was first isolated from the juice of watermelon, *Citrullus vulgaris*.

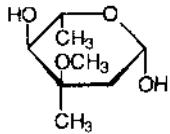

**citrullinemia** or **citrullinuria** an autosomal recessive genetic disease involving a deficiency of the enzyme argininosuccinate synthase. It is characterized by a high plasma citrulline level and excessive secretion of the amino acid in the urine. It results in neurological damage and mental retardation.

**CJD** abbr. for Creutzfeldt-Jakob disease.

**C-kinase** see protein kinase C.

**CJ symbol** for chlorine.

**cladinose** 2,6-dideoxy-3-C-methyl-3-O-methyl-L-ribo-hexose; 3-O-methyl mycarose; a component of erythromycins A and B.

β-L anomer

## clavulanic acid

**cladistics** a method of classification that attempts to reconstruct a phylogeny using characters that are unique to each taxonomic group. The term cladistic is currently used to describe an evolutionary or phylogenetic tree based on gene sequence similarities and gene association.

**c'adogenesis** a process of adaptive evolution leading to the development of a greater variety of organisms; branching evolution. -c'ladogenetic adj.

**cladogram** a diagram depicting cladogenetic evolution, i.e. the evolution of some character through the descendants of a common ancestor.

**clarify** to make or become clear, especially to remove finely divided suspended material from a solution, e.g. by centrifugation or filtration. -clarified adj.; clarification n.

**Clark and Lubs buffers** one of the early series of buffer mixtures of predetermined pH, covering the range pH 2.2-10.0. [After William Mansfield Clark (1884-1964), US biochemist, and Herbert A. Lubs.]

**Clark electrode** a type of oxygen electrode. [After Leland Charles Clark (1918- ).]

**class** a taxonomic category ranking below the phylum (or division) and containing several orders (or sometimes only a single order).

**classical pathway of complement activation** see complement.

**class switch** a change (switch) in the expression of B lymphocytes from one class of antibody to another.

**clastic** dividing into parts, especially of a chemical reaction in which one molecular species is divided into parts; e.g. phosphoroclastic, thioclastic.

**clastogen** an agent that is able to bring about breakage in chromosomes. -clastogenic adj.

**clathrate** 1 or cage compound (in chemistry) a solid complex or an addition compound in which the crystal lattice or structure of one component (the host molecule) completely encloses spaces in which a second component (the guest molecule) is located. There is no chemical bonding between the two components. Compare inclusion complex. 2 designating or relating to a clathrate. 3 (in biology) lattice-shaped.

**clathrin** a 180 kDa protein that is the main component of the coat of coated vesicles and coated pits, which are concerned in the transfer of molecules between the membranous components of eukaryotic cells. Clathrin also occurs in synaptic vesicles. The clathrin coat is a polyhedral lattice of subunits; each subunit, or clathrin triskelion, comprises three heavy chains and three light chains. Examples from rat; light chain A: database code CLCA\_RAT, 248 amino acids (26.95 kDa); light chain B: database code CLCB\_RAT, 229 amino acids (25.09 kDa); heavy chain: database code CLH\_RAT, 1675 amino acids (191.38 kDa).

**clathrin uReoating protein** or uncoating ATPase a protein from brain or erythrocyte cytosol that disassembles clathrin coats to triskelions in an ATP-dependent manner. Present in substantial excess of clathrin triskelions, it binds to a C-terminal domain of the heavy chain of clathrin triskelions.

**Claude**. Albert (1899-1983), Belgian-born US cell biologist distinguished for his development of methods of separating cellular components by differential centrifugation and for identifying mitochondria as the primary cellular site for biological oxidation; Nobel Laureate in Physiology or Medicine (1974) jointly with C. R. M. J. de Duve and G. E. Palade 'for their discoveries concerning the structural and functional organization of the cell'.

**clavulanic acid** 3-(2-hydroxyethylidene)-7-oxo-4-oxa-1-azabicyclo[3.2.0]heptane-2-carboxylic acid; a weak antibacterial agent but potent p-lactamase inhibitor produced by *Streptomyces clavuligerus*. It protects lactamase-sensitive but otherwise potent antibiotics from deactivation, and is used in combination with p-lactam antibiotics to increase their efficacy. It has no antibacterial activity but by inactivating penicillinases it makes a combination active against penicillin-

clearance

resistant bacteria. These include *Staphylococcus aureus*, 50% of many *Bacteroides*, and *Klebsiella* spp. A commonly used proprietary combination is Augmentin.

**clearance (in physiology) symbol:** C; a measure of the efficiency of the kidney in removing a substance from the blood.  $C = UV/P$ , where  $U$  and  $P$  are the concentrations of the substance in the urine and plasma, respectively, and  $V$  is the rate of urine flow in ml min $^{-1}$ . Clearance is therefore a rate, with the dimensions of ml plasma per min.

**clearing 1 (in histology)** the process of preparing tissue samples for microscopical examination by removing the dehydrating agent and rendering the sample transparent. 2 (in physiology) the removal of a substance from the body or from the blood; *see* clearance.

**clearing factor lipase** *an alternative name for* lipoprotein lipase; an enzyme found in the capillary endothelium of various tissues, notably heart, lung, and adipose tissue, so called because it clears the opalescence from lipemic plasma.

**cleavage** 1 the tendency of a crystal to split in certain preferred directions with the formation of smooth surfaces, or the act of so splitting a crystal; hence cleavage plane, cleavage face. 2 the rupture of a (usually specified) chemical bond in a molecule with the formation of smaller molecules. 3 *or* segmentation (in embryology) the series of mitotic divisions by which a fertilized animal ovum changes, without any overall change in size, into a ball of smaller cells constituting the primitive embryo.

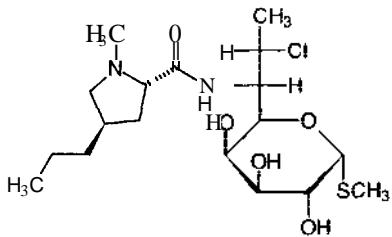

**cleavage division** the mitotic division of a fertilized egg up to the point at which the regions of the egg shift relative to each other.

**cleave** to split or cause to divide, especially along the line of a natural weakness; to split a chemical bond; to effect or undergo cleavage. -cleavable *adj.*

**Cleland's reagent** *see* dithiothreitol. [After William Wallace Cleland (1937- ).]

**climacteric 1 (in medicine)** the female menopause, or the corresponding time of life in men. 2 (in botany) the marked increase in respiration in fruit just prior to and during ripening.

**clindamycin** (7S)-7-chloro-7-deoxylincomycin; a semisynthetic antibiotic that is useful against anaerobic bacteria; for structure and action *see* lincomycin, lincosamide.

**clinical** of, or pertaining to, the course of disease in an individual, or the examination and treatment of an individual directly, as opposed to the laboratory investigation of disease.

**clinical chemistry** a branch of applied biochemistry concerned with the nature and determination of chemical substances of interest in the investigation of diseases.

**CLIP abbr. for** 1 corticotropin-like intermediate peptide. 2 Class-II-associated invariant-chain peptide (*see* Class II MHC antigens in major histocompatibility complex).

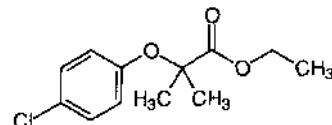

**CLIP-170** *see* restin.

**clofazimine** N,5-bis(4-chlorophenyl)-3,5-dihydro-3-[(1-methyl-ethyl)imino]-2-phenazinamine; an iminophenazine dye with anti-inflammatory, tuberculostatic, and leprostatic activity. It is used to treat multibacillary or sulfone-resistant leprosy.

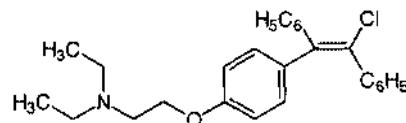

**clofibrate ethyl** 2-(p-chlorophenoxy)-2-methylpropionate; 2-(4-chlorophenoxy)-2-methylpropanoic acid ethyl ester; a drug that reduces high plasma levels of triacylglycerols, very-low-

clonidine

density lipoproteins (VLDL), and (less so) cholesterol. Its actions are probably mediated by the stimulation of lipoprotein lipase, which reduces the triacylglycerol composition of VLDL and stimulates clearance of low-density lipoproteins by liver. It is used primarily in the treatment of type III (but also in type IV, type V, and type IIb) hyperlipoproteinemia. *Compare* gemfibrozil.

**clomifene** *or* clomiphene 2-[4-(2-chloro-1,2-diphenylethenyl)phenoxy]-N,N-diethylethanamine; an antiestrogenic aminoether derivative of stilbene; it blocks estradiol receptors in the hypothalamus and may stimulate the secretion of gonadotropin-releasing hormone. It is active as an antitumour agent against mammary carcinomas, and can be used to induce ovulation in infertile women. Both its structure and actions are similar to those of Tamoxifen.

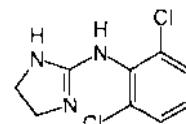

**clonal culture** any culture of cells produced in such a way that an individual clone (def. 1) can be selected.

**clonal selection theory** *or* Burnet's theory of immunity a theory to account for the phenomenon of acquired immunity and the ability of the immune system to produce large quantities of highly specific antibody for any particular immunogen. According to the theory, the ability to produce a given antibody is a pre-existing and genetically determined characteristic of a particular clone of B lymphocytes. An encounter with the antigen triggers proliferation of the corresponding clone, producing a greatly expanded population of cells that secrete specific antibody. Some members of the expanded clone assume the role of memory cells, which respond to any subsequent encounter with the same immunogen which accounts for the secondary response being greater than the primary response. *See also* Burnet.

**clone** 1 the descendants produced vegetatively or by apomixis from a single plant, or asexually or parthenogenetically from a single animal; a group of cells produced by division from a single cell. The members of a clone are of the same genetic constitution, unless mutation has occurred amongst them. 2 a homogeneous population of DNA molecules; *see* molecular cloning. 3 to propagate a selected organism or cell, or to replicate a particular DNA molecule so as to produce a clone. -clonal *adj.*; cloning *n.*

**cloned library** *an alternative name for* gene library.

**clonidine** 2,6-dichloro-N-2-imidazolidinylidenebenzeneamine; an antagonist at  $\alpha_2$  (presynaptic) adrenergic receptors,  $P_1$  purinergic receptors, and  $H_2$  histamine receptors. It is used as a central antihypertensive drug; it also abolishes most symptoms of opiate withdrawal.

## cloning vector

cloning vector or cloning vehicle the DNA of any transmissible agent (e.g. plasmid or virus) into which a segment of foreign DNA can be spliced in order to introduce the foreign DNA into cells of the agent's normal host and promote its replication and transcription therein. (1) Plasmid vectors contain (i) an origin of replication, so that the plasmid can be replicated; (ii) an antibiotic resistance gene to allow selection of transformed host cells; (iii) often, a 'polylinker' containing several different restriction enzyme recognition sites and a second marker gene (e.g. *lacZ*; see X-gal) which will be inactivated when foreign DNA is inserted therein, thus allowing identification of transformants bearing plasmids containing inserts, rather than 'empty' vectors. Examples include pBR322 and the pUC vectors. See also expression vectors. (2) Bacteriophage vectors, usually based on lambda phage, can accommodate longer fragments of foreign DNA. In insertion vectors (e.g.  $\lambda$ gt10) the foreign DNA is inserted into the phage DNA while in replacement vectors (e.g.  $\lambda$ EMBL4) the foreign DNA is ligated between two phage fragments, or arms. (3) Hybrid vectors, cosmids, phagemids and phasmids (def. 1), with features of both plasmids and phage, have also been constructed. See also molecular cloning.

closed circle (of DNA) see covalent (closed) circle (of DNA).

closed double-stranded DNA see covalent (closed) circle (of DNA).

closed duplex DNA or DNA I a closed double-stranded DNA molecule in which the DNA helical structure is preserved.

closed-loop system a type of system, e.g. a metabolic pathway or an electrical circuit, in which control is exerted by feedback. Compare open-loop system.

closed system any (thermodynamic) system that cannot gain or lose matter, heat, or work. Compare open system.

close packing the structure of a solid in which nonbonded atoms (or molecules) are surrounded by other nonbonded atoms (or molecules) in such a way that the distance between them is close or equal to the sum of their van der Waals contact radii (see van der Waals radius).

clostridiopeptidase A the collagenase obtained from *Clostridium histolyticum*.

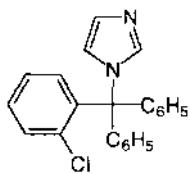

*Clostridium* a genus of spore-forming rod-shaped bacteria of the family Bacillaceae. Its members are chemoorganotrophic, obligately anaerobic, and typically Gram-positive. They are widespread in soil, mud, and in the intestinal tract of animals. Some species are pathogenic if they gain access to the tissues, and produce a range of toxins.

*Clostridium histolyticum* collagenase see microbial collagenase.

clostripain or clostridiopeptidase B EC 3.4.22.8; a cysteine proteinase enzyme from *Clostridium histolyticum*. It preferentially cleaves Arg-I-Xaa and Arg-I-Pro bonds and is inactivated by substituted arginine and lysine chloromethyl ketones. It is a heterodimer of  $\alpha$  and  $\beta$  chains. Example from *C. histolyticum* ( $\alpha$  chain): database code CLOS\_CLOHI, 526 amino acids (59.73 kDa).

clot retraction the contraction of a blood clot after its formation, accompanied by the expression of serum.

clotrimazole 1-[(2-chlorophenyl)diphenylmethyl]-1H-imidazole; an imidazole used topically as an antifungal agent. It inhibits ergosterol synthesis and disrupts the transport of amino acids into the fungus.

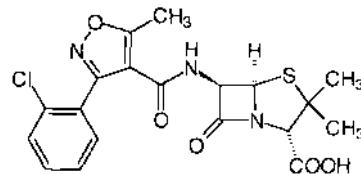

clotting factor an alternative term for coagulation factor; see blood coagulation.

clotting time an alternative term for coagulation time.

clover-leaf structure one of the models for the secondary structure of transfer RNA (tRNA). The nucleotide sequences of different tRNAs can be arranged in similar two-dimensional representations, resembling a clover leaf in shape, in which there are four bihelical regions, containing the maximal number of base pairs, connected by three loops. Some tRNAs have a small extra loop. The clover leaf structure has been largely supported by the tertiary structure of those tRNAs for which structure has been determined by X-ray crystallography.

cloxacillin a semisynthetic penicillin that is resistant to penicillinase and is useful against certain staphylococci.

Clp protease a proteinaseATPase from *Escherichia coli* with little protein specificity (EC 3.4.21.-). It is a heat-shock protein but supposedly a housekeeping proteinase; counterparts occur in many organisms (five motifs). The enzyme is a heterodimer with subunits named from the *clp* genes. The proteolytic subunit is ClpP, database code CLPP\_ECOLI, 207 amino acids (23.16 kDa); the ATP-binding subunit is one of ClpA (database code CLPA\_ECOLI, 758 amino acids (84.07 kDa) or ClpX (database code CLPX\_ECOLI, 423 amino acids (46.17 kDa)).

CLUSTALV a computer program for the sequence alignment of proteins, etc.

cluster 1 a group of iron and sulfur atoms, e.g. Fe2S2 or Fe4S4, in an iron-sulfur protein. The term is sometimes extended to include other metal atoms, as in the MoFe6\_SS4 cluster in nitrogenase. 2 or cluster of enzymes or enzyme cluster the phenomenon of the emergence of new enzymes, or the upsurge of enzymes already present in low concentration, at certain (usually defined) periods along the age axis of the organism.

cluster analysis a method of statistical analysis used, e.g., in phylogeny deduced from phenetic characters.

cluster-crystal any of the globular aggregates of calcium oxalate crystals found in some plants.

clustering the occurrence of a number of objects, like or unlike, in clusters; the term is used especially of components of cell membranes, such as receptors.

cm symbol for centimetre, i.e.  $10^{-2}$  m.

Cm symbol for 1 the carboxymethyl group, -CH<sub>2</sub>-COOH. 2 curium.

CM abbr. for carboxymethyl; e.g. CM-cellulose.

CMARa gene, cloned from a colon cancer cell line, encoding an 82-amino-acid protein that enhances the attachment of cells to collagen and laminin; the gene is named from cell matrix adhesion regulator. The protein has an N-terminal myristylation motif (underlined in the partial sequence) and a tyrosine phosphorylation site (bold in the partial sequence), this tyrosine being required for activity. Sequence:

**M**LRGSDM**K**G**P**

TALRIVEILY.

CMC abbr. for 1 critical micellar concentration. 2 carboxymethylcellulose.

CMH abbr. for ceramide monohexoside (Cer(Hex) preferred).

CMP abbr. for cytidine monophosphate, i.e. cytidine phosphate. CMR (spectroscopy) (sometimes) abbr. for 13C-nuclear magnetic resonance (spectroscopy).

CMU abbr. for 3-(p-chlorophenyl)-1,1'-dimethylurea; monuron;

a herbicide that acts by blocking noncyclic photophosphorylation.

**13C-NMR (spectroscopy)** abbr. for carbon-13 nuclear magnetic resonance (spectroscopy).

CNP abbr. for C-type natriuretic peptide; it is similar to atrial natriuretic peptide.

CNS abbr. for central nervous system.

co+ prefix denoting I together, joint or jointly; in partnership, an equality; to the same degree. 2 (in mathematics) of the complement of an angle.

Co I symbol for cobalt. 2 abbr. for coenzyme.

Co I (obsolete) abbr. for coenzyme I; see nicotinamide adenine dinucleotide.

Co II (obsolete) abbr. for coenzyme II; see nicotinamide adenine dinucleotide phosphate.

CoA symbol for (free or combined) coenzyme A.

coacervate any viscous phase obtained by coacervation of solutions of two or more polymers.

coacervate droplet any of the droplets that, it has been suggested, may have formed in the primordial soup by coacervation and, perhaps, entrapped primitive catalyst(s); they may have given rise to the first cells. *Compare* probobiont.

coacervation any process in which there is a spontaneous separation of a continuous one-phase aqueous solution of a highly hydrated polymer into two aqueous phases, one with a relatively high polymer concentration, the other with a relatively low polymer concentration.

coactone an econome active in the process of relationship between an active and directing organism and a passive and receiving organism.

coagulant any substance that produces, or aids the production of, coagulation.

coagulase any of a number of serologically distinguishable bacterial enzymes that catalyse the coagulation of citrated or oxalated blood plasma. The extracellular bacterial protein specifically forms a complex with human prothrombin; this complex can clot fibrinogen without any proteolytic cleavage of prothrombin. Example from *Staphylococcus aureus*: database code STCLSTAAU, 658 amino acids (74.42 kDa).

**coagulase/fibrinolysin** precursor see plasminogen activator.

coagulate I to cause a fluid or part of a fluid to change into a solid or semisolid mass by the action of, e.g., heat or chemical substances; to clot. 2 the solid or semisolid mass produced by coagulation. -coagulable adj.; coagulation n.

coagulation factors see blood coagulation.

coagulation time or clotting time 1 the time taken for a freshly drawn specimen of blood or blood plasma to coagulate (clot) when measured under standard, controlled conditions; it is an indication of the state of the coagulation processes in the specimen. 2 the time taken for a specimen of milk, or of a casein fraction, to coagulate in standard, controlled conditions.

coagulogen a  $\approx$ 16 kDa fibrinogen-like protein that is found in the hemocyte (amoebocyte) of horseshoe crab (*Limulus polyphemus*) hemolymph and participates in hemostasis. Coagulogen consists of a single, basic polypeptide chain and constitutes about 50% of the protein in horseshoe-crab hemocyte lysates.

coagulum (pl. coagula) any semisolid coagulated mass or, clot, especially that formed by clotting of blood.

coarctation the state of being pressed together or constricted, especially of the aorta or other blood vessel.

coarse descriptive of I things that are rough in texture or structure. 2 particles that are large or powders composed of such particles. 3 threads, filaments, or fibres of relatively large diameter. 4 means of adjustment (as of instruments or processes) that provide only inaccurate or gross control, or the adjustments so made.

CoASAc symbol for acetyl-coenzyme A.

CoASH symbol for (free) coenzyme A.

coated pit an invagination of the cell membrane of many eu-

karyotic cells, concerned in receptor-mediated selective transport of many proteins and other macromolecules across the cell membrane. During endocytosis it is converted into a coated vesicle. The coat is of clathrin.

coated-tube method a solid-phase radioimmunoassay method in which the specific antibody is immobilized on the inner surface of a small test tube.

coated vesicle a vesicle, formed from a coated pit. Observed in the cytoplasm of many eukaryotic cells, coated vesicles measure 50–250 nm in diameter and are characterized by a 'bristle' coat on the outer surface of their lipid membrane. This coat is made up of a polyhedral lattice of clathrin subunits together with smaller amounts of other proteins, notably ones of about 100 kDa (adaptins), 50 kDa and 20 kDa. Coated vesicles are concerned with the rapid and continuous transport of molecules between specific membranous organelles of the cell and to and from the cell membrane.

coatomer a large protein complex that forms part of the coat of specific Golgi intercisternal transport vesicles that are involved in constitutive vesicular transport between endoplasmic reticulum, Golgi apparatus, and plasma membrane. It has seven subunits known as COPs (from coat protein). COPI-coated vesicles are formed by combination of ARF with coatomer. They participate in retrograde traffic from the Golgi apparatus to the endoplasmic reticulum. COPII-coated vesicles are formed from other proteins that include the gene products Sec 13p and Sec 23p. Example: the yeast coatomer is a complex (700–800 kDa); one component is the transport protein product of SEC21, database code SC2LYEAST, 935 amino acids (104.71 kDa).

coat protein 1 one of the outer structural proteins of a coated virus. 2 any of those subunits of the coatomer known as COPs.

cobalamin the trivial name for many members of the vitamin B<sub>12</sub> group and their derivatives. A cobalamin is a cobamide in which 5,6-dimethylbenzimidazole is the aglycon that forms a link between the cobalt atom and the αi-position of the ribose residue. The sixth position of the cobalt atom may be (artefactually) filled by a variety of groups, e.g. a cyano group giving cyanocobalamin. The oxidation state of the cobalt may be indicated by using a Roman numeral, e.g. cob(I)alamin for CoI.

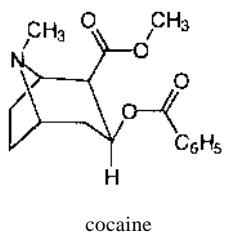

cob(I)alamin adenosyltransferase EC 2.5.1.17; other name: aquacob(I)alamin adenosyltransferase; an enzyme that catalyses the formation of adenosylcobalamin from ATP, cob(I)alamin, and H<sub>2</sub>O, with release of orthophosphate and pyrophosphate. The enzyme requires manganese. Example from *Escherichia coli*: database code BTUR\_ECOLI, 196 amino acids (21.97 kDa).

cob(II)alamin reductase EC 1.6.99.9; other name: vitamin B<sub>12</sub> reductase; a flavoprotein enzyme that catalyses a reaction between NADH and two molecules of cob(u)alamin to form two molecules of cob(I)alamin and NAD<sup>+</sup>.

cobamide any member of a group of compounds (including the cobalamins) that have molecules consisting of a highly substituted tetrapyrrole ring system (corrin) in which a cobalt atom is linked to the four pyrrole nitrogen atoms and with an α-D-ribofuranose 3-phosphate residue attached to one of the side chains.

cobamide coenzyme any of the biochemically active forms of vitamin B<sub>12</sub>. They are cobalamins in which either a methyl or 5'-deoxy-5'-adenosyl residue is attached to the sixth position on the cobalt atom.

cocaine 2p-carbomethoxy-3p-benzyloxytropane; an alkaloid obtained from dried leaves of the South American shrub *Erythroxylon coca* or by chemical synthesis. It is a cerebral stimulant and narcotic, and has been used as a local anaesthetic. Cocaine acts by blocking neuronal reuptake of, especially, norepinephrine, hence its potent vasoconstrictor effects, which can lead to tissue necrosis. Its use is restricted in many countries.

**cocarboxylase** *a former name for thiamine diphosphate (see vitamin B<sub>1</sub>).*

**cocarcinogen** any noncarcinogenic agent that enhances the effect of a carcinogen.

**cochromatography** a chromatographic technique in which an unknown substance is applied to a chromatographic support together with one or more known compounds, in the expectation that the relative behaviour of the unknown and known substances will assist in the identification of the unknown one.

**cocktail** a mixture of substances prepared according to a recipe, especially reagent mixtures such as those for use in electrofocusing (electrofocusing cocktails), in liquid scintillation counting (scintillation cocktails), and in cell-free translation systems (translation cocktails). Many such cocktails are commercially available.

**COD** *abbr. for* chemical oxygen demand.

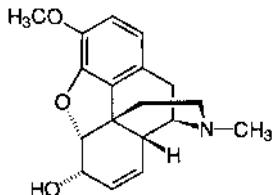

**code** 1 any system of symbols, together with the rules for their association, that can be used to represent or transfer information; e.g. the genetic code. 2 to contain, to be arranged in, or to be expressed through a code; used especially of DNA and mRNA. A gene is said to code for (or encode) its protein product. *Compare decoding.*

**coded amino acid** any of the 20 α-amino acids whose occurrence in proteins is under direct genetic control, i.e. for which a codon exists.

**codehydrase I** *or* codehydrogenase I *an obsolete name for* nicotinamide adenine dinucleotide.

**codehydrase II** *or* codehydrogenase II *an obsolete name for* nicotinamide adenine dinucleotide phosphate.

**codeine** methylmorphine; (5a,6a)-7,8-didehydro-4,5-epoxy-3-methoxy-17-methylmorphinan-6-01; an opioid found in opium and manufactured by the methylation of morphine. It acts as an agonist at μ, δ, and κ-opioid receptors but is generally less potent than morphine, being metabolized in the liver to morphine and norcodeine. It is a narcotic analgesic with antitussive activity and is a controlled substance in the US Code of Federal Regulations.

**coding ambiguity** an adjustment to the prediction of Francis Crick that a single nucleotide triplet (codon) would not code for more than one particular amino acid, which was shown by subsequent work to require modification. Thus two codons, AUG and GUG, code not only for the amino acids, methionine and valine respectively, but also are important in chain initiation. Furthermore, there are differences between codon usage in the cytoplasm and mitochondria. In mitochondria UGA codes for Trp rather than chain termination, AUU for

Met rather than Ile, and AGA for termination rather than Arg. There is also the problem of proteins containing selenocysteine which is coded by a unique tRNASEc, the codon being UGA which usually codes for termination.

'coding' problem the description given by Francis Crick and co-workers in 1957 to the crucial puzzle of the genetic code, namely how a sequence employing combinations of only four different nucleotides (i.e. genes) can determine sequences containing combinations of up to 20 different amino acids (i.e. proteins). Crick predicted that groups of three nucleotides would code for each amino acid providing the possibility of 64 codons, more than sufficient for the 20 amino acids. (A binary code of two nucleotides would only provide 16 codons.) The prediction was confirmed with the elucidation of the genetic code in the early 1960s.

**coding region** or **coding sequence** 1 (of a DNA molecule) *an alternative name for* exon. 2 (of a messenger RNA molecule) the portion of its complete nucleotide sequence that is translatable into polypeptide.

**coding strand** the strand in genomic duplex DNA that contains the same sequence of bases as messenger RNA transcribed from the DNA (excepting uracil in RNA in place of thymine in DNA). Its complement is the noncoding strand. In some bacteria and viruses, alternate segments of both strands of duplex DNA may be coding, in some instances with overlap. *Other names:* antitemplate strand; codogenic strand; non-transcribing strand; plus strand; sense DNA; sense strand.

**coding triplet** or **coding unit** *an alternative name for* 1 codon. 2 anticodon.

**cod-liver oil** a fish oil obtained from the liver of cod, especially the Atlantic cod (*Gadus morhua*). It is a good source of long-chain n-3 fatty acids. The typical composition (% total) of major acids is: 16:0, 14%; 16:1 n-7, 12%; 18:1 n-9, 22%; 20:1 n-9, 12%; 22: In-II, 11%; 20:5 n-3, 7%; 22:6 n-3, 7%. *See also* fish oil.

**codogenic strand** *an alternative name for* coding strand.

**codon** any group of three consecutive nucleotide bases (base triplet) in a given messenger RNA molecule that, by its composition and sequence, specifies either a particular amino-acid residue in the polypeptide chain synthesized by translation of that messenger RNA, or signals the beginning or the end of the message (i.e. start codon, stop codon). The term is also used loosely for base triplets in the genomic nucleic acid – in the case of duplex DNA, either on the coding strand or noncoding strand. For the full set of codons *see* genetic code.

**coefficient of danger** (of a drug or other agonist) the percentage lethal responses to be expected at a dose level that is effective in 95% of trials.

**coefficient of variation** or **coefficient of variability** a parameter used in comparing dispersion in distributions. It is the ratio of the standard deviation to the mean, i.e.  $s_x/\bar{x}$ . The coefficient of variation is an abstract number independent of the units of measurements; it may also be expressed as a percentage, i.e.  $100s_x/\bar{x}$ .

**coefficient of viscosity** *see* viscosity.

**coeliac** *a variant spelling (esp. Brit.) of celiac.*

**coenzyme** any of various nonprotein organic cofactors that are required, in addition to an enzyme and a substrate, for an enzymic reaction to proceed. Compared with a prosthetic group a coenzyme is more easily removed from the apoenzyme. The term 'coenzyme' is frequently used imprecisely, although it is now possible to give more informative chemical names to such substances and to define their roles in specific enzymic reactions.

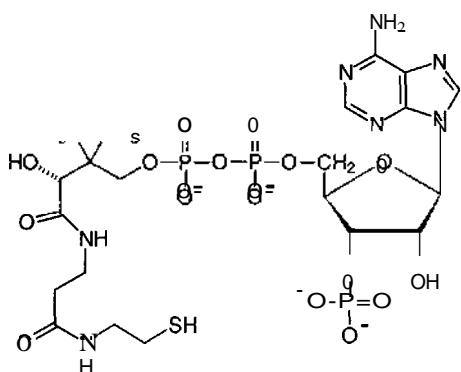

**coenzyme I** *an obsolete name for* nicotinamide adenine dinucleotide.

**coenzyme II** *an obsolete name for* nicotinamide adenine dinucleotide phosphate.

**coenzyme A** *symbol:* (combined form) CoA or (free form) CoASH; 3'-phosphoadenosine-(5')diphospho(4')pantetheine; a heat-stable compound that functions as an acyl carrier in a

## coenzyme C

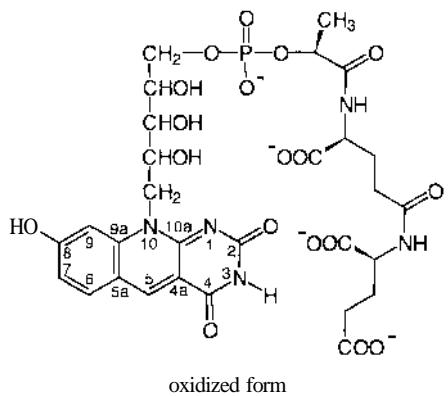

number of biochemical acylation and acyl-transfer reactions, in which the intermediate is a thiol ester. It was originally known as the acetylation coenzyme, hence its present name.

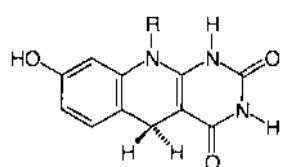

coenzyme C a name sometimes given to a polyglutamate derivative of tetrahydrofolate.

coenzyme F abbr.: CoF; a name sometimes given to tetrahydrofolate or some of its derivatives.

coenzyme F<sub>420</sub> the N-(N-L-lactyl-y-glutamyl)-L-glutamic acid phosphodiester of 7,8-didemethyl-8-hydroxy-5-deazariboflavin that functions as a coenzyme for several oxidoreductases e.g. methylenetetrahydromethanopterin dehydrogenase. It was first found in methanogenic Archaea, but later also in other Archaea, and some Bacteria and Eukarya. The oxidized form acts also as a photosensitizer in DNA photolyases. Reduction results in addition of hydrogen at C-1 and C-5, in all cases so far reported being stereospecific for the Si-face of the coenzyme.

oxidized form

reduced form (R = substituent at N<sub>o</sub>)

coenzyme F<sub>430</sub> see factor F<sub>0</sub>.

coenzyme factor an alternative name for diaphorase.

coenzyme M abbr.: CoM; 2-thioethanesulfonate, HSCH<sub>2</sub>-CH<sub>2</sub>SO<sub>3</sub><sup>-</sup>; it is involved as a coenzyme in the pathway of methanogenesis in methanogenic bacteria. In the terminal step of the pathway, a methyl group is transferred from methyltetrahydromethanopterin (see tetrahydromethanopterin) to CoM to form CH<sub>3</sub>-S-CoM, from which methane is formed in a reductive step involving factor F<sub>0</sub>.

coenzyme Q abbr.: CoQ; an obsolete name for ubiquinone (the abbreviation Q is, however, frequently used in diagrams).

coenzyme R (sometimes) an alternative name for biotin.

CoF abbr. for coenzyme F; see tetrahydrofolate.

cofactor 1 any accessory, nonprotein substance, commonly of low molecular mass, that is necessary for the activity of an enzyme. Metal-ion cofactors have been called activators; organic cofactors that are easily removable from the enzyme (e.g. by dialysis) may be called coenzymes, but if they are tightly bound they are often termed prosthetic groups. See also apoenzyme, holoenzyme. 2 any amino acid that must be present in the medium to allow certain phages to be adsorbed by host bacteria.

cofilin a pH-sensitive nuclear actin depolymerization factor, similar to destin (five motifs in common). Example from pig: database code COFI\_PIG, 166 amino acids (18.50 kDa).

cognitive neuroscience the area of neurobiology that aims to explain how the brain enables an animal to interact successfully with its environment. The term cognition has come to refer to that level of description that links molecular science to behaviour.

Cohen, Stanley (1922- ) US biochemist; Nobel Laureate in Physiology or Medicine (1986) jointly with R. Levi-Montalcini 'for their discoveries of growth factors'.

coherent (in physics) describing two or more waves having the same wavelength and the same phase, e.g. coherent light. The laser is a source of coherent light.

coherent anti-Stokes Raman spectroscopy abbr.: CARS; a nonlinear optical technique for obtaining Raman spectra with high efficiency. The signal levels, signal-to-noise ratios, resolution, and fluorescence rejection are far better than with normal Raman spectroscopy. CARS can be used for substances at about 1 mM concentration in aqueous solution.

cohesive end or cohesive terminus or sticky end the protruding (3' or 5') single-stranded terminus on a double-stranded DNA fragment that can associate with a complementary, similarly protruding sequence at the opposite end of the same DNA fragment, or on another fragment, to form a circular, or larger, DNA molecule.

Cohn fractionation a method for the fractionation of human blood plasma proteins to produce minimally altered proteins suitable for clinical use. It involves fractional precipitation with ethanol at temperatures near or below 0°C, with careful control of pH and ionic strength and additions of certain bivalent metal ions, especially Zn<sup>2+</sup>. The numbered Cohn fractions contain the following main constituents: I, fibrinogen; II, y-globulins; III, β-globulins; IV, α-globulins; V, albumin; VI, glycoproteins. The method has also been applied to the fractionation of plasma proteins of other animals. [After Edwin Joseph Cohn (1892-1953), US biochemist.]

coiled coil an alternative name for supercoil.

coincidence 1 (in physics) the occurrence of radioactive nucleide disintegrations within a time span too short for them to be resolved by a radiation counter. 2 (in genetics) the ratio of the number of observed double crossovers to the number expected from the random combination of single crossovers among three or four linked genes.

coincidence correction a correction applied in counting radioactive events for coincidence losses, i.e. those events occurring at high count rates when two or more pulses arrive within the resolving time of the counter.

coincidence counter a counter for radioactive events that consists of two opposed detectors and appropriate electronic circuitry so that only those pulses observed by both detectors

co-ion

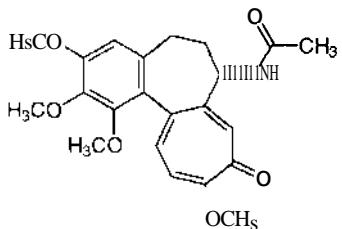

collagen

are registered. This arrangement, common in liquid scintillation spectrometers, considerably reduces the number of background counts attributable to random thermionic noise arising in the detectors.

**co-ion** any ion of low molecular mass present in a colloidal solution or substance that has a charge of the same sign as the (net) charge of a (specified) colloidal ion under particular conditions. *Compare counterion.*

**colcemide** or **demecolcine** a derivative of colchicine in which the amino group (attached to the non-tropolone seven-membered ring) is methylated instead of acetylated. It binds tubulin and inhibits formation of the mitotic spindle.

**colchicine** a major alkaloid from the autumn crocus, *Colchicum autumnale* L. It is used experimentally to inhibit the polymerization of tubulin, to which it binds specifically and tightly, and to encourage depolymerization of microtubules. This action inhibits spindle formation, arrests mitosis at metaphase, and promotes polyploidy in plants. Colchicine also disrupts neutrophil migration and phagocytosis, and inhibits leukotriene B<sub>4</sub> synthesis; it is useful in the treatment of gout. The molecule is noted for a tropolone ring, which is rather rare in natural products. *See also* colcemide.

**cold** 1 of low, or lower than normal, temperature. 2 (*in radiochemistry*) containing no, or an insignificant amount of, a radioactive nuclide; the nonradioactive counterpart of a radionuclide-labelled substance. *Compare hot.*

**cold agglutinin** *see* cold autoantibody.

**cold autoantibody** or **cold agglutinin** an antibody that attaches to red cells at low temperatures, reacting better at 4 °C than at 37°C, and dissociates as the red cells are warmed. Cold autoantibodies are mainly directed against antigens of the li system of blood groups.

**cold-insoluble globulin** a cryoglobulin present in blood plasma or serum. It is normally present at only very low concentrations in human serum but may be elevated in certain rare diseases such as systemic lupus erythematosis. *See also* fibronectin.

**cold-labile enzyme** or **cold-sensitive enzyme** any enzyme that, unlike most enzymes, is less stable at 0 °C than at room temperature. In some, but not all, instances activity slowly returns on warming. The phenomenon can be due, e.g., to exothermic dissociation of a stabilizing cofactor from the enzyme or to dissociation into inactive subunits.

**cold-sensitive mutation** any mutation producing a gene that is functional at a high temperature (the permissive temperature) but inactive at a low temperature (the restrictive temperature). *See* temperature-sensitive mutation.

**cold-shock protein** any of various proteins, synthesized by microorganisms in response to a sudden drop in temperature. These are typically DNA-binding transcription activators, many of which have a characteristic cold-shock domain (*abbr.*: CSD); the protein has three motifs. Example from *Escherichia coli*: database code CSPA\_ECOLI, 69 amino acids (7.26 kDa). *Compare* heat-shock proteins.

**coleoptile** the protective sheath covering the first leaves of seedling grasses.

**colestipol** a basic anion-exchange resin that when given orally as the Cl- form, exchanges anions of chloride in the intestine

with those of bile salts, which are then excreted and thus removed from the enterohepatic circulation as an insoluble complex. The resulting reduction in cholesterol absorption culminates in reduced circulating levels of low-density lipoproteins but can increase plasma triacylglycerols. It has therapeutic application in relieving hyperlipoproteinemia.

**colestyramine resin** *proprietary name:* Dowex I-X2-Cl; a basic anion-exchange resin that consists predominantly of polystyrene trimethylbenzylammonium chloride. If administered orally, it exchanges anions of chloride with those of intestinal bile salts, which are then excreted as an insoluble complex. The resulting reduction in cholesterol absorption culminates in reduced circulating levels of low-density lipoproteins (LDLs), hence its therapeutic application in relieving hyperlipidemia and LDL-induced hypercholesterolemia.

**Col factor** (*formerly*) *an alternative name for* Col plasmid.

**colforsin** *an alternative name for* forskolin.

**colicin** or (*formerly*) **colicine** any member of a range of 40-80 kDa proteins secreted by those strains of the Enterobacteriaceae that kill, but do not lyse, other susceptible strains within this family; a subcategory of bacteriocin. Different colicins are designated B, E<sub>1</sub>, E<sub>2</sub>, I, K, or V, and may be distinguished by their diffusibility and immunogenic and host specificities; their mechanisms of action may vary. They may be coded for by a Col plasmid.

**colicin factor** or **colicinogenic factor** (*formerly*) *an alternative name for* Col plasmid.

**colicinogenic** describing bacteria that are able to produce colicins.

**colicinogenic factor** *see* Col plasmid.

**coliform** 1 describing any bacterium belonging to the genera *Escherichia* or *Klebsiella*. 2 describing any Gram-negative, lactose-fermenting, enteric bacillus or, more loosely, any Gram-negative, enteric bacillus or related organism. 3 any coliform microorganism.

**colipase** a cofactor of pancreatic lipase that inhibits the surface denaturation of lipase and anchors the protein to the lipid-water interface of lipid micelles to prevent inhibition and displacement by bile salts (four motifs). Example (precursor) from human: database code COL\_HUMAN, 112 amino acids (11.94 kDa): amino acids 1-17 form the signal; 18-22, enterostatin activation peptide; 23-112, colipase.

**coliphage** any bacteriophage that infects a strain of *Escherichia coli*.

**colistin** or **polymyxin E** a polymyxin antibiotic derived from *Bacillus colistinus* and comprising colistins A, B, and C. It acts as a cationic surface-active detergent, disrupting microbial cell wall structure.

**colitose** 3,6-dideoxy-L-xylo-hexose; 3,6-dideoxy-L-galactose; a sugar present in lipopolysaccharide of some strains of *Escherichia coli*. For the D enantiomer, *see* abequose.

**collagen** a group of fibrous proteins of very high tensile strength that form the main component of connective tissue in animals. Collagen is highly enriched in glycine (up to one-third of its amino-acid residues) and somewhat less so in proline plus 3- and 4-hydroxyproline (about 21%); prolines at the third position of the tripeptide repeating unit (G-X-P) are hydroxylated in some or all of the chains. Collagen of bones and skin is metabolically stable, but that of organs such as liver has a high metabolic turnover. Collagens are products of a superfamily of closely related genes found in multicellular animals. The products have been classified into types I to XIII in the order in which they were purified and characterized, and grouped into classes I to 4 according to their properties. All contain a typical triple-helical domain formed from three independent chains. Class I comprises types I to III, V, and XI. All of these types are fibre-forming, of approximately the same length, having a lengthy uninterrupted collagenous domain with three *a* chains in the form of a triple helix, and a large globular domain at the C-terminal end. Each of these

## collagenase

types is synthesized as a procollagen molecule. Several types of  $\alpha$  chain are found variously in the different types of class I collagen. All of these types aggregate into staggered arrays, first into microfibrils of five collagen molecules that then aggregate into fibres. Class 2 comprises types IX and XII. Type IX was first isolated from pig hyaline cartilage. It is composed of three different  $\alpha$  chains,  $\alpha$ -1,  $\alpha$ -2, and  $\alpha$ -3 and has three short triple-helical domains interrupted by non-collagenous domains.

At the N-terminal end there is a large globular domain. A glycosaminoglycan molecule, chondroitin sulfate, is attached to the  $\alpha$ -2 chain. Example from human,  $\alpha$ -I chain (precursor): database code CAI9\_HUMAN, 931 amino acids (92.97 kDa); residues 1-23 are the signal, and 24-931 the  $\alpha$ -I chain. Type XII was discovered by screening a DNA library and has structural similarities to type IX. The function of these molecules is not known. Class 3 comprises types IV, VI, VII, and X, which serve unique functions. Type IV is the major component of basement membranes. It has long triple-helical domains with a complex globular domain at the C-terminal end. There are six  $\alpha$ - $\chi$  chain isoforms, numbered 1 to 6; example from human  $\alpha$ -I (IV) chain precursor: database code CAI4\_HUMAN, 1669 amino acids (160.61 kDa); residues 1-27 are the signal, 28-172 a propeptide, and 173-1669 the  $\alpha$ -I (IV) chain. Type VI is a short molecule having a triple-helical domain, 105 nm in length, separating two globular domains. It aggregates into tetramers stabilized by disulfide bonds. Carbohydrate chains consisting of glucosamine, mannose, galactose, fucose, and sialic acid are associated with type VI amounting to 10% of the total mass. Example from *Mus musculus*,  $\alpha$ -I (VI) (precursor): database code CAI6\_MOUSE, 1025 amino acids (108.49 kDa); residues 1-19 are the signal, 20-1025 the  $\alpha$ -I (VI) chain. Type VII is known as the anchoring fibril network and is the largest collagen yet described with a total molecular mass of the precursor of  $\approx$ 1050 kDa. It has an N-terminal globular domain, a triple-helical domain 424 nm long, and a highly complex C-terminal globular domain. Anchoring fibrils are found within the sub-basal lamina, and appear to anchor the lamina densa to the underlying matrix. Example from human,  $\alpha$ -I (VII) chain (precursor): database code CAI7\_HUMAN, 2944 amino acids (295.21 kDa); residues 1-16 are the signal, 17-2944 the  $\alpha$ -I (VII) chain. Type X collagen has a restricted tissue distribution, being synthesized mainly by chondrocytes, and is 1438 nm in length. Class 4 comprises types VIII and XIII. Type VIII was first observed as a cell culture product of endothelial cells. It is a 130–140 nm rod found in specialized tissues including the sclera, periosteum, perichondria, and cartilage growth plate. Type XIII was identified from a eDNA clone encoding short chains that form a triple-helical domain. Its function is unknown. *See also* hydroxyproline.

**collagenase** any of the proteinases that hydrolyse collagen, in particular *Clostridium histolyticum* collagenase (clostridiopeptidase A, EC 3.4.24.3), which preferentially cleaves at Xaa-I-Gly in the sequence

-Zaa-Pro-Xaa-Gly-Pro-Xaa.

It is widely used experimentally in the release of many types of cells from animal tissues, e.g. adipocytes and hepatocytes. *See also* gelatinase, interstitial collagenase, microbial collagenase.

**collectin** one of a family of plasma lectins with a trimeric structure similar to complement Clq.

**colligation** the formation of a covalent bond by means of two combining groups donating one electron each; the reverse of unimolecular homolysis. *Compare* coordination (def. 2). -colligative vb.

**colligative property** the property of any substance or system (e.g. an ideal solution) that depends only on the number of particles (atoms, molecules, and ions) and not on their nature. For example, gaseous pressure and osmotic pressure are colligative properties.

**collimator** any device, generally embodying a system of slits and (sometimes) lenses (optical, electric, or magnetic), that is

## colony

used to produce a nondivergent beam of electromagnetic radiation or particles.

**collinear** 1 lying in or on the same (straight) line. 2 having a (straight) line in common. 3 describing the state of congruence between the order of amino acids along a polypeptide chain and the order of the corresponding codons along the polynucleotide chain encoding the polypeptide. -collinearity n.

**Collip, James Bertram (1892-1965)**, Canadian biochemist and endocrinologist notable for his pioneering investigations in endocrinology but particularly for his role in developing (with J. J. R. Macleod) a method for the fractionation of pancreatic extracts to give insulin-containing preparations pure enough to permit the first clinical trials of the hormone to take place; this achievement was duly recognized by Macleod by dividing his share of the Nobel prize with Collip.

**collision coupling hormone-receptor-enzyme model** a model of enzyme activation summarized by the scheme:

where H is the hormone, R is the receptor, E is the inactive enzyme, E' is the activated enzyme,  $K_{\text{mH}}$  is the hormone-receptor dissociation constant,  $k_J$  is the bimolecular rate constant governing HRE formation, and  $k_3$  is the rate constant governing enzyme activation. In this model the enzymically inactive intermediate, HRE, never accumulates and constitutes only a small fraction of the total receptor and enzyme concentrations.

**collision frequency** or **collision number** the number of collisions per second when there is only one molecule of reactant per cubic centimetre of gas or liquid e.g. in kinetics.

**collodion** a solution of 4 g pyroxylin (mainly nitrocellulose) in 100 ml of a mixture of 25 ml ethanol and 75 ml diethylether. When exposed to the atmosphere in thin layers it evaporates leaving a tough, colourless film that may be used as a dialysis membrane.

**colloid** or **colloidal system** 1 a state of subdivision of matter implying that the molecules or polymolecular particles (the dispersed phase) dispersed in a medium (the continuous phase) have, at least in one direction, a dimension roughly in the range 1 nm-1  $\mu$ m or that in a system discontinuities are found at distances of this order. All three dimensions need not be in the colloidal range nor is it necessary for the units of a colloidal system to be discrete. Colloids may comprise many individual large molecules such as proteins or polysaccharides, or aggregations of smaller molecules such as colloidal gold. The colloids do not pass, or pass very slowly, through semipermeable membranes. 2 (*in histology*) the structureless substance seen in thyroid gland follicles. -colloidal adj.

**colloidal dispersion** any thermodynamically unstable colloidal system in which particles of colloidal size of any nature (e.g. solid, liquid, or gas) are dispersed in a continuous phase of different composition (or state), and which cannot easily be reconstituted after separation of the dispersed phase and the dispersion phase. *Compare* colloidal solution.

**colloidal electrolyte** any electrolyte that gives ions of which at least one is of colloidal size; it includes polyelectrolytes.

**colloidal solution** any thermodynamically stable solution consisting of colloidal macromolecules and solvent that can be easily reconstituted after separation of the macromolecules from the solvent. *Compare* colloidal dispersion.

**colloid osmotic pressure** that part of the osmotic pressure exerted by a solution that is due to dissolved colloids. *See* osmotic pressure (def. 1).

**colon** 1 (*in invertebrates*) the part of the large intestine that extends from the cecum to the rectum. 2 (*in insects*) the second part of the intestine.

**colon bacillus** a former term for *Escherichia coli*.

**colony** (*in microbiology*) a circumscribed group of cells, normally derived from a single cell or small cluster of cells, growing on a solid or semisolid medium.

## colony hybridization

colony hybridization or colony hybridisation a blot-transfer method (*see* blotting) whereby a very large number of colonies of a bacterium carrying different hybrid plasmids can be rapidly screened to determine which hybrid plasmids contain a specified DNA sequence or gene(s). The bacterial colonies are grown on an agar plate, then replica plated onto nitrocellulose filters. A reference set of the colonies is retained. Then the colonies on the filter are lysed and their DNA is denatured and fixed to the filter *in situ*. The resulting DNA-prints of the colonies are then hybridized to a radioactive RNA probe for the sequence or gene of interest. DNA that binds the probe is then assayed by autoradiography or another detection method, enabling the selection of corresponding colonies from the reference plate.

colony stimulating factor *abbr.:* CSF; any of the cytokines that control the differentiation of hemopoietic stem cells, both in the bone marrow and in the periphery. The group consists of granulocyte, macrophage, and granulocyte/macrophage CSFs. These promote the development of their specific subsets of leukocytes. Interleukin-3 (IL-3), interleukin-5 (IL-5), and erythropoietin are also members of this group. IL-3 promotes the differentiation of all the leukocyte lineages, whereas IL-5 is necessary for eosinophil development. Erythropoietin promotes the expansion of erythroid colony forming units. Granulocyte-colony stimulating factors (G-CSFs) are cytokines that act in hemopoiesis by controlling the production, differentiation, and function of two related white cell populations: granulocytes and monocytes-macrophages. Example from human (precursor): database code CSF3\_HUMAN, 207 amino acids (22.27 kDa). Granulocyte/macrophage-colony stimulating factors (GM-CSFs) are cytokine glycoprotein growth factors; they also act in hemopoiesis by controlling the production, differentiation, and function of the granulocytes and the monocytes-macrophages. Example (precursor) from human: database code CSF2\_HUMAN, 144 amino acids (16.28 kDa); 3-D structure known. Macrophage-colony stimulating factor (M-CSF) is produced by fibroblasts, endothelium, and epithelium; it stimulates growth of macrophage colonies. The molecule is a homodimer; example (precursor) from human: database code CSFLHUMAN, 554 amino acids (60.05 kDa).

colorimeter a device for measuring colour intensity or differences in colour intensity, either visually or photoelectrically. It is used for quantitative determination of coloured compounds in solutions.

colorimetry any method of quantitative chemical analysis in which the concentration or amount of a compound is determined by comparing the colour produced by the reaction of a reagent with both standard and test amounts of the compound, often using a colorimeter.

colostrum the milk secreted by the mammary gland just prior to and for a short period after parturition. It has high levels of protein and immunoglobulin, and its ingestion confers passive maternal immunity on the offspring of some species.

Colour Index *abbr.:* CI; a catalogue of commercially available dyes, identifying each by chemical class, colour, and generic name, and giving their chemical composition where disclosed. Each dye is assigned a five-digit number, prefixed by 'CI'. The preferred trivial name of each dye, its commoner synonyms, and the name(s) of its known manufacturer(s) also are listed.

colour quenching the quenching that occurs in liquid scintillation counting due to the absorption of the scintillation emission by the specimen, resulting in a decrease in the light-collecting factor. It can often be reduced by prior bleaching or dilution of the specimen before introduction into the scintillator. *Compare* chemical quenching.

Col plasmid or (formerly) Col factor or colicin factor or colicinogenic factor any plasmid that carries genetic information for the production of a colicin; a subcategory of bacteriocinogenic factor.

columbinic acid or ranunculeic acid (5E,9Z,12Z)-octadeca-5,9,12-trienoic acid; a fatty acid occurring in some seed oils. It

## committed step

can relieve many of the symptoms of essential fatty acid deficiency, although it does not act as a precursor for prostaglandin synthesis.

column an upright cylindrical shaft or tube, especially the tube used to contain the stationary phase in column chromatography or column electrophoresis, or to contain the packing material in fractional distillation. By extension, the term is also used for the tube (whether vertical, horizontal, or spiral) used in gas chromatography.

column chromatography any method of chromatography in which the stationary phase is a porous solid contained in a column through which the liquid or gas phase percolates. The principal examples are adsorption chromatography, gel-filtration chromatography, gas-liquid chromatography, and ion-exchange chromatography.

column electrophoresis any method of electrophoresis in which the support material is contained in a column. Such a technique is usually used for preparative scale separations by electrofocusing or isotachophoresis.

column volume *symbol:* X; the volume (empty) of that part of a chromatographic column that contains the packing, calculated from the inner diameter and the height or length of the column occupied by the stationary phase under the conditions of use. *Compare* bed volume.

CoM *abbr.:* for coenzyme M.

combination electrode an electrode comprising a glass electrode and a reference electrode in the same envelope providing a smaller, more compact instrument and ensuring the two electrodes are in the same environment.

combinatorial describing any process that is governed by a specific combination of factors, rather than by any single factor, with different combinations having different effects.

combinatorial chemistry the use of a process to prepare large numbers of structurally diverse sets of organic compounds by combining sets of chemical building blocks (called monomers), often in every possible combination.

combined test of pituitary function a test for suspected hypopituitarism. Insulin, luteinizing hormone-releasing hormone (LHRH), and thyrotropin releasing hormone (TRH) are administered and the response of pituitary hormones is compared with their levels before insulin administration. The lowering of the blood glucose level should stimulate a rise in the blood levels of cortisol and growth hormone; LHRH should increase follicle stimulating hormone (FSH) and luteinizing hormone (LH); and TRH should increase thyrotropin and prolactin.

combining site the site on an antibody molecule that combines with the corresponding antigen.

combustion the act or process of burning, especially the quantitative conversion of organic compounds to carbon dioxide and water for elementary analysis, in the estimation of carbon-14 and tritium, or in the determination of a heat of combustion.

co-metabolism any oxidation of substances by a microorganism in which the energy yielded by the oxidation is not used to support microbial growth. The presence or absence of growth substrate therefore cannot be inferred from such an oxidation.

command language the language used for giving computers simple instructions. The commands can be assembled into files referred to as batch files (DOS), command files (VMS), or scripts (UNIX).

commensal 1 describing either of two different species of organism that live in close physical association with benefit to one partner but with little effect - either beneficial or harmful - on the other partner. 2 any organism in a commensal association. *Compare* symbiosis. -commensalism n.

committed step or committing reaction a reaction in a multi-enzyme reaction sequence (e.g. a metabolic pathway) that once it occurs, causes all the ensuing reactions of the sequence to take place. The sole metabolic role of the committed step is

**co-monomer**

to provide precursors of the final product of the pathway; it is usually a physiologically irreversible step.

**co-monomer** the cross-linking agent added to the monomer in forming the gel used in **polyacrylamide gel electrophoresis**.

**COMP** abbr. for cartilage oligomeric matrix protein; now called thrombospondin-5 (see **thrombospondin**).

**compactin** an alternative name for **mevastatin**.

**compartment I** (in *tracer kinetics*) any anatomical, physiological, chemical, or physical subdivision of a system throughout which the concentration ratio of labelled to unlabelled substance is uniform at any given time. It is understood that the rate at which the tracer entering the compartment is mixed with tracer in the compartment is rapid compared with the rate at which the substance leaves the compartment. 2 any subdivision of a model used for the analysis of experimental observations.

**compartmentation or compartmentalization** the unequal distribution of a metabolite, enzyme, or metabolic pathway between different parts of a cell (e.g. in cell organelles) or of a whole organism. Consequently only a part of the total of any given chemical present is apparently available for a given reaction. It may refer to morphologically recognizable structures or to **metabolic pools**.

**compatibility group** see **incompatibility group**.

**competence** 1 the ability of a cell to take up a molecule of exogenously added DNA, and to be transformed by it (see **transformation**). 2 the ability of bacterial cells to incorporate phage DNA and to produce phage progeny (see **bacteriophage**). 3 the state of reactivity of a cell, tissue, or organism that allows it to respond to specific stimuli by forming new morphological structures or by synthesizing specific proteins (enzymes).

**competence factor** a secreted protein, or other substance added in culture, that is essential for **competence** in a bacterial or other cell. A 10 kDa basic protein of this type has been isolated from streptococci. It does not bind to DNA but interacts with the cell surface.

**competition** (in *chemistry*) rivalry between two or more different, but often similar, chemical species for a specific biochemical system, e.g. a receptor, enzyme, transport system, antibody molecule, or ion exchanger.

**competition binding** see **displacement binding**.

**competitive antagonism** the competition between an **agonist** and an antagonist for a receptor that occurs when the binding of agonist and antagonist is mutually exclusive. This may be because the agonist and antagonist compete for the same binding site, or combine with adjacent but overlapping sites. A third possibility is that different sites are involved but that they influence the receptor macromolecule in such a way that agonist and antagonist molecules cannot be bound at the same time. If the agonist and antagonist form only short-lived combinations with the receptor, so that equilibrium between agonist, antagonist, and receptor is reached during the presence of the agonist, the antagonism will be surmountable over a wide range of concentrations (see **reversible competitive antagonism**). In contrast, some antagonists, when in close enough proximity to their binding site, may form a stable covalent bond with it (see **irreversible competitive antagonism**); the antagonism becomes insurmountable when no spare receptors remain. More generally, the extent to which the action of a competitive antagonist can be overcome by increasing the concentration of agonist is determined by the relative concentrations of the two agents, by the association and dissociation rate constants for their binding, and by the duration of the exposure to each. The action of a competitive antagonist can therefore be surmountable under one set of experimental conditions and insurmountable under another.

**competitive inhibition** any inhibition of an enzyme activity by an inhibitor that binds to the same active site on the enzyme as does the substrate and when there is no interaction between the inhibitor and the enzyme-substrate complex, nor

**complement**

between the substrate(s) and the enzyme-inhibitor complex. Characteristically, analysis using a Lineweaver-Burk plot reveals that in the presence of a **competitive inhibitor**  $V_{max}$  is unchanged and  $K_m$  is increased.

**competitive inhibitor** any inhibitor that produces **competitive inhibition** of the activity of an enzyme. Inhibition produced by a given level of inhibitor can be overcome by an increase of substrate concentration.

**competitive protein-binding assay** abbr.: CPBA; a form of **saturation analysis** in which a naturally occurring proteinaceous binding substance is used.

**complement** or (formerly) alexin(e) a system of plasma proteins, found in the blood of vertebrates (and freshly prepared sera), that acts as an effector mechanism in immune defence against infection by microorganisms; the activation products of complement components cause lysis of antigenic cells, attract phagocytic cells to the site of activation, and assist the uptake and destruction of antigenic cells by phagocytes. Complement is also involved in immunological tissue injury. Activity in serum is lost on standing for several days at room temperature or for 30 min at 56°C. The components of complement, mostly  $\beta$ - or  $\gamma$ -globulins, are generally designated by the symbol C and an identifying suffixed numeral; activated components are indicated by a superscribed bar.

**C1**, the first component of complement, is a serum proteinase of  $M_r$  400 000 (Sepharose); its concentration in human serum is approximately 250 mg L<sup>-1</sup>. **C1** is a Ca<sup>2+</sup>-dependent termolecular complex of Clq, Clr, and Cls in the molar ratio of 1:2:2. The Clq subcomponent is composed of nine subunits, six of which are disulfide-linked dimers of the A and B chains, and three of which are disulfide-linked dimers of the C chain. It is one of the few proteins that contain **hydroxyproline** Clr and Cls form a Ca<sup>2+</sup>-dependent tetramer ( $M_r$  350 000), which is composed of two molecules each of the zymogens Clr ( $M_r$  83 000) and Cls ( $M_r$  83 000). Clr has proteinase activity (EC 3.4.21.41), cleaving Lys(or Arg)-Ile bonds in Cis, which can then activate C2 and C4. Example CIQa: database code CIQA\_HUMAN, 705 amino acids (80.08 kDa).

**C2**, the second component of complement, has an  $M_r$  of 110000 and a concentration in human serum of approximately 15 mg L<sup>-1</sup>. It is activated by Cis to form C2a and C2b. C2a combines with complement components C2b and C4b to form C3IC5 convertase, a serine proteinase (EC 3.1.21.43). C2 is a class II MHC protein sequence; example (human, precursor): database code C02\_HUMAN, 752 amino acids (83.14 kDa).

**C3**, the third component of complement, is a glycoprotein of  $M_r$  180000; its concentration in human serum is approximately 1200 mg L<sup>-1</sup>. It activates the complement system, being processed by the removal of four Arg residues to form two chains,  $\alpha$  and  $\beta$ , linked by a disulfide bond. C3/C5 convertase activates C3 by cleaving the  $\alpha$  chain, releasing C3a anaphylatoxin and generating the  $\alpha'$  chain +  $\beta$  chain of C3b. C3b is split in two positions by complement factor I to form IC3b and C3dg. C3 resembles C4, C5, and  $\alpha_2$ -**macroglobulin**. Database code (human, precursor) C03\_HUMAN, 1663 amino acids (186.95 kDa).

**C4**, the fourth component of complement, has an  $M_r$  of 200 000 and a concentration in human serum of approximately 400 mg L<sup>-1</sup>. The precursor is cleaved enzymatically to form three chains ( $\alpha$ ,  $\beta$ , and  $\gamma$ ); the human form is polymorphic, the allotype being C4a. C4a alleles carry blood group Rogers and C4b alleles carry Chido. Total deficiency of C4a6 allotype is associated with hemolytic disease. C4a anaphylatoxin is a mediator of local inflammatory processes. It induces the contraction of smooth muscle, increases vascular permeability, and causes histamine release from mast cells and basophilic leukocytes. C4 is an MHC class III protein, similar to

## complement

C3, C5, and urmacroglobulin. Database code (human, precursor) C04\_HUMAN, 1741 amino acids (192.12 kDa).

C5, the fifth component of complement, is a glycoprotein of  $M_r$  180 000; its concentration in human serum is approximately 80 mg L<sup>-1</sup>. Activation of C5 initiates the spontaneous assembly of the late complement components, C5-C9, into the membrane attack complex (*see MAC (def. 1)*). C5b has a transient binding site for C6. The C5b-C6 complex is the foundation upon which the lytic complex is assembled. The C5 precursor is first processed by the removal of four basic residues, to form two chains, u and  $\beta$ , linked by a disulfide bond. C5 convertase activates C5 by cleaving the u chain, releasing C5a anaphylatoxin and generating the u' chain +  $\beta$  chain of C5. C5 anaphylatoxin is a mediator of local inflammatory processes. C5a also stimulates the locomotion of polymorphonuclear leukocytes and directs their migration toward sites of inflammation. C5 is similar to C3, C4, and  $\alpha_2$ -macroglobulin: database code (human, precursor) C05\_HUMAN, 1676 amino acids (118.12 kDa).

C6, C7, C8, and C9, the sixth, seventh, eighth, and ninth components of complement. These four components, together with C5b, constitute the membrane attack complex; all are related and similar to perforin. C6 is a 6S  $\beta_2$ -globulin, and contains nine Cys-rich structural units, believed to be linked by disulfide bonds: database code (human, precursor) C06\_HUMAN, 934 amino acids (104.73 kDa). C7 is a 5.2S  $\beta_2$ -globulin, and serves as a membrane anchor: database code (human, precursor) C07\_HUMAN, 843 amino acids (93.41 kDa). C8 is a Y-globulin of  $M_r$  150 000; its concentration in human serum is 10-20 mg L<sup>-1</sup>. The molecule is a heterotrimer comprising the following subunits: u (human, precursor), database code C08A\_HUMAN, 583 amino acids (64.84 kDa);  $\beta$  (human, precursor), database code C08B\_HUMAN, 591 amino acids (66.87 kDa); and  $\gamma$  (human, precursor), database code C08B\_HUMAN, 202 amino acids (22.19 kDa). C9, a 4.4S U2-globulin, forms transmembrane channels. It is cleaved by thrombin to form C9a and C9b. Database code (human, precursor) C09\_HUMAN, 559 amino acids (63.09 kDa).

Factor B, a zymogen of  $M_r$  100 000, is activated by factor D, which selectively cleaves an Arg-I-Lys bond when factor B is complexed with C3b to form factor Bb. Following cleavage the C3b-Bb complex acts as alternative-complement-pathway C3/C5 convertase (EC 3.4.21.47), which can convert C3 to C3a and C3b by cleaving an Arg-I-Ser bond, and C5 to C5a and C5b by cleavage of an Arg-I-Xaa bond. Database code (human, precursor) CFAB\_HUMAN, 739 amino acids (82.91 kDa).

Factor  $\bar{D}$ , is a serine proteinase (EC 3.4.21.46) of  $M_r$  24 000; its concentration in human plasma is approximately 1.5 mg L<sup>-1</sup>. Database code (human, precursor) CFAD\_HUMAN, 246 amino acids (26.15 kDa); residues 19-246 are factor D.

Factor H (human, precursor: database code CFAH\_HUMAN, 1231 amino acids, 138.97 kDa) is a cofactor for factor I (EC 3.4.21.45), a serine proteinase that cleaves the  $\alpha$  chains of C4b and C3b in the presence of the cofactors for C4-binding; human, precursor: database code CFALHUMAN, 583 amino acids (65.65 kDa).

Properdin, a glycoprotein of  $M_r$  220 000, is composed of four, probably identical, noncovalently linked polypeptide chains.

Two alternative reaction cascades for the activation of complement exist. In the so-called classical pathway, activation (which requires both Ca<sup>2+</sup> and Mg<sup>2+</sup>) is initiated by the binding of the Clq moiety of Cl to the C<sub>H</sub>2 regions of antibody molecules in antibody-antigen aggregates or in antibody bound to cells, thus causing Cl to be converted to a proteinase, Cl<sup>-</sup>. Cl<sup>-</sup> activates C4 and C2 leading to the formation of C3 convertase, a comExL proteinase, C42, consisting of the activated components C4 and C2. C42 splits C3 to the chemotactic and anaphylatoxic fragment C3a and the fragment C3<sub>b</sub>,

## complement fixation

C3b, which associates with C42 to give a C423 complex, C5 convertase. The latter is a complex proteinase that in turn splits C5 to C3 and the chemotactic and anaphylatoxic fragment C5a. In the so-called alternative pathway, activation (which requires Mg<sup>2+</sup> but not Ca<sup>2+</sup>) is initiated by polysaccharides such as those present on bacterial and yeast cell walls. The proteinase  $\bar{D}$  is analogous to Cl<sup>-</sup> but is normally present in serum, where it causes a continuous slow activation, which is greatly enhanced when polysaccharides are present.  $\bar{D}$  acts on Band C3 to produce C3B, an alternative C3 convertase. C3B, which is stabilized by properdin, acts on C3 to produce (C3)<sub>n</sub>B, an alternative C5 convertase. In both pathways, C5 production is the last proteolytic step, and there follows a spontaneous association of C5 with C6, C7, C8, and C9 to form a lytic complex, C56789. See also lysinolarginine) carboxypeptidase.

complementarity 1 the interrelationship between one or more units supplementing, being dependent on, or being in a polar position to another unit or units. 2 a reverse correspondence of part of one molecule to part of another molecule, especially of antigen to antibody, enzyme to substrate, or the partners in a base pair.

complementary base sequence a sequence in a polynucleotide chain in which all the bases are able to form base pairs with a sequence of bases in another polynucleotide chain.

complementary catalysis catalysis in the presence of a prototype molecule, leading to the formation of products with a structure that is in some way complementary to that of the prototype.

complementary DNA abbr.: cDNA; a single-stranded DNA molecule that has a complementary base sequence to a molecule of a messenger RNA, from which it is produced by the action of reverse transcriptase and is used for molecular cloning, or as a molecular probe (def. 3) in hybridization tests for a specific sequence in cellular DNA. It has the advantage that, unlike genomic DNA, it contains no introns. It must be distinguished from the complementary strand of duplex DNA (see noncoding strand).

complementary genes any genes that interact to produce a qualitative effect that is distinct from the effects of anyone of them separately.

complementary RNA abbr.: cRNA; a single-stranded RNA molecule that has a complementary base sequence to a specific (chromosomal) DNA sequence (of either strand), from which it is produced by the action of DNA-directed RNA polymerase. Naturally occurring cRNA may represent pre-messenger RNA, ribosomal RNA, or transfer RNA. Compare antisense RNA.

complementary strand (of duplex DNA) see noncoding strand.

complementation 1 any instance in which the interaction of two incomplete, nonfunctional systems results in a fully functional system. 2 the interaction between viral gene products or gene functions in cells that are multiply or mixedly infected with virus(es), leading to an increased yield of infective virus of one or more parental types. 3 genetic complementation.

complementation test any experimental test for genetic complementation. See *cis-trans* complementation test.

complement-3 convertase an alternative name for C3 convertase; see complement.

complement-S convertase an alternative name for C5 convertase; see complement.

complement decay-accelerating factor abbr.: DAF; a factor that interferes with catalysis of the conversion of component C2 and factor B of complement, and prevents the formation of the amplification convertases of the complement cascade. DAF is expressed on the plasma membranes of all cell types that are in intimate contact with plasma complement proteins, and is a glycosylphosphatidylinositol-anchored protein. Human proteins DAF1 and DAF2 are formed by alternative splicing of a transcript of the same gene. Example (precursor of DAF1) from human: database code DAF1\_HUMAN, 440 amino acids (48.66 kDa).

complement fixation activation of the complement system,

## complement-fixation inhibition test

characteristically *in vitro* by an antigen-antibody interaction, in which complement components Cl to C9 are activated sequentially.

**complement-fixation inhibition test** a serological test in which the presence of a substance of known structure either may or may not inhibit the interaction of antibody with complex antigen, and hence also the fixation of complement. *Compare* complement-fixation test.

**complement-fixation test** a serological test for the presence of antibody that can fix complement on interaction with antigen. The presence or absence of residual complement is detected by an indicator system, e.g. added sheep erythrocytes sensitized with an antibody to sheep erythrocytes. If complement is still present, lysis of the erythrocytes occurs, but if no complement remains, no lysis takes place.

**complement receptor** any cell-surface receptor that binds activated complement components, e.g. the receptor for C3b found on macrophages, neutrophils, and B lymphocytes.

**complete Freund's adjuvant** *see* Freund's adjuvant.

**complex** 1 any distinct chemical species in which two or more identical or nonidentical chemical species (ionic or uncharged) are associated, usually in stoichiometric proportions, and bound together by weaker interactions than covalent bonds. The term is used for various entities, e.g. coordination complexes, antigen-antibody complexes, enzyme-substrate or enzyme-inhibitor complexes, multienzyme complexes, and receptor-agonist complexes; it is often employed where the precise nature of the interaction is uncertain. 2 to make a complex or incorporate into a complex, especially of a metal ion and a chelating agent; to chelate.

**complex I, II, III, IV** the protein complexes, mainly cytochromes, that with associated ligands including ubiquinone, Fe-S clusters, FMN, FAD, and nicotinamide nucleotides form the mitochondrial electron-transport chain or respiratory chain. Each complex can be isolated from the others, and, if suitable substrates and electron acceptors are provided, can function independently in transporting electrons. Complexes I, III, and IV are also involved in proton translocation, a function that requires the complex to be embedded in an orientated environment such as that provided by the intact lipid bilayer of the mitochondrial inner membrane. Purification has led to the identification of the components of each complex. Complex I contains altogether  $\approx 25$  different polypeptide subunits including NADH dehydrogenase (ubiquinone), together with FMN and a number of different iron-sulfur clusters containing non-heme iron in the forms Fe-S, Fe<sub>2</sub>-S<sub>2</sub>, and Fe4-S4, the iron of which undergoes oxidation-reduction between oxidation states II and III. The reaction catalysed is the oxidation of NADH by ubiquinone. Complex II contains four subunits of succinate dehydrogenase (ubiquinone), FAD, and iron-sulfur. It catalyses the oxidation of succinate by ubiquinone. Complex III contains  $\approx 10$  polypeptide subunits including the four redox centres: cytochrome *b*<sub>562</sub>, cytochrome *b*<sub>566</sub>, cytochrome *c*<sub>1</sub>, and an Fe<sub>2</sub>-S<sub>2</sub> cluster. It catalyses the oxidation of ubiquinol by oxidized cytochrome *c*. The transfer of electrons to cytochrome *c*<sub>1</sub> involves the protonmotive Q cycle. Complex IV contains the 13 polypeptide subunits of cytochrome *c* oxidase, including cytochromes *a* and *a3*, and Cu<sup>2+</sup>. It catalyses the oxidation of reduced cytochrome *c* by dioxygen.

**complexation** the act or process of forming a (chelate) complex, e.g. to render inorganic substances soluble in organic solvents.

**complex closed DNA** a DNA structure comprising catenated and concatenated circular polynucleotide oligomers. *See* catenane, concatemer.

**complex formation** *see* complex (def. 2), complexation.

**complexity (in molecular biology)** the number of different sequences in DNA as defined by hybridization kinetics.

**complexometric titration** any titration in which the titrant contains a complexing (chelating) agent that interacts with a metal ion or other chemical species in the test solution, the end

## concanavalin A

point being determined either electrometrically or with an indicator.

**complexometry** any method for the determination of a metal ion (or other chemical species) involving the formation of a chemical complex.

**complexone** any complex-forming or chelating agent, especially any macrocyclic antibiotic that complexes metal ions.

**Complexone** a proprietary name for EDTA.

**compound** any substance containing two or more identical or nonidentical chemical atoms in fixed numerical proportions and held together by one or more kinds of chemical bond.

**compound A, B, C (etc.)** *see* Kendall's compounds.

**compression** *see* band compression.

**Compton, Arthur Holly** (1892-1962), US physicist noted for his studies of cosmic rays and X-rays; Nobel Laureate in Physics (1927) 'for his discovery of the effect named after him' [prize shared with C. T. R. Wilson].

**Compton effect** or Compton scattering the scattering of photons by free particles that results in an increased photon wavelength (i.e. a decrease in photon energy) and a corresponding increase in the particles' velocity (i.e. an increase in the particles' kinetic energy).

**computer-assisted tomography abbr.: CAT; see** tomography.

**computer of average transients abbr.: CAT;** an electronic device of many separate channels in which a set of signals (e.g. an NMR spectrum) is repeatedly scanned and the signals stored additively. The stored signals grow linearly with the number of scans but the noise, being random, grows only as the square root of the number of scans taken, thereby improving the signal-to-noise ratio.

**COMT abbr. for** catechol O-methyltransferase, EC 2.1.1.6.

**comutagen** any nonmutagenic agent that enhances the effect of a mutagen.

**comutation** the occurrence of a mutation near to, and at the same time as, another specified mutation.

**con A abbr. for** concanavalin A.

**conalbumin** or ovotransferrin a protein of  $\approx 77$  kDa that comprises about 12% of the total solids of egg white. It is distinguishable from ovalbumin by its lower thermal coagulation point. It binds Fe<sup>3+</sup> ions. The amino-acid sequence of conalbumin is probably identical to that of chicken serum transferrin, but their carbohydrate moieties are different. Conalbumin precursor, example from *Gallus gallus* (chicken): database code TRFE\_CHICK, 705 amino acids (77.76 kDa).

**conantokin G** also called sleeper peptide; a toxic peptide from the venom of *Conus geographicus* (fish-hunting cone snail). It is an antagonist of brain NMDA receptors. It has the sequence

OEXXLQXNQLRDXKSN,

where X =  $\gamma$ -carboxyglutamate (Ola). The five Ola residues bind Ca<sup>2+</sup>.

**conarachin** a minor globulin occurring, along with arachin (def. 1), in seeds of the peanut, *Arachis hypogaea*.

**conc. abbr. for** concentrated.

**concanavalin A abbr.: con A;** an agglutinating and mitogenic protein (*see* lectin) that constitutes the major component of the subsidiary globulin fraction (originally named concanavalin because it accompanied canavulin in purification) obtained from the ripe seeds of the jack bean. It is separable from canavulin and from the minor component concanavalin B by differences in solubility. It is a crystallizable tetramer with 27.5 kDa subunits, dissociating to a dimer below pH 5.8. Each subunit contains one binding site for Mn<sup>2+</sup> (or other transition metal ion), one for Ca<sup>2+</sup>, and one for carbohydrate (specifically  $\alpha$ -D-mannopyranoses or  $\alpha$ -D-glucopyranoses with unmodified hydroxyl groups at C-3, C-4, and C-6); carbohydrate does not bind until the metal binding sites are filled. It agglutinates erythrocytes, and precipitates polysaccharides containing a sufficient number of appropriate terminal residues. It is mitogenic, transforming lymphocytes to blast cells, and can agglutinate some animal tumour cells and inhibit their growth.

## concanavalin B

The precursor - database code CONA\_CANEN, 290 amino acids (31.49 kDa) - is processed in an unusual way: the mature chain consists of residues 164-281 followed by 30-148; to form a mature chain the precursor undergoes further post-translational modification after removal of the signal sequence; cleavage after Asn at positions 148, 163, and 281 is followed by transposition and ligation (by formation of a new peptide bond) of residues 164-281 and 30-148. The 3-D structure is known (database code NRL\_3CNA).

**concanavalin B** a minor crystallizable protein obtained from ripe seeds of the jack bean and separable from cannavalin and concanavalin A.

**concatemer** or **concatenate** originally, an intermediate structure in the biosynthesis of certain DNA viruses, consisting of a number of genomes connected together end to end, and thought to be the immediate precursor to the mature viral genome. The term is now extended to include any linear or circular DNA structure composed of viral genomes joined end to end. The term is also used for circular DNAs which are physically inseparable, one being threaded through the other. *Compare* catenane. -concatemeric *adj.*

**concatenate** 1 to join or link together, end to end. 2 joined or linked together. 3 *an alternative term for concatemer. Compare* catenate. -concatenated *adj.*; concatenation *n.*

**concatenated dimer** or **circular dimer** any circular concatemer containing two DNA molecules.

**concentrate** 1 to reduce the volume of a solution or dispersion by removal of solvent or dispersing medium. 2 to make or become purer or more concentrated by removal of impurities from a substance or material. 3 a concentrated solution or material, especially of foodstuffs, e.g. a vitamin concentrate. —concentrating *n.*

**concentrated** 1 *abbr.: conc.; (of a solution, dispersion, or mixture)* containing a relatively high concentration (of a specified solute, kind of dispersed particle, or component); (of substance, particles, etc.) present at relatively high concentration (in a solution, dispersion, etc.). *Compare* dilute (def. 1). 2 *(of a solution, dispersion or mixture)* increased in concentration and reduced in volume by removal of solvent, dispersing medium, or admixed material. *Compare* diluted.

**concentration** *abbr.: concn.; 1 (a) mass concentration or mass density symbol: p or γ; an SI derived physical quantity; it equals the mass of a specified component per unit volume of the system in which it is contained. It is expressed in kg m<sup>-3</sup>. (b) amount-of-substance concentration or amount concentration or (in clinical chemistry) substance concentration symbol: c; an SI derived physical quantity; it equals the number of moles of a specified component per unit volume of the system in which it is contained. Where there is no risk of confusion the term concentration may be used alone. It is expressed in mol m<sup>-3</sup> or mol dm<sup>-3</sup>. Amount concentration continues to be expressed often in terms of the litre (symbol: l or L), which is not an SI unit, although 1 L ≈ 1 dm<sup>3</sup>. The older, non-SI, term molarity is still commonly used for this quantity; a solution of, say, 1 mol dm<sup>-3</sup> concentration may thus be referred to also as a 1 molar solution or denoted a 1 M solution, where M is treated as a symbol for mol dm<sup>-3</sup> (or mol L<sup>-1</sup>). - see molar (def. 2). (c) surface concentration symbol: r; an SI derived physical quantity; it equals the number of moles of a specified substance per unit area of the surface at which it is present. It is expressed in mol m<sup>-2</sup>. (d) number concentration or number density symbol: C or (sometimes) n; an SI derived physical quantity; it equals the number of specified particles or molecular entities per unit volume of the system in which it is contained. It is expressed in m<sup>-3</sup>. Note: The concentration of a solute in solution may sometimes be expressed in more convenient units esp. in a percentage; e.g. (for solids) as the mass of solute in grams per 100 millilitres of solution (*abbr.: % w/v*), or (for liquids) as the number of volumes of solute per 100 volumes of solution (*abbr.: % v/v*). See also activity (def. 3), molality, osmolality, osmolarity.*

molarity. 2 the act or process of concentrating. *See* concentrate (def. 1, 2).

**concentration equilibrium constant** any equilibrium constant expressed in terms of concentrations rather than activities.

**concentration gradient** the change of concentration with distance, e.g. the change in concentration of a solute across a membrane or along a gradient.

**concentration of enzymic activity** (*obsolete*) *see* enzymic activity.

**concentration polarization** (*in membrane ultrafiltration*) the accumulation of retained macrosolutes on the membrane, forming a secondary membrane, that results in restriction of transport through the filter and alteration of selectivity, which may lead to rejection of normally permeating species.

**concentration quenching** the quenching of fluorescence that becomes significant when the fluor concentration is increased beyond a certain point. It is of importance, e.g., in liquid scintillation counting and in experiments involving the introduction of fluorescent groups (probes) into macromolecules.

**concentration ratio** or **dose ratio symbol: r**; the ratio of the concentration of an agonist that produces a specified response (often but not necessarily 50% of the maximal response to that agonist in an assay) in the presence of an antagonist, to the agonist concentration that produces the same response in the absence of antagonist.

**concentric cylinder viscometer** *an alternative name for* Couette viscometer.

**concerted reaction** any chemical reaction in which two chemical processes occur within the same reaction step; i.e. one in which a new chemical bond is formed at the same time as, and as a direct result of, the breaking of another chemical bond.

**concerted symmetry model** a model of ligand binding to oligomeric proteins in which the characteristic assumption is that molecular symmetry of the oligomer is conserved so that only two states are accessible to it: either with all the protomers in the first conformational state or all the protomers in the second state. *See* Monod-Wyman-Changeux model.

**concerted transition** the simultaneous transition of all identical subunits (i.e. protomers) of an oligomeric molecule from the first conformational state to the second state and vice versa, as is required in any concerted symmetry model for allosteric proteins.

**concn.** *abbr. for concentration.*

**concordance** the condition in which both members of a twin pair demonstrate the same phenotype or trait.

**condensate** any product of a condensation, especially a liquid from a gas or vapour.

**condensation** 1 the act or process of condensing; the state of being condensed. 2 the product of condensing; a condensed mass. 3 any (usually stepwise) chemical reaction in which two or more identical or nonidentical molecular entities, or two parts of one entity, combine with the elimination of a molecule of water, ammonia, ethanol, hydrogen sulfide, or other simple substance. The combining entities or parts each (formally) contribute a moiety to the molecule eliminated.

**condensation polymerization** a polymerization by repeated condensation, i.e. with elimination of some simple substance, to form a condensation polymer.

**condense** 1 to make or to be made more compact or denser. 2 to change or cause to change a gas or vapour to a liquid or solid. 3 (of a compound) to undergo or cause to undergo a condensation (def. 3).

**condensed** 1 converted to a dense or denser form; e.g. condensed DNA in nucleosomes or in the early stages of maturation of T-even phages; or the condensed form of mitochondria in which the cristae are swollen, the matrix volume is much reduced, and the inner membrane space is increased. 2 reduced from the gaseous to the liquid state.

**condenser** 1 any device for converting a gas or vapour into a liquid (or solids) by cooling. 2 a lens or set of lenses that con-

## condensing enzyme

centres light into a small area. *3 a former name for capacitor; an electrical component that stores electric charge.*

**condensing enzyme** 1 citrate condensing enzyme, EC 4.1.3.7; *see citrate (sil-)synthase.* 2 p-oxoacyl-ACP synthase, EC 2.3.1.41; 3-oxoacyl-[acyl-carrier-protein]synthase (*see fatty acid synthase complex*).

**conditional association constant** or **conditional stability constant** an association constant determined in conditions similar to those in which the reaction under consideration is taking place, e.g. in the internal milieu of a cell.

**conditional lethal mutation** any mutation that produces a mutant (conditional lethal mutant) whose viability depends on the conditions of growth. It grows normally in permissive conditions but in restrictive conditions it does not grow, thereby expressing its lethal mutation. *See, e.g., temperature-sensitive mutation.*

**conduct** to allow the passage of electricity, heat, or electromagnetic radiation.

**conductance** *see electric conductance.*

**conductance water** *an alternative name for conductivity water.*

**conductimetric** or **conductiometric** *a variant spelling of conductometric; see conductometry.*

**conductometry** or **conductiometry** *a variant spelling of conductometry.*

**conduction** 1 the transfer of heat or electricity through a material. 2 the transmission of an impulse, either electrical or chemical, along a nerve fibre.

**conductivity** 1 electrical conductivity *symbol: K;* a measure of the ability of a material to conduct an electric current or impulse. It is defined as the reciprocal of the resistivity of the material, and is expressed in siemens m<sup>-1</sup>. *See also electrolytic conductivity.* 2 thermal conductivity.

**conductivity water** or **conductance water** very pure water, of electrolytic conductivity <1 x 10<sup>-4</sup> siemens m<sup>-1</sup>.

**conductometric titration** any titration in which the end point is indicated by an inflection in the curve of conductivity against volume of titrant added. For instance when an HCl solution is titrated with an NaOH solution, the conductivity decreases as the faster moving H<sub>3</sub>O<sup>+</sup> ions are replaced by slower moving Na<sup>+</sup> ions; after the equivalence point the conductivity increases as the concentration of the fast-moving OH<sup>-</sup> ions increases.

**conductometry** or **conductimetry** or **conductiometry** any method of chemical analysis based on measurements of electrical conductivity. -conductometric ad).

**conductor** any substance or system that allows the passage of electricity, heat, or electromagnetic radiation.

**cone cell** or **cone** one of the two types of light-sensitive cell of the vertebrate retina (*compare rod cell*). Cone cells are conical or flask-shaped, and contain the photopigment iodopsin or (in freshwater and migratory fishes and some amphibians) cyanopsin. They are responsible for photopic (daylight) vision; and are densest in the fovea and absent from the margin of the retina. Human cone cells are thought to be of three types, each containing an iodopsin of different spectral sensitivity; hence they are responsible also for colour vision.

**confidence limits** (*in statistics*) the upper and lower limits of the range of values within which the true mean is expected to lie, on the basis of an estimate of the mean obtained from a sample of values. The confidence limits vary according to the (specified) probability that they will be correct.

**configuration** classically, the arrangement of the atoms of a molecule in space, without regard to arrangements that differ only as after rotation about one or more single bonds; the term is now sometimes limited so that no regard is paid to  $\pi$ -bonds or to bonds of a partial order between one and two, and sometimes further limited so that no regard is paid to rotation about bonds of any order, including double bonds. Interconversion of molecules of different configurations requires the formal making and breaking of covalent bonds, no account being taken of changes to hydrogen bonds. *Compare*

## conformation

conformation. *See also absolute configuration, pyrimidine dimer. -configurational ad.*

**configurational base unit** (of a polymer) a constitutional base unit of the polymer whose configuration is defined at the minimum at one site of steric isomerism in the main chain of the polymer.

**configurational block** a block in a polymer containing only one species of configurational base unit.

**configurational inversion** *see racemize, Walden inversion.*

**configurational isomer** any of two or more isomers that differ only in stereochemical configuration.

**confluence** (*in cell culture*) the state reached when one or more cells or groups of cells, grown in culture on (so-called) solid medium, have multiplied to cover the surface of the medium completely but without overlying each other. -confluent ad).

**confocal microscope** a microscope that produces a series of images, often called optical sections, that have much better resolution than images of the same specimens obtained using conventional epifluorescence light microscopy. Such a microscope depends on laser light focused through a pinhole onto a single point in the specimen. From a succession of such images a 3-D image can be created. This is primarily used in biological imaging for mapping the distribution of fluorescently labelled macromolecules, such as antibodies, in various tissues.

**conformation** the various arrangements of the atoms of a molecule (of defined configuration) in space that differ only as after rotation about single bonds; the term is now sometimes extended to include rotation about  $\pi$ -bonds or bonds of partial order between one and two, and sometimes further extended to include also rotation about bonds of any order, including double bonds. Interconversion of molecules of different conformations does not involve the breaking and making of chemical bonds (except hydrogen bonds) or changes in chirality. The following special terms and symbols distinguish different possible conformations of various classes or portions of molecules.

(1) **Cyclic compounds.** Nonplanar six-membered rings may exist in boat conformation, chair conformation, half-boat conformation, half-chair conformation, skew conformation (def. I), or twist conformation (def. II); and nonplanar five-membered rings may exist in envelope conformation or twistconformation (def. 2). For a six-membered or five-membered ring form of a monosaccharide or monosaccharide derivative these conformations may be designated by the following conformational descriptors suffixed to their chemical names: -B, boat; -C, chair; -E, envelope; -H, half-chair; -S, skew; -T, twist; the locants of the ring atoms that lie above and/or below the reference plane, when the numbering appears clockwise, may be added to these symbols as left superscripts and/or right subscripts, respectively. A bond to a tetrahedral atom in a six-membered ring is termed axial (*abbr.: a*) if it or its projection makes a large angle with the plane containing a majority of the ring atoms, and equatorial (*abbr.: e*) if this angle is small; the same terms are applied to atoms or groups attached to such bonds. The corresponding terms for a bond from an atom directly attached to a doubly bonded atom in a monounsaturated six-membered ring are pseudoaxial (*abbr.: a'*) and pseudoequatorial (*abbr.: e'*), respectively.

(2) **Nucleotides.** When atom C-2' or C-3' of the ribo- or deoxyribofuranose ring of a nucleotide lies out of the plane of the other four ring atoms, the ring conformation is designated by the descriptor *endo-* if either atom lies above the ring, i.e. towards the nitrogenous base, and by the descriptor *exo-* if it lies below the ring, i.e. away from the base. In addition the base and sugar rings may be in either of two relative positions: the conformation is said to be anticalinal (*abbr.: anti-*) if the groups at positions 2 and 3 of a pyrimidine residue or positions I, 2, and 6 of a purine residue lie away from the sugar ring, and synclinal (*abbr.: syn-*) if these groups lie over the sugar ring.

## conformational analysis

(3) Torsion angle. If rotation about a given bond in a molecule is restricted for any reason, the conformation of atoms or groups about that bond may be described by the torsion angle (*symbol*:  $\theta$ ). When, in a Newman projection, two atoms or groups attached at opposite ends of a bond appear one more or less directly behind the other, i.e.  $\theta \approx 0^\circ$ , these atoms or groups are termed eclipsed, and that portion of the molecule is described as being in the eclipsed conformation. If not eclipsed (in an ideal case, when all torsion angles equal  $60^\circ$ ), the atoms or groups are termed staggered, and the molecule is described as being in the staggered conformation; such a conformation is termed synperiplanar (*abbr.*: *sp*) (or sometimes *cis* (*abbr.*: *c*), synclinal (*abbr.*: *sc*) (or sometimes *gauche* (*abbr.*: *g*) or *skew*), anticlinal (*abbr.*: *ac*), or antiperiplanar (*abbr.*: *ap*) (or sometimes *trans* (*abbr.*: *t*)) according as the torsion angle is, respectively, within  $\pm 30^\circ$ ,  $\pm 60^\circ$ ,  $\pm 120^\circ$ , or  $\pm 180^\circ$  of  $0^\circ$ , the torsion angle being defined according to specified criteria. (Note: Because the terms *cis* and *trans* have other meanings, their use in this context is not recommended.) -conformational *adj.*

conformational analysis the application of a set of specific rules to determine the conformation of a molecule in which the strain will be minimal, i.e. the most stable and preferred conformation of the molecule.

conformational change 1 any change in conformation 2 any change in the three-dimensional structure of a macromolecule, membrane, or other entity.

conformational-coupling hypothesis a hypothesis (now superseded) that the energy yielded by the processes of electron transport, e.g. in mitochondria, is conserved in the form of a conformational change in an electron carrier protein or in the coupling factor ( $F_1$  ATPase) molecule. The high-energy conformational state results from an energy-dependent shift in the number and location of weak bonds that maintain the three-dimensional conformation of the protein. The energy inherent in this 'energized' conformation is thought to be used to cause the formation of ATP from ADP and inorganic phosphate. This hypothesis was put forward after attempts to find a high-energy intermediate that coupled electron transport to oxidative phosphorylation, failed. It has been superseded by the chemiosmotic coupling hypothesis.

conformational formula a diagrammatic representation on a plane surface of the structural formula of a molecule that shows the relative dispositions in space of the constituent atoms or groups. Such representations are used especially to depict instances of conformational isomerism. For a monosaccharide or monosaccharide derivative, the conformational formula may be combined with a Haworth representation. See also Newman projection.

conformational isomer or (sometimes) conformer any of two or more isomers that differ only in their stereochemical conformation.

conformational map an alternative name for Ramachandran plot.

conformer 1 a molecule in a conformation into which its atoms return spontaneously after small displacements. 2 an alternative term for conformational isomer.

conformon a quantized energy package that, according to the conformational-coupling hypothesis, is associated with a localized conformational change in a protein in the mitochondrial membrane.

congener 1 any member of a (specified) group. 2 (in taxonomy) any member of a specified genus. 3 (in chemistry) a chemical substance related to another, e.g. as a derivative or as an element of the same group of the periodic table. b a secondary product retained in an alcoholic beverage (or extract of a natural product) that contributes significantly to the final characteristics of the beverage (or the extract).

congenic of, or pertaining to, a congener; homogenic.

congenital describing a character or trait (phenotype) that exists at or dates from birth. It neither includes all inherited con-

## coniine

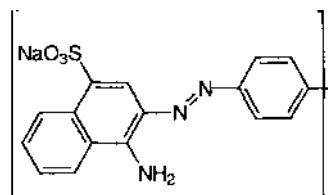

ditions nor excludes characters resulting from environmental causes.

congenital adrenal hyperplasia a syndrome embracing a group of inherited enzyme deficiencies of adrenal steroid hormone biosynthesis. A deficiency of 21-hydroxylase (steroid 21-monooxygenase, EC 1.14.99.10) accounts for the great majority of cases; it leads to failure to synthesize cortisol and results in overproduction of ACTH (due to release from negative feedback by cortisol) and consequently there is hyperplasia of the adrenal and overproduction of 17-hydroxyprogesterone and androstene 3,17-dione by overstimulated alternative pathways. Deficiency (usually partial) of 11P-hydroxylase (steroid 11P-monooxygenase, EC 1.14.15.4) accounts for most other cases; in this condition, 11-deoxycorticosterone accumulates. Very rarely, deficiency of 17-hydroxylase (steroid 17a-monooxygenase, EC 1.14.99.9) or 18-hydroxylase (corticosterone 18-monooxygenase, EC 1.14.15.5) may occur.

conglutination the agglutination of bacterial or red blood cells, that have been sensitized with specific antibody, in the presence of (nonhemolytic) complement and conglutinin.

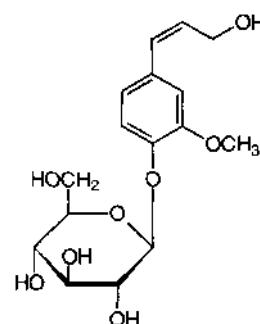

conglutinin a nonimmunoglobulin protein, present in the plasma of cattle and other bovids, that aggregates complement-coated immune complexes or cells.

Congo Red sodium diphenyldiazo-bis-a-naphthylaminesulfonate; CI 22120; Direct Red 28; an indicator dye that is blue-violet at pH 3.0 and red at pH 5.0. It is used for detecting and estimating free HCl in gastric contents, as an addition to culture media, and for staining amyloid.

Congo Red fibrin a preparation obtained by heating fibrin to 80°C in a slightly alkaline Congo Red solution and thoroughly washing. It was formerly used in the detection of proteolytic activity since the dye does not dissolve in aqueous solutions unless the fibrin is digested.

coniferin 4-(3-hydroxy-1-propenyl)-2-methoxyphenyl P-D-glucopyranoside; the major glycoside present in conifers and some other plants.

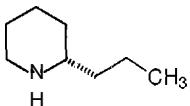

coniferyl alcohol the aglycon of coniterin; it occurs as a building unit of plant lignins.

coniine 2-propylpiperidine; the toxic alkaloid of poison hem-

## conjugase

lock, *Conium maculatum*. The natural enantiomer has S configuration.

**conjugase** *y-G1u-X* carboxypeptidase, EC 3.4.19.9 (formerly EC 3.4.22.12); y-glutamyl hydrolase; an enzyme that hydrolyses y-glutamyl bonds in N-pteroyl-y-oligoglutamate, pteroyl-y-diglutamate being a prominent product.

**conjugate** 1 to effect or undergo conjugation. 2 describing either of a pair of interconvertible substances, e.g. a conjugate acid-base pair. 3 the product formed as a result of conjugation.

**conjugate acid-base pair** the relationship between two chemical species, BH<sup>+</sup> and B, that are related by the reaction: BH<sup>+</sup> = B + H<sup>+</sup>. Then BH<sup>+</sup> is the conjugate acid of the base B, B is the conjugate base of the acid BH<sup>+</sup>, and BH<sup>+</sup> and B are a conjugate acid-base pair.

**conjugate base** see conjugate acid-base pair.

**conjugated** 1 describing a compound that is formed by the linking of two compounds. 2 displaying or having undergone conjugation.

**conjugated double bond** any of two or more double bonds in a molecule where each double bond is separated from the next one by one single bond. *Compare* conjugation (def. 2).

**conjugated protein** any protein that contains a nonprotein component, often in stoichiometric proportion. The nonprotein component may be a metal ion, a lipid, a carbohydrate, or a nucleic acid, and may be either loosely or tightly bound to the polypeptide chain(s).

**conjugation** 1 the act of joining together; the state of being joined together. 2 an alternating sequence of multiple and single chemical bonds containing at least two multiple bonds with delocalization of pi-electrons and resultant additional chemical stability. 3 the covalent or noncovalent joining together of one (larger) molecule, e.g. a protein or bile acid, with a second (smaller) molecule. 4 a process of sexual reproduction occurring in various types of unicellular organisms. In bacteria, e.g. *Escherichia coli*, it involves the transfer of DNA from a donor cell to a recipient cell via a sex pilus; in protozoa, e.g. *Paramecium aurelia*, a true exchange of DNA occurs between the participating cells, which belong to different mating types.

**conjugation labelling** a procedure for introducing a label into a large molecule of interest by covalently coupling it, in a specific chemical reaction, to a small molecule containing the label (see conjugation (def. 3)). It is particularly useful for labelling with radioiodine any protein or peptide that is sensitive to oxidative procedures or to noxious components of commercial radioiodine, that lacks tyrosine residues reactive to iodine, or that requires to be labelled at a residue other than tyrosine. *See also* Bolton and Hunter reagent.

**conjugative plasmid** any plasmid that can bring about the transfer of DNA by conjugation (def. 3).

**conjugon** any genetic element that is required for bacterial conjugation (def. 4), e.g. fertilityfactor.

**connective tissue** any supporting tissue that lies between other tissues and consists of cells embedded in a relatively large amount of extracellular matrix.

**connective tissue growth factor abbr.:** CTGF; a growth factor of testis, spleen, kidney, lung, heart, and brain, that is similar to CEF10; one of a family of growth regulators that belong to a group of immediate-early genes expressed after induction by growth factors or certain oncogenes. The family includes Cyr61,  $\beta$ IG-M1, and f3IG-M2. Example (precursor) from mouse: database code CTGF\_MOUSE, 348 amino acids (37.75 kDa).

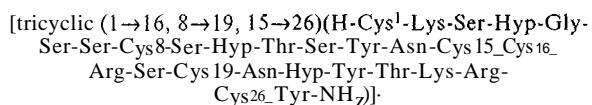

## conserved

**connectivity (in chemistry)** the information in any molecular formula or model regarding the order in which the constituent atoms of the molecule are linked, irrespective of the nature of the linkages.

**connexin** the main protein component of a connexon. Each connexin contains four putative membrane-spanning a-helices, and six connexins make up each connexon. A number of different subtypes of connexin exist within each species, contributing different functional behaviour to different connexons. Example from human: database code CX26\_HUMAN, 208 amino acids (24.27 kDa); four motifs.

**connexon** the structural subunit of a gap junction, the structure that forms a bridge between adjacent cells in certain tissues of vertebrates. Seen by electron microscopy or low-angle X-ray diffraction, an individual gap junction consists of a number (10-10<sup>4</sup>) of connexons, often in hexagonal array, embedded in and protruding from either side of each of the opposed cell membranes in register and linked to one another. Each connexon is a cylindrical proteinaceous structure, about 6-8.5 nm in diameter and 7.5 nm long; it consists of six rod-shaped, essentially rigid subunits (connexins) of about 25 kDa arranged in an annulus. The diameter of the central opening can apparently be varied by radial displacement of the subunits at their cytoplasmic extremities. Each connexin spans one cell membrane, two with connecting ends being required to form a channel across both membranes. Such channels provide a regulable hydrophilic pathway permitting the passage of small molecules (up to about 800 Da) between adjacent cells; the specificity of each channel is determined by the type of connexin it utilizes.

**conotoxin abbr.:**  $\omega$ -CT; any of several peptides of the family of ro-conotoxins isolated from the venoms of two marine snails, *Conus geographicus* and *C. magus*. All ro-conotoxins have a conserved pattern of cysteine residues linked by four disulfide bridges. They are neurotoxins that inhibit voltage-gated Ca<sup>2+</sup> channels and neurotransmitter release. ro-Conotoxin GVIA has the structure:

**consensus sequence** an idealized sequence of nucleotides, or their constituent bases, or amino acids, base, or amino acid that represents the nucleotide most likely to occur at each position in the sequence. Consensus sequences are used to identify RNA splicing sites, other sites, plasmids, and families of proteins.

**conservation** the retention of structure by a macromolecule, or by a specified segment of one, with variation of circumstance (environmental, genetic, etc.). When used of primary structure, it can be synonymous with sequence homology. The degree of retention of structure is usually specified. *See also* conserved.

**conservation of energy (law of the)** *see* thermodynamics.

**conservative base change** or **conservative base substitution** any mutational change, including substitution of a base, in a particular base triplet in a DNA molecule such that either the amino acid encoded by that base triplet is not altered, or there is no major change in the properties of the R group of the amino acids involved, e.g. Glu for Asp. *See* genetic code, wobble hypothesis.

**conservative replacement** or **conservative substitution** any replacement or substitution in a polypeptide chain of a particular amino acid residue by another one with similar properties, e.g. Arg for Lys, Phe for Tyr, Glu for Asp.

**conserved** describing a tendency to invariance in corresponding residues or sequences of residues of encoded macromolecules (e.g. proteins) obtained from specimens of genetically different sources. Macromolecules showing a high degree of

## constant region

invariance of their primary structure are said to be highly conserved; ones exhibiting considerable variation are described as poorly conserved. *See also* conservation, homologous.

**constant region** the region of a chain of an immunoglobulin molecule that is characterized by invariability of the amino-acid sequence from molecule to molecule, apart from certain residues at allotypic marker sites. The constant region of the light chain (corresponding to the C-terminal part) is designated  $C_L$ , while the constant region of the heavy chain is designated  $C_H$ . Within a constant region, individual domains may be further designated  $CH_1$ ,  $CH_2$ , etc. In a more precise designation of a heavy chain the 'H' subscript is replaced by the Greek letter corresponding to the type of heavy chain that defines the particular class of immunoglobulins. Hence, the constant region of an immunoglobulin G, in which the heavy chain is designated  $\gamma$ , can be designated  $C_\gamma 1$ ,  $C_\gamma 2$ , etc.

**constitutional base unit** the smallest possible regularly repeated unit (i.e. identical group of monomers) of a regular polymer.

**constitutional block** a block of a polymer that contains only one species of constitutional base unit.

**constitutional isomer or (formerly) structural isomer** any of two or more isomers that differ in their molecular constitution, i.e. in the nature and sequence of bonding of their atoms rather than in the arrangement of their atoms in space. For example, ethanol,  $CH_3-CH_2-OH$ , and dimethyl ether,  $CH_3-O-CH_3$ , are constitutional isomers. *Compare* stereoisomer.

**constitutive enzyme** any enzyme that is formed at a constant rate and in constant amount in a given cell, regardless of the metabolic state of the cell or organism. *Compare* induced enzyme.

**constitutive genes** genes that are expressed following interaction between a promoter and RNA polymerase without additional regulation. *Also known as* housekeeping genes, they are expressed in virtually all cells since they are essential for the cell's activity.

**constitutive mutation** any mutation that results in an increased constitutive synthesis (i.e. synthesis as if by a constitutive gene) by a prokaryote of several functionally related, inducible enzymes. In such mutations either an operator gene is modified so that the repressor cannot combine with it or the regulator gene is modified so that the repressor is not formed.

**contact amino acid** any of the amino-acid residues in the active site (def. I) of an enzyme that are at some stage within one bond distance of some point on the substrate molecule in the enzyme-Substrate complex. They may include both catalytic residues and specificity residues. *Compare* auxiliary amino acid.

**contact hypersensitivity** a form of immunological hypersensitivity, immediate or delayed, that is provoked in the skin or mucous surfaces by contact with specific agents acting as either antigens or haptens.

**contact inhibition** a phenomenon, seen in cultures of normal eukaryotic cells, in which cell division is inhibited by cell-to-cell contact. When one cell contacts another cell as a result of increased cell density, it first ceases to move, then metabolizes more slowly and ceases to divide. An outstanding feature of malignant cells is their loss of contact inhibition so that they multiply unchecked. *See also* transformation (def. 2).

**contact residue** *see* contact amino acid.

**contact sensitivity** the ability of an organism to respond to a biocide, e.g. an insecticide or a selective herbicide, applied to the integument.

**containment** the use of any structural or procedural safeguards to minimize the possible risks, to the experimenter or to the environment, in hazardous or potentially hazardous operations, especially genetic manipulations or the use of ionizing radiation.

**contamination** the presence of any contaminant; the act of introducing a contaminant; pollution; the presence of harmful

## continuous variation

or invasive microorganisms in a population of desirable ones. *Compare* decontamination.

**context** 1 any parts of a piece of writing or speech that precede or follow a specified word or passage and contribute to its full meaning. 2 (*in mycology*) the layers that develop between the hymenium and the true mycelium in certain fungi.

**context effect** any effect of nucleotide residues outside a codon in an mRNA molecule in influencing the efficiency of the reading of that codon by the appropriate tRNA molecule. *Compare* context (def. I).

**context mutation** any mutation that brings about an alteration in the context effect of nucleotide residues outside a particular codon in an mRNA molecule.

**contig** one of a set of overlapping clones that represent a continuous region of DNA. Each contig is a genomic clone, usually in a cosmid or a VAC. They are used in contig mapping.

**contig mapping** a technique used in projects such as the Human Genome Project to enable the physical map of (part of) a chromosome to be determined. The method relies on the use of overlapping clones, referred to as contigs.

**contiguous gene syndrome** any of the complex disease phenotypes associated with a chromosomal microdeletion affecting multiple, unrelated genetic loci physically contiguous on a chromosome.

**continuous culture** any cell culture in which the cells are in the growth phase over a prolonged period of time. *See also* chemostat.

**continuous distribution** any nonquantized distribution; e.g. in a large population one measurement,  $x$ , may be considered to vary continuously, and the probability,  $y$ , of the occurrence of a particular value of  $x$  is given by  $y = f(x)$ .

**continuous epitope** an immunological determinant (i.e. epitope) on an antigen that is formed from a single linear stretch of amino acids. It is much less common than a discontinuous epitope.

**continuous-flow centrifugation** any preparative centrifugation technique, used for collecting materials from relatively large volumes of liquid, in which a liquid is continuously fed into a rotor, the sediment is collected, and the supernatant is withdrawn continuously as the rotor rotates. *See* centrifugal elutriation, Sharples supercentrifuge, lonal centrifugation.

**continuous-flow electrophoresis** a method of electrophoresis in which the protein (or other) solution is applied continuously to an inert support such as paper (then usually called curtain electrophoresis) or glass beads or is allowed to flow between two closely spaced parallel plates. The solution flows down the support by gravity and an electric potential applied at right angles causes migration of components away from the main stream. Fractions are collected at different positions across the bottom of the support.

**continuous-flow technique** a technique for following rapid chemical reactions in which two solutions, containing the reactants, are rapidly mixed and the mixture pumped at a pre-determined speed through a tube of known dimensions that contains an observation chamber. By changing the rate of flow, the time between mixing and observation can be varied. Thus, given a method of analysis for reactants or products in the observation chamber, the extent of reaction as a function of time can be determined.

**continuous process** a method of cultivation in which nutrients are supplied and components of the culture medium are removed continuously at volumetrically equal rates, maintaining the cells in a condition of stable multiplication and constant growth rate.

**continuous variation or Job's method** a method for investigating metal-ligand (or other) equilibria in solution in which the mole ratio of, e.g., metal ion to ligand species is varied while the sum of their concentrations is kept constant and some property that varies in a fashion proportional to the concentration of one of the molecular entities present, e.g. absorbance or conductivity, is measured. The curve of the

## contractile vacuole

magnitude of the property observed versus the concentration ratio gives information about the stoichiometry of the metal-ligand (or other) complex formed and allows the stability (association) constant to be calculated.

**contractile vacuole** any of the small spherical vesicles, found in the cytoplasm of freshwater protozoans, that function to expel surplus water from the organism.

**contrapsin** a glycoprotein plasma serine protease inhibitor, similar to the serpin-type inhibitors. It specifically inactivates serine proteases of the trypsin class but not of the chymotrypsin class. It has 64% homology with human u)-antichymotrypsin. Example (precursor) from *Mus musculus*: database code COTR\_MOUSE, 418 amino acids (46.83 kDa).

**contributing amino acid** (in an enzyme) any amino-acid residue whose only function appears to be that of a foundation for the contact amino acid and auxiliary amino acid residues in the active site. They are required in the natural enzyme to maintain the framework to which the contact and auxiliary amino acids are attached.

**contributing structure or (formerly) canonical form** anyone of two or more formal valence bond representations of a mesomeric molecular structure. *Compare* mesomerism.

**control** 1 any object or system in an experiment that is a standard of comparison. A control is prepared or carried out exactly as the other parts of an experiment but differs in respect of a single variable, allowing the significance of the latter to be assessed. *Compare* experimental (def. 3). 2 the regulation of a biochemical process such as a metabolic pathway or the expression of a gene.

**controllability coefficient** former name for elasticity coefficient.

**controlled pore glass** a type of glass in the form of rigid particles honeycombed with a great number of pores of selected, precisely defined size. It is useful as a supporting matrix in a large variety of chromatographic techniques, including affinity, gel-permeation, and ion-exchange methods.

**control point** the point - corresponding to a particular enzyme - in a metabolic pathway or other biochemical sequence where control is exercised.

**control region or control sequence** the part of a DNA molecule containing the promoter and the operator region of an operon.

**control strength** former name for flux control coefficient.

**convergence** see convergent evolution.

**convergent evolution or convergence evolution** such as to produce an increasing similarity in some characteristic(s) between initially different groups of, e.g., organisms or gene products. *Compare* divergent evolution.

**convertin** an alternative name for factor VIIa (see blood coagulation).

**convertin enzyme (factor)** see serum converting enzyme.

**convolution** 1 a twisting together, a coil. 2 a folding, such as those that produce the irregular ridges on the surface of the cerebrum of the brain.

**Conway microdiffusion method** a microchemical analytical method applicable to substances from which a gas, e.g. ammonia or carbon dioxide, can be liberated quantitatively by a specific reagent or enzyme; the method can also be used to assay an enzyme. The technique employs a special microdiffusion dish, variously termed a Conway cell, Conway dish, Conway unit, or Conway vessel. This consists of a shallow circular glass vessel, 40-70 mm in diameter, containing a central well and with a closely fitting lid sealed with grease; the lid closes the outer annular space but does not touch the wall of the central well. The sample is placed in the outer annulus, and a gas-absorbing reagent is placed in the centre well. The specific reagent is added to the sample, the lid is closed, and diffusion of the evolved gas allowed to proceed. Subsequently the remaining gas-absorbing reagent is titrated. [After Edward Joseph Conway (1894-1968), Irish biochemist.]

**Coombs's test** an alternative name for antiglobulin test. [After

## copigmentation

Robert Royston Amos Coombs (1921- ), British immunologist.]

**cooperative** acting together or with others. *See also* cooperativity.

**cooperative affinity** the state of increased potency, receptor affinity, and resistance to destruction that is exhibited by agonist molecules covalently attached to a macromolecule in any situation where ligand and acceptor possess more than one mutual recognition or binding site, deployed in such a manner that simultaneous interaction is stereochemically feasible.

**cooperative binding** *see* cooperative ligand binding.

**cooperative feedback inhibition** the feedback inhibition of an enzyme by two or more end products of a reaction sequence such that the degree of inhibition caused by the mixture is greater than the sum of the effects of the individual end products.

**cooperative hydrogen bonding** the interaction between adjacent hydrogen bonds in a molecule such that the energy required to form them is less than the sum of the energies required to form the individual bonds, and the energy required to break these bonds is greater than the sum of the energies required to break the individual bonds. Such an interaction increases the stability of the molecular conformation in which it occurs.

**cooperative ligand binding** the binding of ligands to interacting sites on a macromolecule such that the binding of one ligand molecule to one site either increases (positive cooperativity) or decreases (negative cooperativity) the affinity of the other site(s) for ligand(s). Such effects may be either homotropic, i.e. one ligand species affects the binding of the same ligand species, or heterotropic (def. I), i.e. one ligand species affects the binding of a different ligand species.

**cooperativity (in biochemistry)** any cooperative phenomenon, especially cooperative ligand binding or the situation in an enzyme that has more than one binding site for its substrate or allosteric effector where the binding of one molecule to the enzyme alters the affinity with which the others are bound.

**cooperativity index** *see* saturation ratio.

**coordinate** 1 to integrate or classify diverse elements or things. 2 (in chemistry) to be or become linked by coordination (def. 2). 3 (in mathematics) any of a set of values that defines the position of a point in space with reference to a system of axes.

**coordinate bond or coordinate covalence or coordinate link** an alternative term for dipolar bond.

**coordinated enzymes** enzymes whose rates of synthesis vary together; they are controlled by cistrons of the same operon.

**coordinated enzyme synthesis** the synthesis of enzymes that are controlled by the genes of one operon and are thus induced or repressed together.

**coordinate induction/repression** the simultaneous induction/repression of a number of enzymes that catalyse a sequence of either consecutive or related reactions and are controlled by scattered genes.

**coordination** 1 the balanced and effective interaction of processes. 2 the formation or existence of a covalent bond whose pair of electrons is regarded as originating from only one of the two parts of the molecular entity linked by it; linking by means of such a bond or bonds. *Compare* colligation. *See also* dipolar bond, pi adduct.

**coordination number or ligancy** the number of other atoms directly linked to a specified atom in a chemical species.

**cooxidation** an alternative term for co-metabolism.

**COP abbr. for coat protein;** protein subunit of a coatomer.

**copeptin** *see* vasopressin-neurophysin 2-copeptin precursor.

**copigmentation** the chemical association between a pigment molecule and another colourless molecule that results in altered absorption characteristics of the pigment and consequently a change in its shade or colour. Some flower petal colours are changed by hydrogen bonding between an anthocyanin pigment and a colourless flavonoid. For example, the anthocyanin in both purple and crimson roses is cyanidin 3,5-diglucoside, but in crimson flowers it is copigmented with

## copolymer

large amounts of gallotannin. This results in a spectral shift of the absorption maximum by 5 nm to longer wavelengths.  
copolymer the product of the polymerization of a mixture of more than one species of monomer.

copolymerization or copolymerisation the polymerization of a mixture of two or more species of monomer.

copper-chelate chromatography a type of metal-chelate affinity chromatography employing  $\text{Cu}^{2+}$  ions.

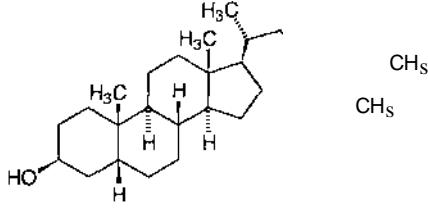

copro+ or (*before a vowel*) copr+ *comb. form* indicating feces.

coprophagy the act of feeding on feces.

coproporphyrinogen III an intermediate in the biosynthesis of metalloporphyrins (hemes and chlorophylls).

coprostane 5, B-cholestane; *see* cholestane.

coprostanol or coprosterol 5, B-cholestane-3, B-ol; a major sterol in feces.

copy-choice hypothesis a hypothesis to explain interchromosomal genetic recombination, according to which copying to form a new DNA strand alternates from one parent strand to the other. If the parent strands contain different alleles, a recombinant chromosome may be produced possessing some alleles from one parental strand and some from the other.

copy error a mutation arising from an error in DNA replication.

copy number the number of copies of any gene or plasmid in a given cell. *See* plasmid.

CoO symbol for coenzyme Q (obsolete; *see* ubiquinone).

CoOH<sub>2</sub> symbol for reduced coenzyme Q (obsolete; the reduced form of ubiquinone).

cord blood blood taken from the umbilical cord.

cord factor 6,6'-dimycolyl trehalose; a highly toxic glycolipid extractable with nonpolar solvents from the cell walls of certain, especially virulent, strains of *Mycobacterium* that characteristically grow in long cords in liquid media.

cordycepin 3'-deoxyadenosine; a substance found in culture fluids of the microfungus *Cordyceps militaris*. It inhibits poly(A) synthesis and interferes with the processing of much eukaryotic mRNA and hence with protein synthesis. The  $\alpha$ -32P-labelled 5'-triphosphate is used to label the 3' ends of DNA fragments in DNA sequence analysis.

cordycepose 3-deoxy-o-ribose; 3-deoxy-o-erythro-pentose; the carbohydrate component of cordycepin.

core the central, innermost, or least easily destroyed or removed part of a structure; e.g. the core of a partially digested biopolymer, the protoplast core of an endospore, or the core of a virus.

core debranching enzyme *see* P-1,3-galactosyl-D-glycosyl-glycoprotein P-1,6-N-acetylglucosaminyltransferase.

core enzyme the part of bacterial (*Escherichia coli*) RNA polymerase lacking the  $\sigma$  subunit. It will catalyse chain elongation but not initiation.

core glycosylation the first of two stages in the biosynthesis of the carbohydrate moiety of some glycoproteins; it takes place in the endoplasmic reticulum.

core particle 1 the RNA-rich particle obtained from a ribosome by the gentle removal of some of the ribosomal proteins. The particle retains peptidyltransferase activity. 2 any of the eukaryotic chromatin particles containing 140 base pairs of DNA and an octamer of the four conservative histones (two

## corpuscular radiation

each of histones H2A, H2B, H3, and H4) but not histone H1. These particles are obtained by the treatment of chromatin with DNase. In the intact chromatin they are linked by stretches of variable length of so-called linker DNA.

core polymerase *see* RNA polymerase.

core protein any of the many types of protein in glycosaminoglycans to which oligosaccharide side-chains are covalently attached and which are themselves covalently attached to a very long oligosaccharide backbone. Each glycosaminoglycan will typically contain many core protein molecules. An example is heparan sulfate proteoglycan core protein.

corepressor any metabolite that by its specific combination with a repressor causes the activation of the latter.

Cori, Carl Ferdinand (1896-1984) and/or Gerty Theresa Cori (née Radnitz, 1896-1957), Czech-born US biochemists distinguished for their studies of glucose and glycogen metabolism, largely carried out in collaboration; joint Nobel Laureates in Physiology or Medicine (1947) 'for their discovery of the course of the catalytic conversion of glycogen' [prize shared with B. A. Houssay].

Cori cycle or lactic acid cycle an energy-requiring metabolic pathway in animals in which carbon atoms of glucose pass along the circular route: muscle glycogen  $\rightarrow$  blood lactate  $\rightarrow$  blood glucose  $\rightarrow$  muscle glycogen. [After C. F. and G. T. Cori who together formulated it in 1929.]

Cori ester an alternative name for a-D-glucopyranose 1-phosphate. [After C. F. and G. T. Cori who reported its isolation in 1936.]

Cori's disease an alternative name for type III glycogen disease. [After G. T. Cori who first described it in 1953.]

cornea the transparent curved part of the front of the eyeball that refracts incident light onto the lens. It is composed of many layers, the thickest being the stroma, which is composed of uniformly fine collagen fibrils. These are kept in an orderly distribution by the expansive force between them of the contained glycosaminoglycan (mainly keratan sulfate I). The cornea has a high oxygen consumption and approximately 50% of the glucose utilized is oxidized via the phosphogluconate pathway. -corneal adj.

Cornforth (Sir) John Warcup (1917- ) Australian-born British organic chemist and biochemist most noted for his elucidation of the stepwise biosynthesis of cholesterol from acetate; Nobel Laureate in Chemistry (1975) 'for his work on the stereochemistry of enzyme-catalyzed reactions' [prize shared with V. Prelog].

cornifin or small proline-rich protein I a cross-linked envelope protein of keratinocytes that first appears in the cell cytosol, but ultimately becomes cross-linked to membrane proteins by transglutaminase. Its presence correlates with squamous differentiation. It is down-regulated by retinoids. Structurally, it is rich in proline, glutamine, and cysteine and contains repeats of an octapeptide, consensus sequence, EPCQPKVP. Example from *Sus scrofa*: database code CORN\_PIG, 97 amino acids (10.71 kDa).

corn-steep liquor or corn-steep water a concentrated fluid obtained by steeping corn (maize) grains in water (containing 0.2% S02) for 36-40 hours at 46-50 DC. It is used in the manufacture of penicillin to increase antibiotic yield.

corn sugar a common name for o-glucose.

corn syrup or (sometimes) liquid glucose a partial hydrolysate of corn (maize) starch containing glucose and glucose oligosaccharides.

coronand an alternative name for crown compound.

coronavirus any of a group of RNA animal viruses consisting of enveloped particles 80-120 nm long, with helical nucleocapsids. They include some of the viruses that cause common colds in humans.

corpuscle any living metazoan cell, especially the red corpuscles (erythrocytes) and the white corpuscles (leukocytes) of the blood.

corpuscular radiation a former term for particulate radiation.

## corpus luteum

**corpus luteum** (*pl.* corpora lutea) a yellow, progesterone-secreting, glandular body formed in the mammalian ovary from a Graafian follicle after extrusion of an ovum.

**correlation (in statistics)** the interdependence of two or more simultaneously variable quantities; or the nature or degree of this interdependence. If two variates both increase or both decrease together there is said to be positive (direct) correlation between them, whereas if they change in opposite directions to each other there is said to be negative (inverse) correlation.

**correlation coefficient (in statistics) symbol:**  $r$ ; a measure of the correlation between two variates,  $x$  and  $y$ . If one variate has the values  $x_1, X_2, \dots, X_n$  and the corresponding values of the other variate are  $y_1, Y_2, \dots, Y_n$  with respective mean values of  $\bar{x}$  and  $\bar{y}$  then the correlation coefficient,  $r$ , is given by:

$$r = \frac{\sum_{i=1}^n (X_i - \bar{X})(Y_i - \bar{Y})}{[\sum_{i=1}^n (X_i - \bar{X})^2 \sum_{i=1}^n (Y_i - \bar{Y})^2]^{1/2}}$$

If  $r = 0$ ,  $x$  and  $y$  are completely independent. If  $r = 1$  there is complete correlation and one variate may be calculated from the other variate.

**correlation time symbol:**  $\tau_c$ ; the average time between molecular collisions for molecules in some state of motion. The reciprocal of the correlation time is given by the equation:

$$1/\tau_c = 1/T_R + 1/T_M + 1/\tau_S$$

where  $1/T_R$  is the rate at which the molecule is tumbling ( $\tau_R$  being the rotational correlation time),  $1/T_M$  is the rate at which two dipoles approach each other ( $\tau_M$  being the residence time), and  $1/\tau_S$  is the electron spin lattice relaxation rate ( $\tau_S$  being the time for the upper electron spin state to dissipate its excess energy).

**correndonuclease** any correctional endonuclease that specifically acts on damaged DNA initiating a correctional pathway *in vivo*. The name is misleading because nuclease activity itself does not lead to repair.

**corrin**  $C19H_{27}N4$ , the fundamental heterocyclic skeleton of the corrinoids. It consists of four reduced pyrrole rings joined into a macrocyclic ring by links between their  $\alpha$  positions; three of these links are formed by a one-carbon unit (methylidyne group) and the other by a direct  $Ca-Ca$  bond. Corrin is so named because it is the core of the vitamin  $B_{12}$  molecule.

**corrinoid** any of a group of compounds containing the corrin skeleton. This group includes various  $B_{12}$  vitamins, factors, and derivatives. Some are more unsaturated than corrin itself; many have a regular pattern of substituents on the methylene carbon atoms of the reduced pyrrole rings and a cobalt atom in the centre of the macrocyclic ring.

**corrole** a trivial name for octadehydrocorrin; see corrin.

**cortex** (*pl.* cortices) 1 the outer layer of an animal organ, situated immediately beneath the capsule or outer membrane. It is usually morphologically distinct from the rest of the organ; e.g. adrenal cortex, cerebral cortex, renal cortex. 2 the unspecialized tissue in plant stems and roots lying between the vascular bundles and the epidermis; the outer layer of a stem. *-cortical adj.*

**corticoid** an alternative name for corticosteroid.

**corticoliberin** an alternative name for corticotropin-releasing hormone (see CRH).

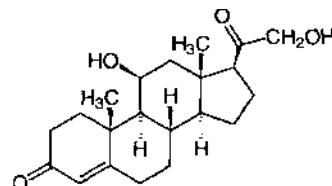

**corticosteroid** or **corticoid** any of a large group of  $C_{21}$  steroids synthesized from cholesterol in the adrenal cortex, especially the adrenocortical hormones. Usage is often extended to include synthetic analogues with hormonal activity. Corticosteroid hormones are divided into glucocorticoids, i.e. cortisol and related compounds and mineralocorticoids, i.e. aldosterone and related compounds.

**corticosteroid-binding globulin** or **corticosteroid-binding protein** an alternative name for transcortin.

**corticosterone** 11 $\beta$ ,21-dihydroxy pregn-4-ene-3,20-dione; Kendall's compound B; Reichstein's substance H; a glucocorticoid, but on the biosynthetic route to aldosterone. Quantitatively it is the second most important corticosteroid of the normal human adrenal cortex. Cortisol, synthesized in the

## corticotropin-releasing-factor binding protein

adrenal zona fasciculata, is the predominant corticosteroid in humans; corticosterone, synthesized in the adrenal zona fasciculata and glomerulosa, much less so, but it is the main corticosteroid in some rodents.

**corticotrope** a type of cell in the anterior pituitary that synthesizes proopiomelanocortin, a polyprotein from which corticotropin and a number of other peptide hormones are formed.

**corticotrophin** (formerly) a variant spelling of corticotropin.

**corticotropin** or **adrenocorticotropin** or **adrenocorticotrophic hormone** (abbr.: ACTH) a 39-residue polypeptide hormone, secreted by the adenohypophysis of the pituitary, that stimulates growth of the adrenal cortex and the synthesis and secretion of various corticosteroids. It has the sequence (human):

[SYSMEHFRWGKPVjGKKRRPV-KVYPNGAEDESAEPLEF.]

The first 13 residues (in brackets) comprise, after proteolysis,  $\alpha$ -melanocyte-stimulating hormone. Under normal conditions its own secretion is under feedback control from the plasma cortisol level, both directly and through hypothalamic regulatory factors. Biosynthesis occurs via the multihormone precursor peptide proopiomelanocortin. Hormonal activity is confined to the species-invariant N-terminal 24 amino acids (see tetracosactide). Corticotropin secretion is regulated by corticotropin-releasing hormone (CRH), is episodic (in bursts at intervals of a few hours), exhibits diurnal rhythm, and is increased by stress such as trauma, surgery, and hypoglycemia. The effects of fever may be mediated by cytokines 1,2, and 6, which act indirectly by causing the release of CRH. See also corticotropin-like intermediate lobe peptide, corticotropin receptor, melanotropin.

**corticotropin-induced secreted protein abbr.:** CISP; a former name for thrombospondin-2 (see thrombospondin).

**corticotropin-like intermediate lobe peptide abbr.:** CLIP; a 22-residue peptide identical in sequence to the C-terminal moiety (residues 18-39) of a molecule of corticotropin from the same species. It is obtained from extracts of the pars intermedia of the pituitary of certain animals (rat, pig, dogfish), and has been found also in a carcinoid tumour from a human patient who was secreting ectopic corticotropin; it has not been found in extracts of human pituitary. It is derived from proopiomelanocortin. CLIP has B-cell tropin activity and acts to stimulate insulin release from B cells. See also beta-cell tropin.

**corticotropin-Iipotropin precursor** see proopiomelanocortin.

**corticotropin receptor** one of a number of membrane proteins that bind corticotropin and couple to heterotrimeric G-protein-activated adenylate cyclase; they are seven-transmembrane-domain proteins and are distributed on cells of the adrenal cortex, on cells of the immune system, and in the brain. EC<sub>50</sub> values for binding are near 10<sup>-8</sup> M for corticotropin. Example from *Bos taurus*: database code ACTR\_BOVIN, 297 amino acids (33.29 kDa). See also melanocortin receptor.

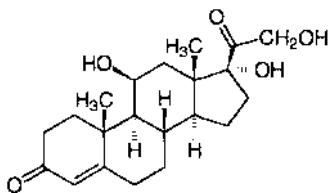

**corticotropin-releasing factor** an alternative name for corticotropin-releasing hormone (see CRH).

**corticotropin-releasing-factor binding protein** a protein that binds and inactivates corticotropin-releasing hormone (CRH), to prevent inappropriate pituitary-adrenal stimulation in pregnancy. Example (precursor) from human: database code CRFB\_HUMAN, 322 amino acids (36.15 kDa).

## corticotropin-releasing hormone

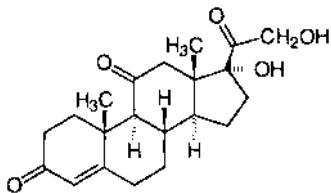

**corticotropin-releasing hormone** see CRH.

**cortisol** or (recommended name) **hydrocortisone** 17-hydroxy-corticosterone; *IIP*, 17,21-trihydroxy-4-pregnene-3,20-dione; Kendall's compound F; Reichstein's substance M; the most powerful naturally occurring **glucocorticoid** hormone and the most abundant product of the adrenal cortex in humans. It is produced by the cells of the zona reticularis; its best known action is anti-inflammatory. The biosynthesis of cortisol is under the control of **corticotropin**.

## cortisol-binding globulin or cortisol-binding protein abbr.: CBG; an alternative name for transcortin.

**cortisone** 11-dehydrocortisol; Kendall's compound E; Reichstein's substance F; a prodrug that is biologically inactive but is converted in the liver and, to a lesser extent, in other tissues, to cortisol, a substance with **glucocorticoid** activity. Cortisone was the first glucocorticoid to be isolated and made available for therapeutic use. It is not a primary secretory product of the adrenal cortex, being formed during tissue metabolism from cortisol by 11P-hydroxysteroid dehydrogenase. In fetal plasma, however, cortisone levels are about three times higher than those of cortisol.

**cortoic acid** any member of a group of acidic metabolites of 17-hydroxycorticosteroids in which the primary alcohol group at C-21 has been oxidized to a carboxylic-acid group. They are the principal acidic metabolites of **cortisol** in humans.

**corynecin** any of a number of antibiotic compounds produced by the cultivation of *Corynebacterium* KY 4339 in a medium containing C<sub>n</sub> to C<sub>14</sub> alkanes as the sole carbon source. Their antibacterial properties are similar to those of **chloramphenicol** but they are less potent.

**coryneform** 1 club-shaped. 2 describing any Gram-positive, asporogenous, club- or rod-shaped bacterium belonging to the genera *Corynebacterium* or *Brevibacterium*, possibly related to *Streptomyces*. Such bacteria are of biotechnological importance (amino-acid fermentations) and are amenable to genetic manipulation. 3 any coryneform microorganism.

**cos** abbr for cosine.

**COS cell** any member of a cell line, derived from monkey cells, that contains an integrated segment of **SV40** DNA coding for T antigen. Hence these cells will support replication of vector molecules containing the SV40 origin of replication, but no other DNA sequences from that virus.

**cosec** abbr for cosecant.

**cosecant** abbr.: cosec or csc; the reciprocal of the **sine** of an angle.

**cosine** abbr.: cos; a trigonometric function defined, for a given angle of a right-angled triangle, as the ratio of the length of

the side adjacent to the angle and the length of the hypotenuse. The cosine of an obtuse angle is numerically equivalent to that of its supplement but of opposite sign.

**cosmid** a hybrid **cloning vector** used for cloning DNA. Cosmids are derived from plasmids but also contain **cos sites** from phage lambda.

**cos site** the cohesive ends (sticky ends) of certain **phage** DNA molecules. The **cos** site usually referred to is from phage lambda.

**costamere** a vinculin-containing myofibril attachment site. Costameres form one of the major linkage sites of the skeletal muscle cell, encircling the cell and connecting the Z-discs to the sarcolemma.

**co-stimulator** an alternative name for **interleukin 2**.

**cost-selectivity equation** a relation between the accuracy gained by editing and the cost in terms of the wasteful hydrolysis of correct products in any enzyme system synthesizing informational macromolecules. It is useful in the rationalization of some observations and proposed editing mechanisms.

**cosubstrate** an imprecise term used for an organic cofactor that is necessary for the activity of some enzymes. Although not the substrate of principal interest, the cosubstrate acts as an acceptor or donor of atoms or of functional groups and participates stoichiometrically in the reaction. Compare **coenzyme**.

**COSY** abbr. for correlated spectroscopy; a technique employed in the first two-dimensional NMR experiment, designed to elucidate which resonances of the NMR spectrum are connected by spin-spin J-coupling. J-couplings arise out of the perturbation of the nuclear energy levels of one nuclear spin by another nuclear spin that is propagated through the intervening electronic orbitals. In a one-dimensional NMR spectrum these J-couplings are manifested as a splitting in the Lorentzian lineshape. In 2D-COSY spectra the couplings are indicated by off-diagonal cross-peaks connecting the frequencies of the J-coupled spectra. Ordinarily the J-couplings are only large enough for pairs of <sup>1</sup>H nuclei separated by a maximum of two or three bonds to exhibit COSY cross-peaks.

**Cot** see *C.t.*

**cotransduction** the **transduction** of two or more identifiable genes in a single event, probably because the transduced element contains more than one genetic locus.

**cotranslation** (in recombinant DNA technology) the synthesis of a hybrid molecule consisting of the desired protein product covalently linked to a normal protein secreted by the organism being used, through translation of a hybrid mRNA molecule generated on the recombinant DNA. -cotranslate vb.

**cotranslational transport** the transport of nascent protein chains through the membrane of the cisterna of the endoplasmic reticulum while translation is still proceeding at the ribosome. It is a common phenomenon in higher eukaryotes.

**cotransmitter** a substance, usually a peptide, that is released from neurons and modifies the actions of the substance regarded as the primary transmitter. For example, vasoactive intestinal peptide is a cotransmitter with acetylcholine, and neuropeptide Y performs a similar role with norepinephrine. Cotransmitters may also have direct effects on target cells.

**cotransport** the concerted movement of two chemical species across a membrane. Compare **antiport, symport**.

**co-trimoxazole** an antibacterial drug that comprises a mixture of **sulfamethoxazole** and **trimethoprim** in a ratio of about 5:1. The combination may have synergistic effects.

**Cotton effect** an anomalous change in optical rotation with wavelength in the region of an absorption band. As the absorption band is approached there is a change in the rotation to a maximum, which may be either positive or negative, followed by a decrease to a minimum passing through zero at the wavelength of maximum absorption. Similarly there is a change in circular dichroism, either positive or negative, coinciding with the absorption band. The magnitudes and directions of these effects have been used to study macromolecular

## cotyledon

conformations. [After Aimé Cotton (1859-1951), French physicist.]

**cotyledon** the leaf-forming part of the embryo of seeds. — *cotyledonous adj.*

**Couette viscometer** an instrument for measuring viscosity, consisting of two concentric cylinders separated by a narrow annulus, which is filled with the sample. One cylinder is fixed and the other is rotated. From the angular velocity at a given torque and the dimensions of the cylinders, the viscosity of the sample can be calculated. The Couette viscometer is designed for use at relatively low shear gradients.

**coulomb symbol:** C; the SI derived unit of electric charge; the quantity of electricity transported in one second by a current of one ampere. Hence,  $1\text{C} = 1\text{A}\cdot\text{s}$ . [After Charles Augustin de Coulomb (1736-1806), French physicist.]

**coulomb force or coulombic force** the electrostatic attraction or repulsion between two charged particles. *See Coulomb's law.* **Coulomb's law (of electrostatics)** the law stating that the force,  $F$ , of attraction or repulsion between two point charges,  $Q_1$  and  $Q_2$ , is proportional to the product of the charges and inversely proportional to the square of the distance,  $d$ , between them multiplied by the permittivity,  $\epsilon$ , of the medium between them. Hence,  $F = (Q_1 Q_2)/\epsilon d^2$ . A similar law exists for magnetism.

**coulometer or coulombmeter or voltameter** an electrolytic cell for measuring a quantity of electricity passing through a circuit containing the cell by determining the amount of a metal (usually copper or silver) deposited on the cathode from a solution of a salt of the metal.

**coulometry or coulombmetry or voltametry** a method of chemical analysis based on the measurement of a quantity of electricity, in coulombs, in an electrode reaction. -coulometric or coulombmetric *adj*; coulometrically or coulombmetrically *adv*.

**Coulter counter** a device for counting particles in a suspension, e.g. blood cells, microorganisms, or spores. Its functioning depends on changes in electric conductivity as the particles pass through a small aperture.

**coumarin** 1 1,2-benzopyrone; 2H-chromen-2-one; a fluorescent indicator. 2 any of a number of coumarin derivatives. The coumarins are important in the perfume industry since they smell of new-mown hay and grass, though some are no longer used (acernocoumarol and phenindiene) because of adverse allergenic effects. Some are useful in forming fluorescent analytes. Others are antibiotics, e.g. novobiocin or mycotoxins (*see* aflatoxin).

**coumarin anticoagulants** *see* dicoumarol.

**counter** any device for enumerating, especially one for detecting and determining particles and photons emitted from the disintegration of a radionuclide. *See, e.g.*, Cherenkov counter, Geiger counter, scintillation counter.

**countercurrent chromatography** a form of partition chromatography that eliminates the need for a solid support, in which one of the components of a two-phase solvent system is allowed to flow through the second component in a coiled tube. The technique is claimed to have the advantages of both countercurrent distribution and liquid-liquid chromatography with the disadvantages of neither, and to be applicable to a broad spectrum of samples ranging from micromolecules to macromolecules, particles, and cells.

**countercurrent distribution or countercurrent separation** a method for the separation and purification of (usually organic) substances that depends on the repetitive distribution of solute between two immiscible liquid phases in a series of vessels in which the phases are in contact. The process is continued until homogeneous substances are distributed in various sets of vessels in accordance with their distribution coefficients between the two liquid phases. *See also* Craig apparatus.

**countercurrent transport** the movement of a solute in or out of a cell against a concentration gradient by an ATP-independent process. It is due to competition between the solute under

## coupling constant

consideration and a second solute, with an opposite concentration distribution, for the same membrane carrier protein.

**counterelectrophoresis** *see* counterimmunoelectrophoresis.

**counterflow** the movement of a substance across a membrane against a concentration gradient.

**counterimmunoelectrophoresis or counterelectrophoresis other names:** countermigration electrophoresis; immuno-electroosmophoresis; *abbr.*: CIE; a one-dimensional double electroimmunodiffusion; a technique wherein diffusion of the reactants towards each other, and hence the formation of precipitin lines, is accelerated by the combination of electrophoresis and electroendosmosis that occurs when an electric potential difference is applied across the gel between the antigen- and antibody-containing wells, with the latter positive to the former.

**counterion** any ion carrying a charge opposite to that of the charged chemical species with which it is associated; an ion of low  $M_r$  with a charge of opposite sign to that of the colloidal ion. *Compare* co-ion.

**countermigration electrophoresis** *an alternative name for* counterimmunoelectrophoresis.

**counterstain** 1 to apply a second stain to a preparation for microscopy. Counterstaining is used to stain in a contrasting way those parts of the preparation that have not been stained by the first stain. 2 any stain so used.

**countertranscript** *an alternative term for* antisense RNA.

**countertransport** *an alternative term for* antiport.

**countertypsin** a glycoprotein trypsin inhibitor from mouse plasma and a member of the fetuin family.

**counting efficiency** the ratio of recorded radioactivity events to the number of actual radioactive disintegrations occurring in the same time and in the same sample. It is sometimes expressed as the percentage efficiency.

**COUP other names:** COUP-TF; v-ErbA-related protein; EAR-3; a transcription factor named from one activity, chicken ovalbumin upstream promoter. In association with transcription factor IIB it stimulates initiation of transcription. It is similar to the steroid/thyroid/retinoic nuclear hormone receptors and seven-up. Example from human: database code COTF\_HUMAN, 423 amino acids (46.10 kDa).

**couple** 1 a pair of equal and opposite, parallel but not collinear, forces acting on a body, thus producing a turning effect. 2 to join or link (two things) together.

**coupled assay** a type of enzymic assay of a substrate (or of an enzyme) employed when the reaction in question does not give chromophoric or fluorescent products. A second enzyme reaction that acts on one of the products of the first reaction, and that gives an easily detectable product, is carried out simultaneously with the first reaction. Many coupled assays are based on the formation or disappearance of NADH, which can be easily detected by its absorbance at 340 nm.

**coupled oxidation and phosphorylation** an intimate relationship between oxidation of substrate and phosphorylation of ADP to ATP such that the two processes cannot proceed independently, as in mitochondria. *See also* coupling (def. 3).

**coupled reaction** either of two reactions, one endergonic and the other exergonic, that are linked energetically, occur simultaneously, and share a common intermediate, such that the overall free energy change for the two reactions is negative.

**coupling** 1 (*in chemistry*) the covalent linking of one chemical entity to another; *see* covalent bond. 2 (*in physics*) a) an interaction between different parts of a system, e.g. between groups of atoms, electrons, or nuclei. b) an interaction between two electronic circuits so that power is transferred from one to the other. 3 (*in biochemistry*) the linking of electron transport and oxidative phosphorylation in isolated mitochondria. Thus, if the phosphorus:oxygen ratio is high the mitochondria are said to be tightly coupled. *See also* uncoupling.

**coupling constant** the separation between any two bands of multiple peaks in nuclear magnetic resonance spectroscopy; it

## coupling factor

## C-reactive protein

is proportional to the magnitude of the spin-spin coupling constant.

**coupling factor abbr.:** CF; *archaic term* for either 1 any of the proteins functioning in the coupling of ATP synthesis to electron transport in mitochondria. CFI-CF4 are obsolete names for the  $\alpha$ - $\delta$  subunits of mitochondrial H<sup>+</sup>-transporting ATP synthase. 2 any of the proteins required for the coupling of ATP synthesis to the photoinduced electron transport in chloroplasts during photosynthesis. The concept has been replaced by the chemiosmotic coupling hypothesis.

**coupling membrane** any biological membrane in which energy-yielding and energy-requiring biochemical processes occur together.

**covalence or covalency** nonionic valence between two atoms in a chemical compound, characterized by their sharing of one or more electrons. *-covalent adj.*

**covalent bond** a chemical bond formed between two atoms in a molecule by the sharing of electrons, usually in pairs, by the bonded atoms.

**covalent catalysis** the catalysis of any reaction in which the substrate is modified by forming a covalent bond with the catalyst (enzyme).

**covalent chromatography** any technique of column chromatography in which the substance of interest binds covalently with groups, e.g. -SH groups, on the support medium and is subsequently displaced by an appropriate reagent.

**covalent (closed) circle (of DNA) or covalently closed circular DNA or closed double-stranded DNA abbr.:** cccDNA; any double-stranded DNA molecule that is circular (but not necessarily geometrically circular) and in which both polynucleotide strands are completely continuous. *Compare Hershey circle, open circle.*

**covalent modification** any of a diverse group of processes in which the initially synthesized structures of biopolymers, especially enzymes, proenzymes, or structural macromolecules, are enzymically modified by the breakage of covalent bonds or the addition of new covalently linked groups. It includes post-translational modification. The term may sometimes be used in the more restricted sense of reversible interconversion of active and inactive forms of certain metabolic enzymes or other proteins by sets of control enzymes, often by phosphorylation-dephosphorylation.

**covariance** a measure of the association between two variables. For  $n$  pairs of values of two random variables,  $x$  and  $y$ , this is given by:

$$\text{Cov. } (x, y) = (x - \bar{x})(y - \bar{y})/(n - 1)$$

where  $\bar{x}$  and  $\bar{y}$  are the means of the populations of  $x$  and  $y$ , respectively. *Compare correlation coefficient, regression coefficient, variance.*

**covariation** any of the codons in a given gene that may concomitantly vary, so resulting in favourable mutations or in mutations leading to amino-acid substitutions that have little or no effect. [From concomitantly variable codon.]

**covirus** any virus that exists as two or more separate particles all of which must be present together in the host organism for the complete replication cycle of the virus to occur.

**covolume** the amount by which the apparent volume of a molecule exceeds the sum of the volumes of the constituent atoms. It is usually 13-14 cm<sup>3</sup> mol<sup>-1</sup> for protein molecules.

**cozymase** originally, the heat-stable, diffusible fraction of a crude aqueous extract of brewers' yeast that, if added to the heat-labile, nondiffusible fraction (zymase), would enable the alcoholic fermentation of glucose to occur in a cell-free system. The term was subsequently applied to one particular substance present in that fraction, now known as nicotinamide adenine dinucleotide.

**C<sub>3</sub> pathway** *an alternative name for* reductive pentose phosphate cycle.

**C<sub>4</sub> pathway** *an alternative name for* Hatch-Slack pathway.

**CPBA abbr.** for competitive protein-binding assay.

**CPE abbr. for** cytopathic effect.

**C peptide 1** a the inactive polypeptide excised from proinsulin during its conversion to insulin. It contains 31 amino-acid residues in the human but shows greater species variability in both length and amino-acid sequence than does insulin. The structure of porcine C-peptide is (including the flanking basic residues):

It is released into the bloodstream concomitantly with insulin, hence the blood level is useful in evaluation of B-cell function. b that segment of the amino-acid sequence of proinsulin lying between the two residues destined to become respectively the C-terminal residue of the B chain of insulin and the N-terminal residue of the A chain. It consists structurally of the above polypeptide plus two flanking pairs of basic residues. C peptide is named from connecting peptide, and perhaps also because, after A (chain) and B (chain), C (peptide) represents alphabetically the third major structural component of proinsulin. 2 *an alternative name for* C fragment (of P-lipotropin) (*see Lipotropin*).

**CpG island** a region of 1-2 kb containing a high density of methylated cytosine residues and occurring immediately 5' to' G residues, i.e. in the sequence CpG. CpG islands are frequently found in animal genomes at the 5' end of genes. In plants the methylated sequence is ...CpNpGp... where N can be any base. Methylation of DNA is a heritable phenomenon that reduces gene expression, probably by increasing the binding of a repressor. CpG islands are a site of high mutational frequency because spontaneous deamination of the methylated cytosine gives thymine, which is not recognized by DNA repair enzymes.

**C<sub>3</sub> plant** any plant in which fixation of carbon dioxide occurs predominantly by the reductive pentose phosphate cycle; i.e. by incorporation initially into the three-carbon compound 3-phosphoglycerate.

**C<sub>4</sub> plant** any plant in which fixation of carbon dioxide occurs predominantly by the Hatch-Slack pathway; i.e. by incorporation initially into the four-carbon compound oxaloacetate. Such plants are found usually in semiarid conditions with high light levels. They include sugar cane, corn (maize), and many weeds.

**cpm or c.p.r.o. abbr. for** counts per minute.

**Cr symbol** for chromium.

**Crabtree effect** the inhibition of respiration by glycolysis. The inhibition is small and occurs only in a few types of cells that possess a high glycolytic capacity, e.g. ascites tumour cells and other neoplastic tissues, renal medulla, leukocytes, and cartilage. *Compare Pasteur effect.*

**Craig apparatus** the most widely used type of apparatus for carrying out countercurrent distribution experiments. The earlier version (1944) was constructed of metal and the later version (1949) was of modular design and constructed of glass. [After Lyman Creighton Craig (1906-74).]

**crambin** a protein obtained from seeds of *Crambe abyssinica*. It comprises 46 amino acids, has a molecular mass of 4.73 kDa (database code CRAM\_CRAAB), and is remarkable for its highly ordered crystals and very high resolution. Its 3-D structure is known.

**cranin** a form of dystroglycan.

**CRE abbr. for** cyclic AMP response element; a sequence,

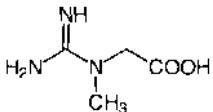

that is present in many viral and cellular promoters. When it binds CREB protein, transcription of the genes regulated by such a promoter is turned on.

**C-reactive protein abbr.:** CRP; an acidic, crystallizable, heat-sensitive protein of  $\approx 118$  kDa that is detectable in human or monkey blood serum early in the course of various infections or when there is inflammation, tissue damage, or necrosis. One of the so-called acute phase proteins, it is normally un-

## creatine

detectable. Not an immunoglobulin and of unknown function, it is named for its ability, in the presence of  $\text{Ca}^{2+}$  ions, to form a precipitate with a pneumococcal somatic C polysaccharide. Example from human (precursor): database code CRP\_HUMAN, 224 amino acids (25.04 kDa).

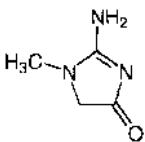

creatine N-(aminoiminomethyl)-N-methylglycine; an important metabolite in muscle, the precursor of phosphocreatine.

creatine kinase EC 2.7.3.2; systematic name: ATP:creatine N-phosphotransferase; an enzyme that catalyses the formation of phosphocreatine from ATP and creatine with release of ADP. The enzyme has M and B subunits, and may exist as the homodimers MM and BB or the heterodimer MB. BB mainly occurs in brain and thyroid, while MM occurs in muscle; MB occurs to a much greater extent in cardiac muscle (30% of total) than skeletal muscle (1% of total) and is thus a useful diagnostic isoenzyme in myocardial infarction, an increased level of the MB isoenzyme occurring between 12 and 36 hours after the infarct. Examples from human; B chain: database code KeRB\_HUMAN, 381 amino acids (42.60 kDa); M chain: database code KCRM\_HUMAN, 381 amino acids (43.05 kDa); sarcomeric mitochondrial precursor: database code KCRS\_HUMAN, 419 amino acids (47.47 kDa); ubiquitous mitochondrial precursor (u-MTCK): database code KCRU\_HUMAN, 417 amino acids (46.98 kDa).

creatine phosphate *an alternative name (not recommended) for phosphocreatine.*

creatinine 2-amino-1,5-dihydro-1-methyl-4H-imidazol-4-one; an end product of creatine metabolism and a normal constituent of urine.

CREB protein *abbr. for cyclic AMP response element binding protein*; a protein that, following phosphorylation by cyclic AMP-dependent protein kinase on a single serine residue, binds to the cyclic AMP response element (CRE). This then stimulates transcription of genes controlled by regulatory regions that contain the CRE. Example (bovine): database code CREB\_BOVIN, 325 amino acids (34.84 kDa).

C region *abbr. for constant region (of an immunoglobulin).*

cretinism a condition of congenital hypothyroidism characterized by arrested mental and physical development.

Creutzfeldt-Jakob disease *abbr.: CJD*; a transmissible spongiform encephalopathy of humans. It has occurred in three forms: (1) familial (about 15% of cases), (2) iatrogenic or acquired due to inadvertent exposure to CJD-contaminated material, notably human cadaveric growth hormone, and kuru, (3) sporadic - the most common form - which is of unknown etiology. They are all associated with the accumulation in affected brains of an abnormal isoform of a glycoprotein. The familial form, which shows an autosomal pattern of disease segregation, is associated with coding mutations in the prion-protein gene. Forms (1) and (3) usually occur in the fifth or sixth decade of life and progress rapidly (within six months) to severe dementia and death typically in one year. Recently a fourth form of CJD has been identified that is believed to be due to consumption of bovine products contaminated with the

## critical electrolyte concentration

agent causing bovine spongiform encephalopathy. *See also prion.* [After Hans Gerhard Creutzfeldt (1885-1964) and Alfons Maria Jakob (1884-1931), German physicians.]

CRF *abbr. for corticotropin-releasing factor; see CRH.*

CRH *abbr. for corticotropin-releasing hormone; other names: corticotropin-releasing factor or corticoliberin or adrenocorticotrophic hormone-releasing factor; one of a number of peptidic mammalian hypothalamic factors released into the hypophyseal-septal circulation in response to neural and/or chemical stimuli. A 41-residue peptide ( $M_r$ , 4758.14 human, rat; database code CRF\_HUMAN), it controls the secretion by the anterior pituitary gland (i.e. adenohypophysis) of corticotropin, and possibly also of  $\beta$ -lipotropin and pro- $\alpha$ -melanotropin - all three are peptides formed within the adenohypophysis from proopiomelanocortin. CRH binds to specific seven-transmembrane-domain receptors (e.g. database code CRFR\_HUMAN, 444 amino acids (50.72 kDa)) on the conicotropic and increases cyclic AMP levels in the cell, stimulating hormone release only in the presence of  $\text{Ca}^{2+}$ . In addition to increasing the rate of release of corticotropin, it enhances the rate of transcription of mRNA coding for that hormone. See also CRH test.*

CRH test a test that is useful in distinguishing Cushing's disease from ectopic corticotropin secretion. If CRH is given intravenously, there is an increase in plasma cortisol in normal individuals, while usually in Cushing's disease there is an exaggerated response; in ectopic corticotropin secretion there is usually no cortisol response.

Crick, Francis Harry Compton (1916- ), British physicist and molecular biologist famous, *inter alia*, for propounding (with J. D. Watson in 1953) the double-helical structure of DNA, for formulating the adaptor hypothesis of protein synthesis and the central dogma of molecular biology, and for defining the codon; Nobel Laureate in Physiology or Medicine (1962) jointly with J. D. Watson and M. H. F. Wilkins 'for their discoveries concerning the molecular structure of nuclear [sic] acid and its significance for information transfer in living material'. *See also Franklin.*

Crigler-Najjar syndrome a familial nonhemolytic jaundice and hyperbilirubinemia due to deficiency in hepatic bilirubin glucuronosyltransferase activity. [After John Fielding Crigler (1919-) and Victor Assad Najjar (1914-), US physicians.]

crinophagy a cellular process in which secretion granules fuse with lysosomes. It serves to dispose of excess secretory products in a cell when the stimulus for their discharge is lacking. cristata (pl. cristae) 1 any of the inward folds of the inner mitochondrial membrane. Their number, extent, and shape differ in mitochondria from different tissues and organisms. They appear to be devices for increasing the surface area of the inner mitochondrial membrane, where the enzymes of electron transport and oxidative phosphorylation are found. Their shape can vary with the respiratory state of the mitochondria. 2 a sensory structure within the ampulla of a semicircular canal of the inner ear.

critical angle symbol: C; the least angle of incidence at which total internal reflection of a ray of light or other electromagnetic radiation occurs when passing through a medium and meeting the boundary with a medium of lesser density (e.g. of glass with air).

critical electrolyte concentration *or critical salt concentration* the concentration of a particular small ion that will displace an ionic molecule (e.g. of a dye or detergent) of like charge from a polyelectrolyte macromolecule. For example, if a polymer P with  $z$  negative charges is stained with a dye R+, the dyed polymer,  $pZzR+$ , is formed according to the equation:

where  $M+$  is a small cation. Hence the ratio of dyed to undyed polymer,  $D$ , is given by:

$$D = [pZ \cdot zR+] / [pZ \cdot zM+] = K[R^+]^z / [M^+]^z$$

## critical micellar concentration

where  $K$  is a constant. If  $z$  is large, there is a very sharp change in  $D$  at a critical value of  $[R+J]/[M+J]$ . Then if  $[R+J]$  is held constant and  $[M+J]$  varied, an 'all-or-none' change in  $D$  is observed at a well-defined  $[M+J]$ . This concept is used in the critical electrolyte concentration method for staining proteoglycans and polynucleotides, and for fractionation of nucleic acids and other polyanions.

**critical micellar concentration or critical micelle concentration abbr.: CMC; symbol:  $c_m$** : the concentration at which surfactant molecules in a lipid-water mixture begin to aggregate amongst themselves to form micelles in the mixture.

**critical pressure** the minimum pressure capable of liquefying a gas at its critical temperature.

**critical temperature** 1 the temperature at or above which a partially miscible two-component system exists as one phase and below which it separates into two phases. 2 the temperature above which liquefaction of a gas cannot occur however great the pressure.

**Crk symbol** for a protooncogene related to *v-crk*, the oncogene of avian sarcoma viruses CTIO. The name derives from CTIO regulator of kinase, because the protein causes tyrosine phosphorylation but is not itself a tyrosine kinase. Human Crk contains SH2 and SH3 domains (see SH domain). Database code: Hscrk, 304 amino acids (33.87 kDa).

**CRM abbr. for** (immunologically) cross-reacting material.

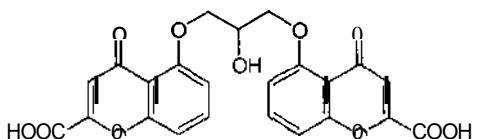

**CRM-positive** describing a mutant strain of a microorganism that produces a substance that is immunologically cross-reactive with another (specified) substance, e.g. an enzyme or a toxin, produced by a nonmutant (wild-type) strain. Similarly, a CRM-negative strain does not produce such a cross-reactive substance.

**cRNA abbr. for** complementary RNA.

**cro symbol** for a regulatory gene in phage lambda, named from 'C-repressor and other things'. Its product, Cro protein, is a repressor that regulates the expression of the *cI* gene. Cro protein is a small globulin, with a helix-loop-helix motif; it occurs as a dimer when bound to the operator. Database code RCRO\_LAMBD, 66 amino acids (7.36 kDa); 3-D structure known.

**Cromer-related blood group** a blood group antigen carried by complement decay accelerating factor.

**cromolyn** 1,3-bis(2-carboxychromon-5-yloxy)-2-hydroxypropane; a chromone complex that prevents mast cell degranulation; its mechanism of action is unclear. Commonly prepared as the disodium salt, disodium chromoglycate, it is used therapeutically to prevent hypersensitivity reactions, especially asthma.

**cross-bridge** any connection, seen in electron microscopy, between the contractile elements of muscle, specifically between the head of a myosin molecule and an actin filament.

**crossed immunoelectrophoresis or (sometimes) quantitative immunoelectrophoresis** two-dimensional single electroimmunodiffusion; a rapid and sensitive technique for separation with high resolution and for quantification of antigenic macromolecules. These are separated first by one-dimensional gel electrophoresis and second by gel electrophoresis orthogonally into a gel containing antibodies to one or more known substances, thereby forming a pattern of loop-shaped precipitation zones between antibodies and corresponding antigens. The height and shape of the loops give information about the quantity and quality of the antigens and of the

## crossover method

precipitating antibodies. In tandem-crossed immunoelectrophoresis two antigen samples are run at the same time with the application holes placed in such a way that related precipitin peaks formed from the respective samples generate double peaks, permitting direct comparison between them. Compare rocket immunoelectrophoresis.

**crossed immunoisoelectric focusing or crossed immunoelectrofocusing** a two-dimensional separation technique for analysing complex mixtures of macromolecules, e.g. samples of body fluids, that combines the high resolution of isoelectric focusing with the selectivity of detection of immunoelectrophoresis. Isoelectric focusing in a thin layer of gel (polyacrylamide or, preferably, specially modified agarose) is followed by electrophoresis into an antibody-containing gel orthogonally to the first separation; a pattern of precipitation zones is formed by reaction of antibody with corresponding antigen as in rocket immunoelectrophoresis.

**crossed-line immunoelectrophoresis** a technique that combines the procedures of crossed immunoelectrophoresis and line immunoelectrophoresis. Antigens are separated in a one-dimensional run (as in crossed immunoelectrophoresis) and the resulting gel is applied to the edge of a spacer gel in which a strip of gel containing a uniform mixture of the antigens (as used in line immunoelectrophoresis) is embedded parallel to the edge; this combination of the spacer gel and the first gel is then applied to the edge of an antibody-containing gel into which the antigens are introduced by electrophoresis. The resulting sum pattern of crossed immunoelectrophoresis peaks, each standing on individual baselines, permits a direct comparison of crossed and line immunoelectrophoresis patterns and in addition provides a higher power of resolution.

**cross-flow filtration** a method of operating a filtration device in which retained fluid is circulated over the membrane surface thus preventing undue build up of filtered material on the membrane.

**cross-hybridization or cross-hybridisation** the hybridization of a polynucleotide probe to another polynucleotide molecule. **crossing over** the reciprocal exchange of segments at corresponding positions along pairs of homologous chromosomes by symmetrical breakage and crosswise rejoining of the chromatids. It results in the recombination of alleles. In eukaryotes, crossing over usually accompanies meiosis. Mitotic homologous recombination, while common in yeast, is rare in higher eukaryotes. See also Holliday junction.

**cross-link** a side bond between different chains (or parts of a single chain) of a polymer, increasing molecular rigidity. - **cross-linked adj.; cross-linking n.**

**cross-matching** a serological procedure used to select blood for transfusion. The donor's erythrocytes are mixed with the recipient's serum; agglutination of the erythrocytes indicates incompatibility, demonstrating that the recipient's serum contains antibodies to the donor's erythrocytes.

**cross of isocline** the dark cross formed in flow birefringence experiments between concentric cylinders when the polarizer and analyser are orthogonal. As the system has cylindrical symmetry, there are two regions where the average orientation is parallel to the polarizer direction and two regions, orthogonal to the first two, where the average orientation is parallel to the analyser. In these regions no light is transmitted and a dark cross appears. See also extinction angle.

**crossover 1** an alternative term for crossover chromatid. 2 the individual resulting from a crossing over.

**crossover chromatid** a chromatid resulting from crossing over of corresponding segments of the chromatids of homologous chromosomes.

**crossover effect (in pharmacology)** the phenomenon in which a drug shows a positive effect at one concentration and a deleterious effect at another.

**crossover method** any method for investigating a metabolic (or electron transport) pathway by application of the crossover theorem.

**crossover nuclease** a deoxyribonuclease that is involved in recombination.

**crossover point** the point in a series of reactions in a metabolic (or electron transport) pathway, that, when one reaction is specifically inhibited, marks the boundary between reactants whose concentrations increase and reactants whose concentrations decrease. In particular, it is the point in the respiratory chain that, because of the specific action of an inhibitor, marks the boundary between respiratory catalysts that are more reduced and ones that are more oxidized (at steady-state levels). *See also* crossover theorem.

**crossover theorem** a theorem stating that when a series of reactions in a metabolic (or electron transport) pathway is inhibited at a specific reaction, the concentrations of reactants before the inhibited reaction increase above their steady-state values while the concentrations of the reactants after the inhibited reaction decrease below their steady-state values.

**crossover unit** *an alternative name for* map unit.

**cross-react** to react with a substance other than that for which the reagent is supposedly specific. *Compare* cross-reaction. - cross-reactive adj.

**cross-reacting antibody** any antibody that is able to react with an antigen that did not specifically stimulate its production. Such cross-reactions may be weaker than the reaction of the antibody with the antigen that caused its production.

**cross-reacting antigen** 1 any antigen that is able to react with an antibody produced in response to another antigen. This may be because the two antigens share the same determinants or carry determinants that are sufficiently alike stereochemically to enable the antibody to react with both of them. 2 any antigen that has an identical structure in two strains of microorganism, so that antibody raised against one strain will react with the second strain.

**cross-reaction** the immunological phenomenon in which an antigen reacts with an antibody raised against a different antigen. *See* cross-reacting antibody, cross-reacting antigen.

**cross-reactivation** the reappearance of activity in the progeny of a lethal mutant virus following mixed infection of a host cell with one or more active viruses. If the active viruses differ from each other in one or more of their genetic loci, the mutant virus is reactivated by genetic exchange leading to the replacement of its damaged nucleic acid.

**cross-sensitivity** a state of immunological hypersensitivity to one substance produced by priming an animal with another substance that bears cross-reacting antigen.

**cross-tolerance** 1 a state of immunological tolerance to one substance produced by priming an animal with another substance that bears cross-reacting antigen. 2 a state of physiological tolerance to one drug resulting from chronic administration of another.

**croton oil** an oil obtained from the seeds of *Croton tiglium*, a member of the family Euphorbiaceae. It is an irritant, and contains tumour-promoting phorbol esters.

**crown compound** or **coronand** any synthetic macrocyclic polydentate nonplanar (generally uncharged) organic compound a molecule of which has three or more ring heteroatoms (usually nitrogen or oxygen) capable of ligation to a metal ion or other cationic entity. The resulting complex is termed a coronate. *See also* crown ether. *Compare* cryptand.

**crown ether** any of a large subclass of crown compounds that are synthetic macrocyclic polyethers, the molecules of which contain 9-60 atoms in the ring, including 3-20 oxygen atoms. Many crown ethers, especially those containing 5-10 ring oxygen atoms in the molecule, can act as ion-selective complexing agents and ionophores with metal cations; some will solubilize inorganic salts in nonpolar solvents.

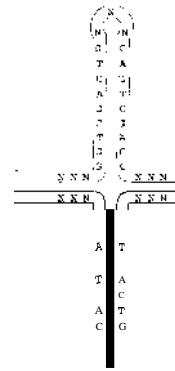

**crown-gall disease** a tumorous disease of many dicotyledonous plants caused by the bacterium *Agrobacterium tumefaciens* and marked by enlargement of the stem near the root crown. The swelling, or gall, is produced by the transformation of cells at an infected wound through transfer of the T-DNA, part

of a large (150-230 kb) plasmid (the Ti plasmid) found in oncogenic strains of the bacterium. Transformed tissue is distinguishable by its ability to grow in tissue culture in the absence of plant hormones and by the synthesis of a characteristic opine, which is invariably a specific substrate for the particular inducing strain of the bacterium.

**CRP** abbr. for 1 C-reactive protein. 2 cyclic AMP receptor protein; a bacterial catabolite (gene) activator protein that complexes with cyclic AMP and binds to specific DNA sites near the promoter to regulate the transcription of several catabolite-sensitive operons. The protein induces a severe bend in DNA and acts as a negative regulator of its own synthesis. It binds to DNA as a dimer. The examples belong to a well-conserved family; there are two motifs. Example from *Escherichia coli*: database code CRP\_ECOLI, 210 amino acids (23.61 kDa); 3-D structure of this and many mutants is known. The example from *Shigellaj7exneri* is identical.

**Crt** symbol for the carotol (i.e. hexacosonyl) group.

**cruciform** 1 cross-shaped. 2 a DNA conformation that can be generated from long palindromes, e.g.

**crustacyanin** a protein occurring in the carapace of lobsters that binds the carotenoid astaxanthin, which provides the blue colour.  $\alpha$ -Crustacyanin is a dimer;  $\beta$ -crustacyanin is a 16-mer. There are five types of subunit: AI, A2, A3, C1, and C2; the subunits are lipocalins. Example, C1 subunit from European lobster: database code CRC1\_HOMGA, 181 amino acids (20.64 kDa).

**cruzaine** *an alternative name for* cruzipain.

**cruzipain** or **cruzaine** a cysteine proteinase (EC 3.4.22.-) that hydrolyses chromogenic peptides at the carboxyl Arg or Lys. It requires at least one more amino acid, preferably Arg, Phe, Val, or Leu, between the terminal Arg or Lys and the amino-blocking group. The purified enzyme digests itself. The enzyme plays a role in development and differentiation of *Trypanosoma cruzi*. Example (precursor): database code CYSP\_TRYCR, 467 amino acids (49.78 kDa).

**cryo+** comb. form indicating low temperature.

**cryobiochemistry** the study of biochemical substances and processes at subzero temperatures, i.e. below the freezing point of water. The field has expanded because of the development of cryosolvents. *See also* cryoenzymology.

**cryobiology** the science that is concerned with the study of the effects of very low temperatures on organisms.

**cryoelectron microscopy** *see* electron microscopy.

**cryoenzymology** the study of enzymes at low temperatures. By employing temperatures below 0 °C and fluid cryosolvents, enzyme reaction rates can be reduced sufficiently for normally transient enzyme-substrate intermediates to be studied.

**cryogen** any substance used to produce a low temperature; e.g. a freezing mixture.

**cryogenic** of, or relating to, very low temperatures.

**cryogenics** the branch of science concerned with the production of very low temperatures and the study of phenomena occurring at these temperatures.

## cryoglobulin

**cryoglobulin** any globulin, especially IgG or IgM, that forms a gel or flocculent precipitate, or spontaneously crystallizes, on cooling of a solution or a sample of serum containing it. *See also* cold-insoluble globulin.

**cryomicrotome** any microtome arranged in a cryostat and used to prepare thin sections of frozen tissue for microscopic examination.

**cryoprecipitate** the precipitate of a cryoglobulin.

**cryopreservation** the science of preserving cells, tissues, or organs over long periods with the aid of very low temperatures.

**cryoscope** any instrument or device for the determination of freezing points.

**cryoscopy** the measurement of freezing points, especially the determination of relative molecular mass or osmotic pressure by measurements of freezing point depressions. -*cryoscopic adj.*

**cryosolvent** any mixture of water and one of a select number of polar organic solvents that is used to maintain proteins in fluid solution at temperatures below 0 °C without denaturation.

**cryostat** an apparatus used to produce and maintain a constant low temperature in an enclosure or liquid bath.

**cryosublimation** the process whereby water, or another solvent, is sublimed from a frozen sample and is collected in a cold trap. *Compare* lyophilization.

**cryptotolerant** tolerant of low temperatures.

**cryptand** any synthetic macrocyclic organic compound, a molecule of which consists of two or more rings linked together by bridgehead (generally nitrogen) atoms to form a three-dimensional cagelike molecular structure having sufficient space within it to accommodate anyone of various cations and thereby form a cryptate. *Compare* crown compound.

**cryptate** the adduct of a cryptand and a metal ion or other cationic entity. The cation is bound within the molecule by polydentate ligation to heteroatoms in the cryptand, an exceptionally stable compound being formed.

**cryptic** 1 hidden, secret. 2 not apparent, unrecognized, masked; e.g. of a medical condition. 3 (especially of the colouring of an animal) serving to conceal. 4 of a particle-bound enzyme, that it is not as accessible to substrate as when it has been solubilized.

**crypticity or latency** the property of being cryptic.

**cryptic plasmid** a plasmid to which no phenotypic traits have been ascribed.

**crypto+ or (before a vowel) crypt+** *comb. form* meaning secret, hidden, concealed, unrecognized.

**cryptotope** a hidden immunological determinant. *Compare* epitope.

**cryst. abbr.** for crystalline, or crystallized.

**crystal** any three-dimensional solid aggregate in which the plane faces intersect at definite angles and in which there is a regular internal structure of the constituent chemical species.

**crystal lattice** the array of unit cells along parallel straight lines that makes up the structure of a crystal.

**crystallin** any of numerous water-soluble structural proteins found in the lens of the eye. Together the crystallins account for almost 90% of the total lenticular protein. Most vertebrate lenses contain three major classes of crystallins, designated  $\alpha$ -,  $\beta$ -, and  $\gamma$ ; in birds and reptiles there is a fourth, designated  $\delta$ . E-Crystallin is homologous with the enzyme lactate dehydrogenase. Although there are wide variations between species in the proportions of the various crystallins and in the extent of their post-translational modification or degree of aggregation, they display noteworthy conservation of primary structures. Examples from golden hamster:  $\alpha$ -crystallin A chain, database code CRA2\_MESAU, 196 amino acids (22.50 kDa); B chain, database code CRAB\_MESAU, 175 amino acids (20.07 kDa).

**crystalline abbr.**: cryst.; having the structure or characteristics of a crystal; made up of crystals; like a crystal.

**crystallize or crystallise** to form, or cause to form, crystals,

## CTP synthase

e.g. by slowly removing solvent from a solution to make a solute form one or more crystals.

**crystallized or crystallised abbr.**: crys.; (of a substance) having been induced into a crystalline form.

**crystallography** the study of the geometric forms of crystals. *See also* X-ray crystallography. -*crystallographer n.*; *crystallographic adj.*

**crystalloid** 1 *an alternative term for* crystalline. 2 any solute that can pass through a semipermeable membrane that does not allow the passage of a colloid. 3 any of the protein crystals that occur in seeds and other plant storage organs.

**C. symbol** for cesium.

**CS abbr.** for choriomammotropin.

**CSD abbr.** for cold-shock domain (*see* cold-shock protein).

**CSF abbr.** for 1 cerebrospinal fluid. 2 colony stimulating factor.

**CSP abbr.** for cell surface protein; *see* fibronectin.

**CSPCP abbr.** for cartilage-specific proteoglycan core.

**Cot or Cot** a measure of DNA kinetic complexity used in the renaturation analysis of DNA genomes. It is the product of initial DNA concentration,  $C_0$ , and time,  $t$ . Highly reiterated sequences will renature at low  $Cot$  values while unique sequences will renature at high  $Cot$  values.  $Cot_0$  is the value representing half complete renaturation.

**CT abbr.** for computerized tomography (*see* tomography).

**CTAB abbr.** for cetyltrimethylammonium bromide.

**CTAP-III abbr.** for connective-tissue activating peptide III; *see* LA-PF4.

**CTD kinase** *see* [RNA-polymerase]-subunit kinase.

**ctDNA** *see* DNA.

**C terminus or C terminal** that end of any peptide chain at which the I-carboxy function of a constituent a-amino acid is not attached in peptide linkage to another amino-acid residue. This function may bear an amide group or other substituent in nonpeptide linkage; more commonly it is free (also unprotonated and negatively charged) – the chain end may then also be termed the carboxyl(I) terminus or carboxyl(I) terminal. *Compare* Nterminus. -C-terminal adj.

**C1-tetrahydrofolate synthase** a trifunctional enzyme that consists of two major domains: an N-terminal domain, containing N5,N10-methylenetetrahydrofolate dehydrogenase and N5,N10-methenyltetrahydrofolate cyclohydrolase (amino acids 1-304 in the example), and a C-terminal domain containing formate-tetrahydrofolate ligase domain (amino acids 305-934). It is a homodimer. Example from human: database code CITC\_HUMAN, 934 amino acids (101.31 kDa).

**CTF 1 abbr.** for CAAT box-binding transcription factor or nuclear factor I (*abbr.*: NF-I); any of a class of transcription factors for the eukaryotic RNA polymerase II promoters, CAAT box sequences; CTF binds to DNA as a homodimer. Examples from human: CTF1, database code NFI1\_HUMAN, 499 amino acids (54.62 kDa); CTF2, database code NFI2\_HUMAN, 430 amino acids (47.85 kDa). 2 *abbr.* for competence transcription factor or competence protein K; a product of a bacterial regulatory gene required for expression of late competence genes. Example from *Bacillus subtilis*: database code COMK\_BACSU, 192 amino acids (22.43 kDa).

**CTGF abbr.** for connective tissue growth factor.

**CTH abbr.** for ceramide trihexoside (Cer(Hex)3 preferred).

**CTP abbr.** for cytidine 5'-triphosphate.

**CTP synthase EC 6.3.4.2; systematic name:** UTP:ammonia ligase (ADP-forming); *other names:* CTP synthetase; UTP-ammonia ligase. An enzyme responsible for *de novo* synthesis of CTP that in bacteria catalyses the reaction between ATP, UTP, and NH<sub>3</sub> to form CTP, ADP, and orthophosphate. Example from *Escherichia coli*: database code PYRG\_ECOLI, 545 amino acids (60.37 kDa). In animals, the amino group is donated by glutamine. The enzyme bears the same EC number and the reaction is analogous to that of the bacterial enzyme, with glutamine replacing ammonium ion, and CTP and glutamate as products. Example from human: database code PYRG\_HUMAN, 591 amino acids (66.7 kDa).

**CTS** (*in clinical biochemistry*) abbr. for catalase.

**Cu symbol** for copper.

**CUA** a codon in mRNA for L-leucine.

**cubic symmetry** the symmetry of one of the three point groups of a globular oligomeric protein; it may be tetrahedral, designated  $Tn'$  where  $n$  is 12; octahedral, designated  $O_n$ , where  $n$  is 24; or icosahedral, with 60 identical subunits.

**CUC** a codon in mRNA for L-Ieucine.

**cucurbitacin** any of a group of complex triterpenoids that are the bitter principles of the cucumber family, Cucurbitaceae.

**CUG** a codon in mRNA for L-Ieucine.

**culture** 1 (a) a collection of cells, tissue fragments, or an organ that is growing or being kept alive in or on a nutrient medium (i.e. culture medium); *see also* cell culture, tissue culture. (b) any culture medium to which such living material has been added, whether or not it is still alive. 2 the practice or process of making, growing, or maintaining such a culture. 3 to grow, maintain, or produce a culture.

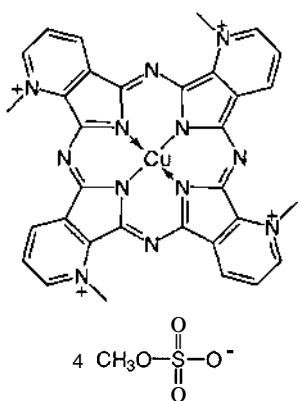

**culture medium** any nutrient medium that is designed to support the growth or maintenance of a culture (def. 1). Culture media are typically prepared artificially and designed for a specific type of cell, tissue, or organ. They usually consist of a soft gel (so-called solid or semisolid medium) or a liquid, but occasionally they are rigid solids.

**cUMP** abbr. for cyclic UMP; *see* uridine 3',5'-phosphate.

**cumulative inhibition** the inhibition of an enzyme resulting from the action of a number of effectors, each of which reduces the activity of the enzyme by a fixed percentage irrespective of the degree of inhibition already extant as a result of the presence of other inhibitors.

**cuprein** any of a group of copper proteins now known as super-oxide dismutase.

**Cuprolinic Blue** *the proprietary name for* quinolinic phthalocyanine (abbr.: QPC; no CI number); a new, copper-containing, intensely blue dye used for the visualization of RNA and other polynucleotides. The size and shape of the molecule have been designed to provide an exactly complementary fit between any pair of adjacent isoindole rings in the dye and base pairs in nucleic acids.

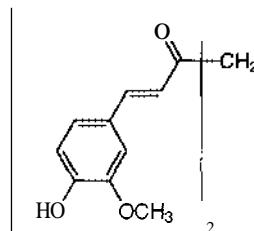

**cuproprotein** any protein containing one or more copper atoms.

**curare** a poisonous extract from certain tropical South American vines of the genera *Strychnos* and *Chondodendron*, used by Amazon and Orinoco Indians as an arrow poison; it blocks neuromuscular transmission in voluntary muscle and is useful as a muscle relaxant, e.g. in surgery. *See I(+)-tubocurarine* (the active principle) for the mechanism.

**curarize** or curarise to treat with (or as if with) curare; especially to cause muscular relaxation or paralysis. -curarization or curarisation *n.*

**curculin** a polypeptide present in the fruit of *Curculigo latifolia*, a stimulant herb that grows wild in western Malaysia. It is sweet tasting and has taste-modifying activity. It exists as a homodimer. Database code CURC\_CURLA, 114 amino acids (12.37 kDa).

**curcumin** I,7-bis(4-hydroxy-3-methoxyphenyl)-1,6-heptadiene-3,5-dione; turmeric yellow; a condiment and dye obtained from dried and powdered rhizomes of *Curcuma domestica* (*C. longa*). It provides the characteristic colour of curries, and is also an inhibitor of 5-lipoxygenase and prostaglandin-endoperoxide synthase cyclooxygenase activity. *See also* catechin.

**curdlan** *see* callose.

**curie** abbr.: Ci (*formerly* C); a non-SI unit of (radio)activity or of radioactive material. Originally (1910) it was defined as the quantity of radon in radioactive equilibrium with one gram of radium. Latterly (1968) it was defined as a unit of activity equal to  $3.7 \times 10^{10}$  disintegrations per second or, less correctly, as the quantity of any radioactive material having such activity. Hence,  $1\text{ Ci} = 3.7 \times 10^{10}$  becquerels. [After Pierre Curie (not after Marie Curie as sometimes stated).]

**Curie** 1 Marie Curie (née Marie Skłodowska, 1867-1934), Polish-born French chemist and physicist, co-discoverer of radium with her husband, P. Curie (*see def. 2*); Nobel Laureate in Physics (1903) jointly with P. Curie 'in recognition of the extraordinary services they have rendered by their joint researches on the radiation phenomena discovered by Professor Henri Becquerel' [prize shared with A. H. Becquerel]; Nobel Laureate in Chemistry (1911), in recognition of her services to the advancement of chemistry by the discovery of the elements radium and polonium, by the isolation of radium and the study of the nature and compounds of this remarkable element'. 2 Pierre Curie (1859-1906), French physicist and chemist, co-discoverer of radium with his wife, M. Curie (*see def. 1*); Nobel Laureate in Physics (1903) jointly with M. Curie. *See also* Joliot-Curie.

**curing** (*in genetics*) the elimination of a plasmid from its host cell.

**curtain electrophoresis** *see* continuous-flow electrophoresis.

**cushingoid** of, or relating to, Cushing's disease or Cushing's syndrome, or any of the signs and symptoms associated with these conditions.

**Cushing's disease** a pituitary-dependent, corticotropin-induced, bilateral adrenal hyperplasia which is one of several conditions embraced by Cushing's syndrome. [After Harvey Williams Cushing (1869-1939), US neurosurgeon.]

**Cushing's syndrome** the group of symptoms and signs resulting from prolonged exposure to inappropriately high plasma cortisol concentrations, caused either by primary disease (e.g. tumour) of the adrenal glands or by excessive production of corticotropin because of disease (e.g. basophil tumour) of the anterior pituitary. It may also be caused by excessive secretion of cortisol or corticotropin from ectopic sites, or by prolonged therapy with (large doses of) cortisol or other glucocorticoids. The syndrome is characterized by obesity of the trunk, polycythemia, osteoporosis, and glycosuria. The underlying disorder may be corticotropin-dependent or -independent. Of the corticotropin-dependent disorders, Cushing's disease is the

**cut**

most common, accounting for 68% of all types of Cushing's syndrome. The remainder (15% of all types) result from ectopic corticotropin-secreting tumours, that is, non-endocrine tumours such as lung, gut, ovarian, or carcinoid, which in some cases secrete corticotropin. Corticotropin-independent disorders include adrenocortical adenoma (5%) or carcinoma (3%) and nodular adrenal hyperplasia (9%).

**cut** 1 to sever, to make an incision, to divide (with a sharp instrument). 2 to separate into **fractions**. 3 a double-stranded scission in a polynucleotide duplex. Compare **nick**. 4 informal term for a **fraction**, such as one obtained in column chromatography or distillation.

**cutaneous** of, pertaining to, or in the skin.

**cutinase** an enzyme that catalyses the hydrolysis of the plant polyester, cutin, to allow penetration by phytopathogenic fungi. Example from *Asochyta rabiei*: database code CUTI\_ASCRA, 223 amino acids (23.49 kDa); five motifs.

**CUU** a codon in mRNA for L-leucine.

**cuvette** a small transparent vessel, often with parallel sides of specified separation, used to hold a liquid specimen, especially for optical or spectral measurements. See also **cell** (def. 2).

**C-value** the quantity of DNA present in a single haploid genome.

**Cya** symbol for a residue of the α-amino acid cysteic acid (an artefact in peptide sequences).

**cyan+** a variant form (before a vowel) of **cyan-**.

**cyanate** 1 the anion,  $\text{N}=\text{C}-\text{O}^-$ , derived from cyanic acid ( $\text{HOC}=\text{N}$ ). 2 any salt of cyanic acid. 3 any organic compound containing the monovalent group  $-\text{O}-\text{C}=\text{N}$ . Compare **isocyanate**.

**cyanelle** a cyanobacterium-like structure, considered as a descendant of an ingested cyanobacterium, that exists as an endosymbiont in the biflagellate protist *Cyanophora paradoxa*. The cyanelle has photosynthetic properties resembling those of cyanobacteria but its genome size is about 10% of those reported for cyanobacteria.

**cyanhydrin** a former name for **cyanohydrin**.

**cyanide** 1 the anion,  $\text{N}\equiv\text{C}^-$ , derived from hydrocyanic acid ( $\text{HCN}$ ). This ion blocks the electron transport chain by reacting with the ferric form of cytochrome  $a_3$  and thus acts as an inhibitor of respiration. 2 any salt of hydrocyanic acid. 3 any organic compound containing the monovalent cyano group,  $-\text{C}\equiv\text{N}$ ; such a compound may also be known either as a nitrile or as a carbonitrile, depending respectively on whether its carbon atom is included in or excluded from the numbering of an attached chain.

**cyanide-resistant respiration** a respiratory pathway, occurring only in plant mitochondria, that is unaffected by **cyanide**. Electron transport from NADH or succinate to  $\text{O}_2$  involves a nonheme iron protein as the terminal oxidase; this is insensitive to cyanide. The cyanide-resistant pathway complements the more usual cyanide-sensitive pathway; this contains cytochrome oxidase, which is inhibited by cyanide. Cyanide-resistant respiration is not found in animals.

**cyano+** or (before a vowel) **cyan-** comb. form denoting 1 the cyanide ion or hydrocyanic acid. 2 the  $-\text{CN}$  group in covalent linkage. 3 (dark) blue.

**cyanobacteria** or (formerly) **blue-green algae** a very heterogeneous group of prokaryotic photosynthetic organisms all of which contain chlorophyll *a*, carotenoids, and phycobiliproteins arranged in thylakoids. They lack chloroplasts, unlike true algae, and differ from photosynthetic bacteria, in, e.g., evolving oxygen during photosynthesis. Many can fix nitrogen.

**cyanoborohydride** any member of a group of compounds with the structure  $\text{MBH}_3\text{CN}$ , where M is an alkali metal (usually sodium). They are reducing agents similar in action to borohydride but more stable, more lipophilic, and more selective. They are especially useful for the facile reduction of aldehydes and ketones in acid conditions to the corresponding alcohols, for the reductive amination of aldehydes and ketones in the presence of an amine, and for the reductive methylation

**cyclamate**

of amines (including amino acids and proteins) in the presence of formaldehyde.

**cyanocobalamin** the most usual form of **vitamin B<sub>12</sub>**, in which the sixth position on the cobalt atom in **cobalamin** is filled by a cyanide group (the cyanide group being an artefact of the isolation procedure).

**cyanogen bromide** or **bromine cyanide**  $\text{CBrN}$ , or  $\text{CNBr}$ , or  $\text{BrCN}$ ; a volatile solid (at ordinary temperatures) with two main uses in biochemistry: (1) in the sequencing of proteins, because (in 90% formic acid) it converts methionine residues in peptide linkage to homoserine residues, with simultaneous cleavage of peptide bonds whose carbonyls are contributed by methionine residues; also (in anhydrous heptafluorobutyric acid) it specifically cleaves tryptophanyl peptide bonds; and (2) for activating cross-linked agarose so that almost any molecule containing amino groups can be coupled to it to prepare a specific affinity adsorbent.

**cyanogenesis** the production or yielding of cyanide ions or hydrocyanic acid.

**cyanogenic** or **cyanogenetic** 1 or **cyanophoric** describing any glucoside or other glycoside containing a cyano group that is released as hydrocyanic acid on acid hydrolysis; e.g. amygdalin. Such compounds occur in the kernels of various fruits. 2 describing any plant that synthesizes such a glycoside.

**cyanoginosin** a cyclic heptapeptide toxic agent responsible for numerous cases of poisoning among South African livestock that consume water contaminated with blooms of cyanobacteria. About seven variants are known.

**cyanoglobin** an unusual monomeric myoglobin-like hemoprotein found in multicellular cyanobacteria. Example from *Nostoc commune*: database code GLBN\_NOSCO, 118 amino acids (12.89 kDa).

**cyanohydrin** or (formerly) **cyanhydrin** any member of a class of a-hydroxynitriles formed by the base-catalysed addition of a cyanide ion to an aldehyde; such compounds are formed also from some reactive ketones.

**cyanolabe** a pigment sensitive to blue light (445 nm) that is found in some cones of the retina in the eye. It is lacking in subjects with blue-blindness. Compare **chlorolabe**, **erythrolabe**.

**cyanophage** any virus whose host is a cyanobacterium.

**cyanophoric** an alternative term for **cyanogenic** (def. 1).

**cyanophycin granule** or **structured granule** a type of granule, without apparent limiting membrane, that is observed in most, if not all, cyanobacteria. These granules are variable in size and shape, with diameters up to about 500 nm, and contain polypeptides of 25–100 kDa with a 1:1 arginine:aspartic acid ratio. They are believed to act as a nitrogen reserve.

**cyanopsin** a greenish-blue, light-sensitive, visual pigment occurring in the cone cells of the retinas of freshwater and migratory fishes and some amphibians. It consists of a cone-type opsin combined (as a Schiff's base) with 3,4-didehydro-II-cis-retinal. It has an absorption maximum at about 620 nm, and is analogous in function to **iodopsin** in other vertebrates. See also **3,4-didehydroretinal**.

**cyanosis** the bluish appearance of the skin and mucous membranes due to insufficient oxygenation of the blood in the capillaries. -**cyanotic** adj.

**evanobome** an alternative name for a **phycobilisome** in cyanophytes.

**eybrid** a portmanteau word used to denote a line of cultured mammalian cells that is a cytoplasmic hybrid of two other lines, as shown by inheritance of biochemical or other characteristics.

**eyeacin** methylazoxymethanol P-D-glucoside; a toxic substance from the seeds of *Cycas revoluta*, the aglycon of which is carcinogenic.

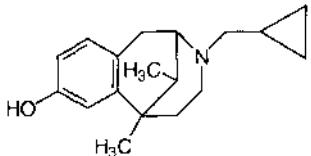

**cycl+** a variant form (before a vowel) of **cyclo+**.

**cyclamate** the anion of cyclamic acid, cyclohexylsulfamic acid. It is used in some countries as a sweetening agent, but is banned in the USA because of its possible carcinogenicity.

## cyclase

cyclase any enzyme that catalyses ring closure, e.g. adenylate cyclase.

cyclazocine 3-(cyclopropylmethyl)-1,2,3,4,5,6-hexahydro-6,11-dimethyl-2,6-methano-3-benzazocin-8-ol; a potent benzomorphan narcotic analgesic agent. It is an antagonist at  $\mu$ , and an agonist at  $\delta$ - and especially K-opioid receptors. Binding to  $\alpha$ -receptors may explain its psychotomimetic actions.

cycle 1 any recurring period of time in which certain events or operations occur, complete themselves, or repeat themselves in a regular sequence. 2 any sequence of changes occurring in a system in which the system is eventually restored to its initial state. 3 (*in biochemistry*) any closed sequence of metabolic reactions in which an end product acts as a reactant in the initiation of the cycle, e.g. the tricarboxylic-acid cycle. 4 (*in ecology*) any closed sequence of large-scale processes that describes the nutritional interdependence of animals, plants, and microorganisms, e.g. the nitrogen cycle. 5 to process through a cycle or cyclic system; to pass through cycles or to vary in a cyclical manner.

cyclic 1 of, relating to, moving in, or being a cycle. 2 (of an organic chemical compound) containing one (i.e. monocyclic) or more (i.e. polycyclic) rings of atoms. Compare heterocyclic, homocyclic. -cyclically *adv.*

cyclic adenosine 5'-diphosphoribose or cyclic ADP-ribose abbr.: cyclic ADPR or cADPR; a metabolite derived from NAD<sup>+</sup> and thought to be responsible for mediating certain of the latter's regulatory effects. It consists of a ribose molecule linked by its C-5 hydroxyl to the P-phosphate of ADP and by its C-1 hydroxyl to the adenosine amino group. It is suggested that it is involved in regulating intracellular Ca<sup>2+</sup> concentrations and in activating the nonskeletal form of the ryanodine receptor Ca<sup>2+</sup> channel.

cyclical a variant form of cyclic (def. 1).

cyclic AMP or cAMP abbr. for adenosine 3',5'-phosphate. See also adenylate cyclase.

cyclic AMP-dependent protein kinase a protein kinase that is regulated by cyclic AMP (cAMP). There are two types with respect to regulation. In type I, the inactive form of the enzyme is composed of two regulatory chains and two catalytic chains; activation by cAMP produces two active catalytic monomers and a regulatory dimer that binds four cAMP molecules. Expression of regulatory chains varies among tissues and is in some cases constitutive and in others inducible. Example (human): database codes: KAPO\_HUMAN (a regulatory chain), 381 amino acids (42.93 kDa); KAPLHUMAN ( $\beta$  regulatory chain), 379 amino acids (43.03 kDa). In type II, regulatory chains mediate membrane association by binding to anchoring proteins, including the MAP-2 kinase and AKAP. The inactive form of the enzyme is composed of two regulatory chains and two catalytic chains; activation by cAMP produces two active catalytic monomers and a regulatory dimer that binds four cAMP molecules. Database codes: KAP2\_HUMAN (a regulatory chain), 417 amino acids (46.16 kDa); KAP3\_HUMAN ( $\beta$  regulatory chain), 403 amino acids (45.34 kDa); catalytic subunits ( $\alpha$ ,  $\beta$ ,  $\gamma$  respectively): database codes KAPA\_HUMAN, 350 amino acids (40.41 kDa); KAPB\_HUMAN, 350 amino acids (40.44 kDa); KAPG\_HUMAN, 350 amino acids (40.24 kDa).

cyclic AMP phosphodiesterase (number EC 3.1.4.17 shared with cyclic GMP phosphodiesterase); recommended name: 3',5'-cyclic-nucleotide phosphodiesterase; an enzyme that catalyses

## cyclic GMP phosphodiesterase

the hydrolysis of a nucleoside 3',5'-cyclic phosphate to a nucleoside 5'-phosphate. The intracellular concentration of cyclic AMP is regulated by low-affinity (type I) and high-affinity (type 2) enzymes. Examples (yeast) type 1: database code CNALYEAST, 369 amino acids (42.00 kDa); type 2: database code CNA2\_YEAST, 526 amino acids (60.83 kDa). The enzymes are monomers; type 2 is well conserved.

cyclic AMP receptor any of various receptor molecules that bind cyclic AMP, especially CRP (def. 2), a bacterial catabolite (gene) activator protein. Other examples are the signalling receptors of the slime mould, *Dictyostelium discoideum*, which are similar to other eukaryotic G-protein-linked receptors. Receptor I is involved in aggregation, and receptor 2 is expressed after aggregation in pre-stalk cells. Receptor I: database code CARI\_DICDI, 392 amino acids (44.26 kDa); receptor 2: database code CAR2\_DICDI, 375 amino acids (43.26 kDa).

cyclic AMP response element see CRE.

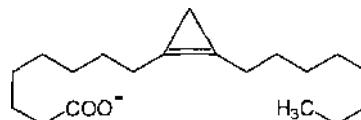

cyclic analysis a procedure that is useful, e.g. in flame spectrophotometry, for minimizing the effects of any mutual interference between two or more components of a sample being analysed. First, the concentration of each such component is estimated. Next, standards for each of the components are prepared containing the other interfering components at their estimated concentrations and the estimations are repeated. Then fresh standards are prepared, using the revised values for the concentrations of the interfering components, and further estimations are made; and so on, until a constant and accurate value for each component is obtained. In practice, usually only two or three such cycles of analysis are necessary.

cyclic CMP see cytidine phosphate.

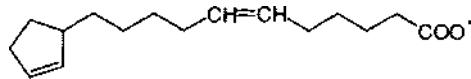

cyclic diguanlylic acid bis(3'-5')cyclic guanylic acid; a potent activator of cellulose synthase in the bacterium *Acetobacter xylinum*.

cyclic electron flow see cyclic photophosphorylation.

cyclic fatty acid any of a class of fatty acids that contain a carbocyclic unit. They include those with a cyclopropane unit, such as lactobacillic acid found in bacterial membranes, those with a cyclopropene unit such as sterculic acid (see structure), found in Sterculiaceae, and those with a cyclopentene unit, found in seed fats of Flacourtiaceae, these including manaoic acid (see structure). Mycolic acids are 2-alkyl-3-hydroxy acids with up to 80 carbons, and contain cyclopropane units. Fatty acids containing a cyclohexane unit are also known.

sterulic acid

manaoic acid

cyclic GMP abbr. for guanosine 3',5'-phosphate.

cyclic GMP phosphodiesterase (EC 3.1.4.17, number shared with cyclic AMP phosphodiesterase); recommended name: 3',5'-cyclic-nucleotide phosphodiesterase. An enzyme that catalyses the hydrolysis of a nucleoside 3',5'-cyclic phosphate

## cyclic IMP

to a nucleoside 5'-phosphate. It is involved in the regulation of the concentration of cyclic GMP, and thereby involved in the transmission and amplification of the visual signal; *see guanosine 3',5'-phosphate*. Example from mouse rod cells has three subunits:  $\alpha$  and  $\beta$  are catalytic subunits (short form of  $\beta$  is  $\beta'$  from alternative splicing), and  $\gamma$  is a regulatory subunit;  $\alpha$  and  $\beta$  are typical cyclic nucleotide phosphodiesterases.  $\alpha$  database code CNRA\_MOUSE, 858 amino acids (99.40 kDa);  $\beta$  database code CNRB\_MOUSE, 856 amino acids (98.39 kDa);  $\gamma$  database code CNRG\_MOUSE, 87 amino acids (9.63 kDa).

**cyclic IMP symbol:** cIMP or Ino-3',5'-P; inosine 3',5'-(cyclic)phosphate.

**cyclic nucleotide** any nucleotide in which the phosphate group is in diester linkage to two positions on the sugar residue, usually 3',5' but also sometimes 2',3'.

**cyclic photophosphorylation** the processes that occurs in photosystem I in which the high-potential electron in bound ferredoxin can be transferred to cytochrome  $b_{563}$ , rather than to NADP<sup>+</sup>, and then back to the oxidized form of P700 through cytochrome  $c_{552}$  and plastocyanin with the generation of one molecule of ATP. *See photosystem.*

**cyclic symmetry** the symmetry of a point group, designated  $C_n$ , having a geometric arrangement of the subunits such that a rotation of  $360^\circ/n$  transposes the structure into itself (i.e. it is indistinguishable from the original one). A dimeric molecule with chemically and spatially identical subunits must necessarily belong to the point group  $C_2$ . In general, a molecule with  $C_n$  symmetry will be a closed ring containing  $n$  subunits (e.g. of triangular, square, pentagonal, and hexagonal appearance for molecules containing three, four, five, and six subunits, respectively). If  $n$  is an odd number,  $C_n$  is the only symmetry possible.

**cyclic UMP symbol:** cUMP or Urd-3',5'-P; uridine 3',5'-(cyclic)phosphate.

**cyclin** any of a group of proteins that are involved in regulation of the eukaryotic cell-division cycle. Cyclins periodically rise and fall in concentration in step with the cycle. Individual cyclins activate particular cyclin-dependent protein kinases and thereby help to control progression from one stage of the cycle to the next (e.g. p34<sup>cdc2</sup>/cyclin B regulates the G<sub>2</sub> to M transition in all eukaryotes). All the following examples are from *Saccharomyces cerevisiae*: (1) G/S-specific cyclin Cln1; this is essential for control of the cell cycle at the G<sub>1</sub>/S (START) transition; it interacts with the Cdc28 protein kinase to form S-phase promoting factor (SPF); database code CG11\_YEAST, 546 amino acids, (62.11 kDa). (2) G/S-specific cyclin Cln2; this has an overlapping function with Cln1. Cln1 and Cln2 mRNAs fluctuate in the cell cycle; database code CG12\_YEAST, 545 amino acids (61.62 kDa). (3) G<sub>1</sub>/mitotic-specific cyclin CIB1; this interacts with the Cdc2 protein kinase to form MPF. G<sub>2</sub>/M cyclins accumulate steadily during G<sub>2</sub> and are abruptly destroyed at mitosis; database code CG21\_YEAST, 471 amino acids (54.81 kDa). G<sub>2</sub>/mitotic-specific cyclins CIB2-4 are similar. (4) S-phase entry cyclins CIB5 and 6; these are maximally expressed just before the S-phase of the cell cycle; database code CGS5\_YEAST, 435 amino acids (50.37 kDa). *See also cdc gene, cyclin-dependent protein kinase, cyclin regulatory protein.*

**cyclin-dependent protein kinase** Cdk; a protein kinase that is only active when complexed with a regulatory protein, a cyclin. Different Cdk-cyclin complexes are thought to trigger different steps in the cell-division cycle by phosphorylating specific target proteins. *See also cyclin regulatory protein.*

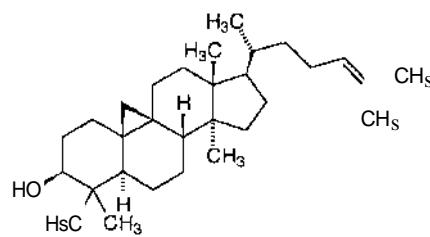

**cyclin regulatory protein** any protein involved in the regulation of cyclin gene expression. An example from *Saccharomyces cerevisiae* is Cdc68. This plays a role in general transcription, with both positive and negative effects on gene expression; it is required for the appropriate synthesis during heat shock, and for continued expression of cyclin genes; database code CC68\_YEAST, 1035 amino acids (118.50 kDa). A

## cycloheximide

further example, also from yeast, is the Ser/Thr protein kinase Cdc28 (*see cdc gene*).

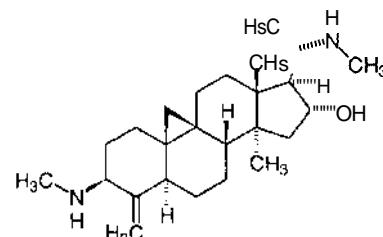

**cyclitol** any cycloalkane containing one hydroxyl group on each of three or more ring atoms. Notable members are the inositols and their derivatives.

**cyclo+** or (before a vowel) **cycl+** comb. form indicating a circle or ring, especially one in a cyclic organic chemical compound. **cycloartenol** the first triterpene intermediate in the biosynthesis of sterols in photosynthetic tissues. It is formed from (S)-squalene-2,3-epoxide by a cyclization reaction catalysed by cycloartenol synthase, EC 5.4.99.8. The corresponding intermediate in animal tissues is lanosterol.

**cyclobutadipyrimidine** a type of pyrimidine dimer formed within a DNA strand between neighbouring pyrimidine residues.

**cyclobuxine** a steroid alkaloid extracted from *Buxus microphylla*. The extracts are used as folk remedies for malaria and venereal diseases. It protects the heart from ischemia and reperfusion damage by inhibiting the release of ATP metabolites during reperfusion.

cyclobuxine 0

**cyclodeaminase** an informal name for formiminotetrahydrofolate cyclodeaminase.

**cyclodepsipeptide** *see depsipeptide.*

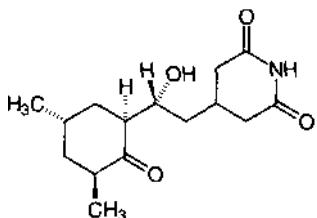

**cyclodextrin** any of a group of cyclic nonreducing dextrans formed from starch or glycogen by the extracellular enzyme cyclomaltodextrin glucanotransferase (EC 2.4.1.19), produced by *Bacillus macerans*. They consist of cyclic polymers containing six, seven, or eight  $\alpha$ -(1,4)-linked D-glucose residues. These were formerly known, respectively, as Schardinger  $\alpha$ -,  $\beta$ -, or  $\gamma$ -dextrans, or  $\alpha$ -,  $\beta$ -, or  $\gamma$ -cyclodextrins, but now are more correctly named cyclomaltohexaose, cyclomaltoheptaose, or cyclomaltooctaose. Cyclodextrins have a toroidal molecular structure enclosing a hydrophobic cavity, thereby permitting the formation of inclusion complexes with a wide variety of molecules.

**cyclofenil** bis-(*p*-acetoxyphenyl)cyclohexylenemethane; an agent that prevents feedback inhibition of ovulation by inhibiting the binding of estrogen in the brain. The resulting increased secretion of gonadotropin-releasing hormone, gonadotropins, and estrogen promotes ovulation.

**cycloheximide** or actidione 3-[2(3,5-dimethyl-2-oxocyclohexyl)-2-hydroxyethyl]glutarimide; an antibiotic produced by

**cyclohydrolase**

some *Streptomyces* spp. It interferes with protein synthesis in eukaryotes by inhibiting peptidyltransferase activity of the 60S ribosomal subunit.

**cyclohydrolase** an informal name for the enzyme **methenyl-tetrahydrofolate cyclohydrolase**, EC 3.5.4.9.

**cyclo-ligase** any **ligase** enzyme of the sub-subclass EC 6.3.3 that catalyses the formation of a heterocyclic ring containing a C-N bond; e.g. dethiobiotin synthase, EC 6.3.3.3.

**cyclomaltoheptaose** see **cyclodextrin**.

**cyclomaltohexaose** see **cyclodextrin**.

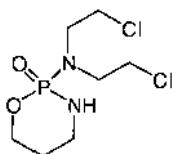

**cyclomaltooctaose** see **cyclodextrin**.

**cyclooxygenase** an alternative (informal) name for **prostaglandin-endoperoxide synthase**.

**cyclooxygenation** the process that introduces one molecule of dioxygen at C-9 and a second dioxygen at C-15 of a molecule of arachidonic acid, accompanied by formation of a bond between C-8 and C-12 and an endoperoxide bridge across C-9 and C-11.

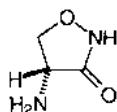

**cyclophilin** the protein to which the immunosuppressant **cyclosporin A** binds. Cyclophilin possesses **peptidylprolyl isomerase** activity. The *in vivo* function of this **immunophilin** is not clear. **cyclophorase** originally, a supposed integrated complex of enzymes that carries out the tricarboxylic-acid cycle, fatty-acid oxidation, oxidative phosphorylation, and terminal electron transport. This system was identified later with **mitochondrie**. The cyclophorase complex and the mitochondria are thus the functional and structural sides of the same unit.

**cyclophosphamide** N,N-bis(2-chloroethyl)tetrahydro-2H-1,3,2-oxazaphosphorin-2-amine 2-oxide; an alkylating agent that is metabolized by the liver cytochrome P450 system to 4-hydroxycyclophosphamide, which is in equilibrium with aldo-phosphamide. These are transported to tissues, which convert them to the cytotoxic agent, phosphoramide mustard, and acrolein. Cyclophosphamide is useful as an immunosuppressant. See also **chlorambucil**.

**cyclopropylamine** see **monoamine oxidase inhibitors**.

**o-eycloserine** D-4-amino-3-isoxazolidinone; a tuberculostatic antibiotic found in cultures of *Streptomyces orchidaceus*. It is a potent inhibitor of alanine racemase (EC 5.1.1.1) and *D*-alanine-o-alanine ligase (EC 6.3.2.4; alanylalanine synthetase), two enzymes concerned in the biosynthesis of bacterial cell wall peptidoglycan.

**cystathionine**

**cyclosporin A** a cyclic undecapeptide isolated from the fungi *Cylindrocarpon lucidum* and *Tolypocladium inflatum* (formerly *Trichoderma polysporum*). It is a potent immunosuppressive drug that prevents the rejection of allografts, and is used extensively in human transplant operations. Its main target appears to be the T lymphocyte: it contains *D*-alanine and several nonprotein amino acids, and blocks a calcium-dependent signal from the **1-cell receptor** that normally leads to T-cell activation. When bound to **cyclophilin**, cyclosporin A binds and inactivates the key signalling intermediate **calcineurin**.

**cyclotron** a machine used to accelerate charged particles of atomic magnitudes to energies of the order of 25 MeV. The particles move in spiral paths under the influence of a uniform vertical magnetic field and are accelerated by a constant frequency electric field.

**Cyd** symbol for a residue of the ribonucleoside **cytidine** (alternative to C).

**CyDP** symbol for cytidine phosphate (see **cytidine phosphate**).

**CyD'P** symbol for cytidine 2'-phosphate (see **cytidine phosphate**).

**Cyd-2'.3'-P** symbol for cytidine 2',3'-phosphate (see **cytidine phosphate**).

**Cyd3'P** symbol for cytidine 3'-phosphate (see **cytidine phosphate**).

**Cyd-3'.5'-P** symbol for cytidine 3',5'-phosphate (see **cytidine phosphate**).

**Cyd5'P** symbol for cytidine 5'-phosphate (see **cytidine phosphate**).

**Cyd5'PP** symbol for cytidine 5'-diphosphate (see **cytidine phosphate**).

**Cyd5'PPP** symbol for cytidine 5'-triphosphate (see **cytidine phosphate**).

**C-yes** see **YES**.

**o-cymarose** 2,6-dideoxy-3-O-methyl-ribo-hexose; the D enantiomer is a constituent of some **cardiac glycosides**.

**cypoterone** 6-chloro-6-dehydro-17 $\alpha$ -hydroxy-1,2a-methyl-eneprogesterone; a progesterone derivative with anti-androgen activity through partial agonist activity at androgen receptors. It inhibits the secretion of gonadotropins and spermatogenesis in humans.

**Cyr61** a growth factor binding protein expressed from *G0/G1* to mid-*G1* of the cell cycle. It is expressed in high amounts in lung. Example (precursor) from *Mus musculus*: database code CYR6\_MOUSE, 379 amino acids (41.66 kDa). Compare **connective tissue growth factor**.

**Cys** symbol for a residue of the *L*-amino acid L-cysteine. When written

it represents L-half-cystine.

**cyst** 1 any saclike structure, generally of a pathological nature, comprising a central cavity lined with epithelium and containing fluid or semisolid material. 2 the capsule enclosing a dormant larva or spore. -cystic adj.

**cystamine**  $\beta,\beta'$ -diaminodiethyl disulfide; 2,2'-dithiobis(ethylamine); 2,2'-dithiobisethanamine;  $H_2N-CH_2-CH_2-S-S-CH_2-CH_2-NH_2$ ; the decarboxylation product of cystine and an oxidation product of **cysteamine**.

**cystate** 1 the **cystine** anion; the dianion,  $-OOC-CH(NH_2)-CH_2-S-S-CH_2-CH(NH_2)-COO-$ , derived from cystine. 2 any salt containing the cystine anion. 3 any ester of cystine. Distinguish from **cysteate** and **cysteinate**.

**y-cystathionase** see **cystathione y-lyase**.

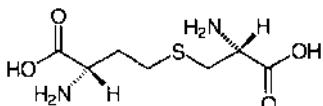

**cystathionine** trivial name for S-(*D*-amino-*p*-carboxyethyl)-homocysteine; (*R*<sup>\*</sup>)-2-amino-4-[*(S*<sup>\*</sup>)-2-amino-2-carboxyethylthio]butanoic acid; HOOC-CH(NH<sub>2</sub>)-CH<sub>2</sub>-S-CH<sub>2</sub>-CH<sub>2</sub>-CH(NH<sub>2</sub>)-COOH; a di(*D*-amino acid) and a mixed thioether with two chiral centres. L-Cystathione

S-(*L*-alanin-3-yl)-L-homocysteine; (*S*<sup>\*</sup>)-2-amino-4-[*(R*)-2-amino-2-carboxyethylthio]butanoic acid - in which both moieties are in the L-configuration, does not occur in proteins but is an

## cystathione y-Iyase

intermediate in the transfer of the sulfur atom from methionine, via homocysteine, to cysteine in mammals. (Note: The pair of (*R*<sup>\*</sup>,*R*<sup>\*</sup>)-enantiomers, in which one moiety is in the D-configuration and the other in the L-configuration, is sometimes known as allocystathione.)

cystathione y-Iyase EC 4.4.1.1; systematic name: L-cystathione cysteine-lyase (deaminating); other names: homoserine deaminase; homoserine dehydratase; y-cystathionase; cystine desulphydrase; cysteine desulphydrase; cystathione; a multifunctional pyridoxal-phosphate enzyme that catalyses the formation of L-cysteine with release of 2-oxobutanoate and ammonium ion from L-cystathione and water. It also acts on homoserine and cysteine to remove NH<sub>3</sub>, forming oxobutanoate from homoserine or pyruvate and H<sub>2</sub>S from cysteine. The enzyme requires pyridoxal-phosphate as coenzyme. Example from human: database code CGL\_HUMAN, 361 amino acids (39.49 kDa). It carries out the final reaction in the pathway for the synthesis of cysteine from methionine. Example from *Saccharomyces cerevisiae*: database code CYS3\_YEAST, 393 amino acids (42.41 kDa).

cystathione  **$\beta$ -synthase** EC 4.2.1.22; systematic name: L-serine hydro-lyase (adding homocysteine); other names: serine sulfhydrase; p-thionase; methylcysteine synthase. An enzyme that catalyses the reaction between L-serine and L-homocysteine to form cystathione and water. This is the first step in the synthesis of cysteine from serine. Pyridoxal-phosphate is a cofactor. Example from *Saccharomyces cerevisiae*: database code STR4\_YEAST, 507 amino acids (55.96 kDa).

cystathione y-synthase EC 4.2.99.9; recommended name: O-succinylhomoserine (thiol)-Iyase. An enzyme in the pathway for the synthesis of methionine in plants and bacteria. It catalyses the formation of cystathione from O-succinyl-L-homoserine and L-cysteine to form succinate. Pyridoxal-phosphate is a cofactor. The enzyme can utilize hydrogen sulfide or methanethiol as a thiol substrate. Example from *Escherichia coli*: database code METB\_ECOLI, 386 amino acids (41.50 kDa).

cystathioninuria a condition of humans in which there is excessive excretion of L-cystathione in the urine. It may be caused by an inherited deficiency of cystathione y-Iyase.

cystatin any of a group of proteins, present in tissues and body fluids, that inhibit cysteine proteinases. The cystatins constitute a single evolutionary protein superfamily, and are classified into three different families. Family 1 proteins contain about 100 amino-acid residues ( $M_r$  11 000–12 000) and lack disulfide bonds. Family 2 proteins have about 120 residues ( $M_r$  13 000–14 000) with two intrachain disulfide bonds. Family 3 proteins (also called kininogens) contain three cystatin-like domains, each of which has two disulfide bonds at positions homologous to those in family 2. Examples: cystatin A (also called stefin A), database code CYTA\_HUMAN, 98 amino acids (10.99 kDa); type 2 cystatin C (also called neuroendocrine basic polypeptide or post-y-globulin): precursor database code CYTC\_HUMAN, 146 amino acids (15.78 kDa); this is expressed in highest levels in the epididymis, vas deferens, brain, thymus, and ovary, and is found in sera from patients with Icelandic cerebrovascular type amyloidosis and related diseases.

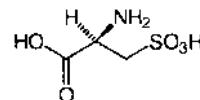

cysteamine thioethanolamine; p-mercaptoproethylamine; 2-aminoethanethiol; HS-CH<sub>2</sub>-CH<sub>2</sub>-NH<sub>2</sub>; the decarboxylation product of cysteine. It readily oxidizes in air to cystamine. Pan-

## cysteine-type carboxypeptidase

theanine, a component of coenzyme A, is the amide formed between cysteamine and pantothenic acid.

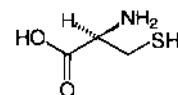

cysteate 1 the common name for cysteate(I-); cysteic-acid monoanion; hydrogen cysteate. (Note: In theory, the term denotes any ion or mixture of ions formed from cysteic acid and having a net charge of minus one, although the species -03S-CH<sub>2</sub>-CH(NH<sub>3</sub><sup>+</sup>)-COO<sup>-</sup> generally predominates in practice.) 2 the systematic name for cysteate(2-); cysteate-acid dianion. 3 any salt containing an anion of cysteic acid. 4 any ester of cysteic acid. Compare cystate, cysteinate.

cysteic acid the trivial name for 3-sulfoalanine; a-amino-p-sulforpropionic acid; 2-amino-3-sulforpropanoic acid; HO<sup>3S</sup>-CH<sub>2</sub>-CH(NH<sub>2</sub>)-COOH; a chiral a-amino acid and an oxidation product of cysteine or cystine. Residues of L-cysteic acid (symbol: Cya), (R)-2-amino-3-sulforpropanoic acid, do not occur normally in proteins although they are found in wool from the outer part of the fleece of sheep following exposure to sunlight. They are commonly encountered during sequencing of peptides and proteins as the end product of oxidative cleavage of the disulfide bonds of cystine residues and concomitant oxidation of cysteine residues.

cysteinate 1 cysteinate(I-); cysteine monoanion; the anion, HS-CH<sub>2</sub>-CH(NH<sub>2</sub>)-COO<sup>-</sup>, derived from cysteine. 2 cysteinate(2-); cysteine dianion; the anion, -S-CH<sub>2</sub>CH(NH<sub>2</sub>)-COO<sup>-</sup>, derived from cysteine. 3 any salt containing an anion of cysteine. 4 any ester of cysteine. Compare cystate, cysteate.

cysteine the trivial name for p-mercaptopalanine; a-amino-p-thiolpropionic acid, 2-amino-3-mercaptopropanoic acid; HS-CH<sub>2</sub>-CH(NH<sub>2</sub>)-COOH; a chiral a-amino acid. In neutral or alkaline solution it is readily oxidized by air to cystine. L-Cysteine (symbol: C or Cys), (R)-2-amino-3-mercaptopropanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: UGC or UGU. In mammals it is a nonessential dietary amino acid and is glucogenic. D-Cysteine (symbol: D-Cys or DCys), (S)-2-amino-3-mercaptopropanoic acid, occurs naturally in firefly luciferin. (Note: application of the sequence rule to the enantiomers of cysteine results in their stereochemical designation as either R or S being the converse of that possessed by most chiral a-amino acids found in proteins.)

L-cysteine

cysteine (acid) the protonated form of a cysteine residue, i.e. with an undissociated thiol group.

cysteine desulphydrase see cystathione v-lyase.

cysteine endopeptidase or (formerly) tbiol proteinase any enzyme of the sub-subclass EC 3.4.22, which consists of proteinases characterized by having a cysteine residue at the active centre and by being irreversibly inhibited by sulphydryl reagents such as iodoacetate. The group includes cathepsins B, H, and L (see cBthepsin B, cethepsin H, and cathepsin L), clostrin, ficain, and papain. See also apoptosis.

cysteine-type carboxypeptidase EC 3.4.18.1; other names: lysosomal carboxypeptidase B; cathepsin B $\gamma$ ; cathepsin IV;

## cysteinyl

acid carboxypeptidase; an enzyme that catalyses the liberation of a C-terminal amino-acid residue from a protein. It is an enzyme with broad specificity, but lacks action on C-terminal proline.

cysteinyl the acyl group,  $\text{HS}-\text{CH}_2-\text{CH}(\text{NH}_2)-\text{CO}-$ , derived from cysteine. (Note: Although this name is formed atypically, its use is recommended to avoid confusion with cysteyl.) Compare cystyl, half-cystyl.

cysteine-S-yl the alkylthio group,  $\text{HOOC}-\text{CH}(\text{NH}_2)-\text{CH}_2-\text{S}-$ , derived from cysteine.

cysteyl 1 the acyl group,  $\text{HO}_3\text{S}-\text{CH}_2-\text{CH}(\text{NH}_2)-\text{CO}-$ , derived from cysteic acid. 2 an alternative name for cysteinyl (use now discouraged).

cystic fibrosis a heterogeneous metabolic disorder affecting all exocrine glands and probably other tissues. It is the most common lethal genetic disorder of Caucasians, although the disease is also found in other races. There is an abnormality in the secretions of the exocrine glands, which have higher than normal concentrations of  $\text{Na}^+$ ,  $\text{Cl}^-$ , nucleotides,  $\text{Ca}^{2+}$ , etc.; a number of abnormal protein factors have been described in the exocrine glands of patients. Many cases are due to an abnormality of cystic fibrosis transmembrane conductance regulator.

cystic fibrosis transmembrane conductance regulator abbr.: CFTR; a 168 kDa integral membrane protein encoded by the cystic fibrosis gene and with a structural similarity to membrane-associated ATP-dependent transporter protein (see ABC transporters), one of a family of proteins involved in the active transport of ions and small molecules across membranes. CFTR belongs to the MDR protein subfamily. The CFTR protein appears to be involved in the functioning of a chloride ion channel. A mutation in this protein has been identified as being responsible for 70% of the cystic fibrosis chromosomes in Northern Europe. Example from human: database code CFTR\_HUMAN, 1480 amino acids (167.92 kDa).

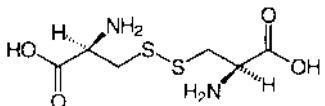

cystine the trivial name for dicysteine; p,P'-dithiodialanine;  $\alpha,\alpha'$ -diamino-p,p'-dithiobis(propionic acid); ( $R^*,R^*$ )-3,3'-dithiobis(2-aminopropanoic acid);

a di(a-amino acid) with two chiral centres, formed by the oxidation of cysteine. L-Cystine,

( $R,R'$ )-3,3'-dithiobis(2-aminopropanoic acid), is found in peptide linkage in proteins, having been formed by post-translational oxidation of cysteine. In mammals it is a nonessential dietary amino acid and is glucogenic. As it is somewhat insoluble in neutral aqueous solutions, it sometimes forms urinary stones. *meso-Cystine*, ( $R,S'$ )-3,3'-dithiobis(2-aminopropanoic acid), is the internally compensated achiral diastereoisomer, in which o- and L-half-molecules are combined. See also note at cysteine.

L-cystine

cystine desulphhydrase see cystathionine  $\gamma$ -lyase.

cystine knot a structure in a protein resulting from three disulfide bonds formed between six cysteine residues that are positioned in a way that results in formation of a knot-like topology. It was originally found in transforming growth factor- $\beta$  and platelet-derived growth factor.

cystinosis a recessively inherited human metabolic disorder characterized by a high intracellular content of free (nonprotein) cystine, apparently compartmentalized within lysosomes,

## cytidine 5'-diphosphate

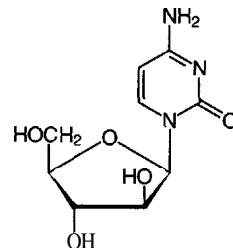

and resulting in deposition of cystine crystals in the cornea, conjunctiva, bone marrow, lymph nodes, leukocytes, and internal organs. -cystinotic adj.

cystinuria a heritable disorder of cystine and diamino acid (arginine, lysine, and ornithine) transport in humans affecting the epithelial cells of the renal tubules and the gastrointestinal tract. It is characterized by the formation of cystine stones in the urinary tract and elevated levels of cystine and diamino acids in the urine.

cystyl the diacyl group,  $-\text{OC}-\text{CH}(\text{NH}_2)-\text{CH}_2-\text{S}-\text{S}-\text{CH}_2-\text{CH}(\text{NH}_2)-\text{CO}-$ , derived from cystine. Compare cysteinyl, half-cystyl.

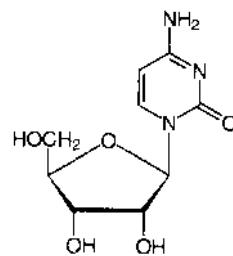

Cyt symbol for a residue of the pyrimidine base cytosine (alternative to C).

cytarabine p-cytosine arabinoside; I-p-o-arabinofuranosyl-cytosine; abbr. ara-C; a cytotoxic drug used as an antineoplastic and antiviral agent. It is effective in the treatment of acute myeloblastic leukemia. It is converted metabolically to I-P-o-arabinofuranosylcytidine 5'-triphosphate (abbr.: ara-CTP), a potent inhibitor of DNA synthesis.

+cyte comb. form indicating a cell (def. I).

cytidine symbol: C or Cyd; cytosine riboside; I-p-o-ribofuranosyl cytosine; a widely distributed nucleoside.

cytidine 2',3'-Cyclic phosphate see cytidine phosphate.

cytidine 3',5'-Cyclic phosphate or cytidine 3',5'-cyclophosphate see cytidine phosphate.

cytidine deaminase EC 3.5.4.5; systematic name: cytidine aminohydrolase. An enzyme that catalyses the reaction:

It is a homodimer, with bound  $\text{Zn}^{2+}$ . Specificity is poor, and deoxycytidine is also a substrate. Example from *Escherichia coli*: database code CDD\_ECOLI, 294 amino acids (31.50 kDa).

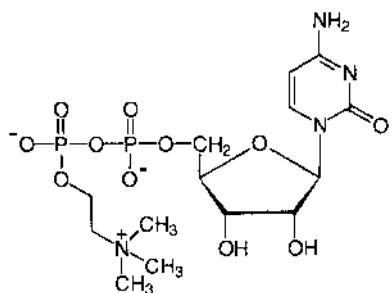

cytidine 5'-diphosphate symbol: Cyd5'PP or ppC; the recommended name for cytidine diphosphate (abbr.: CDP), 5'-diphosphocytidine, 5'-cytidylyl phosphate, cytidine 5'-trihydrogen diphosphate), a universally distributed nucleotide that occurs both in the free state and as a component of certain nucleotide coenzymes. It is a metabolic precursor of cytidine 5'-triphosphate, CTP. It is a product of nucleoside

## cytidine(5'diphosphocholine

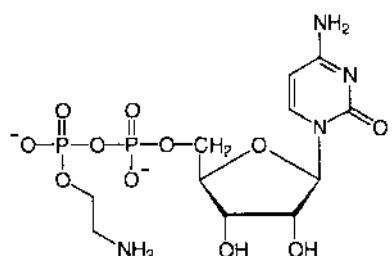

## cytochemical bioassay

triphosphatase, EC 3.6.1.15, and is also formed in a few cases when CTP is involved in phosphotransferase reactions (e.g. dolichol kinase, EC 2.7.1.108); it is converted to deoxycytidine 5'-diphosphate by ribonucleoside-diphosphate reductase (EC 1.17.4.1).

**cytidine(5')diphosphocholine** or cytidine diphosphate choline; intermediate in phospholipid synthesis, especially of phosphatidylcholines and sphingomyelins.

**cytidine(5')diphosphoethanolamine** or cytidine diphosphate ethanolamine; intermediate in the synthesis of phosphatidylethanolamines.

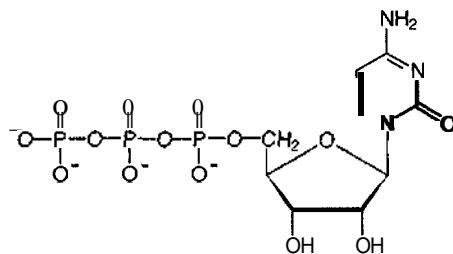

**cytidine monophosphate** abbr.: CMP; an alternative name for any cytidine phosphate, but in particular for cytidine 5'-phosphate, especially when its distinction from cytidine (5')-diphosphate and cytidine (5')-triphosphate requires emphasis. **cytidine phosphate** symbol: *CydP*; cytidine monophosphate (abbr.: CMP); any phosphoric monoester or diester of cytidine. There are three monoesters: cytidine 2'-phosphate, cytidine 3'-phosphate, and cytidine 5'-phosphate, and two possible diesters: cytidine 2',3'-phosphate and cytidine 3',5'-phosphate, although cytidine 5'-phosphate is the ester commonly denoted (the locant being omitted if no ambiguity may arise). Cytidine 2',3'-phosphate (symbol: *Cyd-2',3'-P*), also named cytidine 2',3'-cyclic phosphate or cyclic cytidine 2',3'-monophosphate (abbr.: 2',3'-cyclic CMP), is formed as an intermediate during the alkaline hydrolysis of ribonucleic acid. This diester then readily hydrolyses to a mixture of the two monoesters cytidine 2'-phosphate (symbol: *Cyd2'P*), also named cytidine 2'-monophosphate (abbr.: 2'CMP) or 2'-cytidylic acid or cytidylic acid a, and cytidine 3'-phosphate (symbol: *Cyd3'P*), also named cytidine 3'-monophosphate (abbr.: 3'CMP) or 3'-cytidylic acid or cytidylic acid b. Cytidine 3',5'-phosphate (symbol: *Cyd-3',5'-P*), also named cytidine 3',5'-cyclic phosphate or cyclic cytidine 3',5'-monophosphate (abbr.: 3',5'-cyclic CMP), is a product of cytidylate cyclase, EC 4.6.1.6.

cytidine 2'-phosphate see cytidine phosphate.  
cytidine 2',3'-phosphate see cytidine phosphate.  
cytidine 3'-phosphate see cytidine phosphate.

**cytidine 5'-phosphate** or 5'-cytidylic acid or 5'-phosphocytidine or 5'-O-phosphonocytidine; symbol: *Cyd5'P*; alternative recommended names for cytidine 5'-monophosphate (abbr.: 5'CMP), cytidine 5'-(dihydrogen phosphate), cytidine (mono)-ribonucleotide. (The locant is commonly omitted if there is no ambiguity as to the position of phosphorylation). It is formed by pyrophosphatase-catalysed cleavage of (inorganic) diphosphate from CTP, and also as a product of a variety of reactions, e.g. that in which phosphatidylcholine is formed from CDPcholine and diacylglycerol (diacylglycerol cholinophotransferase, EC 2.7.8.2).

**cytidine 5'-triphosphate** symbol: *Cyd5'PPP* or *pppC*; recommended name for cytidine triphosphate (abbr.: CTP), 5'-triphosphocytidine, 5'-cytidylyl diphosphate, cytidine 5'-(tetrahydrogen triphosphate), an important coenzyme. It is formed by CYP synthase. It participates as coenzyme in reactions in which a cytidylyl group is transferred e.g. in lipid metabolism, to choline phosphate (EC 2.7.7.15, to form CDP-choline) and similar reactions, or in carbohydrate metabolism to form CDPglucose (EC 2.7.7.33), or in the phosphotransferase dolichol kinase (EC 2.7.1.108).

**cytidyl** any chemical group formed by the loss of a 2', a 3', or a 5'-hydroxyl group from the ribose moiety of cytidine. Compare cytidVVI.

**cytidylate** 1 either the mono- or the di-(phosphoric) anion of cytidVlic acid. 2 any mixture of cytidylic acid and its anions. 3 any salt or ester of cytidylic acid.

**cytidylic acid** the trivial name for any phosphoric monoester of cytidine. The position of the phosphoric residue on the ribose moiety of a given ester may be specified by a prefixed locant. See cytidine phosphate. However, 5'-cytidylic acid is the ester commonly denoted, its locant usually being omitted if no ambiguity may arise. 5'-Cytidylic acid is also an alternative recommended name for cytidine 5'-phosphate.

**cytidylyl** the cytidine[mono]phospho group, the acyl group derived from cytidVlic acid. Compare cytidVI.

**cytidylylation** the process of introducing a cytidylyl group into a substance.

**cyto+** comb. form indicating a cell (def. 1).

**cytochalasin** any of a group of structurally related fungal metabolites (designated A, B, C, D, E, F, etc.) that share a number of unusual and characteristic effects on cultured mammalian cells. The most notable are inhibition of cytoplasmic cleavage following nuclear division, induction of nuclear extrusion, and inhibition of cell motility. They bind to the growing plus ends of actin filaments, preventing further addition of actin molecules, and thus affect functions that involve assembly and disassembly of actin filaments. The basic structure is a benzyl-substituted hydroisoindolone nucleus to which is fused a small macrolide-like ring. [From Greek *cytos*, cell; *chalasis*, relaxation.]

**cytochemical bioassay** a technique for the assay of various polypeptide hormones, based on function rather than structure. It involves measuring changes in the biochemical activity of a specific target cell, appropriate to the physiological effect of the hormone in question, by quantitative cytochemical

## cytochemistry

## cytochrome P450

methods. It is claimed to be more sensitive and more specific than equivalent radioimmunoassays.

**cytochemistry** the chemistry of living cells, especially the cellular localization of biochemical substances and processes; microscopic biochemistry. -cytochemical adj.

**cytochrome** any member of a class of hemoproteins whose characteristic mode of action involves the transfer of electrons in association with a reversible change in oxidation state (between Fe(n) and Fe(m), and sometimes Fe(lv)) of the heme iron. The name embraces all intracellular hemoproteins except hemoglobin, myoglobin, peroxidases, catalase, tryptophan 2,3-dioxygenase, nitrite and sulfite reductases, and heme-thiolate proteins. There are four major established subclasses; well-established members of each subclass are generally distinguished by consecutive numerical subscripts; remaining members are designated by a suffixed number based upon the wavelength (in nanometres) of the a-band (e.g. cytochrome  $c_1$ , cytochrome  $c_{555}$ ); see cytochrome absorption bands. (1) In cytochromes  $a$  the heme prosthetic group contains a formyl side-chain, i.e. heme  $a$ . (2) Cytochromes  $b$  contain protoheme or a related heme (without a formyl group) as prosthetic group, not covalently bound to the protein. The group includes cytochrome  $o$ , cytochrome P-450, and helicorubin, as well as ubiquinol-cytochrome  $c$  reductase, cytochrome  $b$ , cytochrome  $b_2$ , cytochrome  $b_5$ , cytochrome  $b_{245}$ , cytochrome  $b_{599}$ , cytochrome  $b_6$  and cytochrome  $b_6-f$  complex. (3) In cytochromes  $c$  there are covalent linkages, not necessarily thioether linkages, between the heme side-chains and the protein (see also cytochrome  $c$ , cytochrome  $c_1$ ). (4) Cytochromes  $d$  contain a tetrapyrrolic chelate of iron as prosthetic group, in which the degree of conjugation of double bonds is less than in porphyrin. See also cytochrome  $f$ .

**cytochrome absorption bands** three principal absorption bands in the absorption spectrum of many ferrohemoproteins, being the a-band,  $\beta$ -band, and  $\gamma$ -band (or Soret band), resulting from the absorption of radiation by the heme groups. They are useful in the characterization and study of these proteins. Characteristic absorption maxima for cytochromes  $a$ ,  $b$ ,  $c$ , and  $c_1$  are for the a-band: 600, 563, 550, and 554 nm respectively; for the  $\beta$ -band: (none for  $a$ ) 532 ( $b$ ), 531 ( $c$ ), and 524 ( $c_1$ ) nm; and for the  $\gamma$ -band 439, 429, 415, and 418 nm.

**cytochrome  $b$**  a component of the eukaryotic mitochondrial respiratory chain complex III. It is an integral membrane protein with two hemes,  $b_{562}$  and  $b_{566}$ . Example (human): database code CYB\_HUMAN, 380 amino acids (42.68 kDa).

**cytochrome  $b_2$**  EC 1.1.2.3; an enzyme (recommended name: L-lactate dehydrogenase (cytochrome)) that catalyses the oxidation of L-lactate by 2 ferricytochrome  $c$  to form pyruvate and 2 ferrocyanochrome  $c$ . Flavin mononucleotide (FMN) and protoheme IX are cofactors. Cytochrome  $b_2$  is a mitochondrial matrix protein induced by lactate during respiratory adaptation (in yeast). Database code CYB2\_YEAST (precursor), 591 amino acids (65.46 kDa); the mature enzyme is a homotetramer; 3-D structure is known.

**cytochrome  $b_5$**  an electron carrier for several oxygenases, present in animal microsomes and in erythrocytes. It is reduced by cytochrome  $b_5$  reductase. Two forms are synthesized by alternative splicing. Example (human): database code CYB5\_HUMAN, 133 amino acids (15.18 kDa).

**cytochrome  $b_6$**  reductase EC 1.6.2.2; a flavoprotein (FAD) enzyme that catalyses the reaction:

**cytochrome  $b_6$  or cytochrome  $b_{563}$**  closely related to cytochrome  $b$ , that is part of the  $bc$  complex functioning between photosystems II and I of photosynthesis. Example (barley, wheat): database code CYB6\_WHEAT, 215 amino acids (24.14 kDa).

**cytochrome  $b_6-f$  complex** a complex, occurring in chloroplasts, of cytochrome  $b_6$ , the 17 kDa polypeptide (*petD* gene product), cytochrome/, and the Rieske protein.

**cytochrome  $b_{245}$**  a component of the phagocyte oxidase complex. The protein is a dimer (human) of  $\alpha$  and  $\beta$  subunits. Examples:  $\alpha$ , database code C24A\_HUMAN, 194 amino acids (20.80 kDa);  $\beta$ , database code C24B\_HUMAN, 569 amino acids (65.13 kDa).

**cytochrome  $b_{599}$**  a cytochrome of photosystem II of photosynthesis. It exists as a dimer of  $\alpha$  and  $\beta$  chains. Examples (pea):  $\alpha$  chain, database code PSBE\_PEA, 82 amino acids (9.27 kDa);  $\beta$  chain, database code (identical in *Oenothera lamarckiana*), PSBF\_PEA, 39 amino acids (4.42 kDa). See photosystem.

**cytochrome  $c$**  a soluble mitochondrial matrix protein that associates with the inner mitochondrial membrane and functions to transfer electrons between respiratory chain complexes III and IV. Its structure has been extensively studied and the sequence from many (>60) species determined. Phylogenetic studies show that about 26 residues are completely invariant, especially those with side chains packing against the heme. The apoprotein is nucleus-encoded, synthesized on free ribosomes, and transported into the mitochondrial matrix, for which the action of heme lyase (holocytochrome-c synthase) is essential. Example (human and chimpanzee): database code CYTC\_HUMAN, 104 amino acids (11.60 kDa).

**cytochrome  $c$** , an inner mitochondrial membrane integral protein that is a component of respiratory chain complex III. Comprising 241 amino acids (bovine heart), and with a molecular mass of 27.94 kDa, it transfers electrons directly to cytochrome  $c$ . Under some conditions it co-purifies with the 'hinge protein' (9.2 kDa) and a small (7.2 kDa) subunit of unknown function.

**cytochrome  $c$  oxidase or cytochrome oxidase or cytochrome  $aa_3$**  EC 1.9.3.1; a copper-containing oxidoreductase enzyme that catalyses the oxidation of cytochrome  $c$  by dioxygen with the production of water. The reaction is:

It is an integral mitochondrial membrane protein comprising a complex of 13 subunits; subunits I, II, and III are encoded in the mitochondrion and the remaining ten are nucleus encoded. Electrons originating in cytochrome  $c$  are transferred via heme  $a$  and Cu(a) to the binuclear centre formed by heme  $a_3$  and Cu(b). Subunit I binds the two hemes and Cu(b): database code COXI\_HUMAN, 513 amino acids (56.97 kDa). Subunit II binds Cu(a) and cytochrome  $c$ : database code COX2\_HUMAN, 227 amino acids (25.53 kDa).

**cytochrome  $c$  reductase** see NADH dehydrogenase.

**cytochrome  $f$**  a cytochrome, designated after the Latin *frons* (leaf), that occurs in high concentration in leaves (up to 25% of the concentration of chlorophyll). It is a typical c-type cytochrome, similar to  $c_1$ , and is a component of thylakoid membrane, transferring electrons from photosystem II to I. Example, apocytochrome precursor (tobacco): database code CYF\_TOBAC, 320 amino acids (35.21 kDa). See also cytochrome  $b_6$ , cytochrome  $b_6-f$  complex.

**cytochrome  $m$**  an alternative name for cytochrome P450.

**cytochrome  $o$**  any b-type prokaryotic cytochrome containing protoheme as the prosthetic group that, unlike a typical cytochrome  $b$ , serves as a terminal electron acceptor (cytochrome oxidase) and is autoxidizable by dioxygen. Use of the term is discouraged.

**cytochrome P450 or (sometimes) cytochrome  $m$**  abbr.: (of protein) CYP, (of gene) CYP; any member of a group of b-type cytochromes that are apparently unique in having a sulfur atom ligated to the iron and that, when reduced, form carbon monoxide complexes – the latter are pigments with a major absorption peak (Soret band) near 450 nm hence the name. These cytochromes are enzymes, including unspecific monooxygenase (EC 1.14.14.1), camphor 5-monooxygenase (EC 1.15.15.1), alkane I-monooxygenase (EC 1.14.15.3), steroid 11 $\beta$ -monooxygenase (EC 1.14.15.4), cholesterol monooxygenase (side-chain-cleaving) (EC 1.14.15.6), prosta-

**cytocuprein**

cyclin synthase (EC 5.3.99.4), and thromboxane synthase (EC 5.3.99.5). They catalyse the reaction:

They occur in most animal cells and organelles, and in plants and microorganisms, and their chief function is thought to be the monooxygenation of lipophilic substances (RH can be steroid, fatty acid, or xenobiotics), as in the case of cytochrome P450<sub>SCC</sub>, cholesterol monooxygenase (side-chain-cleaving). In mammals, as liver microsomal enzymes, many are inducible by drug and other treatment e.g. the major phenobarbital-inducible cytochrome in rabbit liver microsomes, known as P450<sub>LM2</sub>. The name heme-thiolate (or Brit. haem-thioJate) protein has been proposed on the grounds of a thiolate ligand at the heme being responsible for the group's unusual spectral and catalytic properties.

A classification of this extensive family is being evolved in a new systematic nomenclature. At present, there are 27 families, of which 10 are found in all mammals. Each family consists of a group of proteins that exhibit 40% or greater sequence identity, and the family is described by an Arabic number. Within these families, subgroups of proteins having greater than 55% identity are classified into subfamilies, designated by a capital letter, and individual proteins within subfamilies are arbitrarily assigned numbers. Under this nomenclature, P450<sub>LM2</sub> is known as CYP2B4, or P4502B4, and the gene as *CYP2B4*. Example, P450 IA1, TCCD inducible, also P450 type 6, P450-C (human): database code CPII\_HUMAN, 512 amino acids (58.10 kDa).

**cytocuprein** *an alternative name for superoxide dismutase.*

**cytoflav(e) or cytoflavin** *a historical name for the yellow pigments* discovered in heart muscle and other tissues. In some cases these pigments were subsequently shown to be riboflavin or a flavin-containing enzyme, especially yellow enzyme.

**cytofluorometry** a technique for the detection, localization, and estimation of substances in or attached to cells, using naturally fluorescent substances or those to which a fluorescent label has been attached. The technique has many applications, including specific labelling of cells using fluorescent antibodies, using fluorescent probes to report intracellular events or membrane dynamics, or following the fate of a protein with a fluorescent label after injection into a cell.

**cytogenetics** the branch of genetics concerned with correlating inherited traits with cytological features, especially the appearance, structure, and behaviour of chromosomes. *-cytogenetic adj.*

**Cytohelicase** *the proprietary name for a commercial enzyme preparation consisting predominantly of a 1,3-p-O-glucanase.* It is useful for the isolation of protoplasts because it lyses cell walls.

**cytokeratin** *see keratin.*

**cytokine** any of a varied group of proteins that are released by mammalian cells and have autocrine or paracrine activity. They elicit from the target cell a variety of responses depending on the cytokine and target cell. Cytokine actions include control of cell proliferation and differentiation, regulation of immune responses, hemopoiesis, and inflammatory responses. Cytokines produced by lymphocytes are known also as lymphokines; those produced by monocytes are also called monokines. Other types of cytokine include chemokines, growth factors, colony stimulating factors, transforming growth factors, interferons, and tumour necrosis factors. *See angiogenin, colony stimulating factor, epidermal growth factor, erythropoietin, fibroblast growth factor, heparin-binding EGF-like growth factor, hepatocyte growth factor, interferon, insulin-like growth factor, interleukin, leukemia inhibitory factor, macrophage inflammatory protein, nerve growth factor, oncostatin M, platelet-derived endothelial growth factor, platelet-derived growth factor, RANTES, stem cell factor, transforming growth factor, tumour necrosis factor, vascular endothelial growth factor.*

**cytoplasmic membrane**

**cytokine receptor common V chain** a glycoprotein subunit common to the receptors for a variety of interleukins (IL-2, IL-4, IL-7, and IL-13). It is a type I membrane protein. Example (precursor) from *Mus musculus*: database code CYRG\_MOUSE, 369 amino acids (42.19 kDa).

**cytokinesis** 1 the changes that occur in the cytoplasm of a cell during nuclear division. 2 the division of the cytoplasm of a parent cell into daughter cells after nuclear division. *Compare karyokinesis.*

**cytokinin** or phytokinin any of a group of plant hormones that have a stimulatory effect on the division of plant cells and a retarding effect on leaf senescence. They are purine derivatives.

**cytolemma** *an alternative name for cell membrane.*

**cytology** the branch of science dealing with the origin, structure, function, biochemistry, and life history of cells. It includes the (microscopic) examination of cells, particularly in the detection and diagnosis of disease.

**cytolysin** any protein, especially an antibody, that can induce cytolysis.

**cytolysis** the breakdown of cells, especially by destruction of their outer membranes; the lysis of cells. *-cytolytic adj.*

**cytometer** 1 a cell counter. 2 a device for measuring cells.

**cytometry** the counting and/or measuring of cells in a fluid suspension.

**cyton** or **cytone** the body of a cell, especially a nerve cell, as distinct from its processes.

**cytopathic** damaging to cells.

**cytopathic effect** the morphological changes that cells may show in response to toxic agents or viruses.

**cytopempsis** the intracellular phase of transcytosis, whereby droplets, molecules, or particles are transported across a polarized cell from one surface to another.

**cytophilic** having an affinity for cells.

**cytophilic antibody** any antibody that binds to the surface of cells by means other than by combination of the antibody-combining site with antigenic determinants on the cell surface. Antibody thus fixed to a cell is still able to bind antigens in the vicinity; i.e. the cells become able specifically to absorb antigen.

**cytophotometry** a technique that employs a combination of microscopy and spectrophotometry for the detection, localization, and determination of substances in cells. It may be done on stained or unstained preparations.

**cytoplasm** all the protoplasm of a living cell excluding the nucleus and the plasma membrane but including the other intracellular organelles and structures. Some authors currently also exclude mitochondria, chloroplasts, or other structures containing independently replicating DNA. The term is not synonymous with cytoplasmic fraction. *See also cytosol, -cytoplasmic adj.*

**cytoplasmic droplet** a large (1-8 µm) piece of membrane-bound cytoplasm, containing the usual cytoplasmic organelles (but no nucleus) and one or more large lipid droplets, found in skimmed freshly secreted goat milk. The droplets are capable of triglyceride biosynthesis.

**cytoplasmic fraction** the material obtained after the removal of unbroken cells, cell debris, and nuclei from a homogenate of eukaryotic cells or tissue. It may be further resolved into a mitochondrial fraction, a microsomal fraction, and a soluble fraction. The term is not synonymous with cytoplasm. *See also cytosol.*

**cytoplasmic gene** any extranuclear gene located in certain eukaryotic cellular organelles, e.g. mitochondria and chloroplasts.

**cytoplasmic inheritance** the inheritance of characters or traits whose determinants are not located on a chromosome. The determinants may be, e.g., viral, mitochondrial, or on plasmids.

**cytoplasmic matrix** *an alternative name for groundplasm.*

**cytoplasmic membrane** 1 any of the membranous structures

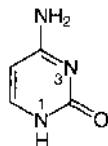

**cytoplasm**

within the cytoplasm of eukaryotes, such as the rough and smooth endoplasmic reticulum and the Golgi apparatus. *See also* microsomal fraction, microsome. 2 *an alternative term for cell membrane (especially in relation to bacteria).*

**cytoplasm** 1 an anuclear eukaryotic cell resulting, e.g., from treatment with cytochalasin B (*see* cytochalasin). 2 the apparent single structural and functional unit of the eukaryotic cell, consisting of the microtrabecular lattice linking the subcellular organelles and structural fibres.

**cytosegresome** *an alternative name for autophagic vacuole.*

**cytosine symbol:** Cyt; 4-amino-2-hydroxypyrimidine; 4-amino-2(1H)-pyrimidinone; a pyrimidine derivative that is one of the five main bases found in nucleic acids; it occurs widely in cytidine derivatives.

**β-cytosine arabinoside** *see* cytarabine.

+cytosis *suffix indicating an increase in the number of cells (in an indicated tissue or organ).*

**cytoskeleton** any of the various filamentous elements within the cytoplasm of eukaryotic cells that remain after treatment of the cells with mild detergent to remove membrane constituents and soluble components of the cytoplasm. The term embraces intermediate filaments, microfilaments, microtubules, and the microtrabecular lattice. The various elements of the cytoskeleton not only serve in the maintenance of cellular shape but also have roles in other cellular functions, including cellular movement, cell division, endocytosis, and movement of organelles. (*Note:* The term was coined to describe hypothetical structural cytoplasmic mosaics envisaged as providing physical support for, and thus spatial coordination of, enzymes effecting sequences of reactions, and as imposing restriction

**cytovillin**

of mobility of the cell. Subsequently the cytoskeleton was regarded also as a possible subcellular site of action of various hormones.) -cytoskeletal *adj.*

**cytosol** the part of the cytoplasm that does not appear to contain membranous or particulate subcellular components. The term is not synonymous with soluble fraction. -cytosolic *adj.*

**cytosol aminopeptidase** *another name for leucyl aminopeptidase.*

**cytosome** any cytoplasmic structure bounded by a single unit membrane and of dubious identity.

**cytostatic** any agent that suppresses cell growth and multiplication.

**cytotactin** *another name for tenascin.*

**cytotaxigen** any substance that acts indirectly to induce cytaxis by inducing cytotaxin formation. For instance, the fixing of complement by antigen-antibody complexes causes the liberation of cytotaxins, and hence cytaxis. -cytotaxigenic *adj.*

**cytotaxin** or (sometimes) chemotaxin any chemotactic substance acting directly to induce cytaxis. *See also* cytotaxigen.

**cytotoxicity** 1 positive or negative chemotaxis of motile cells in response to diffusible substances (cytotaxins) emitted by other cells. 2 the rearrangement of cells leading to the ordering and arranging of new structures. -cytotactic *adj.*

**cytotoxic** causing cell death.

**cytotoxicity** the attribute of being cytotoxic.

**cytotoxicity test** any test of cell viability after exposure of cells to (potentially) toxic agents, e.g. antibody and complement. Loss of viability may be demonstrated by a dye exclusion test.

**cytotoxic T-cell** any of a subset of T lymphocytes, bearing the CD8 (human) or Ly2 (mouse) surface marker, that have the ability to kill infected cells. This requires cooperation from T-helper cells. Each cytotoxic T-cell specifically recognizes one antigen, which must be associated with a syngeneic class I MHC molecule.

**cytropism** the mutual attraction of two or more cells. -cytropic *adj.*

**cytovillin** *another name for ezrin.*

# Dd

**d** symbol for 1 deci+ (SI prefix denoting  $10^{-1}$  times). 2 a deuteron. 3 day.

**d+** 1 abbr. for deoxy+ (def. 1); used as a prefix especially to form the symbol dRib for deoxyribose. 2 deoxy+ (def. 2); used as a prefix to form symbols for 2'-deoxyribonucleosides (e.g. dAdo or dA for deoxyadenosine) and abbreviations for 2'-deoxyribonucleotides (e.g. dGMP for deoxyguanosine monophosphate).

**d** symbol for 1 diameter, distance, or thickness. 2 relative density.

**d-** abbr. for dextro- used (formerly) as symbol denoting dextrorotatory; (+)- should now be used. See optical isomerism.

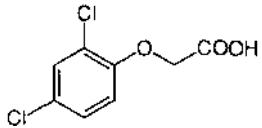

**D** symbol for 1 a residue of the α-amino acid L-aspartic acid. 2 a residue of an incompletely specified base in a nucleic-acid sequence that may be adenine, guanine, or either thymine (in DNA) or uracil (in RNA). 3 a residue of the ribonucleoside (5,6-)dihydrouridine. 4 debye. 5 deuterium (use deprecated).

**D600** gallopamil, 5-methoxyverapamil, a-(3-[(2-(3,4-dimethoxyphenyl)ethyl] methylamino)propyl]-3,4,5-trimethoxy-a-(1-methylethyl) benzeneacetonitrile; a drug used in the laboratory to block transport of calcium ions in biological membranes; it is more potent than verapamil.

**2,4-D** abbr. for 2,4-dichlorophenoxyacetic acid, a synthetic auxin used as a herbicide and to increase latex output from old rubber trees. When sprayed onto foliage at appropriate concentrations it kills broad-leaved plants but not grasses.

**D** symbol for 1 diffusion coefficient. 2 (decadic) attenuance. 3 absorbed dose. 3 (bond) dissociation energy. 4 dilution rate.

**D<sub>i</sub>** symbol for 1 electric polarization. 2 internal transmission density (formerly called optical density).

**D-** prefix denoting one of two possible absolute configurations around a chiral element in certain classes of compounds. See **DL** convention.

**da** symbol for deca+ (the SI prefix denoting 10 times).

**dA** a residue of the deoxynucleoside deoxyadenosine (alternative to dAdo).

**Da** symbol for dalton.

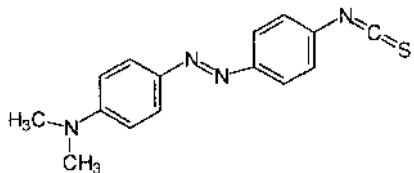

**DA** abbr. (sometimes) for dopamine.

**Dab** see **A<sub>2</sub>bu**.

**DAB** abbr. for diaminobutyric acid.

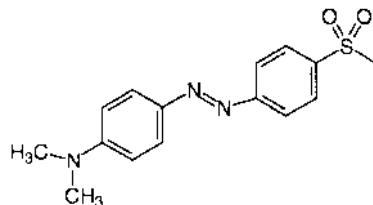

**DABA** abbr. for diaminobenzoic acid.

**DABITC** abbr. for dimethylaminobenzene isothiocyanate, 4-N,N-dimethylaminoazobenzene 4'-isothiocyanate; a sensitive and versatile chromophoric reagent used in sequencing polypeptides by the Edman degradation.

**dabsyl** abbr. for dimethylaminobenzenesulfonyl, 4-dimethyl-

aminobenzene-4'-sulfonyl; a group used as a chromophoric label for free amino groups in amino acids, peptides, and proteins. It is introduced by reaction with dabsyl chloride, 4-dimethylaminobenzene-4'-sulfonyl chloride.

**dAdo** symbol for a residue of the deoxynucleoside deoxyadenosine; 2'-deoxyribosyladenine; adenine 2'-deoxyriboside (alternative to dA).

**dAdo5'P** symbol for deoxyadenosine 5'-phosphate.

**DAF** abbr. for complement decay-accelerating factor.

**DAG** abbr. for diacylglycerol.

**DAHP** abbr. for 3-deoxy-D-arabino-(2-)heptulosonate 7-phosphate.

**dal** (sometimes) symbol for dalton (Da is usual).

**Dale**, (Sir) Henry Hallett (1875-1968), British physiologist and pharmacologist distinguished for his discovery of acetylcholine and for his fundamental physiological studies of the actions of acetylcholine, epinephrine, and histamine (see also Schultz-Dale reaction); Nobel Laureate in Physiology or Medicine (1936) jointly with O. Loewi 'for their discoveries relating to chemical transmission of nerve impulses'.

**Dale's principle** the principle that a given neuron is likely to release the same active substance from all its active terminals. Sometimes aggrandized into Dale's law - one neuron, one neurotransmitter - its only subsequent modification has been the recognition that a neuron may release more than one active substance. See cotransmitter.

**dalton** symbol: Da; a non-SI unit of atomic and molecular mass, equal to one-twelfth of the mass of the nuclide carbon-12. It is identical with the unified atomic mass unit. It is widely used in biochemistry. Sometimes it is used incorrectly as a supposed unit of the dimensionless terms relative atomic mass and relative molecular mass. [After John Dalton (1766-1844), British chemist and physicist.]

**Dalton's law of partial pressures** a statement that the total pressure of a mixture of gases is equal to the sum of the partial pressure of the constituent gases.

**Dalziel coefficient** any of the coefficients of an equation expressing the initial rate,  $\nu$ , of a sequential two-substrate enzymic reaction of the form:

$$\nu = EAB I [AB\phi_0 + B\phi_1 + A\phi_2 + \phi_{12}]$$

where  $E$  is the enzyme concentration,  $A$  and  $B$  are the substrate concentrations, and  $\phi_0, \phi_1, \phi_2$ , and  $\phi_{12}$  are the Dalziel coefficients. The method can be extended to the evaluation of the eight Dalziel coefficients needed to describe the rate of a three-substrate reaction. [After Keith Dalziel (1921-94), British biochemist.] Compare Michaelis kinetics.

**dam** a gene of *Escherichia coli* encoding DNA-adenine methylase. See DNA methylase.

**Dam**, Henrik Carl Peter (1895-1976), Danish biochemist noted for his discovery in green plants of an antihemorrhagic principle which he named vitamin K (later termed vitamin K<sub>1</sub> or phylloquinone); Nobel Laureate in Physiology or Medicine

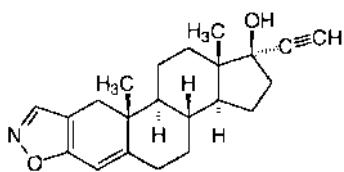

**damascenine**

(1943), for his discovery of vitamin K<sup>1</sup> [prize shared with E. A. Doisy].

**damascenine** 3-methoxy-2(methylamino) benzoic acid methyl ester; a protoalkaloid from the seeds of *Nigella damascena* (love-in-a-mist) and the odoriferous principle of the oil of nigella.

**dAMP** abbr. for deoxyadenosine monophosphate, the common name for 2'-deoxyadenosine 5'-phosphate; 2'-deoxy-5'-adenylic acid; adenine 2'-deoxyriboside 5'-phosphate.

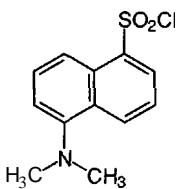

**danazol** 17a-pregna-2,4-dien-20-yneol[2,3-d]isoxazol-17fj-ol; a derivative of ethisterone that is an inhibitor of anterior pituitary function. It inhibits secretion of gonadotropins and synthesis of sex steroids and acts as a ligand for their receptors.

**Dane particle** see hepatitis.

**Danielli-Davson model** see Davson-Danielli model.

**danByl** symbol: Dns; abbr. for 5-dimethylaminonaphthalene-1-sulfonyl, a group used in extrinsic fluorescence studies of proteins. See also dansylate.

dimethylaminonaphthalene sulfonyl chloride

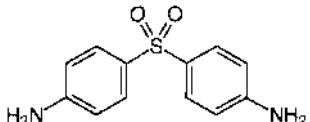

**dansylate** to derivatize with a dansyl group by reacting with dansyl chloride, 5(dimethylamino)naphth-1-ylsulfonyl chloride. The method is used to acylate free amino groups in protein end-group analysis. The dansyl amino acids, isolated after hydrolysis of the protein, are highly fluorescent and amounts as small as 1 nmol may be detected. **-dansylated adj.; dansylation n.**

**Danysz's effect or Danysz's phenomenon** the variation in the toxicity of toxin-antitoxin mixtures dependent on whether toxin is added to equivalence in one lot (nontoxic mixture produced) or in smaller lots over a time period (toxic mixture produced). When added in small lots the toxin reacts with more than one equivalent of antitoxin (antibody) so that insufficient antibody is left to neutralize all the subsequent lots of toxin. [After its discoverer, Jean Danysz (b. 1860), Polish pathologist working in Paris.]

**DAP** abbr. for diaminopimelate.

**DAP pathway** see diaminopimelic-acid pathway.

**dapsone** 4,4'-diaminodiphenyl sulfone; bis(4-aminophenyl)sulfone; an antibacterial and antiprotozoal substance used especially against *Mycobacterium leprae*, the causative agent of leprosy, and as an adjunct in the treatment of malaria. It acts as a competitive antagonist of p-aminobenzoic acid and an inhibitor of folate synthesis.

**Davson-Danielli model**

**dark adaptation** the process by which the rods of the retina gradually become fully responsive to dim light when no longer exposed to bright light. **-dark-adapted adj.**

**dark band** see light band.

**dark current** the electric current observed in any photoelectric device in the absence of incident radiation. It is caused by thermal effects.

**dark-field microscope or dark-ground microscope** a form of light microscope in which the specimen is illuminated by the apex of a hollow cone of light. On diverging, the light does not enter the aperture of the objective lens, so that unstained or transparent specimens appear as bright objects on a black background.

**dark reactions of photosynthesis** traditional term for the reactions of the reductive pentose phosphate cycle that utilize the ATP and NADPH produced by the light-driven reactions of photosynthesis. The term misleadingly indicates that these reactions occur in the dark. This is true only in the sense that, over very short time intervals, they can occur in the absence of light provided ATP and NADPH are present. However, they are subject to regulatory mechanisms that are stimulated by light, and inhibited by the dark. In growing plants, these reactions occur during daylight hours. The reactions of photosynthesis are used to convert CO<sub>2</sub> into hexoses and other organic compounds by the reactions of the reductive pentose phosphate cycle.

**dark reactivation or dark repair** any light-independent enzymic mechanism for the repair of damaged DNA molecules. Compare photoreactivation.

**DATD** abbr. for diallyltartardiamide, a cross-linking agent.

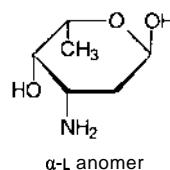

**ulative bond** an alternative term for dipolar bond.

**datP** abbr. for deoxyadenosine triphosphate, the common name for 2'-deoxyadenosine 5'-triphosphate, 2'-deoxy-5'-adenylyl diphosphate, adenine 2'-deoxyriboside 5'-triphosphate.

**daughter** (as modifier) 1 denoting a cell (or cell nucleus) produced by the fission of the original (mother) cell or nucleus. 2 denoting either of the two strands of DNA that originate from the parental duplex DNA molecule at replication. 3 denoting a nuclide produced by the nuclear disintegration (either spontaneous or induced) of another nuclide.

**daunomycin or daunorubicin** an anthracycline antibiotic and antineoplastic isolated from fermentation broths of *Streptomyces peucetius* widely used in the treatment of cancer. It is a glycoside formed from the tetracyclic aglycon daunomycinone (C21H18O5) and the aminohexose daunosamine. It inhibits DNA replication by intercalation into duplex DNA and also inhibits RNA transcription. Compare doxorubicin.

**daunosamine** 3-amino-2,3,6-trideoxy-L-lyxo-hexose; the aminodeoxy sugar component of adriamycin, daunomycin, doxorubicin, and other antibiotics.

α-L anomer

**Dausset, Jean Baptiste Gabriel Joachim** (1916- ), French physician and hematologist noted for first establishing the existence in humans of the major histocompatibility complex; Nobel Laureate in Physiology or Medicine (1980) jointly with B. Benacerraf and G. D. Snell 'for their discoveries concerning genetically determined structures on the cell surface that regulate immunological reactions'.

**Davson-Danielli model** or (sometimes) Danielli-Davson

model a structural model of the plasma membrane consisting, as originally proposed, of a lipid bilayer covered on both surfaces by a film of adsorbed globular proteins. Essentially it was a lamellar model: two sheets of protein separated by a sheet of lipid. The lipid layer had a hydrophobic core and more hydrophilic surfaces. To account for the permeability properties of the plasma membrane the model was subsequently modified by the proposal that pores allow polar solutes to penetrate the lipid layer, and that these pores are lined by protein molecules, providing hydrophilic tubes through the membrane. The model has been totally superseded by more recent concepts. *See* cell membrane. [After Hugh Davson (1909-96), British biochemist and physiologist and J. F. Danielli (1911-84), British biochemist.]

**day symbol:** d; a non-SI unit of time equal to 24 hours or 86400 s.

**dBCAMP** abbr. for dibutyryl cyclic AMP; N6,02'-dibutyryl-adenosine 3',5'-(cyclic)phosphate; a fat-soluble analogue of cyclic AMP, adenosine 3',5'-phosphate.

**DLB** a gene, isolated and named from a human diffuse B cell lymphoma, that encodes a protein of unknown function and is expressed tissue-specifically in brain, adrenals, and gonads. The protein has been found to catalyse guanine nucleotide exchange *in vitro* on the CDC42Hs protein, a human cell-division-cycle protein. Database code DLB\_HUMAN, 925 amino acids (107.66 kDa).

**DBM** abbr. for 2-diazobenzyloxymethyl,  $-\text{CH}_2\text{O}-\text{CH}_2\text{C}_6\text{H}_4\text{N}_2^+$ ; a group that introduces reactive diazonium groups into cellulose or paper forming DBM-cellulose or DBT-paper in blot transfer of proteins or nucleic acids. DBM is formed by diazotization of 2-aminobenzyloxymethyl (ABM) groups previously coupled to the support.

**DBMIB** abbr. for 2,5-dibromo-3-methyl-6-isopropyl-p-benzoquinone; a competitor of plastoquinone in photosynthetic electron flow.

**DBP** *see* vitamin D binding protein.

**d.c.** or **DC** abbr. for 1 direct current. 2 a voltage of constant polarity.

**dC** symbol for a residue of the deoxynucleoside deoxycytidine (alternative to dCyd).

**DCC** or **DCCD** or **DCCI** abbr. for N,N'-dicyclohexylcarbodiimide, a coupling agent useful in peptide synthesis and other coupling reactions. *See also* carbodiimide.

**DCCa** human gene, named from 'deleted in colonic carcinoma', that is considered to encode a tumour suppressor, characterized as a cell adhesion molecule of the immunoglobulin superfamily. Database code HSDCCG, 1447 amino acids (158.28 kDa).

**D cell** or (formerly) A) cell or  $\alpha_1$  cell a type of endocrine cell of the apud series, found in gut mucosa and the pancreatic islets. It was formerly thought to produce gastrin, but is now believed to produce somatostatin.

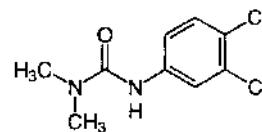

**dCMP** or **dCyd5'P** abbr. for deoxycytidine monophosphate, the common name for 2'-deoxycytidine 5'-phosphate; 2'-deoxy-5'-cytidylic acid; cytosine 2'-deoxyriboside 5'-phosphate.

**dCMP hydroxymethylase systematic name:** 5,10-methylenetetrahydrofolate:deoxycytidylate 5-hydroxymethyl transferase. EC 2.1.2.8; *other names:* deoxycytidylate hydroxymethylase; deoxycytidylate hydroxymethyltransferase; an enzyme that catalyses the reaction:

It is a gene product of T-even bacteriophage; the DNA of these phages contains glycosylated 5-hydroxymethylcytosine residues in place of cytosine residues. Example from T4 phage: database code DCHM\_BPT4, 246 amino acids (28.46 kDa); there is similarity to *Escherichia coli* thymidylate synthase.

**DCMU** abbr. for 3-(3,4-dichlorophenyl)-1,1-dimethylurea; a herbicide that blocks electron transport on the reducing side of photosystem II. One proprietary name is Diuron.

DCMU

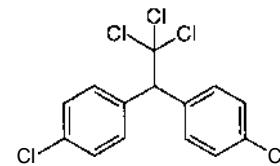

**Dco** symbol for the decanoyl group,  $\text{CH}_3\text{-[CH}_2\text{]}_8\text{-CO-}$ .  
**dCTP** abbr. for deoxycytidine triphosphate, the common name for 2'-deoxycytidine 5'-triphosphate, 2'-deoxy-5'-cytidyl diphosphate, cytosine 2'-deoxyriboside 5'-triphosphate.

**dCyd** symbol for a residue of the deoxynucleoside deoxycytidine; 2'-deoxyribosylcytosine; cytosine 2'-deoxyriboside (alternative to dC).

**dCyd5'P** symbol for deoxycytidine 5'-phosphate.

**dd+** abbr. for dideoxy+ (def. 2); 1 used as a prefix to the appropriate three-letter or one-letter symbols for ribonucleosides in order to form symbols for 2',3'-dideoxyribonucleosides (e.g. ddNuc or ddN, symbol for any (unknown or unspecified) 2',3'-dideoxyribonucleoside; ddAdo or ddA, symbol for dideoxyadenosine). 2 used similarly to form abbreviations for 2',3'-dideoxyribonucleoside 5'-triphosphates (e.g. ddNTP, abbr. for any (unknown or unspecified) 2',3'-dideoxyribonucleoside 5'-triphosphate; ddCTP, abbr. for dideoxyctidine triphosphate).

**DDT** abbr. and common name for dichlorodiphenyl-trichloroethane; 1,1,l-trichloro-2,2-bis(p-chlorophenyl)ethane; a contact insecticide that has proved particularly valuable in controlling insect disease vectors, especially mosquitoes (*Anopheles* spp.). However, it is toxic to higher animals as well. It has a very long persistence of activity from residual deposits which has caused it to be banned in many countries.

**de+** prefix (in organic chemical nomenclature) denoting replacement of a specified group or atom in a specified chemical compound by a hydrogen atom. An exception is deoxy+ when applied to hydroxy compounds, which denotes replacement of a hydroxyl group by a hydrogen atom. *See also* dehydro+, des+.  
**deacylase** informal name for any enzyme that catalyses a deacylation reaction; it may be a hydrolase or a transferase.  
**deacylation** the act or process of removing an acyl group from a chemical compound.

**DEAD box** a highly conserved motif in a family of putative RNA helicases, named after the single-letter code for the amino-acid sequence involved, i.e. Asp-Glu-Ala-Asp. The first DEAD-box protein that was shown to have RNA-helicase activity was the eukaryotic translational initiation factor eIF4-A. Other proteins have since been included in the family, based on sequence similarities; some have been shown to have ATP-dependent RNA-helicase activity, while in others this remains to be experimentally confirmed. *See also* DEAH family, Appendix E.

**dead-end complex** an alternative name for abortive complex.

**DEAE** abbr. for diethylaminoethyl,  $(\text{C}_2\text{H}_5)_2\text{N-CH}_2\text{-CH}_2^-$ , a weakly basic group widely used as a substituent in hydroxylated chromatographic support matrices, e.g. cellulose, Sephadex, to form anion exchangers. *Compare* QAE.

## de-aerate

de-aerate to remove air from a liquid or a slurry, commonly by heating and/or reduction of pressure.

**DEAH family yeast proteins** that are structurally similar to DEAD-box proteins, but larger. They differ from DEAD-box proteins in parts of the conserved region, especially in that they have a conserved DEAH sequence rather than DEAD. Some of them are known to be involved in RNA splicing, e.g. in trans-esterification steps and spliceosome release.

**deamidase** name sometimes used for an enzyme that catalyses the hydrolytic cleavage of the C-N bond in a carboxamide, but that is correctly termed an amidase.

**deamidation** the process of removing an amino group from an amide, either by hydrolysis or by a transfer reaction.

**deaminase** any of the enzymes that catalyse the nonoxidative removal of amino groups, with production of ammonia. They are usually aminohydrolase enzymes (sub-subclass EC 3.5.4), which hydrolytically deaminate amino-substituted cyclic amidines including various (free or combined) pterins, purines, or pyrimidines. Certain hydro-lyase (sub-subclass EC 4.2.1) and hydrolytic or nonhydrolytic ammonia-lyase (sub-subclass EC 4.3.1) enzymes also are commonly called deaminases.

**deamination** the process of removing an amino group from an organic compound. Compare transamination.

**deaminoxytocin** or demoxytocin a synthetic analogue of oxytocin, in which the N-terminal half-cystine residue has been replaced by a residue of 3-mercaptopropanoic acid. It is more potent than the parent compound.

**de-ashing** a procedure in which interfering inorganic (i.e., ash-forming) components are removed from samples of carbohydrates being analysed by liquid chromatography by passing them first through anion- and cation-exchange resins.

**death domain** a region of limited homology, consisting of about 80 residues close to the intracellular C terminus of certain cell-membrane receptors (e.g. the TNF receptor) that is essential for the receptors to generate a signal leading to apoptosis.

**deblock** to remove a blocking group. -deblocking n.

**debrancher deficiency** an alternative name for type III glycogen (storage) disease.

**debranching enzyme** any enzyme that catalyses the cleavage of branch points in particular branched biopolymers, e.g. isoamylase, oligo-1,6-glucosidase and pullulanase.

**debye symbol:** D; a non-SI unit of molecular dipole moment:  $ID \approx 3.335 \times 10^{-30} \text{ C m}$ .

**Debye**, Petrus ('Peter') Josephus Wilhelmus (1884-1966), Dutch-born US physicist and physical chemist; Nobel Laureate in Chemistry (1936) 'for his contributions to our knowledge of molecular structure through his investigations on dipole moments and on the diffraction of X-rays and electrons in gases'.

**Debye-Hückel theory** a theory used to calculate the electric potential at a point in a solution in terms of the concentrations and charges of the ions and the properties of the solvent. It yields the logarithm of the mean rational activity coefficient:

$$Igf+I^- = (AlzJzzl IIIZ)/(I + BaIIIZ),$$

where the constants A and B involve the temperature and the dielectric constant of the solvent,  $a$  is an adjustable 'ion-size' parameter,  $[I]$  is the ionic strength, and  $|Iz|zzl$  is the absolute value of the valence product of the electrolyte under consideration. [After P. J. W. Debye and Eric Huckel (1896-1980), German physicist.]

**dec+** see deca+ (def. 2).

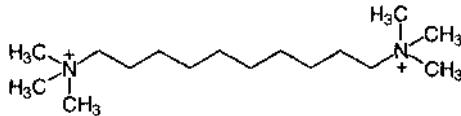

**Dec symbol** for the decyl group,  $\text{CH}_3\text{-}[\text{CH}_2]_8\text{-}\text{CH}_2^-$ .

**deca+** 1 symbol: da; the 51 prefix denoting 10 times. 2 or (before a vowel) dec+ comb. form denoting ten, tenfold, or ten times; formerly sometimes written as deka+ or dek+.

**decamethonium**  $N,N,N,N,N',N'$ -hexamethyl-1,10-decanediaminium a nicotinic receptor ligand that causes sustained activation of the receptors, with consequent blockade of

## dCTP deaminase

synaptic transmission (termed 'depolarizing block'). See also suxamethonium.

**decanoate** 1 the anion,  $\text{CH}_3\text{-}[\text{CH}_2]_8\text{-COO}^-$ , derived from decanoic acid (formerly capric acid). 2 any mixture of decanoic acid and the anion. 3 any salt or ester of decanoic acid.

**decanoyl symbol:** Dco; the univalent acyl group,  $\text{CH}_3\text{-}[\text{CH}_2]_8\text{-CO}-$ , derived from decanoic acid. See also caproyl (def. 1).

**decant** to pour off a supernatant liquid from a precipitate or other sediment. -decantation n.

**decap** to (enzymically) remove a cap (def. 1) from the 5' end of a capped mRNA molecule. -decapped adj.

**decapsidate** to remove the capsid from a virus. -decapsidation n.

**decarboxylase** any of the enzymes of the sub-subclass EC 4.1.1. carboxy-lyases; they catalyse the removal of carboxyl groups from carboxylic acids.

**decarboxylation** the act or process of removing the carboxyl group from a carboxylic acid as carbon dioxide. The reaction may be enzyme-catalysed by a decarboxylase or, in some instances, particularly with 2-oxo acids, it may be spontaneous. -decarboxylate vb; decarboxylated adj.

**decay** 1 a decrease in activity, force, quantity, or other physical attribute, especially with a characteristic time constant. 2 (a) nuclear decay: the spontaneous change of one nuclide into another, its daughter, with a different proton number or nucleon number. (b) radioactive decay: nuclear decay in which particulate or electromagnetic radiation (or both) is emitted, or in which spontaneous fission of the nucleus occurs. See also disintegration. 3 the decline of an atom or molecule from an excited state. 4 the biochemical decomposition of plant and animal remains, due chiefly to the activities of microorganisms. **decay accelerating factor** see complement decay-accelerating factor.

**decay constant** an alternative term for disintegration constant.

**deci+** 1 symbol: d; the 51 prefix denoting  $10^{-1}$  times. 2 comb. form denoting one tenth, one in ten.

**decimolar (informal)** one-tenth molar; i.e. denoting a solution of concentration  $0.1 \text{ mol dm}^{-3}$ .

**decinormal (informal; not now recommended)** one-tenth normal; i.e. denoting a solution of concentration 0.1 equivalents per litre (see normal (def. 2)).

**Declomycin** proprietary name for demeclocycline. See also tetracycline.

**decoding (informal)** an alternative term for translation (def. 1). **decontaminant** an agent for removing or neutralizing a contaminant.

**decontamination** the act or process of removing or neutralizing any toxic or potentially toxic materials, or of reducing their concentrations to nonhazardous levels. The term is used especially in regard to microbes, toxic chemicals, carcinogens, and radioactive substances. Compare contamination.

**decorin** or bone proteoglycan II precursor a collagen-binding protein of the extracellular matrix, so called because it 'decorates' collagen fibrils. The core protein has a single glycosaminoglycan chain, together with other oligosaccharide substituents. Example from human: database code H5R-NAFIB, 376 amino acids (43.10 kDa).

**decose** any aldose having a chain of ten carbon atoms in the molecule.

**dCTP deaminase** EC 3.5.4.13; systematic name: dCTP aminohydrolase; other name: deoxycytidine triphosphate deaminase.

## deculose

An enzyme that hydrolyses the amino group of dCTP to form dUTP and NH<sub>4</sub><sup>+</sup>. Example from *Escherichia coli*: database code DCD\_ECOLI, 193 amino acids (21.23 kDa).

deculose any ketose having a chain of ten carbon atoms in the molecule.

decyl symbol: Dec; the alkyl group, CH<sub>3</sub>-[CH<sub>2</sub>]<sub>8</sub>-CH<sub>2</sub>-, derived from decane.

n-decyl-j3-o-glucopyranoside a nonionic detergent, useful for solubilizing membrane proteins; CMC 2-3 mM.

n-decyl-13-o-maltopyranoside a nonionic detergent, useful for solubilizing membrane proteins; CMC 1.6 mM.

dedifferentiation the loss of the characteristics of a specialized cell and regression to a simpler state. -dedifferentiate vb. de Duve, Christian René Marie Joseph (1917- ), Belgian biochemist and cell biologist distinguished for his discoveries of the lysosome and the peroxisome and for studies of their properties in health and disease; Nobel Laureate in Physiology or Medicine (1974) jointly with A. Claude and G. E. Palade 'for their discoveries concerning the structural and functional organization of the cell'.

defective virus a virus that is unable to reproduce itself whilst infecting a cell without the presence of a helper virus.

defensin any of a family of small cationic peptides, containing six cysteines in disulfide linkage, that have broad-spectrum antibiotic action and contribute to host defence against microorganisms. They are abundant in phagocytes and small intestinal mucosa of humans and other mammals and in the hemolymph of insects. Defensins adopt multimeric pore-forming complexes in membranes, thereby rendering the membrane permeable. They are distinguished by a predominantly beta-sheet structure. Examples, p-defensin I from *Bos taurus*: database code BDOLBOVIN, 38 amino acids (4.28 kDa); hemolymph defensin from *Mytilus galloprovincialis*: database code DEFLMYTGA, 38 amino acids (4.27 kDa).

deficiency disease any disease resulting from the deficiency of one or more essential nutrients, e.g. a vitamin, an essential amino acid, or an essential mineral.

deficient lacking some essential component; inadequate in amount. The term can be used, e.g., for a deficient (culture) medium, deficient diet, or deficient strain (of an organism).

defined medium any culture medium in which the concentrations of all the constituents, including trace substances, are quantitatively known.

deformylase see fomnylmethionine deformylase.

degeneracy 1 (in a code) the existence of two or more synonyms specifying a particular item or function; *see also* degenerate code. 2 (in a quantized system) the existence of two or more linearly independent eigenfunctions with the same eigenvalue, especially the condition of an atom or molecule. 3 (of an atom or molecule) the condition in which the energy levels of different quantum states have the same energy level. -degenerate adj.

degenerate code a code in which more than one symbol represents the same entity. One such is the genetic code, wherein a specific amino acid may be encoded by two or more nucleotide triplets, or codons present in a nucleic acid or polynucleotide.

degeneration the process whereby a cell, tissue, or organ changes to a less specialized or functionally less active form.

degradation (in chemistry) 1 the gradual stepwise and deliberate conversion of a molecule into smaller chemical entities, commonly to elucidate its chemical structure. 2 any undesired breakdown of a molecule or material with impairment or loss of its characteristic properties. 3 depolymerization; decomposition. 4 (in biochemistry) catabolism.

degranulation 1 any process by which granular cells lose their granules. 2 the stripping of polysomes from rough endoplasmic reticulum *in vitro*.

degree *see* angle, temperature.

degree Celsius symbol: °C; the SI derived unit of Celsius temperature. It denotes the same interval of temperature as the kelvin on a scale with different reference points.

## 3-dehydroquinate dehydratase

degree of polymerization the number of monomeric units in the molecule of a polymer.

degrees of freedom 1 (*in statistics*) the number of unrestricted independent variables constituting a statistic; thus in a sample of *n* values of *x* there are *n* deviations (*x*; -  $\bar{x}$ ), where  $\bar{x}$  is the estimate of the mean, used in calculating the sample variance, *s*<sup>2</sup>, but they are not all independent, since there is a linear relation connecting them, namely:

$$\sum_{i=1}^n (x_i - \bar{x}) = 0$$

hence only (*n* - 1) of the quantities are independent, and there are (*n* - 1) degrees of freedom in the calculation of *s*<sup>2</sup>. 2 (*in physics*) the minimum number of parameters necessary to the description of the state of a system. 3 the number of independent equations by which the energy of a system may be expressed. 4 (*in chemistry*) the number of independently variable intensive properties that must be specified in order to describe completely the state of the system. *See* phase rule. de Hevesy *see* Hevesy.

dehydrase obsolete term for dehydratase or dehydrogenase.

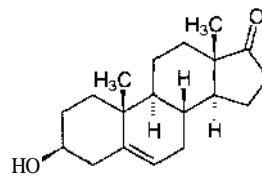

dehydratase or (formerly) dehydrase any hydro-lyase enzyme, of sub-subclass EC 4.2.1, that catalyses the (reversible) breakage of a carbon-oxygen bond leading to the formation of an unsaturated product and the elimination of water; e.g. citrate dehydratase, EC 4.2.1.4. When named after the alternative, i.e. unsaturated, substrate, the enzyme is termed a hydratase; e.g. aconitate hydratase, EC 4.2.1.3. *See also* carbonate dehydratase.

dehydration 1 the removal of combined, or adsorbed, water from a chemical compound; *see also* anhydrous. 2 the process or result of losing water, especially the abnormal loss of water from an organism. 3 the replacement of water by solvents.

dehydro+ prefix (*in chemical nomenclature*) denoting the loss of two hydrogen atoms. In common usage it is often used in place of dihydro+; e.g. 7,8-dihydrocholesterol is often termed dehydrocholesterol. *Distinguish from* anhydro+.

2-dehydro-3-deoxyphosphooctonate aldolase another name for 3-deoxy-D-manno-octulonic acid α-phosphate synthase.

dehydroepiandrosterone abbr.: DHEA; androstenolone, *trans*-dehydroandrosterone (abbr.: DHAS), 3β-hydroxy-androst-5-en-17-one; an intermediate in androgen and estrogen biosynthesis, formed from 17α-hydroxypregnolone in testis, ovary, and adrenal cortex by the action of 17α-hydroxyprogesterone aldolase, EC 4.1.2.30. It is the immediate precursor of androstenedione, which is formed from it by the action of 3β-hydroxy-Δ<sup>5</sup>-steroid dehydrogenase, EC 1.1.1.145 and it can be converted to androst-5-en-17-one 3β-sulfate (DHEA-S), in which form it is measured in plasma, there being about 1000 times more DHEA-S than DHEA in plasma.

dehydrogenase any donor:acceptor oxidoreductase enzyme, of the class EC I, when named after the alternative, i.e. more reduced, substrate and when dioxygen is not the acceptor.

dehydrogenate to oxidize an organic compound by the removal of one or more hydrogen atoms. -dehydrogenation n.

3-dehydroquinate dehydratase EC 4.2.1.10; systematic name: 3-dehydroquinate hydro-lyase; other name: 3-dehydroquinase; an enzyme that catalyses the reaction:

### 3-dehydroquinate synthase

The reaction forms part of the shikimate pathway. For example, *see* 8rol. *See also* pentafunctional arom polypeptide.

**3-dehydroquinate synthase** EC 4.6.1.3; an enzyme that catalyses the hydrolysis of 7-phospho-3-deoxy-arabino-heptulonate to 3-dehydroquinate and orthophosphate. *See* pentafunctional arom polypeptide; shikimate pathway.

(3-)dehydroretinal *an alternative name for* 3,4-didehydroretinal (not recommended, except for nutritional usage).

(3-ldehydroretinoic acid *an alternative name for* 3,4-didehydroretinoic acid (not recommended, except for nutritional usage).

(3-)dehydroretinol *an alternative name for* 3,4-didehydroretinol (not recommended except for nutritional usage).

deionize or deionise to remove all ions from a solution. - deionization or deionisation *n. See also* desalt.

deionizer or deioniser a device used to remove ions from solutions, usually by the use of ion exchangers.

**Deisenhofer, Johann** (1943- ), German-born US biochemist; Nobel Laureate in Chemistry (1988) jointly with R. Huber and H. Michel 'for the determination of the three-dimensional structure of a photosynthetic reaction centre'.

deka+ or (before a vowel) dek+*former spelling* of deca+ (def. 2). delayed early gene *see* early gene.

delayed hypersensitivity or type IV hypersensitivity (*in immunology*) a hypersensitivity reaction that arises more than a day after encounter with the antigen and is mediated by antigen-sensitized CD4+ T cells that release cytokines, attracting macrophages to the site and activating them. This type of hypersensitivity is seen in skin contact reactions and in response to some chronic pathogens such as those that cause leprosy, tuberculosis, and schistosomiasis. *Compare* immediate hypersensitivity.

**Delbriick, Max** (1906-81), German-born US physicist, molecular geneticist, and sensory physiologist; notable in particular for his development of the plaque technique for studying viruses and for his research on the interaction of bacteriophages with bacteria; Nobel Laureate in Physiology or Medicine (1969) jointly with A. D. Hershey and S. E. Luria 'for their discoveries concerning the replication mechanism and the genetic structure of viruses'.

deletion the loss of a segment of genetic material from a chromosome. A deletion can vary in size from a single nucleotide residue to a segment containing a number of genes. A terminal deletion occurs at one end of the chromosome, whereas an intercalary deletion occurs elsewhere along the chromosome.

delipidation the removal of lipid from sample.

deliquescent (*of certain salts*) tending to absorb water from the surrounding atmosphere at ordinary temperature and pressure and then to dissolve in the water so taken up. *Compare* hygroscopic. -deliquesce *vb.*; deliquescence *n.*

delocalization or delocalisation a quantum-mechanical concept implying that the unpaired electron density in a molecule is spread over several atoms. Analogously, delocalization of the spin of an unpaired electron can occur.

delta symbol:  $\delta$  (lower case) or  $\Delta$  (upper case); the fourth letter of the Greek alphabet. For uses *see* Appendix A.

deltahedron (*pl.* deltahedra) any polyhedron whose faces are all equilateral triangles. Some viruses disaggregate to form particles that are deltahedra. -deltahedral *adj.*

deltakephalin ( $\alpha$ -Thr<sup>2</sup>)-Leu-enkephalin-Tlu; a highly potent and specific synthetic hexapeptide  $\delta$ -opiate receptor agonist; structure Tyr- $\alpha$ -Thr-Gly-Phe-Leu-Thr. *See also* enkephalin.

delta-sleep-inducing peptide or sleep peptide a nonapeptide, Trp-Ala-Gly-Gly-Asp-Ala-Ser-Gly-Glu, found in the plasma of rats and rabbits, that shows a several-fold increase in concentration during sleep. It rapidly induces slow-wave (i.e. delta) sleep on injection into awake animals.

dematin a protein involved in the formation of actin bundles, abundantly expressed in brain, heart, skeletal muscle, kidney, and lung, whose activity is abolished upon phosphorylation by cAMP-dependent protein kinase. It is a member of the villin

density

family. Example from human: database code DEMA\_HUMAN, 383 amino acids (43.07 kDa).

demeclocycline 6-demethyl-7-chlorotetracycline; *see* tetracycline.

demethylation any reaction involving the removal of one or more methyl groups from a molecule, whether by oxidation or transfer to an acceptor molecule.

demineratization or demineratalisation 1 the process of removing inorganic salts, e.g. from water or other liquid; deionization. 2 excessive loss of mineral salts from the tissues, especially bone, as occurs in certain diseases.

demoxycytocin *an alternative name for* deaminooxytocin.

denaturation 1 (*of a protein*) a process in which the three-dimensional shape of a molecule is changed from its native state without rupture of peptide bonds. It is sometimes taken to include disulfide bond rupture or chemical modification of certain groups in the protein if these processes are also accompanied by changes in its overall three-dimensional structure. Denaturation is frequently irreversible and accompanied by loss of solubility (especially at the isoelectric point) and/or of biological activity. 2 (*of a nucleic acid*) a process whereby a molecule is converted from a firm, two-stranded, helical structure to a flexible, single-stranded structure. *Compare* renaturation.

denaturation loop a non-base-paired interstrand loop formed in the more thermally unstable regions (i.e., of high A+T content) of a duplex DNA molecule during melting (def. 3).

denaturation mapping the identification of regions of low thermal (or alkali) stability (i.e., of high A+T content) in a duplex DNA molecule, by trapping the partly melted structure and blocking renaturation, e.g. with formaldehyde (which preferentially couples with the amino groups of the single-stranded regions), and subsequently examining the specimen by electron microscopy.

dendrite a freely branching protoplasmic process of a nerve cell that transmits nerve impulses to the body of the cell and that communicates functionally with dendrites or bodies of other nerve cells.

dendrogram any branching treelike diagram that illustrates the relationships between organisms or objects.

**Denhardt's solution** a buffer, containing Ficoll, polyvinylpyrrolidine, and bovine serum albumin, that is used as a blocking reagent for hybridization with nitrocellulose filters. [After David Tilton Denhardt (1939- ), US biochemist.]

denitrification the reduction, especially by denitrifying bacteria, of simple inorganic nitrogen compounds, such as nitrates and nitrites, to gaseous products such as nitric oxide, nitrous oxide, and/or dinitrogen. *See also* nitrate reduction. *Compare* nitrification, nitrogen fixation (def. 1).

denitrifying bacterie soil bacteria that, in the absence of dioxygen, reduce nitrates and nitrites to gaseous products. *Compare* nitrifying bacteria.

de novo Latin anew, from the beginning; e.g. *de novo* synthesis.

densimeter *an alternative name for* densitometer (def. 2).

**densitometer** 1 or photodensitometer an apparatus for measuring the extent to which a material absorbs light (*see* absorptiometer (def. 1) or reflects light (*see* reflectometer). It is useful for scanning chromatograms or electrophoretograms, for determining the opacity of solutions or suspensions, or for measuring the blackening of photographic films. 2 or densimeter an instrument for measuring the mass density or relative density of liquids or gases. -densitometry *n.*; densitometric *ad.*

**density** 1 a or mass density symbol:  $P$ ; the mass of a substance per unit volume. b or linear density symbol:  $P_l$ ; the mass of a substance per unit length. c or surface density symbol:  $PA$  or  $Ps$ ; the mass of a substance per unit area. *Compare* relative density. 2 the distribution of a scalar physical quantity per unit area of space (e.g. radiant energy density) or per unit volume (e.g. charge density). 3 the distribution of a vector physical quan-

## density-gradient centrifugation

ity per unit area of space (e.g. electric current density, magnetic flux density). 4 optical density. *See* absorbance.

density-gradient centrifugation *see* isopycnic centrifugation.

density-gradient sedimentation equilibrium *see* isopycnic centrifugation.

density-marker bead any small coloured bead of accurately known mass density that is used for calibrating density gradients. Generally a set of several such beads, covering a range of densities, is used.

dentate having teeth or toothlike projections. *See also* multideterminate.

denticity the number of distinct but linked atoms of a specified ligand binding to the central atom in a coordination entity.

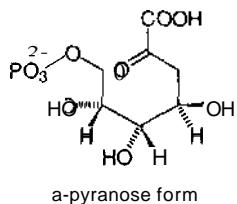

*Compare* ligancy.

dentine or dentin the hard, dense, calcified tissue of a tooth lying between the enamel and the pulp. It is 75% mineral, mainly hydroxyapatite.

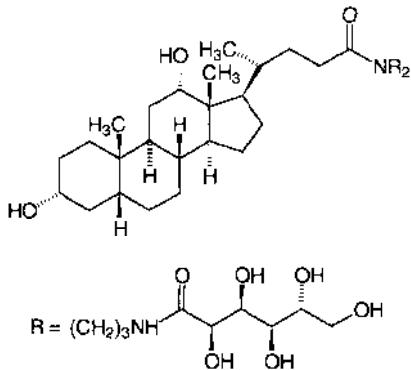

deoxy+ or (formerly) desoxy+ prefix (*in organic chemical nomenclature*) 1 denoting the replacement of a hydroxyl group by a hydrogen atom; *see also* de+. 2 (abbr.: d+) indicating the presence of one or more residues of 2-deoxy-D-ribose. *Compare* ribo+ (def. 2). 3 used especially with hemoglobin, to signify absence or removal of dioxygen. *Compare* oxy+.

5'-deoxy-5'-adenosylcobalamin or adenosylcobalamin *see* cobamide coenzyme.

3-deoxy-D-arabino-(2)-heptulosonate 7-phosphate or (*less formally*) 3-deoxy-D-arabino-heptulosonate 7-phosphate; abbr.: DAHP; an early intermediate in aromatic amino acid biosynthesis by the shikimate pathway in autotrophic organisms.

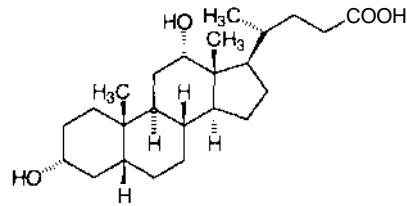

deoxy-BigCHAP N,N-bis-(3-O-glucuronamidopropyl)-(7-deoxy)-cholamide; a nonionic detergent analogue of CHAPS, CHAPSO, and BigCHAP; aggregation number 8-16; CMC 1.1-1.4 mM.

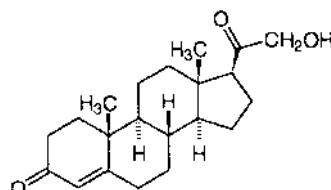

deoxycholic acid 3a,12a-dihydroxy-5p-cholan-24-oic acid; one of the bile acids occurring as its conjugate with glycine or taurine in the bile of most mammals, including dog, goat, human, ox, sheep, and rabbit. The sodium salt, sodium deoxycholate, is used as a detergent. Aggregation number 3-12; CMC 2-6 mM.

## deoxypolymeric tailing

deoxycholic acid

deoxycorticosterone abbr.: DOC; Kendall's desoxy compound B, Reichstein's substance Q, 21-hydroxyprogesterone, 21-hydroxypregn-4-ene-3,20-dione; a mineralocorticoid hormone with little glucocorticoid activity, synthesized by the adrenal gland. For clinical purposes it may be administered as its ester, deoxycorticosterone acetate (abbr.: doca or DOCA).

deoxycytidine deaminase *see* cytidine deaminase.

deoxycytidylate deaminase *an alternative name for* dCMP deaminase.

3-deoxy-D-manno-octulose-2-phosphate synthase EC 4.1.2.16; *recommended name:* 2-dehydro-3-deoxyphosphooctonate aldolase; *other name:* phospho-2-keto-3-deoxyoctonate (abbr.: phosphoKDO) aldolase; an enzyme that catalyses the formation of 3-deoxy-D-manno-octulose-2-phosphate from D-arabinose 5-phosphate and phosphoenolpyruvate with release of orthophosphate. It is the first step in the biosynthesis of the bacterial lipopolysaccharide, lipid A, and is required for cell growth. Example from *Escherichia coli*: database code KDSA\_ECOLI, 284 amino acids (30.80 kDa).

deoxynojirimycin an antibiotic produced by *Bacillus* species, the reduced form of nojirimycin; it inhibits formation of N-linked complex oligosaccharides in culture.

deoxynucleoside *an alternative name for* deoxyribonucleoside.

deoxynucleotide *an alternative name for* deoxyribonucleotide.

deoxynucleotidyltransferase EC 2.7.7.31; *recommended name:* DNA nucleotidyltransferase; *other names:* terminal addition enzyme; terminal transferase; terminal deoxyribonucleotidyltransferase. It is a Mg<sup>2+</sup>-dependent polymerase enzyme that extends the 3' end of a DNA strand one nucleotide at a time, independent of a template. It catalyses the reaction (if *n* nucleotides are added in all):

Example (bovine): database code TDT\_BOVIN, 520 amino acids (59.60 kDa).

deoxypentose any monosaccharide in which one alcoholic hydroxyl group of a pentose has been replaced by a hydrogen atom.

deoxypentose nucleic acid *former term for* deoxyribonucleic acid.

deoxypolymeric tailing extension of the 3' end of a strand of DNA, or of each strand of (a fragment of) duplex DNA, by a tail comprising a homooligomer or homopolymer of a deoxyribonucleotide. It is effected by the enzyme deoxynucleotidyl

## deoxyribonuclease

transferase. The process is useful for forming cohesive termini to DNA fragments in the preparation of recombinant DNA. *See* cohesive end.

**deoxyribonuclease abbr.:** DNase (*or sometimes* DNAse or DNAase); any enzyme within subclass EC 3.1, esterases, that catalyses the hydrolytic cleavage of phosphodiester linkages in DNA. If such an enzyme catalyses endonucleolysis (i.e. hydrolysis of nonterminal phosphodiester linkages) it is termed an endodeoxyribonuclease; if it catalyses exonucleolysis (i.e. hydrolysis of terminal linkages) it is termed an exodeoxyribonuclease. *See also* AP endonuclease, crossover point, deoxyribonuclease I, deoxyribonuclease II, deoxyribonuclease III, deoxyribonuclease IV (phage T4-induced), deoxyribonuclease V, deoxyribonuclease X, deoxyribonuclease KI, deoxyribonuclease (pyrimidine dimer), endonuclease, exodeoxyribonuclease I, exodeoxyribonuclease V, exodeoxyribonuclease VII, exodeoxyribonuclease (phage SP3-induced), *myt5*, restriction enzyme.

**deoxyribonuclease I** EC 3.1.21.1; *other names:* pancreatic DNase; DNase; thymonuclease. An enzyme that catalyses the endonucleolytic cleavage of DNA to 5'-phosphodinucleotide and 5'-phosphooligonucleotide end products. It shows a preference for double-stranded DNA. Example from *Bos taurus*: database code DRNLBOVIN, 260 amino acids (29.06 kDa). *See also* streptodornase.

**deoxyribonuclease II** EC 3.1.22.1; *other names:* DNase II; pancreatic DNase II. An enzyme that catalyses endonucleolytic cleavage of DNA to 3'-phosphomononucleotide and 3'-phosphooligonucleotide end products.

**deoxyribonuclease III** EC 3.1.11.2; *other name:* exonuclease III. An enzyme that catalyses exonucleolytic degradation of double-stranded DNA progressively in the 3'- to 5'-direction, releasing 5'-phosphomononucleotides. Example endodeoxyribonuclease III from *Escherichia coli*: database code EX3\_ECOLI, 268 amino acids (30.91 kDa); this enzyme is also the major AP endonuclease (i.e. an endonuclease) in *E. coli*.

**deoxyribonuclease IV** (phage T4-induced) EC 3.1.21.2; *other names:* endodeoxyribonuclease IV (phage T4-induced); endonuclease IV. An enzyme that catalyses endonucleolytic cleavage of DNA to 5'-phosphooligonucleotide end products. Example from *Bacillus subtilis*: database code END4\_BACSU, 297 amino acids (33.07 kDa).

**deoxyribonuclease V** EC 3.1.22.3; *other name:* endodeoxyribonuclease V. An enzyme that catalyses endonucleolytic cleavage at apurinic or apyrimidinic sites within DNA to yield products with a 3'-phosphate. It is involved in DNA repair. The enzyme from *Escherichia coli* consists of three subunits, RECB, RECC, and RECD, also known as the  $\beta$  chain,  $\gamma$  chain, and  $\alpha$  chain, respectively. Example,  $\alpha$  chain: database code EX5A\_ECOLI, 608 amino acids (66.96 kDa).

**deoxyribonuclease X** EC 3.1.22.5; an enzyme that catalyses endonucleolytic cleavage of supercoiled plasmid DNA to produce linear DNA duplexes.

**deoxyribonuclease K1** *or Aspergillus* deoxyribonuclease K1 EC 3.1.22.2; *other name:* *Aspergillus* DNase KI. An enzyme that catalyses endonucleolytic cleavage of DNA to 3'-phosphomononucleotide and 3'-phosphooligonucleotide end products.

**deoxyribonuclease (pyrimidine dimer)** EC 3.1.25.1; *other name:* endodeoxyribonuclease (pyrimidine dimer). An enzyme involved in DNA repair; it can induce single-strand breaks in DNA on the 5'-side of pyrimidine dimers in the strand containing the lesion, after formation of the dimers as a result of, e.g., ultraviolet radiation.

**deoxyribonuclease I abbr.:** DNA; any anionic form of deoxyribonucleic acid. 2 any salt of deoxyribonucleic acid.

**deoxyribonucleic acid former names:** desoxyribonucleic acid *or* thymonucleic acid; *also* deoxypentose nucleic acid *or* deoxyribose nucleic acid *or* desoxyribose nucleic acid *or* thymus nucleic acid. *See* DNA.

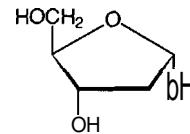

**deoxyribonucleoprotein abbr.:** DNP; any conjugated protein that contains DNA as the nonprotein moiety.

## depolarization ratio

deoxyribonucleoside *or* deoxynucleoside any nucleoside (def. I) in which the glycone moiety is 2-deoxy-p-D-ribofuranose. **deoxyribonucleoside monophosphate kinase** any of several enzymes within sub-subclass EC 2.7.4 that catalyse the transfer of a phosphoric residue from a nucleoside triphosphate to a deoxyribonucleoside monophosphate, e.g. from ATP to a deoxyribonucleoside phosphate to form ADP and a deoxyribonucleoside diphosphate.

**deoxyribonucleotide** *or* deoxynucleotide a deoxyribonucleoside in ester linkage to phosphate, commonly at the 5' position of its deoxyribose moiety. *See* nucleotide.

**deoxyribose 1 symbol:** dRib; *the trivial name for* 2-deoxyribose; 2-deoxy-erythro-pentose. The D-enantiomer, as 2-deoxy- $\beta$ -D-ribofuranose, forms the glycone moiety of all deoxyribonucleosides, deoxyribonucleotides, and deoxyribonucleic acids. 2 3-deoxyribose (*see* cordycepose).

2-deoxy-a-D-ribofuranose

**deoxyribose nucleic acid** *former name for* deoxyribonucleic acid.

**deoxyriboside** any glycoside or glycosylamine in which deoxyribose forms the glycone moiety, especially a deoxyribonucleoside.

**deoxyribosome** *see* nu body.

**deoxyribosylthymine** *an alternative name for* thymidine.

**deoxyribotide** any deoxyriboside esterified with phosphate at the 5' position on its ribose moiety, especially a deoxynucleotide.

**deoxyribovirus** *an alternative name for* DNA virus.

**deoxysaccharide** *or* deoxysugar any saccharide in which one alcoholic hydroxyl group has been replaced by a hydrogen atom.

**depactin** a protein isolated from starfish eggs, able to depolymerize F-actin and inhibit the extent of actin polymerization. It binds to actin monomers from filaments and in solution. Example from *Asterias amurensis*: database code DEPA\_ASTAM, 150 amino acids (17.21 kDa).

**dependent form of glycogen synthetase** the phosphorylated form of the enzyme glycogen synthetase that is 'dependent' for its activity on the presence of glucose 6-phosphate, a positive effector.

**dependent variable** any variable in a mathematical statement or equation whose value depends on the values taken by the related independent variables.

**dephospho-[reductase kinase] kinase** EC 2.7.1.110; *other name:* reductase kinase kinase; an enzyme that catalyses the phosphorylation of dephospho-[3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)] kinase by ATP with release of ADP. It is involved in the regulation of hydroxymethylglutaryl-CoA reductase (HMGCoA reductase). By phosphorylating reductase kinase, it activates that enzyme to phosphorylate HMGCoA reductase, thereby inactivating the latter.

**dephosphorylation** the process of removing one or more phosphoric (ester or anhydride) residues from a molecule.

**depolarization** *or* depolarisation 1 a reduction in the electric potential measured across a cell membrane, especially that brought about in a nerve or muscle cell by an electrical stimulus or a drug. 2 the decrease of the angle of polarization of polarized light so that it appears altered when viewed through an analyser. *See also* fluorescence depolarization.

**depolarization ratio** *or* depolarisation ratio (*in light scattering*) the ratio of the horizontally to the vertically polarized

**deproteinization**

components of the light scattered by scattering particles when illuminated by unpolarized light. If the scattering particles are isotropic the depolarization ratio will be zero; if they are anisotropic it will not be zero.

**deproteinization or deproteinisation** the process of removing protein from a biological sample, either by precipitation of protein from solution or by hydrolysis of protein with proteolytic enzymes.

**depside** any of a family of natural or artificial compounds derived from two or more molecules of various trihydroxybenzoic acids by esterification of a carboxyl group on one molecule with a hydroxyl group on another molecule (which may not be of the same structure as the first). By analogy with peptides, depsides derived from two, three, etc., or several trihydroxybenzoic acid units may be termed **didepside**, **tridepside**, etc., or **polydepside**, respectively. Depsides occur widely in lichens and also as components of some tannins.

**depsidone** any compound derived from two phenolcarboxylic acid molecules (which may not be the same molecules) that are joined together by both an ester and an ether link. Such substances are found in lichens.

**depsipeptide** any linear or macrocyclic compound containing (alternating) amino-acid and hydroxy-acid residues, linked by amide, N-methylamide, and ester bonds. Among the naturally occurring **cyclodepsipeptides** (sometimes alternatively termed peptolides) are the antibiotics **valinomycin**, the **enniatins**, and the monamycins.

**depurinate** to remove purine residues from a polynucleotide. -depurinated adj.; depurination n.

**depyrimidinate** to remove pyrimidine residues from a polynucleotide. -depyrimidinated adj.; depyrimidination n.

**derepression** the phenomenon in which a repressor is prevented from interacting with the operator component of an **operon** and an increase in the synthesis of a gene product thereby occurs. With an inducible enzyme, the inducer derepresses the operon. Derepression may also result from mutations, either in the **regulator(y) gene**, thus blocking repressor synthesis, or in the operator gene, thus rendering it insensitive to the repressor.

**deRib** (sometimes) symbol for 2-deoxy-D-ribose (dRib is the correct symbol).

**derivative** 1 any compound that may, at least theoretically, be formed from another compound to which it is structurally related. 2 see **derivative of a function**.

**derivative of a function** (in mathematics) the limit of the ratio of an increment of a dependent variable to the corresponding increment of an associated independent variable as the latter increment tends to zero.

**derivative or derivatise** to convert a chemical compound into a derivative. -derivation or derivatisation n.

**dermaseptin** any of a series of antimicrobial peptides derived from amphibian skin. Dermaseptins sl-5 constitute a family of cationic lysine-rich amphipathic antifungal peptides of 28–34 residues. Presumed to protect the naked frog skin from infections, they have wider application, being the first vertebrate peptides to show lethal effects against the filamentous fungi that can cause infections in immunodeficiency syndrome, or during the use of immunosuppressive agents. Compare **magainin**.

**dermatan sulfate or chondroitin sulfate B** any of a group of glycosaminoglycans with repeats consisting of  $\beta 1 \rightarrow 4$ -linked L-iduronyl-( $\beta 1 \rightarrow 3$ )-N-acetyl-D-galactosamine 4-sulfate units. They are important components of ground substance or intercellular cement of skin and some connective tissues (see **matrix** (def. 3)). They usually occur attached to proteins as proteoglycans, the mode of linkage being the same as for **chondroitin sulfate**. A hereditary deficiency in the ability to degrade dermatan sulfate characterizes certain types of **mucopolysaccharidoses**.

**dermis or corium** the thick layer of tissue forming part of the skin and lying beneath the epidermis. It consists of loose connective tissue in which are blood capillaries, smooth-muscle

**descriptive name**

fibres, sweat glands and sebaceous glands with their ducts, hair follicles, and sensory nerve endings. -dermal, dermic adj.

**dermorphin** any of a group of heptapeptide amides of the general structure H-Tyr-DAla-Phe-Gly-Tyr-Xaa-Ser-NH<sub>2</sub>, isolated from the skin of frogs of the genus *Phyllomedusa* and some other amphibians; they show high and long-lasting opiate-like activity.

**DES** abbr. for diethylstilbestrol.

**des+** prefix 1 (in the trivial name of a polycyclic compound, e.g. a steroid) indicating the removal of a terminal ring, with addition of a hydrogen atom at each junction arm with the adjacent ring; it should be followed by the italic capital letter designating the terminal ring in question, e.g. des-A-androstan. 2 (in the trivial name of a polypeptide) indicating the removal of an amino-acid residue, terminal or otherwise; it should be followed by the name or symbol for the amino acid in question and an arabic number indicating its position in the normal polypeptide, e.g. des-7-proline-oxytocin, or des-Pr<sup>0</sup>-oxytocin. 3 indicating the removal of a specified atom or group from a molecule of an indicated substance; see **des-amido+**, **desthio+**; see also **descarboxy-clotting factor**. 4 (formerly) a variant of de+(still preferred in some languages, e.g. French, German).

**desalinate** to remove salt, especially from seawater to render it suitable for drinking or irrigation. Compare **desalt**. -desalination n.

**desalt** to remove small, usually inorganic ions from a sample. Methods that may be used include electrodialysis, electrophoresis, gel filtration, and ion-exchange chromatography. See also **deionize**. Compare **desalinate**.

**desamidation** the hydrolysis of one or more carboxamide groups in a molecule to carboxyl groups.

**desamido+** prefix indicating **desamidation** of a molecule, especially of a peptide.

**desaturase** general name for any enzyme catalysing a desaturation reaction. The name specifically often refers to any of several fatty-acyl-CoA desaturases, enzymes coming within sub-subclass EC 1.14.99; in animals these are associated with the endoplasmic reticulum, require dioxygen, and insert double bonds into saturated and Z(i.e. cis)-unsaturated fatty acids. They also occur in higher plants, protozoa, and fungi. These enzymes are specific for position in the fatty-acyl chain, and are termed A5-desaturase, A9-desaturase, and so on, according to the distance from the carboxyl carbon atom to the first carbon atom of the double bond. In mammals, there is a lack of any desaturase that inserts a double bond nearer to the terminal methyl group of the fatty acid than nine carbon atoms, hence the need for *n*-3 and *n*-6 precursor fatty acids (the **essential fatty acids**). See also **linoleic family**, **linolenic family**.

**desaturation** 1 any process or reaction in which an organic compound becomes **unsaturated** (def. 2), e.g. by removal of two hydrogen atoms, or a hydrogen atom and a hydroxyl group, from adjacent carbon atoms. 2 any process in which ligands are removed from a macromolecule so that all the binding sites for that ligand are no longer occupied. -desaturate vb; desaturated adj.

**descarboxy-clotting factor** any of the abnormal blood clotting factors containing glutamic acid residues instead of  $\gamma$ -carboxyglutamic-acid residues. They are formed in animals deficient in vitamin K or during administration of vitamin K antagonists. Compare **PIVKA**.

**Descartes**, René (1596–1650), French philosopher and mathematician. See also **Cartesian**.

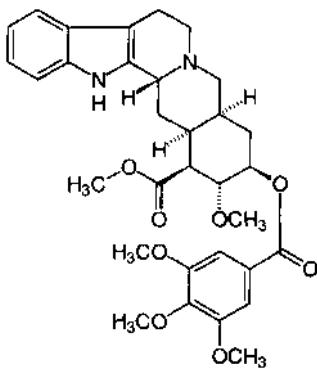

**descending chromatography** any chromatographic technique in which a liquid mobile phase runs downwards through the supporting matrix.

**descriptive name** name of an organic substance that is more descriptive of action or function and often more convenient than its **trivial name**, **semisystematic name**, **systematic name**, or other type of name permitted by the rules of chemical nomenclature.

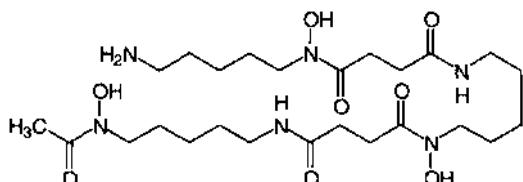

## desensitization

**desensitization** or desensitisation 1 a spontaneous decline in response resulting from continuous application of agonist, or to repeated applications or doses; such attenuation may result within minutes of prior stimulation, or may take hours to develop. It is recommended that this term be used where fade or tachyphylaxis are considered to involve the receptor itself, or to be a direct consequence of receptor activation. Homologous desensitization results from prior stimulation with the receptor's own agonist, whereas heterologous desensitization results from the activity of other agonists acting at other receptors. On the longer time scales, desensitization may result from receptor internalization in coated pits, and over shorter time scales from modification of the receptor in a way that uncouples it from signal transduction systems, e.g. by phosphorylation (see adrenergic receptor kinase). 2 the modification of an enzyme, either by mutation or chemically, so that it no longer responds to effectors but retains its catalytic activity. 3 the suppression of an established (immunological) hypersensitivity by injection of antigen, usually in very small doses. In delayed hypersensitivity the antigen reacts with sensitized cells, so neutralizing them. In immediate hypersensitivity the antigen either causes blocking antibody production (in atopy) or forms nontoxic complexes with existing antibodies (in anaphylaxis). -desensitize *vb.*; desensitized *adj.*

**deserpidine** desmethoxyreserpine, II-desmethoxy-O-(3,4,5-trimethoxybenzoyl)reserpine acid methyl ester; an alkaloid derived from roots of *Rauwolfia canescens* with pharmacological actions similar to the parent methoxy compound, reserpine.

**desferrioxamine** a siderophore of the hydroxamate type derived from *Streptomyces pilosus* that forms a chelate complex specifically with Fe(m) ions, yielding ferrioxamine. It is used parenterally to treat acute iron poisoning and to reverse iron and aluminium overload. Its natural function is to transport iron into the microbial cell and/or to make iron available for the synthesis of heme.

**desiccant** a substance such as CaCl<sub>2</sub> or P<sub>2</sub>O<sub>5</sub> that has a high affinity for water and is used to remove moisture from a gas or another substance; a drying agent.

**desiccate** to remove (most of) the water from a substance or

## desorb

material containing moisture, especially with the aid of a desiccant; to dry. -desiccation *n.*

**desiccator** an apparatus in which to effect desiccation.  
**desmin** or (formerly) skeletin a 50-55 kDa protein found in the Z disk of skeletal and cardiac muscle cells and in intermediate filaments in smooth muscle and non-muscle cells.

**desmo+** or (before a vowel) desm+ comb. form denoting ligament or bond.

**desmofibrin** a stabilized insoluble fibrin polymer formed from soluble fibrin polymer (see fibrin) in the final stage of blood coagulation by the action of factor XIII (fibrin-stabilizing factor) (see blood coagulation).

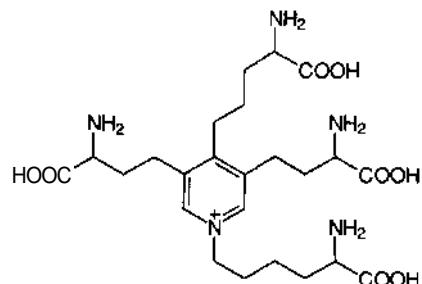

**desmoglein** a type I membrane protein of the mature desmosomal junction, involved in the interaction of plaque proteins and intermediate filaments mediating cell-cell adhesion. It contains cadherin-like repeats. Example (desmoglein I precursor) from human: database code DSGLHUMAN, 1049 amino acids (113.59 kDa).

**desmolase** former term for any enzyme that catalyses the formation or rupture of a carbon-carbon bond.

**desmoplakin** any of several intracellular desmosome proteins that are probably involved in attaching intermediate filaments (e.g. keratin filaments in epithelial cells, desmin filaments in heart cells) to the desmosome. Example, desmoplakin I from human foreskin: database code HUMDPI, 2832 amino acids (327.35 kDa). See also plakoglobin (for desmoplakin III).

**desmopressin** 1-(3-mercaptopropanoic acid)-8-D-arginine vasopressin, desamino-[8-D-arginine]vasopressin; a synthetic analogue of vasopressin with greater antidiuretic activity and less pressor activity than the parent compound.

**desmosine** 4-(4-amino-4-carboxybutyl)-L-(5-amino-5-carboxypentyl)-3,5-bis(3-amino-3-carboxypropyl)pyridinium; a tetra(a-amino acid) isolated from hydrolysates of the fibrous protein elastin. Desmosine and isodesmosine covalently cross-link two or more polypeptide strands in this protein, the postulated mode of formation of both compounds being condensation of two residues of allysine in one polypeptide chain with one allysine and one lysine residue in a second polypeptide chain.

**desmosome** or macula adherens a patchlike intercellular junction found in vertebrate tissue. It consists of parallel zones of two cell membranes, separated by an interspace of 25-35 nm and having dense fibrillar plaques in the subjacent cytoplasm. The interspace is continuous with the intercellular space and contains a dense, central plaque of material rich in protein. These proteins are known as linker proteins and consist of cell-cell adhesion molecules of the cadherin type. Desmosomes are important in cell-to-cell adhesion and are particularly numerous in stratified squamous epithelium that is subject to mechanical stress. A similar type of intercellular junction, the zona adherens, sometimes also referred to as a desmosome, encircles the cell like a belt. -desmosomal *adj.*

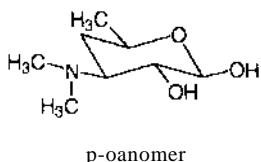

**desmotubule** see plasmodesma.

**desorb** to remove adsorbed substances from a surface.

-desorption *n.*; desorbed *adj.*

## desosamine

desosamine 3,4,6-trideoxy-3-(dimethylamino)-D-*xylo*-hexose; an aminodeoxy sugar component of several macrolide antibiotics, including erythromycins A, B, and C.

**desoxy**+ *an obsolete variant of deoxy+*.

**destain** to remove dye in excess of that required to stain specifically the material in question, e.g. in staining proteins in an electrophoretogram. -destaining *n.*

**destainer** any apparatus used for removing excess dye electrophoretically from stained gels.

**desthiobio**+ *prefix* indicating the replacement of a sulfur atom by two hydrogen atoms.

**destrin** an actin binding protein similar to cofilin with wide tissue distribution. It severs actin filaments and binds to actin monomers. Example from pig: database code DEST\_PIG, 165 amino acids (18.48 kDa).

**Desul'ovibrio** a genus of Gram-negative, obligately anaerobic, asporogenous, chemotrophic bacteria that obtain energy by anaerobic respiration using reducible inorganic sulfur compounds.

**detergent** 1 a cleansing agent, especially a soap or (usually synthetic) soaplike substance that, when used in aqueous solution, cleanses by reducing surface tension. 2 having the properties of a detergent. See also BigCHAP, Brij, C<sub>x</sub>E<sub>y</sub>, cetyltrimethylammonium bromide, CHAPS, CHAPSO, cholic acid, **n-decyl-β-D-glucopyranoside**, **n-decyl-β-D-maltopyranoside**, deoxy-BigCHAP, deoxycholic acid, digitonin, dodecylglucopyranoside, dodecylmaltoside, N-dimethylglycine, Genapol, glycocholate, glycodeloxycholate, heptyl glucoside, heptyl thioglucoside, hexyl glucoside, lauryldimethylamine oxide, sodium dodecylsulfate, Lubrol, Mega-B, nonyl glucoside, NP-40, octyl glucoside, octyl thioglucoside, taurocholate, taurodeoxycholate, Triton, Tween, Zwittergent.

**detergent gel electrophoresis** *an alternative name for SDS-polyacrylamide gel electrophoresis.*

**deteriosome** a microvesicle that is found in eukaryotic cells and is rich in phospholipase A<sub>2</sub> (*see* phospholipase). It is believed to represent a stage in membrane degradation.

**detoxication** or (*sometimes*) detoxification; the act or process of counteracting or rendering innocuous a poisonous substance. In an organism this involves various enzymic reactions by which harmful compounds, whether produced in the organism or introduced into it, are converted into (normally) less harmful substances and into more readily excretal products. Enzymic detoxication is brought about by chemical modification (frequently by oxidation) and/or conjugation with a normal metabolite. The enzymic process does not always result in a less toxic product and the term is sometimes restricted to those instances in which a less toxic product actually occurs, as distinct from intoxication. Enzymic detoxication may be divided into two phases. Phase 1 concerns metabolic transformation by a wide variety of oxidations, reductions, hydrolyses, etc., usually resulting in the introduction of functional groups that increase the polarity of the molecule and act as centres for phase 2 reactions. Phase 2 involves conjugation, in which the foreign compound itself or the compound resulting from phase 1 reactions is combined with endogenous substances, such as acetate, glucuronate, sulfate, or an amino acid, or is alkylated by introduction of methyl, or other groups, to form the more water-soluble ultimate excretory metabolite. See also lethal synthesis. -detoxicate *vb.*

## dextran

**detoxification** 1 the removal of poison. 2 (*sometimes*) detoxication.

**detoxify** 1 to remove a poison or the effect of a poison. 2 to bring about detoxication.

**deuterate** to combine or label with deuterium. -deuteration *n.*; deuterated *adj.*

**deuterium symbol:** 2H or (*deprecated*) D; a stable isotope of hydrogen, relative atomic mass 2.014, sometimes known as heavy hydrogen. Its relative abundance in natural hydrogen is 0.015 atom percent. It was much used as a tracer in studies of the chemistry and biochemistry of compounds containing non-labile hydrogen before the ready availability of tritium and carbon-14; its use continues in tracer experiments with detection by NMR spectroscopy, and where the use of radioactive compounds is contra-indicated. See also heavy water, protium, tritium.

**deuterium** (discharge) lamp a hydrogen (dischargellamp filled with dideuterium in place of dihydrogen; this substitution increases the intensity 3- to 5-fold for the same power consumption and extends the upper limit of the continuum further into the visible range.

**deutero**+ or (*before a vowel*) deuter+ *comb. form* 1 denoting that an indicated chemical compound or class of compound contains deuterium. 2 denoting second or secondary.

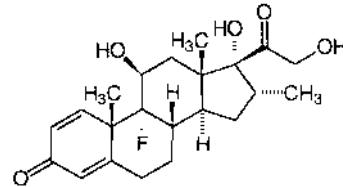

**deuteron** 1 *symbol:* zH<sup>+</sup>; the cation derived from an atom of deuterium. Compare hydron. 2 *symbol:* d; a particle of nucleon number two, having a charge equal and opposite to that of an electron and having a mass of 2.0136 dalton.

**develop** 1 to process an exposed photographic film with a developer in order to render the image visible. 2 to render visible the colourless substances on a chromatogram or electrophoretogram by treatment with a stain or chromogenic reagent. 3 to cause a solvent to flow through a chromatographic support in order to separate the components of an applied mixture. 4 (*of a cell, organ, or organism*) to undergo or cause to undergo a series of orderly changes whereby a mature state is attained. -development *n.*

**developer** 1 a solution of a reducing agent that renders visible the latent image on an exposed photographic film or paper by reducing to metallic silver those areas of silver halide that had been exposed to light. 2 a solution of a stain or chromogenic reagent used to render visible the colourless substances on a chromatogram or electrophoretogram.

**Dewar flask** or **Dewar** a double-walled vessel or flask, usually of silvered glass but sometimes of metal, in which the space between the walls is evacuated to prevent conduction and convection of heat between the inner and outer walls. It is used to maintain the contents at temperatures either higher or lower than that of the environment. [After its inventor Sir James Dewar (1842-1923), British chemist and physicist.]

**dexamethasone** 9a-fluoro-16a-methylprednisolone; a synthetic glucocorticoid with negligible mineralocorticoid activity that has actions similar to adrenal corticosteroids.

**dextr+** *see* dextro+.

**dextran** any glucan of very high relative molecular mass and consisting of linear chains of  $\alpha(1 \rightarrow 6)$ -linked D-glucose residues, often with  $\alpha(1 \rightarrow 2)$ - or  $\alpha(1 \rightarrow 3)$ -branches. Native dextran, produced by a number of species of bacteria of the family Lactobacillaceae, is a polydisperse mixture of components

**dextranosome**

of  $M_r < 10^3$  to  $> 10^7$ . Specific fractions of (partially hydrolysed) native dextran that have a narrow and well-defined size distribution may be designated by a numeric suffix equal to  $10^{-3} \times$  mass-average molar mass; e.g. Dextran T 500. Dextrans used in medicine are acid-degraded native dextrans.

**dextranosome** a lysosome loaded with dextran. It has higher than normal density.

**dextranucrase EC 2.4.1.5; systematic name:** sucrose: 1,6-a-o-glucan 6-a-o-glucosyltransferase; **other name:** sucrose 6-glucosyltransferase. An extracellular bacterial enzyme that catalyses the reaction:

*Streptococcus mutans* dextranases are of several types: dextranucrase S produces water-soluble glucans ( $\alpha(1 \rightarrow 6)$ -linked glucose); dextranucrase I produces water-insoluble glucans ( $\alpha(1 \rightarrow 3)$ -linked glucose and some  $\alpha(1 \rightarrow 6)$ -linkages); and dextranucrase SI produces both types; the sequences are related. Example dextranucrase SI precursor from *S. mutans*: database code GTFC\_STRMU, 1375 amino-acid residues (152.85 kDa); the first 24 residues are the signal. See also sucrase (def. 3).

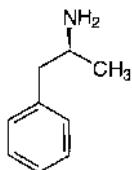

**dextrin** any of the poly-o-glucosides of intermediate chain length that are formed during the hydrolytic degradation of starch or glycogen by enzymes, acid, or heat. See also limit dextrin, Schardinger dextrin.

**$\alpha$ -dextrin** endo-1,6-a-glucosidase EC 3.2.1.41; **other names:** pullulanase; pullulan 6-glucanohydrolase; limit dextrinase; debranching enzyme; amylopectin 6-gluconohydrolase; the starch-debranching enzyme, which hydrolyses (1 $\rightarrow$ 6)- $\alpha$ -D-glucosidic linkages in pullulan and starch to form maltotriose. Example from *Klebsiella pneumoniae*: database code PULA\_KLEPN, 1090 amino acids (117.97 kDa).

**dextro-** symbol: *do*; a prefix, no longer used, to denote a compound that is dextrorotatory; the dextrorotatory enantiomer of compound A is now designated as (+)-A.

**dextro+** or (before a vowel) **dextr+** comb. form denoting on or towards the right. Compare levo+.

**dextroamphetamine** (S)-methylbenzeneethanamine; the potent (-)-stereoisomer of amphetamine. One proprietary name is Dexamphetamine.

**dextrorotatory** or (US) **dextrorotary** 1 symbol: (+)- or (formerly) *do*; describing a chemical compound that rotates the plane of polarization of a transmitted beam of plane-polarized light to the right, i.e. in a clockwise direction as viewed by an observer looking toward the light source. 2 describing any rightwards or clockwise rotation. Compare levorotatory. -dextrorotation *n*.

**dextrorphan** see levorphanol.

**dextrose** traditional name (still used in pharmacy) for o-glucose, D-(+)-glucopyranose, the dextrorotatory component of invert sugar. Compare levulose.

**DFP** abbr. for diisopropyl fluorophosphate.

**dG** symbol for a residue of the deoxynucleoside deoxyguanosine (alternative to dGuo).

**dGMP** abbr. for deoxyguanosine monophosphate, the common name for 2'-deoxyguanosine 5'-phosphate; 2'-deoxy-5'-guanylic acid; guanine 2'-deoxyriboside 5'-phosphate.

**diabetes mellitus**

**dGuo** symbol for a residue of the deoxynucleoside deoxyguanosine; 2'-deoxyribosylguanine; guanine 2'-deoxyriboside (alternative to dG).

**dGuo5'P** symbol for deoxyguanosine 5'-phosphate.

**dGTP** abbr. for deoxyguanosine triphosphate, the common name for 2'-deoxyguanosine 5'-triphosphate, 2'-deoxy-5'-guanylyl diphosphate, guanine 2'-deoxyriboside 5'-triphosphate.

**DH+** abbr. for dehydro+ or dihydro+ or dihydroxy+, sometimes prefixed to chemical names or alternatives. Its use is deprecated.

**DHAS** abbr. for *trans*-dehydroandrosterone, i.e. dehydroepiandrosterone.

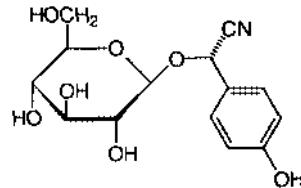

**DHEA** abbr. for dehydroepiandrosterone.

**DHFR** abbr. for dihydrofolate reductase.

**DHPR** abbr. for dihydropteridine reductase.

**DHU arm** abbr. for dihydrouridine arm of transfer RNA.

**dhurrin** L-p-hydroxymandelonitrile-p-D-glucopyranoside; a glucoside from the fruit of young *Sorghum vulgare*. See also amygdalin.

**di+** comb. form 1 (in chemical nomenclature) (distinguish from bis+ (def. 2)) a indicating the presence in a molecule of two identical unsubstituted groups, e.g. diethylsulfide, 1,3-dihydroxyacetone. b indicating the presence in a molecule of two identical inorganic oxoacid residues in anhydride linkage, e.g. adenosine 5'-diphosphate. 2 or bis+ (def. 1) denoting two, twofold, twice, doubled.

**diabetes** any clinical condition characterized by thirst and the passing of large volumes of dilute urine, especially diabetes mellitus. See also diabetes insipidus. -diabetic adj., n.

**diabetes-associated peptide** abbr.: DAP; another name for amylin.

**diabetes insipidus** a disease characterized by thirst and the excretion of large volumes of hypotonic (dilute) urine, caused by any lesion, nervous or endocrine, that interferes with the normal secretion of vasopressin by the posterior pituitary gland. See also nephrogenic diabetes insipidus.

**diabetes mellitus** or (commonly) diabetes a disorder in which the level of blood glucose is persistently above the normal range. Two main forms of the disease are generally recognized. Type 1 diabetes mellitus, the so-called juvenile type, often manifests itself in children and young adults. There is a marked failure to release insulin from the B cells of the islets of Langerhans in the pancreas, and frequently an almost complete absence of insulin in the B cells. The only effective treatment is administration of insulin, hence the frequent designation of this form as insulin-dependent diabetes mellitus (abbr.: IDDM). Type 1 diabetes mellitus is thought to arise in many patients from autoimmune attack on the B cells. Without insulin a severe ketoacidosis rapidly develops, with tissue wasting resulting from breakdown of muscle protein and hydrolysis of triacylglycerols in fat depots. Type 2 diabetes mellitus or maturity onset diabetes tends to manifest itself in adults, especially if obese, though the distinction between types 1 and 2 is blurred. In type 2 there may often be secretion of significant amounts of insulin, but for reasons not well understood these are not fully effective. There is by definition a failure to lower blood glucose adequately after a glucose tolerance test; patients of this type seldom develop severe ketoacidosis. Tolbutamide and re-

## diabetes mutation

lated sulfonylureas can be used to stimulate insulin release in type 2. In both types of diabetes mellitus there may develop serious complications, including neuropathy, retinopathy, atherosclerosis, peripheral vascular disease, and nephropathy. Type 2 diabetes mellitus is also referred to as non-insulin-dependent diabetes.

**diabetes mutation** a mutation first identified in mice that spontaneously develop diabetic symptoms. It appears to be a mutation in the leptin receptor gene.

**diabetic** a sufferer from diabetes.

**diabetogenic** causing or being caused by diabetes.

**diabetogenic hormone** *former term for somatotropin.*

**diabolic** a term suggested to categorize enzymes that appear to serve a complex or multiple metabolic function. *See also amphibolic.*

**diacylchitobiose** 4-O-(2-acetamido-2-deoxy-*D*-glucopyranosyl)-2-acetamido-2-deoxy-*O*-glucose; the repeating unit of chitin. *See also chitobiose.*

**diacetylmorphine** *other names:* diamorphine, heroin; a semi-synthetic narcotic analgesic derived from morphine by acetylation and used either as the free base or its hydrochloride. It has more potent analgesic activity than the parent compound but otherwise its actions are similar. Noted for its dependence-inducing actions and potential for abuse, it is a controlled substance under the US Code of Federal Regulations; import and manufacture of diacetylmorphine and its salts are forbidden in the USA and other countries. *See also codeine.*

**diacylglycerol** or (*formerly*) diglyceride any (1,2- or 1,3-) ester of glycerol and two fatty acids; the latter may be identical or different.

**diacylglycerol D-acyltransferase** EC 2.3.1.20; *other name:* diglyceride acyltransferase; an enzyme that catalyses the synthesis of triacylglycerol from acyl-CoA and 1,2-diacylglycerol with release of CoA.

**diacylglycerol cholinephosphotransferase** EC 2.7.8.2; *other names:* phosphorylcholine-glyceride transferase; alkylacylglycerol cholinephosphotransferase; 1-alkyl-2-acetylglycerol cholinephosphotransferase; an enzyme of the pathway for the *de novo* synthesis of phosphatidylcholines. It catalyses the formation of a phosphatidylcholine from CDPcholine and 1,2-diacylglycerol with release of CMP. Example from yeast: database code CPTLYEAST, 407 amino acids (46.25 kDa).

**diacylglycerol kinase** *abbr.:* DGK; EC 2.7.1.107; *systematic name:* ATP:1,2-diacylglycerol 3-phosphotransferase; *other name:* diglyceride kinase. An enzyme that catalyses the reaction between ATP and 1,2-diacylglycerol to form ADP and 1,2-diacyl-sn-glycerol 3-phosphate (phosphatidic acid). It plays an important part in the response of cells to agonists that stimulate the phosphatidylinositol cycle, being involved in the resynthesis of inositolphospholipids. The enzyme is stimulated by Ca<sup>2+</sup> and phosphorylated by protein kinase C; it is an EF-hand protein. Example from human: database code KDGL\_HUMAN: 735 amino acids (82.49 kDa).

**diacytosis** the process of transporting material across a cell, especially an epithelial cell, by pinocytosis at one surface, movement of the pinocytic vesicle across the cell, and exocytosis of its contents at another part of the cell surface.

**diafiltration** the process of separating microsolutes, e.g. salts, from a solution of larger molecules (or of exchanging them for different microsolutes) by ultrafiltration with continuous addition of solvent (or of a solution of the new microsolutes). This rapidly removes the original microsolutes from the solution, whose volume remains constant.

**diagonal chromatography** a two-dimensional chromatographic technique used to determine the sensitivity of a constituent of a mixture to some (photo)chemical process, e.g. oxidation. The sample is chromatographed in one direction, the process carried out *in situ*, and the specimen is then rechromatographed at right angles. Compounds unmodified by the treatment all lie on a diagonal line across the chromatogram.

## diamagnetism

**diagonal electrophoresis** a two-dimensional electrophoretic technique for determining the position of disulfide bonds in a polypeptide. The polypeptide is partially hydrolysed and the resulting smaller peptides separated by paper electrophoresis in one direction. After treatment on the paper with performic acid vapour, they are subjected to a second electrophoresis step at right angles. Those peptides not falling on a diagonal line on the paper contain cysteic acid residues formed by the oxidation of disulfide groups.

**diakinesis** the final phase of prophase I in meiosis.

**dialdose** any monosaccharide derivative containing two (potential) aldehydic carbonyl groups. *Compare aldose, diketose.*

**diallyltartardiamide** *abbr.:* DATD; *N,N'*-diallyl-L-tartramide, [CH(OH)-CO-NH-CH<sub>2</sub>-CH=CH<sub>2</sub>]Z; a compound sometimes used as a cross-linking agent in the preparation of polyacrylamide gels for electrophoresis or related separative procedures. Its structure contains a 1,2-diol grouping, which is susceptible to periodate oxidation. Such gels may thereby be solubilized after use to facilitate recovery of separated substances.

**dialysable** or (*esp. US*) dialyzable capable of being purified or separated by dialysis. The term has been used also, variously, to describe material that either can or cannot traverse a dialysis membrane. Some authorities prefer the term diffusible for material that can traverse a dialysis membrane. *See also dialysate.*

**dialysate** or (*esp. US*) dialyzate the solution resulting from dialysis that is free from colloidal material, i.e. free from material unable to pass through a dialysis membrane; the opposite of retentate. In the past the term has been used confusingly to describe both the material retained by the membrane and the material that has passed through a membrane. Some authorities prefer the term diffusate for the resulting colloid-free material and the term analysis residue for the retentate. *See also dialysable.*

**dialyser** or (*esp. US*) dialyzer an apparatus consisting of two or more compartments separated by dialysis membranes, in which to carry out dialysis.

**dialysis** a process in which solute molecules are exchanged between two liquids through a membrane in response to differences in chemical potentials between the liquids. It is used especially for separating macromolecules (colloids) in solution from smaller dissolved substances (crystalloids) by selective diffusion through a semipermeable membrane, which allows the passage of all components of the system except the macromolecules. *See also diafiltration, diasysis, electrodecantation, electrodialysis, equilibrium dialysis, reverse dialysis, thin-film dialysis, ultrafiltration.* [From Greek *dialusis*, a separation or dissolution.] -dialyse or (*esp. US*) dialyze vb.; dialytic adj.; dialytically adv.

**dialysis bag** the significant component of a simple dialyser, commonly made from a convenient length of dialysis tubing by knotting or tying off one or both ends. When filled with the colloidal solution to be dialysed it is immersed or suspended in an appropriate colloid-free aqueous medium.

**dialysis cell** any small device for use as a dialyser.

**dialysis membrane** any semipermeable membrane suitable for dialysis, often made of cellulose acetate, cellulose nitrate, or regenerated cellulose. It may be fashioned into flat sheets or into continuous tubing. Most dialysis membranes are permeable to molecules of up to 12-14 kDa.

**dialysis residue** *an alternative name for retentate.*

**dialysis tubing** seamless tubular dialysis membrane.

**diamagnetic pair** a diamagnetic dimer produced by spin coupling of two paramagnetic (molecular or atomic) species.

**diamagnetism** the property displayed by substances that have a very small negative magnetic susceptibility, due to the changes induced in the orbital motions of atomic electrons by an applied external magnetic field; such changes generate a magnetic field in opposition to the applied field. Whereas such a phenomenon occurs in all substances it is often masked by

## diamine

the opposing and stronger effects of ferromagnetism or paramagnetism. -diamagnetic *adj.*

diamine any compound containing two amino groups or substituted amino groups.

diamine oxidase *see* amine oxidase (copper-containing).

diamino+ prefix (*in chemical nomenclature*) indicating the presence of two (unsubstituted or substituted) amino groups.

diamino acid any organic acid, usually an alcanoic acid, that contains two (unsubstituted or substituted) amino groups.

di(*a*-amino acid) any compound whose molecules may be derived from two (identical or differing) molecules of  $\alpha$ -aminoalkanoic acid however they are linked. The term includes (but is not limited to) any dipeptide.

diaminobenzoic acid *abbr.*: DABA; 3,5-diaminobenzoic acid; a compound that gives fluorescent products when heated in mineral acid solution with aldehydes. It is used for the microfluorimetric determination of DNA (as it does not react with RNA) and in the analysis of sialic acid.

diaminobutyric acid *symbol*: A<sub>2</sub>bu; *abbr.*: Dab; *a,y*-diaminobutyric acid; 2,4-diaminobutanoic acid; a diamino acid not occurring in proteins. The L enantiomer is sometimes found replacing meso-diaminopimelic acid in peptidoglycan of bacterial cell walls and several residues per molecule are present in the peptide antibiotics of the polymyxin group (together with one residue of the D enantiomer in polymyxin B<sub>1</sub>). It also occurs in higher plants as a nonprotein amino acid.

diaminocaproic acid *see* lysine.

2,7-diaminofluorene a dye used in the chromogenic assay of peroxidases. It replaces benzidine, which was formerly used but is now known to be carcinogenic.

diaminopimelic acid *symbol*: A<sub>2</sub>pm or Dpm; *abbr.*: DAP;  $\alpha,\epsilon$ -diaminopimelic acid, 2,6-diaminoheptanedioic acid; a  $\alpha,\epsilon$ -diaminodicarboxylic acid with two chiral centres. *meso*-Diaminopimelic acid is the stereoisomer occurring in peptidoglycan in the cell walls of *Escherichia coli* and all other Gram-negative bacteria. *See also* diaminopimelic-acid pathway.

diaminopimelic-acid pathway or DAP pathway a metabolic pathway for the synthesis of L-lysine from L-aspartic acid via  $\alpha,\epsilon$ -diaminopimelate. Found in bacteria, some lower fungi, and green plants, it involves an initial condensation between pyruvate and aspart-4-al, yielding, following dehydration, 2,3-dihydriodicollinate. This substance is then reduced; ring opening occurs followed by succinylation to form *a*-(succinyl-amino)-*e*-oxo-L-aminopimelic acid. Transamination, deacylation, and epimerization yield the corresponding *meso-a,e*-diaminopimelic acid; then decarboxylation completes the overall synthesis of L-lysine. *Compare* aminoacidic pathway.

diamorphine *see* diacetylmorphine.

diaphorase name formerly applied indiscriminately to any enzyme capable of catalysing the oxidation of either NADH or NADPH in the presence of an electron acceptor such as a dye (e.g. Methylene Blue, or 2,6-dichlorophenolindophenol), ferricyanide, a quinone, or a cytochrome but not dioxygen. *Also formerly known as coenzyme factor.*

diaphragm 1 (*in chemistry*) a semipermeable membrane, or porous plate, used to separate two solutions in dialysis or osmosis. 2 (*in anatomy*) any separating membrane, especially the thin, domed fibromuscular partition separating the thorax from the abdomen. Flattening of the diaphragm, accompanied by expansion of the rib cage, causes air to be sucked into the lungs. 3 (*in optics*) any device, sometimes adjustable (e.g. iris diaphragm), that can limit or vary the aperture of a lens or optical system. 4 any other thin dividing membrane.

diarylpropane peroxidase *see* ligninase.

diasolysis a membrane permeation process for the separation of organophilic from hydrophilic solutes, akin to dialysis but differing in that separation depends primarily on the relative solubilities of the solutes in the membrane rather than on their molecular dimensions. Such a process may play a part in the selective passage of solutes through membranes of living cells.

## diauxy

diastase 1 *obsolete name for* a-amylase (EC 3.2.1.1). 2 the crude mixture of amylases obtained commercially as a yellowish white amorphous powder from malt. (From Greek *diastasis*, a separation.) -diastatic *adj.*

diastatic activity the enzymic activity of a-amylase.

diastereoisomer or diastereomer any stereoisomer that is not enantiomeric; it may be either chiral or achiral. The term includes *cis-trans* isomer, configurational isomer, conformational isomer, and epimer. -diastereoisomeric or diastereomeric *adj.*; diastereoisomerism or diastereomerism *n.*

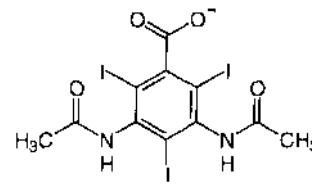

diastereotopic 1 chemically-like ligands in constitutionally equivalent locations that are not symmetry related (cannot be interchanged by rotation about an axis (C<sub>N</sub>) or alternating axis (S<sub>n</sub>) of symmetry) are diastereotopic; the two ligands are in a stereochemically different, nonmirror-image environment. Separate replacement of each ligand by a different achiralligand yields two products that are in a diastereoisomeric relationship. Example: replacement of the H<sub>R</sub> hydrogen of the methylene group in (R)-CH<sub>3</sub>-CH<sub>2</sub>-CHBr-CH<sub>3</sub> with chlorine yields (2R,3R)-2-bromo-3-chlorobutane; the similar replacement of the H<sub>S</sub> hydrogen yields the diastereoisomeric (2R,3S)-2-bromo-3-chlorobutane. A biochemically important example is that both of the methylene groups of citric acid have diastereotopic hydrogens. 2 the two faces of a double bond or of a planar cyclic ring system that are not related by any symmetry operation (axis, plane, centre, or alternating axis) are diastereotopic; the two faces show stereochemical difference, nonmirror-image environments. Separate addition of an achiral reagent to each face yields two diastereoisomeric products. Example: hydrogenation of the C=O bond in (3S)-CH<sub>3</sub>-CH<sub>2</sub>-CH(CH<sub>3</sub>)-CO-COOH (in absence of any chiral influence such as a chiral catalyst) yields the two diastereoisomers, (2R,3S)-2-hydroxy-3-methylpentanoic acid and (2S,3S)-2-hydroxy-3-methylpentanoic acid. A biochemical example is the two diastereotopic faces, A and B, of the (dihydro)pyridine ring of nicotinamide-adenine coenzymes (*see* nicotinamide-adenine dinucleotide (reduced)). *Compare* enantiotopic.

diastole 1 the passive dilatation of the chambers of the heart that occurs between the rhythmical contractions. 2 the rhythmical expansion of a pulsating vacuole. *Compare* systole. -diastolic *adj.*

diatomaceous earth or kieselguhr a friable, whitish material consisting mostly of silica, derived from diatomite, a rock consisting largely of the remains of diatoms. It is used as a filter aid and as an absorbent in column chromatography. *See also* Berkefeld filter.

diatomic (*of a molecular entity*) composed of only two atoms. -diatomicity *n.*

diatrizoato the anion 3,5-diacetamido-2,4,6-triiodobenzoate. Its sodium salt forms solutions of low viscosity and high relative density. A mixture with Ficoll provides a solution having the optimal density and osmolarity for the rapid, one-step isolation of lymphocytes from small volumes of blood by centrifugation. It is also used as a radiopaque material.

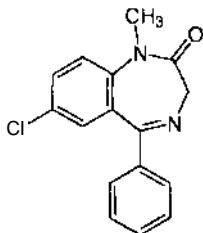

diauxy the adaptation of microorganisms to culture media containing two different carbohydrates. Growth occurs in two phases separated by a period of less rapid or zero growth. In the first phase, the organism utilizes the carbohydrate for which it possesses constitutive enzymes. During the interlude

## diazepam

the organism synthesizes the required induced enzymes for the metabolism of the other carbohydrate, which it then proceeds to exploit in the second growth phase. *-diauxic adj.*

**diazepam** 7-chloro-1,3-dihydro-1-methyl-5-phenyl-2H-1,4-benzodiazepin-2-one; one of the most widely used benzodiazepine drugs, noted for its CNS depressant effects. Used as an anti-anxiety-hypnotic agent at subsedative doses, its actions are similar to those of chlordiazepoxide, but it has greater potency. One proprietary name is Valium.

**diazepam binding inhibitor** a 10 kDa 86-residue polypeptide, that acts as an endogenous ligand for a mitochondrial receptor (formerly regarded as a peripheral benzodiazepine binding site) in steroidogenic cells (i.e. adrenocortical, glial, and Leydig cells) and regulates stimulation of steroidogenesis by tropic hormones. It also binds to the benzodiazepine binding site on the GABA<sub>A</sub> receptor and modulates glucose-dependent insulin secretion and synthesis of acyl-CoA esters.

**diazo compound** any organic compound, other than an azo compound, that contains the bivalent  $\text{--}\ddot{\text{N}}\equiv\text{N}\text{--}$  (or  $=\text{N}_2$ ) in covalent linkage. It may be (1) any aliphatic compound of general formula  $\text{R}-\text{CH}=\text{N}_2$ , in which both nitrogen atoms are linked to the same carbon atom by replacing two hydrogen atoms of the parent molecule, e.g. diazomethane,  $\text{CH}_2=\text{N}_2$ ; or (2) any aromatic compound of general formula  $\text{Ar}-\text{N}=\text{N}-\text{X}$  in which one nitrogen atom is linked to a carbon atom of the aromatic ring by replacing one hydrogen atom of the parent molecule, and the other nitrogen atom is linked covalently to a group X through an atom other than carbon (except when X = CN), e.g. benzenediazohydroxide,  $\text{C}_6\text{H}_5\text{N}=\text{N}-\text{OH}$ .

**diazonium compound** any aromatic organic compound of general formula  $\text{Ar-N}_Z^+$ , containing the univalent cationic diazonium group,  $-\text{N}^+\equiv\text{N}$ , linked to a carbon atom of an aromatic ring system by replacing one hydrogen atom of the parent molecule. The positive charge is balanced by an anion to form a diazonium salt, e.g. benzenediazonium chloride,  $\text{C}_6\text{H}_5\text{N}_Z^+\text{Cl}^-$ .

**diazotize** or **diazotise** to cause a primary aromatic amine to form a diazonium compound by reaction with nitrous acid in the presence of a strong acid, according to the equation:

*-diazotized adj.; diazotization n.*

**dibasic cleavage site** a site within a proprotein structure at which endopeptidases act specifically to cleave the protein to one or more active polypeptides. It comprises a connected pair of basic amino-acid residues (Arg-Arg, Arg-Lys, Lys-Arg, or Lys-Lys). The cleavage is effected by a family of cellular endoproteases. These have catalytic domains related to subtilisin and go under the general name mammalian prohormone convertases (PCs). Examples are **kex2**, first described in yeast, PC2 in human insulinoma, PC3, and furin. Dibasic cleavage sites occur e.g. in proinsulin, proopiomelanocortin, and chromogranins.

**dibenzazepine** any of a group of compounds with a tricyclic structure related to phenothiazines that prevent the neuronal reuptake of norepinephrine or 5-hydroxytryptamine from the

## dictyosome

synaptic cleft, and are useful as drugs in the treatment of depression, e.g. imipramine, clomipramine.

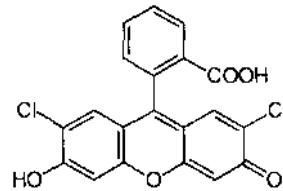

**dibenzocycloheptene** any of a group of agents that prevent neuronal reuptake of norepinephrine and 5-hydroxytryptamine from the synaptic cleft and are useful as drugs in the treatment of depression, e.g. amitriptyline.

**dicarboxylate transport protein** *former name for oxoglutarate/malate carrier protein.*

**dicarboxylic acid** any organic compound containing two carboxyl groups.

**dicaryon** *a variant spelling of dikaryon.*

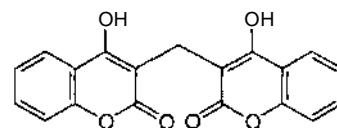

**2',7'-dichlorofluorescein** a dye useful as a detection reagent for lipids, yielding fluorescent spots on chromatograms under UV light.

**dichroic ratio** the ratio of the absorbance of light polarized perpendicularly to the axis of a nonisotropic sample (e.g. the fibre axis of a protein or nucleic-acid molecule or one axis of a crystal) to the absorbance of light polarized parallel to the sample axis. If the dichroic ratio is greater than unity, the vibrational transition observed is said to exhibit perpendicular dichroism; if less than unity, it is said to show parallel dichroism.

**dichroism** 1 the directional effect observed in the absorption of electromagnetic radiation resulting from the relative orientations of the absorbing chromophore and the direction of the electric vector in the polarized electromagnetic radiation. Thus the absorption of such radiation may be restricted only to atoms or groups that vibrate in a specific direction or to a component of the radiation that is polarized in a specific direction. See circular dichroism, dichroic ratio, electric dichroism. 2 concentration- and path-length-dependent changes in the frequencies of electromagnetic radiation absorbed by solutions of certain substances. *-dichroic adj.*

**dicoumarol** or **dicumerol** or *(esp. US)* dicumarol (*formerly bishydroxycoumarin*); 3,3'-methylenebis(4-hydroxycoumarin), 3,3'-methylenebis(4-hydroxy-2H-1-benzopyran-2-one); a substance originally isolated from spoiled sweet clover but now synthetic, that prevents the normal formation of prothrombin and other blood coagulation factors. It interferes with the action of vitamin K in  $\gamma$ -carboxylation of certain glutamic residues in the precursors of the coagulation proteins. It is used therapeutically as an anticoagulant, and is also used as a rodenticide. Warfarin is one of the coumarins.

dicoumarol

**dictyosome** 1 or **golgiosome** *an alternative name for Golgi apparatus, especially in cells of invertebrates and plants; there are usually several scattered dictyosomes per cell.* 2 a collar-like

***Dictyostelium discoideum***

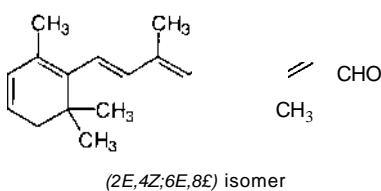

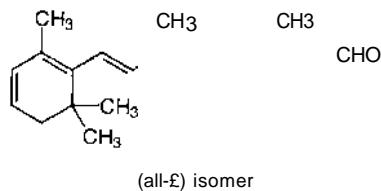

structure that may form an anchor for the base of the flagellum in uniflagellate fungi.

***Dictyostelium discoideum*** a cellular **slime mould**. It exists in the vegetative form as unicellular, haploid **myxamoebae**, 8–12 µm maximum dimension, using bacteria as food. In the absence of bacteria, chemotactic aggregation of myxamoebae occurs, mediated by myxamoebal secretion of acrasin (i.e., cyclic AMP), to form an elongated, finger-like, multicellular **pseudoplasmodium**, 1–4 mm maximum dimension. Aggregation is assisted by the synthesis of a multivalent carbohydrate-binding lectin, **discoidin**, found in the outer membrane of starved cells. The pseudoplasmodium differentiates to form a single, unbranched stalk, the sorocarp, which carries a spheroidal or ovoid mass of yellow spores, each commonly 5–10 µm x 3–6 µm with a thick cellulose-containing wall. Germination of spores only occurs in the presence of an adequate supply of amino acids.

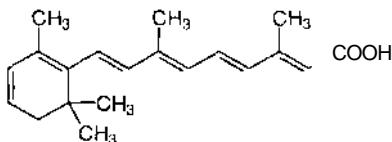

**dicyclohexylcarbodiimide** see **DCC**. See also **carbodiimide**.

**didehydro+** prefix (in chemical nomenclature) denoting the loss of two hydrogen atoms. See also **dehydرو**.

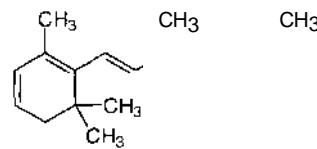

**3,4-didehydroretinal** recommended trivial name for (3-)dehydroretinal; (3-)dehydroretinaldehyde; retinalz; vitamin A<sub>z</sub> aldehyde; retinenez; (2E,4E,6E,8E)-3,7-dimethyl-9-(2,6,6-trimethylcyclohex-I,3-dien-I-yl)nona-2,4,6,8-tetraen-1-al; the didehydro derivative of **retinal** (def. 2). This all-E-isomer, 3,4-didehydro-all-trans-retinal, often termed *all-trans*-retinalz, plays a role in the visual process in freshwater fish and some amphibians analogous to that of *all-trans*-retinal in other vertebrates; see **retinal** (def. 2). Its isomerization product, the (2E,4Z,6E,8E)-stereoisomer, generally termed *ll-cis*-retinalz, combines (as a **Schiff base**) with an opsin to form (in cone cells) **cyanopsin** or (in rod cells) **porphyropsin**. Note: The numbering system of the systematic name is different from that of the trivial name, the latter following the rules used for carotenoids.

**3,4-didehydroretinoic acid** recommended trivial name for (3-)dehydroretinoic acid; vitamin A<sub>z</sub> acid; (2E,4E,6E,8E)-3,7-dimethyl-9-(2,6,6-trimethylcyclohex-I,3-dien-I-yl)nona-2,4,6,8-tetraenoic acid; the didehydro derivative of **retinoic acid**.

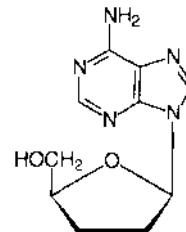

**dideoxyinosine**

**3,4-didehydroretinol** recommended trivial name for (3-)dehydroretinol; retinolz; vitamin A<sub>z</sub>; vitamin A<sub>z</sub> alcohol; (2E,4E,6E,8E)-3,7-dimethyl-9-(2,6,6-trimethylcyclohex-I,3-dien-I-yl)nona-2,4,6,8-tetraen-I-ol; the didehydro derivative of **retinol**, being characterized by a second double bond in the terminal ring of the molecule. It is the predominant form of vitamin A in freshwater fishes. See also **vitamin A**.

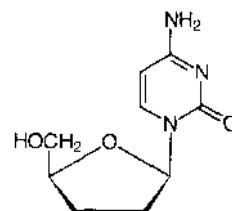

**dideoxy+** prefix (in organic chemical nomenclature) 1 denoting the replacement of two hydroxyl groups by two hydrogen atoms. 2 (abbr.: dd+) indicating the presence in a nucleoside of a residue of 2,3-dideoXY-D-ribose.

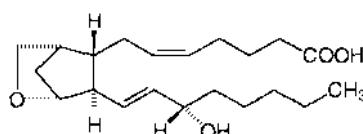

**dideoxyadenosine** symbol: ddAdo or ddA; abbr.: DDA; 2',3'-dideoxyadenosine; an adenosine analogue with antiviral activity.

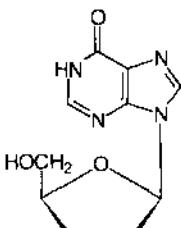

**dideoxycytidine** symbol: ddCyd or ddC; abbr.: DDC; 2',3'-dideoxycytidine; a cytidine analogue with antiviral activity.

**9,11-dideoxy-9a,11a-epoxymethanoprostaglandin F<sub>2α</sub>** U46619; a stable **thromboxane A<sub>2</sub>** mimetic.

**dideoxyinosine** symbol: ddIno or dDI; abbr.: DDI; 2',3'-dideoxyinosine; an **inosine** analogue with antiviral activity.

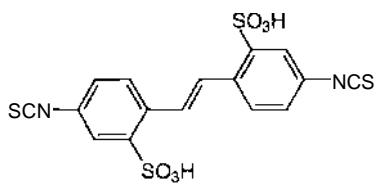

dideoxyinosine

**dideoxy method** or **dideoxy(nucleotide)** sequencing analysis *an alternative name for* chain-termination method (for sequencing DNA molecules).

**dideoxynucleoside triphosphate** *abbr.:* ddNTP; any artificial nucleoside triphosphate in which both of the hydroxyl groups on C-2' and C-3' of the pentose moiety have been replaced by hydrogen atoms. They are used in sequencing DNA molecules by the chain-termination method.

**DIDS** *abbr. for* 4,4'-diisothiocyanato-2,2'-disulfonic acid stilbene; a powerful anion-transport inhibitor

**didymium glass** a glass with a bluish-pink coloration due to the inclusion of a mixture of rare-earth elements, chiefly neodymium and praseodymium. It has intense, narrow, light-absorption bands, and is used for calibrating spectrometers. An example is a glass known as Corning 5120, which has absorption bands at 441,528.7, 585, 684.8, 743.5, 754, 808, 883, and 1067 nm.

**dielectric** 1 a substance or medium that can sustain an electric field but does not conduct electricity; an insulator. 2 of, relating to, or being a dielectric.

**dielectric absorption** the strong absorption of microwave electric fields shown by polar liquids, particularly water. It is especially troublesome in electron spin resonance spectroscopy.

**dielectric constant** *an obsolete term for* relative permittivity.

**dielectric dispersion** variation of the relative permittivity with the frequency of the applied electric field.

**dielectric increment** the change in the relative permittivity of a solution with the change in the concentration of the solute. For low concentrations of solute in polar solvents, the dielectric increment,  $\delta D/\delta c$ , is equal to  $(D - D_0)/c$ , where  $D$  and  $D_0$  are the relative permittivities of the solution and solvent, respectively, and  $c$  is the solute concentration.

**dielectrophoresis** the translational motion of neutral suspended particles relative to that of the suspending medium when the suspension is subjected to a nonuniform electric field. The movement is the result of polarization induced in the particles, the degree of which is dependent on the ratio of the relative permittivities (*formerly dielectric constants*) of particles and medium. In positive dielectrophoresis (that most commonly observed), movement of the particles is towards the region of highest field intensity, irrespective of its sign (*compare electrophoresis*). Negative dielectrophoresis may be observed in certain frequencies when an alternating field is used, the particles then being attracted less than the medium to the region of most intense field; at such frequencies the polariz-

ability of the particles is not greater than that of the medium. Dielectrophoresis is used, e.g., in the concentration of certain biological products, the characterization of single-celled organisms or cellular organelles by their characteristic yield spectrum (i.e. yield vs. field frequency), and the determination of the diffusion coefficients of proteins in solution.

**diene** any alkadiene or substituted alkadiene.

**+diene(+)** or (*before a vowel*) **+dien+** (*in chemical nomenclature*) infix or suffix in systematic names denoting the presence in a molecular structure of an unsaturated aliphatic hydrocarbon chain containing two (conjugated or unconjugated) double bonds. The position of each double bond may be indicated by a locant for its lowest-numbered carbon atom; e.g. cyclohexa-1,3-diene, eicosa-8,11-dienoic acid.

**dienoic** indicating a compound having an aliphatic chain with two double bonds and a carboxyl group.

**dienoyl** general name for any acyl group derived from an unsaturated fatty acid containing two (conjugated or unconjugated) double bonds.

**2,4-dienoyl-CoA reductase** (NADPH) EC 1.3.1.34; *systematic name:* trans-2,3-didehydroacyl-CoA:NADP+ 4-oxido-reductase; *other name:* 4-enoyl-CoA reductase (NADPH). An enzyme of the pathway for oxidation of unsaturated fatty acids that catalyses the reduction by NADPH of *trans, trans*-2,3,4,5-tetrahydroacyl-CoA to *trans-2,3-didehydroacyl-CoA*, a normal substrate of  $\beta$  oxidation. For the bacterial enzyme, this is a direct product of the enzyme, but for the mammalian enzyme the product is *trans-3,4-didehydroacyl-CoA*, which must undergo isomerization to *trans-2,3-didehydroacyl-CoA*. Example from rat liver: database code RATDCR, 335 amino acids (36.16 kDa). See also unsaturated fatty acid oxidation.

**diesterase** see phosphodiesterase.

**dietary deficiency** a nutritional deficiency due to inadequate intake of one or more specific and necessary constituents of the diet, even though the diet may in other respects be adequate quantitatively.

**diethyl ether** see ether.

**diethylstilbestrol** or (*esp. UK*) diethylstibestrol 4,4'-(1,2-diethyl-1,2-ethenediyi)biphenol; a nonsteroidal compound that possesses the activity of an estrogen. It is used therapeutically to replace natural hormones, and was formerly used as a growth promoter in livestock (this use is now prohibited in many countries, including the UK and USA). It was originally used for the treatment of prostatic cancer.

**difference spectrophotometry** a spectrophotometric method for investigating the effects of potential perturbants on a chemical substance or system in solution. Two samples are prepared containing identical solutions except that one contains a potential perturbant, e.g. a protein denaturant. The absorbances of the two samples at each frequency are subtracted one from another generating a difference spectrum and thereby highlighting any small differences between the spectra of the normal and perturbed systems.

**differential centrifugation** centrifugation of a suspension in a succession of increasing gravitational fields so that particles of differing sizes and/or relative densities may be separated and collected.

**differential counting** counting of the pulses produced in a scintillation counter that fall within two or more differing energy ranges selected for with a pulse-height analyser. The technique is used for counting the disintegrations due to two or more radionuclides in the same sample.

**differential labelling** a method of determining the part of a molecule that reacts in a particular way by blocking one part with a specific reagent and investigating whether a particular reaction will still occur. It is used, e.g., for investigating the combining sites of antibodies.

**differential medium** any medium used for growing micro-organisms that reveals specific properties of the organism(s)

## differential scanning calorimetry

grown and hence aids in identification of the organism(s). *See also* selective medium.

**differential scanning calorimetry abbr.:** DSC; a form of differential thermal analysis in which the temperatures of both the sample and the reference substance are maintained at either the same or a constant difference; the amount of heat that must flow into the sample to maintain the temperature differential during a transition is then measured.

**differential thermal analysis abbr.:** DTA; a method for analysing temperature-induced transitions in a sample. The sample and an inert reference material are heated or cooled at the same rate and the difference in temperature between them is monitored. This difference is zero or constant until a thermally induced transition occurs in the sample, when the temperature difference changes. The direction of the change shows whether the transition is endo- or exothermic.

**differential titration** the titration of a group, e.g. an acid group, before and after another group in the same molecule has reacted with some other reagent. It is used to determine the extent, if any, of linkage between the functions of the groups in question. *See titrate.*

**differentiating-stimulating factor** *see* leukemia inhibitory factor.

**differentiation** the process whereby relatively unspecialized cells, e.g. embryonic or regenerative cells, acquire specialized structural and/or functional features that characterize the cells, tissues, or organs of the mature organism or some other relatively stable phase of the organism's life history.

**differentiation antigen** any cell-surface antigen whose expression varies during successive developmental stages of a particular cell type.

**diffraction** the bending of light, or other waves, by an obstacle or aperture, into the region of the geometrical shadow of the object; any redistribution in space of the intensity of waves resulting from the presence of an object in their path causing variations of either their amplitude or their phase. The effect is particularly marked when the size of the object is of the same order as that of the wavelength of the waves. Diffraction accounts for the phenomenon observed when light passes through an aperture and falls on a screen; this takes the form of patterns of light and dark bands (with monochromatic light) or coloured bands (with heterochromatic light) near the edges of the beam and extending into the shadow. Diffraction is also responsible for the propagation of radio waves over the surface of the globe and of sound waves around solid objects.

*See* diffraction grating, electron diffraction, X-ray diffraction.

**diffraction grating** a glass or quartz plate on the surface of which there is a large number of equidistant parallel black lines (500 or more per millimetre). When light or other electromagnetic radiation passes through such a grating it is diffracted in a manner dependent on the wavelength of the radiation. Other plane surfaces, e.g. metals, may be used.

**diffusate** a product of a process of diffusion, especially the material that enters into or traverses a barrier of restricted or selective permeability. In dialysis the term is sometimes preferred to dialysate. *Compare* nondiffusible material.

**diffusible** 1 capable of diffusing. 2 (sometimes) a preferred alternative term for dialysable (i.e. capable of passing through a semipermeable membrane used in dialysis).

**diffusion** 1 the net flow of molecules from a region of high concentration, or high chemical potential, to one of low concentration, or low chemical potential, due only to random thermal motion. *See also* facilitated diffusion. 2 the irregular reflection or transmission of light or other electromagnetic radiation; scattering. 3 the act or process of dispersing or of being dispersed widely. -diffuse *vb.* *adj.*

**diffusion cell or diffusion chamber** 1 a cell or chamber with porous walls that allow the passage of dissolved substances but not of biological cells. It is used in studying materials released by cells. 2 a device for measuring the diffusion of macromolecules and consisting of two chambers separated by

## digitogenin

a porous membrane of nearly parallel channels. The channels are large compared with the size of the macromolecules but small enough that the bulk flow of liquid through them is negligible.

**diffusion coefficient or diffusion constant symbol:** *D*; a coefficient of proportionality between flux and concentration gradient for a solute diffusing in a system of constant temperature and pressure in accordance with Fick's first diffusion law and Fick's second diffusion law. For an ideal solute it is a constant, but in practice usually varies with concentration. The cgs unit for *D* is  $\text{cm}^2\text{s}^{-1}$  (*see also* Fick unit) and the SI unit is  $\text{m}^2\text{s}^{-1}$ .

**diffusion-controlled or diffusion-limited** describing a chemical reaction (or other process) whose velocity is dependent on the rate at which one or all of the reactants (or participants) can diffuse to the site at which the reaction (or process) occurs, as to the active site of an enzyme catalysing the reaction.

**diffusion gradient** any gradient e.g. in the concentration of a dissolved solute that forms if the solute is capable of diffusing from a region of higher concentration to a region of lower concentration until its concentration in the solution is uniform.

**diffusion-limited** *see* diffusion-controlled.

**diffusion potential** an electric potential difference across a membrane due to the diffusion through the membrane of more cationic charges than anionic charges, or vice versa.

**diffusive** characterized by diffusion. -diffusively *adv.*

**DIFP** *see* DFP.

**digest** 1 to subject material to enzymic or chemical breakdown. 2 to subject food to digestion (def. 1). 3 to break down nitrogenous compounds by hot sulfuric acid to convert them to ammonium salts. 4 to treat biological materials with powerful oxidants to facilitate determination of trace elements present. 5 the mixture of compounds obtained from the enzymic or chemical degradation of a macromolecule or other substance. -digester *n.* an apparatus that facilitates digestion procedures.

**digestion** 1 the whole of the physical, chemical, and biochemical processes carried out by living organisms to break down ingested nutrients into components that may be easily absorbed and directed into metabolism. 2 the process of breaking down complex substances or materials into smaller parts either enzymically or chemically, especially in the course of their analysis.

**digestive enzyme** any hydrolytic enzyme that brings about or assists in digestion (def. 1).

**digestive juice** any of the secretions entering the digestive tract that contain digestive enzymes. They include saliva, gastric juice, intestinal juice, and pancreatic juice.

**digestive system** the digestive tract together with related organs, such as the pancreas and liver.

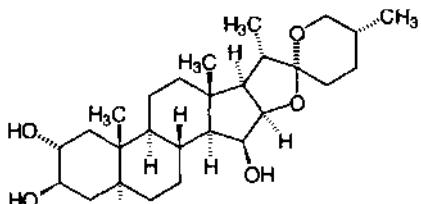

**digestive tract or alimentary tract** the tubelike passage in higher animals, extending from the mouth to the anus, in which the food is digested, from which absorption of nutrients occurs, and which serves to eliminate waste products.

**diginose** the  $\alpha$  enantiomer, 2,6-dideoxy-3-O-methyl- $\alpha$ -lyxohexose, is a component of some cardiac glycosides

**digitalis** 1 any plant of the genus *Digitalis*. 2 a preparation of powdered dried leaves of the purple foxglove (*Digitalis purpurea*). It contains the cardiac glycosides digitoxin, gitoxin (a glycoside of 3,14,16-trihydroxy-20(22)-enolide), and gitaloxin (16-formylgitoxin), and is used therapeutically to increase the strength of the heart's contraction and to slow auricular-ventricular conduction.

**digitalose** the  $\alpha$  enantiomer, 3-methyl- $\alpha$ -fucose, 6-deoxy-3-O-methyl- $\alpha$ -galactose, is a component of some cardiac glycosides, e.g. digitoxin.

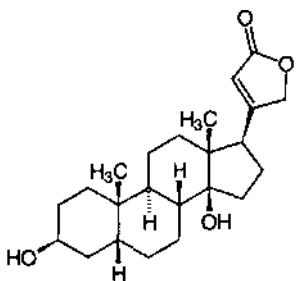

**digitogenin** (*2SR*)-*Sa*-spirostan-*2a,3p*,ISFJ-triol; the aglycon of the glycosides (saponins) present in digitonin.

**digitonin**

digitogenin

**digitonin** a mixture of at least four steroid saponins obtained from the seeds of the purple foxglove, *Digitalis purpurea*. It is useful in the fractional precipitation and analysis of cholesterol and other steroids and as a nonionic detergent in the solubilization of membrane proteins. Aggregation number 60. Its aglycon is **digitogenin**.

**digoxigenin** 3P,14-dihydroxy-5p-card-20(22)-enolide; the aglycon of **digoxin**.

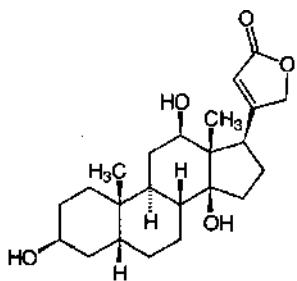

**digoxin** a secondary glycoside, or mixture of glycosides comprised mainly of digitoxin, that is extracted from *Digitalis purpurea*. It has actions similar to, but longer-lasting than, **digoxin**. Its aglycon is digitoxigenin. See also **cardiac glycoside**.

**digitoxose** the D enantiomer, 2,6-dideoxy-D-ribo-hexose, is a component of some **cardiac glycosides**.

**diglyceride** former name for **diacylglycerol** (it is still quite commonly used, as in 'diglyceride fraction', but its use is discouraged for such purposes as diglyceride is properly a generic term for any compound having two glyceryl residues, e.g. **phosphatidylglycerol**).

**digoxigenin** 3P,12P,14-trihydroxy-5p-card-20(22)-enolide; the aglycon of **digoxin**.

**digoxin** a secondary glycoside extracted from the Austrian (or woolly) foxglove, *Digitalis lanata*. It acts on the heart to potentiate contractility and reduce conductivity mainly through inhibition of Na<sup>+</sup>,K<sup>+</sup>-ATPase, hence its use in congestive

**dihydrolipoamide 5-acetyltransferase**

heart failure and atrial dysrhythmia. Its aglycon is digoxigenin. See also **cardiac glycoside**.

**dihedral** having or contained by two planes or plane faces.

**dihedral angle** the inclination of two planes that meet at an edge.

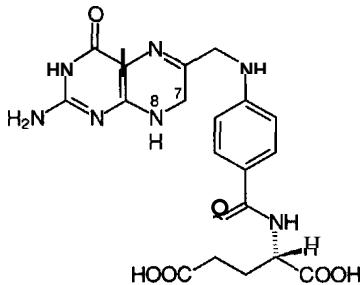

**dihedral symmetry** the symmetry of a **point group**, designated  $D_n$ , containing an n-fold axis with n twofold axes perpendicular to it.

**dihomo-(6,9,12,15-linolenate)** dihomogammalinolenate, **dihomo-y-linolenate**, (*all-Z*)-eicos-8,11,14-trienoate; an intermediate in the synthesis of arachidonate from linoleate, formed by  $\Delta^6$  desaturation and chain elongation. It acts as a precursor for the PG<sub>1</sub> series of **prostaglandins**. See also **eicosatrienoic acid**.

**dihydrlic** describing a chemical compound containing two hydroxyl groups per molecule. It is used especially of **alcohols**. Compare **dihydroxy+**.

**dihydro+** prefix (in chemical nomenclature) indicating the presence of two additional hydrogen atoms.

**dihydrofolate abbr.:** H<sub>2</sub>folate (DHF not recommended); 1,7,8-dihydrofolate, 7,8-dihydropteroylglutamate; the trivial name for the 7,8-dihydro derivative of **folate** (def. 1). 2 any **folate** (def. 2) that is a dihydro compound, especially any of the respective 7,8-dihydro intermediates in the conversion of non-reduced folates to their corresponding folate coenzymes (i.e. tetrahydrofolates) by the enzyme dihydrofolate reductase. See also **antifolate**, **tetrahydrofolate**.

**dihydrofolate reductase abbr.:** DHFR; EC 1.5.1.3; systematic name: 5,6,7,8-tetrahydrofolate:NADP+ oxidoreductase; other name: tetrahydrofolate dehydrogenase. An enzyme that catalyses the interconversion of 5,6,7,8-tetrahydrofolate and 7,8-dihydrofolate, and also slowly interconverts 7,8-dihydrofolate and folate; both reactions are linked to the reduction/oxidation of NADP+/NADPH. It is inhibited by **aminopterin**, **amethopterin** (also termed **methotrexate**), and **trimethoprim**. Example from human: database code NDL\_IDRF, 186 amino acids (21.30 kDa); 3-D structure known; four motifs.

**dihydrofolate synthase** EC 6.3.2.12; other name: dihydrofolate synthetase; an enzyme of the pathway for the *de novo* synthesis of dihydrofolate. It catalyses the formation of dihydrofolate from ATP, dihydropterate, and L-glutamate with release of ADP and orthophosphate. Example from *Escherichia coli*: database code FOLC\_ECOLI, 422 amino acids (45.39 kDa).

**dihydrogen** systematic name for the diatomic compound H<sub>2</sub>, commonly termed (molecular) hydrogen.

**dihydrolipoamide 5-acetyltransferase** EC 2.3.1.12; other names: lipoate acetyltransferase; thioltransacetylase A; an enzyme that catalyses the formation of acetyl-CoA and dihydrolipoamide from S-acetyl-dihydrolipoamide and CoA. A lipoyl group is required as a coenzyme, the enzyme having three covalently linked lipoyl groups. This is the E<sub>2</sub> component of the **pyruvate dehydrogenase complex**. Example: dihydro-

**dihydrolipoamide dehydrogenase**

lipoamide acetyltransferase component ( $E_2$ ) of a human pyruvate dehydrogenase complex precursor (PDC- $E_2$ ): (incomplete sequence) ODP2\_HUMAN, 61S amino acids (68.32 kDa).

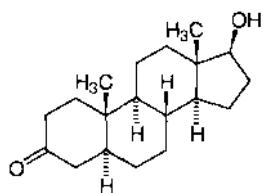

**dihydrolipoamide dehydrogenase** EC 1.8.1.4; *other names*: lipoamide reductase (NADH); lipoyl dehydrogenase; dihydrolipoyl dehydrogenase; diaphorase; the  $E_3$  component of  $\alpha$ -ketoacid dehydrogenase complexes, an FAD-flavoprotein enzyme that catalyses the oxidation by NAD<sup>+</sup> of dihydrolipoamide to lipoamide and NADH. Example (precursor) from human: DLDH\_HUMAN, S09 amino acids (84.09 kDa). *See also oxoglutarate dehydrogenase complex; pyruvate dehydrogenase complex.*

**dihydrolipoamide S-succinyltransferase** EC 2.3.1.61; an enzyme that catalyses the formation of succinyl-CoA and dihydrolipoamide from S-succinyl dihydrolipoamide and CoA. It is the  $E_\zeta$  component of the **oxoglutarate dehydrogenase complex**. Example from human (precursor): database code OD02\_HUMAN, 483 amino acids (48.69 kDa); the enzyme is formed from residues 68–483, 1–67 forming the transit peptide.

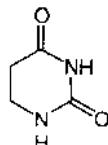

**dihydroorotate** EC 3.8.2.3; *systematic name*: (S)-dihydroorotate amidohydrolase; *other names*: carbamoylaspartic dehydrase; DHOase. An enzyme that catalyses the formation of N-carbamoyl-L-aspartate from (S)-dihydroorotate. In many eukaryotes this is an activity of **CAD protein**.

**dihydropyridine receptor** a protein located in skeletal muscle transverse tubules that specifically binds 1,4-dihydropyridine compounds. It forms one of the subunits of the L-type **calcium channel**.

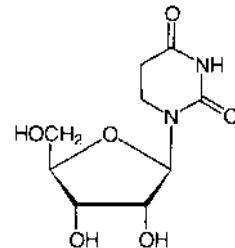

**5 $\alpha$ -dihydrotestosterone** 4,5-dihydrotestosterone; 5 $\alpha$ -androstan-17 $\beta$ -ol-3-one; a potent metabolite of testosterone, formed in the cytoplasm of target cells by the action of progesterone 5 $\alpha$ -reductase, EC 1.3.1.30. It mediates many of the differentiating, growth-promoting, and functional actions of testosterone by binding to the **androgen receptor** and forming a complex. *See also testicular feminization.*

**dihydrouracil** S,6-dihydouracil, a minor pyrimidine base. It occurs in the **dihydrouridine arm of transfer RNA**.

**dihydrouridine** *symbol*: D or hU; S,6-dihydouracil riboside; 1-J-D-ribofuranosyl-S,6-dihydouracil; a rare nucleoside occurring in the **dihydrouridine arm of transfer RNA**.

**diiodotyrosine**

dihydrouridine

**dihydrouridine arm** *abbr.*: DHU arm: the base-paired segment of the **clover leaf structure of transfer RNA** that has attached to it the loop containing S,6-dihydouracil (see **dihydrouracil**).

**dihydroxy+** *prefix* (*in chemical nomenclature*) indicating the presence of two substituent hydroxyl groups.

**dihydroxyacetone** *older name for glycerone*.

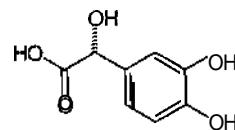

**dihydroxyacetone phosphate** *older name for glycerone phosphate*.

**dihydroxyacetone synthase** see **formaldehyde transketolase**.

**dihydroxyacetone transferase** see **transaldolase**.

**dihydroxyeicosatetraenoate** *abbr.*: diHETE; any of several products resulting from dioxygenation of arachidonate at two sites, normally resulting from **lipoxygenase** action on **hydroxy-eicosatetraenoates**. (6 $E$ ,8 $Z$ ,10 $E$ ,14 $Z$ )-(SS,12S)-S,12-dihydroxy-eicosa-6,8,10,14-tetraen-1-oate (*abbr.*: S(S),12(S)-diHETE) is synthesized in human leukocytes by two successive lipoxygenase reactions and acts as a leukotriene B<sub>4</sub> antagonist. *See leukotriene B*. (6 $E$ ,8 $Z$ ,11 $Z$ ,13 $E$ )-(SS,ISS)-S,IS-dihydroxy-eicosa-6,8,11,13-tetraen-1-oate (*abbr.*: S(S),IS(S)-diHETE) is synthesized in human neutrophils and enhances neutrophil degranulation. (S $Z$ ,9 $E$ ,11 $Z$ ,13 $E$ )-(S8,ISS)-8,IS-dihydroxyeicosa-8,9,11,13-tetraen-1-oate (*abbr.*: 8(S),IS(S)-diHETE) is synthesized in human leukocytes, eosinophils, and platelets and is chemotactic for human polymorphonuclear leukocytes.

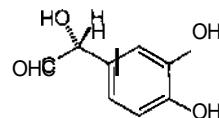

**3,4-dihydroxymandelate** an intermediate in the formation of 4-hydroxy-3-methoxymandelate from **norepinephrine**.

**3,4-dihydroxyphenylalanine** see **dopa**.

**3,4-dihydroxyphenylethylamine** see **dopamine**.

**3,4-dihydroxyphenylglycolaldehyde** the product of the action of monoamine oxidase on **norepinephrine**. It is converted by an NAD<sup>+</sup>-dependent aldehyde dehydrogenase to 3,4-dihydroxymandelate.

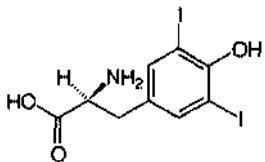

**1,25-dihydroxyvitamin  $D_3$**  *another name for calcitriol*.

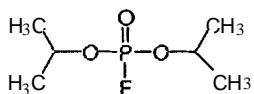

**diiodotyrosine** *abbr.*: DIT; 3,S-diiodotyrosine; iodogorgoic acid, 3,S-diido-4-hydroxyphenylalanine, 2-amino-3-(3,S-diido-4-hydroxyphenyl)propanoic acid. Residues of the L enantiomer, together with residues of the monoiodo com-

## diisopropylfluorophosphonate

pound, 3-iodo-L-tyrosine, are formed by iodination of L-tyrosine residues in thyroglobulin as precursors of thyroid hormones.

**diisopropylfluorophosphonate** diisopropylfluorophosphonate; dyflos; abbr.: DIPF or DFP; an inhibitor of cholinesterase and other serine proteases. It phosphorylates the serine in the enzyme's active site, causing long-lasting inhibition. Recovery of enzymic activity requires *de novo* enzyme synthesis.

**diisopropylphospho symbol:** Dip; abbr.: DIP; the doubly esterified phosphoric acyl group,  $[(CH_3)_2CH-O-]_2P(O^-)$ , derived from diisopropyl fluorophosphate by loss of a fluorine atom.

**dikaryon** or **dicaryon** a living cell containing two nuclei, or a structure (e.g. a mycelium) composed of such cells. It may contain nuclei of the same genetic constitution (i.e. homokaryons) or of differing genetic constitutions (i.e. heterokaryons). -dikaryotic or dicaryotic adj.

**diketose** any monosaccharide derivative containing two (potential) ketonic carbonyl groups. Compare ketose.

**dikinase** either of the two enzymes belonging to the sub-sub-class EC 2.7.9, comprising phosphotransferases with paired acceptors. For example, pyruvate,orthophosphate dikinase, EC 2.7.9.1, catalyses the reversible reaction:

**dil.** abbr. for dilute (def. 2).

dilate to expand or cause to expand; to make larger or wider; e.g. of the pupil of the eye or a chamber of the heart. -dilation or dilatation n.

**dilatometer** any instrument for measuring small changes in the volume of liquids. One design consists of a (glass) bulb fitted with a graduated hollow stem in which changes in volume may be observed. In another design, the (glass) bulb is fitted with a stopper through which runs a capillary tube so that any increased volume of the contained liquid may escape; the change in mass of the bulb and its contained liquid may then be determined. -dilatometry n.

**diluent** a diluting agent; see dilute (def. I).

**dilute** 1 a to lower the concentration of a solute in a solution (or of particles in a suspension). b to mix one fluid with another thereby lowering the concentration of the first. 2 abbr.: dil.; describing a solution (dispersion or mixture) having a relatively low concentration (of a specified solute, type of dispersed particle, or component). Compare concentrated (def. I). diluted (of a solution or suspension) lowered in concentration and increased in volume by addition of solvent or other diluent. Compare concentrated (def. 2).

**dilution** 1 the act or process of making more dilute (def. 2). 2 a diluted solution or suspension. 3 the (specified) extent to which a solution or suspension has been diluted.

**dilution end-point analysis** the determination of the concen-

## dimethylaminoazobenzene

tration of antibody in a solution by allowing a given amount of antigen to react with increasing dilutions of the antibody. The most dilute solution that produces a detectable effect, e.g. precipitation, is taken as the end point.

**dilution law** see Ostwald dilution law.

**dilution quenching** the lowering of counting efficiency of a liquid scintillation counter by the addition of solvent to the contents of the scintillation vial. See also quenching.

**dilution rate symbol:**  $D$ ; the rate,  $F$ , at which existing medium is replaced with fresh medium in a continuous culture, divided by the volume,  $V$ , of the culture:  $D = F/V$ . Under steady-state conditions the dilution rate numerically equals the specific growth rate of the culture. See also auxostat, chemostat.

**dilution value of a buffer symbol:**  $(\Delta pH)_{1/2}$ ; the change in pH that occurs when a buffer solution is diluted with an equal volume of water.

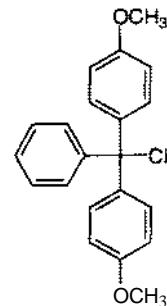

**dimer** 1 any molecular structure of any size in which two initially identical chemical entities have become covalently combined. 2 any macromolecular structure in which two (either identical or nonidentical) subunits are noncovalently associated. See also heterodimer, homodimer. -dimeric adj.

**dimercaprol** or **British anti-lewisite** (abbr.: BAL); 2,3-dimercaptopropanol; an antidote to the arsenical war gas, lewisite, that is also useful as a chelating agent and detoxificant for heavy-metal ions and as a protective agent for sulphydryl groups in enzymes, coenzymes, or the like.

**dimerize** or **dimerise** cause a dimer to be formed. -dimerization or dimerisation n.

**dimerizer hypothesis** or **dimeriser hypothesis** an unsubstantiated model of facilitated diffusion proposed to explain the rates of entry of sugars into human erythrocytes from various mixtures of sugar species. According to this hypothesis, permeation occurs as a result of pairs of sugar molecules interacting with a membrane component, followed by the association of the sugars into dimers, a form in which a reduced number of free hydrogen-bond-forming groups would be available.

**dimethoxytrityl** abbr.: DMT; 4,4'-dimethoxytriphenylmethyl; a group used for protecting hydroxyl groups (especially the 5'-hydroxyl groups of nucleosides) during chemical synthesis or other procedures. It is usually introduced by reaction with dimethoxytrityl chloride, 4,4-dimethoxytriphenylmethyl chloride. Compare trityl.

4,4-dimethoxytrityl methyl chloride

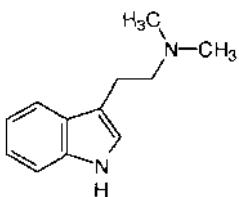

**dimethylallyl *transtransferase*** EC 2.5.1.1; systematic name: dimethylallyl-diphosphate:isopentenyl-diphosphate dimethylallyltransferase; other names: prenyltransferase; geranyl-diphosphate synthase. An enzyme that catalyses the reaction of dimethylallyl diphosphate with isopentenyl diphosphate to form pyrophosphate and geranyl diphosphate. It participates in the pathway for the formation of polypropyl groups, sesquiterpenes, and cholesterol.

**dimethylaminoazobenzene isothiocyanate** see DABITe.

**dimethylaminoazobenzene sulfonyl chloride** see dabsyl.

## dimethylaminobenzaldehyde

dimethylaminobenzaldehyde *see* Ehrlich's reagent.  
 dimethylaminonaphthalene sulfonyl chloride *see* dansyl, dansylate.  
 dimethylformamide *see* DMF.  
 dimethyltryptamine N,N-dimethyltryptamine; 3-[2-(dimethylamino)ethyl]indole; a hallucinogenic agent extracted from several plant species including *Piptadenia peregrina*. It is also a metabolite of 5-hydroxytryptamine. It is a controlled substance under the US Code of Federal Regulations.

dimorphism 1 the existence of a chemical compound in two distinct physical forms, e.g. two different crystalline forms. 2 the existence of individuals belonging to two distinct forms within the same species of organism; e.g. in sexual dimorphism the males and females of the same species are markedly different. 3 the occurrence in certain plants of two distinct forms of leaves or other parts in the same individual. -dimorphic or dimorphous *ad.*

dinactin *see* nonactin.

dinitrofluorobenzene *abbr.*: DNFB; *a (less correct) name for* fluorodinitrobenzene. *See* Sanger's reagent.

dinitrogen systematic name for the diatomic compound  $N_2$ , commonly termed (molecular) nitrogen.

dinitrophenate the strongly yellow-coloured anion,  $(NO_2)_2-C_6H_3-O^-$ , formed from dinitrophenol.

dinitrophenol *abbr.*: DNP; 2,4-dinitrophenol; a pale-yellow crystalline solid. It is a powerful uncoupler of oxidative phosphorylation, and hence toxic.

dinitrophenyl symbol: Dnp; the group formed by loss of the phenolic hydroxyl group from 2,4-dinitrophenol. *See* Sanger's method.

dinitrophenylation to introduce a dinitrophenyl group into a compound. -dinitrophenylation *n.*

dinoprost a generic name for prostaglandin F<sub>2α</sub>. *See* prostaglandin.

dinor+ prefix (in chemical nomenclature) indicating shortening of a carbon chain or contraction of a ring by two methylene groups. *See also* nor+.

Dintzis procedure a procedure for investigating the direction and rate of biosynthesis of a polypeptide. It requires the addition to a protein-synthesizing system *in vitro*, at a given time, of a pulse of a labelled form of an amino acid, of which there are several residues at different positions in the structure of the polypeptide. After various periods of elapsed time, within the time required for synthesis of a complete chain, completed molecules of the polypeptide are isolated, and the extents of incorporation of the labelled amino acid into them are determined for each position in which a residue occurs naturally. Over all the samples, a gradient of radioactivity (increasing from the N terminus to the C terminus of the chain) is found, indicating that the pulse tends to enter the more C-terminal positions and that the more N-terminal region has already been synthesized. By these means it was clearly shown for the first time that polypeptide chains are assembled from amino acids on a template and that synthesis takes place from its N terminus. [After Howard Marvin Dintzis (1927- ), US biochemist, who conceived the procedure and described its use in 1961.]

dinucleotide 1 any oligonucleotide consisting of two mononucleotides in 3'-5' phosphodiester linkage. 2 any nucleotide coen-

## 2,5-diphenyloxazole

zyme in which either of the mononucleotides adenosine 5'-phosphate or adenosine 2',5'-bisphosphate is in 5'-5' diphosphate (i.e. phosphoric anhydride, pyrophosphate) linkage with nicotinamide mononucleotide or riboflavin 5'-phosphate. dinucleotide fold *an alternative name for* nucleotide binding fold.

diode 1 a semiconductor device, containing one p-n junction, used in circuits to rectify alternating current to a direct current: semiconductor diode. 2 a thermionic valve containing an anode and a cathode and functioning in a similar manner: thermionic diode.

dioestrus *see* estrous cycle.

diol any organic compound (or portion of such a compound) containing two hydroxyl groups.

diol lipid any of various neutral lipids that are fatty-acid esters of dihydroxy alcohols (i.e. are not glycerides). They occur in small amounts in seed oils; e.g. 1-palmitoleoyl-2-trans-vaccenoyl-erythro-butane-2,3-diol, which is found in seeds of *Coix lachrima*.

dioxin receptor *see* ARNT.

dioxygen systematic name for the diatomic compound O<sub>2</sub>, commonly termed (molecular) oxygen. Compare trixygen.

dioxygenase any oxidoreductase enzyme of the sub-subclass EC 1.13.11. Such enzymes catalyse reactions involving the incorporation of both oxygen atoms of dioxygen into a second substrate; *see* e.g. ethylene-forming enzyme, benzoate t,z-dioxygenase.

Dip symbol for the diisopropylphospho group.

DIP abbr. for the diisopropylphospho group.

dipentene a racemic mixture of the (+) and (-) enantiomers of limonene.

dipeptide any oligopeptide consisting of two (usually, α-) amino-acid residues.

dipeptide mimic any synthetic dipeptide that inhibits angiotensin-converting enzyme. An example is captopril.

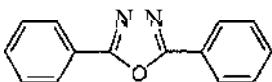

dipeptidyl-peptidase *abbr.*: DPP; any member of a group of enzymes belonging to the sub-subclass EC 3.4.14, dipeptidylpeptide and tripeptidylpeptide hydrolases, that release an N-terminal dipeptide from an oligo- or polypeptide. Dipeptidyl-peptidase I (*or cathepsin C*), EC 3.4.14.1, is a lysosomal cysteine-type peptidase that acts on polypeptides, but not if the terminal amino-acid residue is Arg or Lys, and not if either of the adjacent residues is Pro. Example from *Rattus norvegicus*: database code CATC\_RAT, 462 amino acids (52.38 kDa). Dipeptidyl-peptidase II, EC 3.4.14.2, is a lysosomal serine-type peptidase that acts preferentially on tripeptides. Dipeptidyl-peptidase III, EC 3.4.14.4 (*other names:* red cell angiotensinase; enkephalinase B), is a cytosolic serine-type peptidase that acts on tetra- or longer peptides. Dipeptidyl-peptidase IV, EC 3.4.14.5 (*other names:* dipeptidyl aminopeptidase IV; Xaa-Pro-dipeptidyl-aminopeptidase; Gly-Pro naphthylamidase; post-proline dipeptidyl aminopeptidase IV), catalyses the release of an N-terminal dipeptide, Xaa-Xbb-j-Xcc, from a polypeptide, preferentially when Xbb is Pro, provided Xcc is neither Pro nor hydroxyproline. The protein is a serine proteinase, type II transmembrane glycoprotein; it is a homodimer: database code DPP4\_HUMAN, 766 amino acids (88.22 kDa); T-cell activation antigen CD26. Dipeptidyl-dipeptidase, EC 3.4.14.6, is a thiol-activated peptidase from *Brassica oleracea* that acts preferentially on tetrapeptides.

dip-F symbol for diisopropyl fluorophosphate.

DIPF abbr. for diisopropylphosphofluoridate. *See* diisopropyl fluorophosphonate.

diphenylamine reaction the reaction of an acidic solution of diphenylamine with deoxypentoses to give a blue colour. It is used in the quantitative determination of DNA, and alone or in combination with other reagents as a detection reagent.

2,S-diphenyloxazole *abbr.*: PPO; a compound used as a primary scintillant in scintillation counting. *See* scintillation counter. *See also* scintillation cocktail.

2,5-diphenyloxazole

**diphosphate** 1 the tetravalent anion,  $P_2O_{7}^{4-}$ , derived from diphosphoric acid (earlier known as pyrophosphoric acid), heptaoxodiphosphoric(v) acid,  $(HO)_2PO-O-PO(OH)_2$ . 2 any mixture of free diphosphoric acid and its anions. *see also* inorganic diphosphate, pyrophosphate. 3 any (partial or full) salt or ester of diphosphoric acid. 4 any organic compound containing two phosphoric residues linked by an oxygen atom. 5 name of the univalent group  $-O-PO(OH)-O-PO(OH)_2$  (irrespective of its state of ionization). 6 *formerly*, any organic compound containing two independent phosphoric residues attached to different parts of the molecule; now incorrect, use bisphosphate.

**1+)****diphospho+** 1 *prefix to (or infix in)* a chemical name indicating the presence in ester (or diester) linkage of a diphosphoric residue. 2 *formerly, prefix to* a chemical name indicating the presence of two independent phosphoric residues in ester linkages; now incorrect, use bisphospho+.

**diphosphoglycerate** *former name for* 1 2,3-bisphospho-D-glycerate. 2 3-phospho-D-glycerol phosphate.

**diphosphoglycerate pocket** *abbr.:* DPG pocket; *see* bisphosphoglycerate pocket.

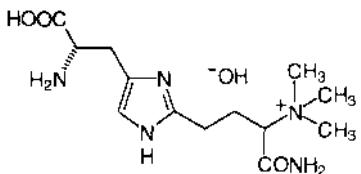

**diphosphoinositide** *former name for* phosphatidylinositol 4-phosphate.

**diphosphopyridine nucleotide (oxidized)** *abbr.:* DPN; *obsolete name for* the oxidized form of nicotinamide adenine dinucleotide; *see* NAD+.

**diphosphopyridine nucleotide (reduced)** *abbr.:* DPNH; *obsolete name for* the reduced form of nicotinamide adenine dinucleotide; *see* NADH.

**diphosphoric symbol:** PP or (in the one-letter convention for nucleotides) pp; *general name for* a residue of diphosphoric acid,  $(HO)_2PO-O-PO(OH)_2$ , whether singly or multiply attached through oxygen to other groups and whether or not any residual hydroxyl groups are dissociated.

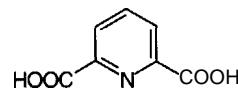

**diphthamide** a modified histidine residue on EF-2. *See* elongation factor.

**diphtheria toxin** an enzyme toxin produced by strains of *Corynebacterium diphtheriae* which are lysogenic for corynephage, whose genome contains the *tox* structural gene (carried by phage  $\beta tox^+$ ). The toxin has the activity of EC 2.4.2.36; *recommended name:* NAD+-diphthamide ADP-ribosyltransferase; *systematic name:* NAD+-peptide-diphthamide N-(ADP-D-ribosyl)transferase. It catalyses the reaction between NAD+ and peptide diphthamide to form nicotinamide and peptide N-(ADP-D-ribosyl)diphthamide. The toxin molecule is a proenzyme comprising a single polypeptide chain of  $\approx 62$  kDa; the toxin is lethal for susceptible animals at around 100 ng per kg of body mass. On cleavage of one peptide bond

and one disulfide bond, the toxin splits into an N-terminal fragment, A (21.15 kDa), the enzyme that specifically inhibits protein synthesis by catalysing transfer of the ADP-ribosyl moiety of NAD+ to eukaryotic EF-2 (*see* elongation factor) in the cytoplasm, and a C-terminal fragment, B ( $\approx 40$  kDa), that is required for recognition of specific surface receptors on sensitive cell membranes. Fragment B is necessary for the toxicity of fragment A because it enables the latter to cross the plasma membrane. Example (precursor) from phage  $\beta$ : database code DTX\_CORBE, 567 amino acids (61.53 kDa); fragment A, amino acids 33-225; fragment B, amino acids 226-567.

**dipicolinate** 2,6-pyridinedicarboxylate; a substance that is abundant (10%) in bacterial spores. Its production is a striking feature of sporulation and it may play a part in making spores resistant to heat.

dipicolinic acid

**diplochromosome** a 'double chromosome', comprising the arms of two daughter chromosomes attached to a single centromere. It arises due to failure of the centromere to divide following duplication of a chromosome.

**diploid** describing a cell or nucleus having two sets of homologous chromosomes; i.e. containing twice the haploid number. -diploidy n.

**diploid state** the chromosome state of a cell in which each type of chromosome, except for the sex chromosomes, is always represented twice.

**diplotene** the fourth phase of prophase I in meiosis.

**dipolar bond** or coordinate bond or coordinate covalence or coordinate link or dative bond or semipolar double bond a covalent bond formed (actually or conceptually) between two initially uncharged moieties by coordination (def. 2). The consequent generation of opposing charges on the linked structures creates a dipole; e.g.

The term is preferred to the alternatives, which are now either obsolescent or obsolete. *Compare* polar bond.

**dipolar correlation time** time taken for an atomic spin system to rotate through one radian from its previous orientation, the rotation being caused by interactions with other, neighbouring spins.

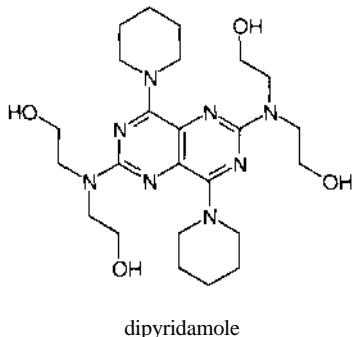

**dipolar interaction** the interaction between two magnetic moments due to the effect of the magnetic field of one on the other.

**dipolar ion** or zwitterion a molecule containing ionic groups of opposite charge in equal numbers. *Compare* amphion.

**dipole** a pair of equal and opposite electric charges or magnetic poles (especially in a molecular entity) separated by a, usually, small distance. -dipolar ad.

**dipole moment** or electric dipole moment symbol:  $p$  or  $\mu$ ; a vector quantity equal to the product of the absolute magnitude of either charge in a dipole (the two are equal in an uncharged molecule) multiplied by the distance separating them. If a molecule possessing a dipole moment is placed in a uniform electric field, it will be subject to torque tending to line it up in the direction of the field.  $p = \sum Q_i r_i$  coulomb metres, where  $Q_i$  is the charge and  $r_i$  is the position vector.

**dipyridamole** an inhibitor of cyclic AMP phosphodiesterase and 5-lipoxygenase, used as a coronary vasodilator.

**diradical** *an alternative term for biradical.*

**direct current** *abbr.: d.c. or DC;* an electric current that flows in only one direction.

**directional selection** any genetic selection that shifts the population mean in the direction desired by the breeder.

**dis+** *prefix indicating 1 reversal. 2 deprivation, exclusion, or lack. 3 negation. 4 removal or release.*

**dis2** a gene in fission yeast that is the equivalent of *DIS2* 51 in budding yeast.

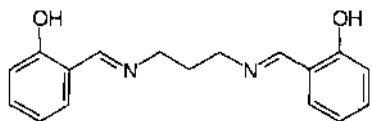

**disabled strain** any strain of organism, especially a microorganism, that because of some character, e.g. a nutritional requirement, is unable to reproduce in the normal environment, including the normal host, and can only survive in laboratory conditions.

**disaccharidase** any enzyme within sub-subclass EC 3.2.1 that hydrolyses a disaccharide to its constituent monosaccharides.

**disaccharidase deficiency** *see lactase deficiency.*

**disaccharide** any oligosaccharide consisting of two monosaccharide residues. It may be a nonreducing disaccharide or a reducing disaccharide, depending on the mode of linkage between the residues.

**disalicylidene propanediamine** *abbr.: DSPD; N,N'-disalicylidene-I,3-diaminopropane;* an inhibitor of photosynthetic electron flow at the ferredoxin level.

**disassociation** *a variant form of dissociation (def. I).*

**disc** *a variant spelling (esp. Brit.) of disk.*

**discharge** 1 *(in physics)* the release of an electric charge, e.g. from a condenser or a battery, or the equalization of an electric potential difference. 2 *(in physics)* the intermittent or continuous flow of electricity through a gas by the formation of electrons and ions. 2 *(in medicine)* an abnormal secretion from a body cavity, or the secretion from a wound.

**discoidin** any of a group of endogenous carbohydrate-binding proteins (lectins) produced by cells of the slime mould *Dictyostelium discoideum* during differentiation. Similar to pallidin, they may be concerned in cell adhesion. Examples (all from *D. discoideum*): discoidin I, A chain: database code DISA-DICDI, 253 amino acids (28.24 kDa); Band C chains: database code DISC-DICDI, 253 amino acids (28.39 kDa).

**discontinuous epitope** an immunological determinant (i.e. epitope) on an antigen that comprises different sections of a protein molecule brought together by folding of the polypeptide chain. *Compare* continuous epitope.

**discriminator** 1 any (electronic) device that gives an output signal only when the input signal is above a certain preset level

or has certain preset characteristics. 2 any criterion used in sorting objects, experimental results, signals, etc.

**disease** any anatomical abnormality or impairment of the normal functioning of an organism or of any of its parts other than one arising directly from physical injury. It may be caused by environmental factors (e.g. malnutrition, toxic agents, etc.), infective agents (bacteria, viruses, etc.), inherent defects in the organism (e.g. genetic disease), or any combination of these factors.

**disequilibrium assay** any radioimmunoassay in which the reagents are not added at the same time and are not allowed to reach thermodynamic equilibrium. *Compare* equilibrium assay.

**disinfection** the destruction or removal of all organisms capable of giving rise to infection. *Compare* sterilize (def. 1).

**disintegration or nuclear disintegration** any process of nuclear decay involving a splitting into more nuclei or the emission of particles (either spontaneously or as a result of a collision).

**disintegration constant or decay constant symbol:**  $\lambda$ ; for a radionuclide, the probability of the nuclear decay of one of its nuclei in unit time. It is given by:

$$\lambda = -(I/t)\ln(A/A_0)$$

where  $A_0$  is the radioactivity at zero time and  $A$  is the activity at time  $t$ . *See also* average life.

**disintegrin** any of a group of compounds that act as inhibitors of platelet-fibrinogen interaction and other aggregations. They are found in certain snake venoms. Example, disintegrin CTF-I1CTF-II from *Trimeresurus flavoviridis*: database code DISC-TRIFL, 75 amino acids (8.32 kDa); two motifs. Example, from *Agkistrodon rhodostoma* (Malayan pit viper) venom: database code DISI\_AGKRH, 68 amino acids (7.32 kDa).

**disjunction** the separation of chromosomes at anaphase during nuclear division.

**disk or (esp. Brit.) disc** 1 a circular, flattened structure, or any object having or resembling such a shape. *See also* retinal rod.

2. *(in computing)* a disk-shaped device on which files are stored electromagnetically.

**disk (gel) electrophoresis** a technique of separation by electrophoresis in which a tube is loaded first with the sample, applied in a gel support (usually polyacrylamide), followed by a spacer gel and finally by the running gel, in which separation occurs. The gels are so formed as to give a gradient of progressively smaller pore size, and a discontinuous buffer system is used. This arrangement causes the separating components of the applied mixture to stack as a series of very thin bands and permits very high resolution.

**dismembrator** an ultrasonic device for rapidly disrupting cells in bacteriological and cytological studies. It consists of a probe oscillating at  $\approx 20$  kHz and an acoustical power of up to 150 W that is dipped into a cell suspension, contained in either a stainless-steel or glass beaker.

**dismutase** *see superoxide dismutase.*

**dismutation** a chemical reaction in which a single compound serves both as an oxidizing agent and as a reducing agent; e.g. the reaction of two molecules of pyruvate and one of water giving rise to one molecule each of lactate, acetate, and carbon dioxide. *Compare* disproportionation.

**disodium chromoglycate** *see cromolyn.*

**disodium etidronate** *see etidronate.*

**disome** a polysome in which two ribosomes are attached to a strand of messenger RNA. *Compare* monosome, nucleodisome.

**Dispase** *proprietary name for* a highly stable neutral metalloproteinase obtained from *Bacillus polymyxa*. It is so named from its use, alone or with collagenase, for gentle enzymic disaggregation and dispersal of animal tissues into separated cells for primary cell culture and for redispersal of cells on subculturing. *See also* Chaetopase, Pronase.

**disperse phase** *or dispersed phase* the phase in a two-phase sys-

## dispersion

term that consists of the particles in a colloid, emulsion, or suspension.

**dispersion** 1 the selective separation of an inhomogeneous emission according to some criterion (especially frequency, particle mass, speed, or energy); e.g. the separation of heterochromatic light into its components. 2 any system in which particles of any nature (e.g. solid, liquid, gas, or composite) are dispersed in a solid, liquid, or gas of different composition. 3 (*in statistics*) the extent to which values of a statistical frequency distribution are scattered around a mean or median value.

**dispersion force** or London force a long-range attractive interaction occurring between atoms or molecules whether or not they have permanent charges or dipole moments. Since the electrons in an atom or molecule are moving, an instantaneous dipole moment is induced in the atom or molecule; this averages to zero over a short time. This instantaneous dipole moment will induce an oppositely oriented dipole moment in a neighbouring atom or molecule in a manner that does not time-average to zero. This interaction energy,  $V(R)$ , is given approximately by:

$$V(R) = -\frac{3}{2} \left( \frac{\hbar\nu_A\nu_B}{\nu_A + \nu_B} \right) \frac{aaAB}{(4\pi\epsilon_0)} \frac{1}{R^6}$$

where  $\nu_A$  and  $\nu_B$  are the approximate frequencies of the first electron transitions of entities A and B,  $aa$  and  $as$  are their polarizabilities,  $\epsilon_0$  is the permittivity of vacuum,  $\hbar$  is the Planck constant, and  $R$  the distance between the entities. [After Fritz London (1900-54), German-born US physicist.]

**dispersive replication of DNA** *see replication of DNA.*

**displacement binding** a technique in which the displacement of radioligand bound to a population of receptors is measured as the concentration of an unlabelled ligand, which binds to the same receptors, is increased. It is used to distinguish different affinity states of the receptor population or receptor selectivity of the radioligand.

**displacement chromatography** an analytical chromatographic technique in which a mixture is applied to a chromatographic column and the components of the mixture are then successively displaced by elution with a solution containing another substance of higher affinity for the column material than that of the most firmly held component. The relative proportions of the components of the mixture are determined by frontal analysis of the eluate.

**displacement electrophoresis** *an alternative term for isotachophoresis.*

**displacement loop** *an alternative name for D-loop.*

**displacement reaction** a chemical reaction in which an atom or group is displaced from its covalent attachment to a central (frequently a carbon) atom following an attack by either an electrophile or a nucleophile.

**disproportionation** any chemical reaction of the type:

where A, A', and A'' are different chemical species. *Compare dismutation.*

**D/IS2** \$1 a gene of budding yeast encoding protein phosphatase I (its equivalent in fission yeast is **dis2**). In the absence of gene function mitosis is arrested. The product in *Saccharomyces cerevisiae* is: database code YSCDIS2S1A, 312 amino acids (35.93 kDa).

**dissimilation** *a less common alternative term for catabolism. Compare assimilation. -dissimilatory adj.*

**dissimilatory nitrate reduction** *see nitrate reduction.*

**dissociation** 1 or disassociation a reversible splitting of a chemical substance into simpler entities; *compare association.* In this sense, the term may be applied to: a the heterolysis of a covalent bond, yielding, in the case of an initially uncharged molecule, positively and negatively charged ions: ionic dissociation; b the disaggregation of a macromolecular homopolymer or heteropolymer into its constituent units (i.e. protomers), usually by a stepwise process through components of interme-

## disulfide bond

diate size (i.e. oligomers) and without rupture of covalent bonds; c the breakdown of an enzyme-substrate complex, which may or may not involve cleavage of a covalent bond; or d the separation of a complex of two or more molecules into the constituent molecules. 2 a splitting of a chemical substance by the homolysis of a covalent bond, yielding radicals. 3 translocation between a large chromosome and a small supernumerary one, in effect splitting the large chromosome into two chromosomes. 4 separation (induced or spontaneous) of the nuclear components of a heterokaryotic dikaryon. -dissociated, dissociable, dissociative *adj.*; dissociate *vb.*

**dissociation constant symbol:**  $K_{\text{diss}}$  or  $K_d$ : the equilibrium constant for the reversible breakdown of a complex or a chemical compound into two or more simpler entities; the reciprocal of the association constant,  $K_{\text{ass}}$ . In some cases, an apparent dissociation constant ( $K'd$ ) is determined (for the distinction *see equilibrium constant*). It is also known as the ionization constant in cases where a substance dissociates into ions. For a dissociation (or ionization) of the general type  $AB \rightleftharpoons A + B$ , the dissociation (or ionization) constant is given by:

$$K_{\text{diss}} = [A][B]/[AB] = K_{\text{ass}}$$

**dissociation energy symbol:**  $D$ : the enthalpy (per mole) required to break a given chemical bond in a specified chemical entity by homolysis.

**distal** situated furthest from an origin, central line, or point of attachment.

**distal protein** a protein that binds late in the assembly of complex structures, such as ribosomes. *Compare proximal protein.*

**distil** or (*US*) distill to undergo, to subject to, to purify, or to separate by distillation.

**distillate** the liquid (or solid) product of distillation.

**distillation** the act or process of evaporating a liquid by boiling so that its components, which are vaporized at different temperatures or at different rates, can be separated and condensed back to a liquid (or solid). It is used to purify one liquid from a mixture of liquids or from (dissolved) solids. *See fractional distillation.*

**distribution** 1 (*in chemistry*) *an alternative term for partition.*

2 (*in biochemistry*) the pattern of occurrence of a substance within or between cells or tissues, or within a group of organisms, taxa, etc. 3 (*in biology*) the geographical range or pattern of occurrence of a particular taxon or genetic variant. 4 (*in statistics*) the frequency of occurrence of a variable at each of a number of discrete values. *See also normal distribution.*

**distribution coefficient** 1 *an alternative term for partition coefficient.* 2 in gel chromatography, the fraction of the stationary phase that is available for diffusion of a given solute species.

**distribution law** *an alternative name for partition law.*

**distributive** 1 of, relating to, or characterized by distribution.

2 (*in molecular biology*) or nonprocessive describing (the action of) any enzyme or catalytic complex that progressively synthesizes or degrades a biopolymer by effecting several or many cycles of the same type of reaction or reaction sequence and dissociates from the template or intermediate product after each catalytic event. *Compare processive. -distributively adv.*

**disulfide or disulphide** (*in organic chemistry*) any compound containing two bivalent sulfur atoms linked by a covalent bond and each attached to a carbon atom.

**disulfide bond** or **disulfide bridge** or **disulfide** link a covalent bond between two sulfur atoms. Such bonds in biomolecules are usually formed by the oxidation of sulphydryl groups in two neighbouring cysteine molecules or residues. Disulfide bonds may link two half-cystine residues in the same polypeptide chain, as in ribonuclease, or in different peptide chains, as in insulin or oxidized glutathione, and they often are important in maintaining the three-dimensional structure of polypeptides and proteins. They may also be reversibly formed in oxidation-reduction reactions as in the interconversion of

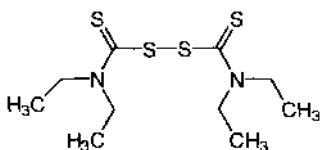

## disulfide interchange

DNA

lipoamide and dihydrolipoamide. Also: disulphide bond or disulphide bridge or disulphide link.  
disulfide interchange or disulphide interchange any chemical reaction in which there is an interchange in the groups attached to two or more disulfide bonds; e.g.:

where R, X, Y, and Z are different polypeptide chains or other SH-bearing molecules. See also protein disulfide isomerase.  
disulfide knot or disulphide knot a region at the centre of a fibrinogen molecule where the six polypeptide chains are linked together by eight disulfide bonds. Compare cystine-knot.  
disulfiram trivial name for tetraethylthiuram disulfide; bis(diethylthiocarbamoyl) disulfide; a drug used to deter alcohol abuse in the treatment of alcoholism. Alcohol ingestion after disulfiram causes vasomotor disturbances, nausea, vomiting, and even unconsciousness and death. It acts by inhibiting the enzyme acetaldehyde dehydrogenase and hence slows the removal of acetaldehyde. It occurs naturally in the otherwise edible fruit body of the agaric mushroom *Coprinus atramentarius*. One proprietary name is Antabuse.

DIT abbr. for diiodotyrosine.

dithioerythritol abbr.: DTE; erythro-1,4-dimercapto-2,3-butanediol; both this and dithiothreitol are known as Cleland's reagent. It has similar properties to dithiothreitol but is less often used.

dithiothreitol abbr.: DTT; threo-1,4-dimercapto-2,3-butanediol; both this and dithioerythritol are known as Cleland's reagent. A water-soluble solid compound which, because of its low redox potential (-0.33 V, pH 7.0), is capable of maintaining monothiols completely in the reduced state and of reducing disulfides quantitatively, so becoming oxidized to a cyclic disulfide; it has little tendency to be oxidized directly by air.

diuresis increased or excessive flow of urine.

diuretic 1 producing an increase in the volume of urine. 2 any agent that increases the volume of urine.

diurnal 1 occurring during the day. 2 repeating every day; having a periodicity of approximately 24 hours. Compare circadian.

Diuron see DCMU.

divergent evolution or divergence biological evolution that tends to produce an increasing difference in some characteristic(s) between initially similar groups of, e.g., organisms or gene products. Compare convergent evolution.

divergent transcription the transcription of adjacent genes from opposite strands of duplex DNA and in opposite directions.

dixenic see synxenic.

Dixon plot a graphical method for the presentation of enzyme-kinetic data by which a Michaelis constant,  $X_m$  (see Michaelis kinetics), or an inhibitor constant,  $X_i$ , may be determined. The method is primarily used as a means of readily obtaining  $X_i$ . The reciprocal of the initial velocity (i.e.  $\frac{V_0}{V}$ ) is plotted against a series of inhibitor concentrations [I], at constant substrate concentration, [S]. When this is done for a number of values of [S], the resulting lines intersect at a point corresponding to  $X_i$ . The value of [I] at which this occurs is to the left of the ordinate (for competitive inhibition) and corresponds to  $-K_i$ . For non-competitive inhibition the lines meet on the abscissa. [After Malcolm Dixon (1899-1985), British enzymologist, who described it in 1972.]

dizygotic describing twin offspring formed from two separate ova fertilized by two separate sperms. Compare monozygotic.

DL prefix (in chemical nomenclature) denoting an equimolar mixture of D and Lenantiomers. See DL convention.

dl- prefix (in chemical nomenclature) formerly used to denote racemic; now obsolete, use  $(\pm)$ , racemo-, or rac-.

DL convention a convention of symbols used to designate the absolute configuration around a chiral element in a-amino acids, cyclitols, monosaccharides, and derivatives of these classes of compounds. Within these classes it can be applied to any molecule of the type  $R,CHXR_2$  that can be oriented in a Fischer projection with the most highly oxidized atom at the top; then if X is on the right the configuration is designated by the prefix D-, whereas if X is on the left the configuration is designated by the prefix L-, relative to D-(+)- or L-(-)-glyceraldehyde. Racemic (i.e. equimolar) mixtures of D and Lenantiomers are designated by the prefix DL-. a-Amino acids are designated D- or L- according to the configuration at the a-carbon atom. Cyclitols are designated D- when the formula is drawn in such a way that the substituent on the lowest-numbered asymmetric carbon atom is above the plane of the ring and the numbering is anticlockwise, and L- when it is clockwise; the locant of the defining centre should precede the prefix D- or L-, e.g. ID-1-O-methyl-mylo-inositol. For monosaccharides the highest-numbered chiral centre (i.e. carbon atom) is the reference atom determining whether the monosaccharide is D or L. When a compound contains more than one class of residue the configuration designators are D<sub>s</sub> or L<sub>s</sub> if they apply to an amino-acid residue, D<sub>c</sub> or L<sub>c</sub> to a cyclitol residue, and D<sub>g</sub> or L<sub>g</sub> to a monosaccharide residue (the subscript s denoting the reference a-amino acid serine, the subscript c denoting cyclitol, and the subscript g denoting the reference monosaccharide glyceraldehyde). The absolute configurations of chiral compounds of classes other than those listed are designated by application of the sequence rule. Compare ambo-, do, l-, dl-, isomerism.

D-loop or displacement loop a DNA structure generated when an additional strand of DNA is taken up by a DNA duplex, so that one strand of the original duplex is displaced, forming a D-shaped loop. Formation of a D-loop is favoured in negatively supercoiled DNA and can occur spontaneously. Such D-loops are formed in covalently closed mammalian mitochondrial DNA, and are prominent as intermediates in genetic recombination, in which their formation is catalysed by strand-exchange enzymes, the best characterized of which is the RecA protein of *Escherichia coli*.

DMF or DMFA abbr. for N,N-dimethylformamide; a neutral liquid of low melting point (-61 °C) and a reasonably high boiling point (153°C), miscible with water and with most common organic solvents, hence sometimes termed the universal solvent.

DMSO abbr. for dimethylsulfoxide (use discouraged, Me<sub>2</sub>SO preferred).

DMT abbr. for the dimethoxytrityl group.

dma symbol for any of various bacterial genes that are involved in DNA replication. For example, *dmaG* is the gene for DNA primase in *Escherichia coli*.

DNA abbr. and common name for deoxyribonucleate (def. I), or deoxyribonucleic acid; one of the two main types of nucleic acid, consisting of a long, unbranched macromolecule formed from one, or more commonly, two, strands of linked deoxyribonucleotides, the 3'-phosphate group of each constituent deoxyribonucleotide being joined in 3',5'-phosphodiester linkage to the 5'-hydroxyl group of the deoxyribose moiety of the next one. Compare RNA. The absence of a 2'-hydroxyl group on each deoxyribose moiety renders these phosphodiester linkages resistant to hydrolytic attack by alkali, in contrast to those of RNA. A DNA strand, unless circular, has polarity, with one 5' end and one 3' end, the two strands in duplex DNA having opposed polarities. Two purines, adenine and guanine, and two pyrimidines, cytosine and thymine, are the major bases present. The linear sequence of the purine and pyrimi-

## DNAase

dine bases carries genetic information, whereas the deoxy-sugar and phosphoric residues play a structural role; the base sequence is written in the 5'→3' direction. See also double helix. Specific forms, functions, molecules, or preparations of DNA may be designated by prefixes or suffixes, thus:

A-DNA or DNA-A, A form of DNA; amDNA, anti-messenger DNA; B-DNA or DNA-B, B form of DNA; cDNA, complementary DNA; cccDNA, covalently closed circular DNA; C-DNA or DNA-C, C form of DNA; ctDNA, chloroplast DNA; dsDNA, double-strand(ed) DNA (see duplex DNA); iDNA, intercalary DNA; msDNA, multicopy single-stranded DNA; mtDNA, mitochondrial DNA; nDNA, nuclear DNA; pDNA, plasmid DNA; rDNA, ribosomal DNA; recDNA, recombinant DNA; rfDNA, replicative-form DNA; rtDNA, recombinant DNA; scDNA, single-copy DNA; ssDNA, single-strand(ed) DNA; tDNA, transfer DNA; T-DNA, transfer DNA of the Ti plasmid. See full entry for T-DNA. Z-DNA or DNA-Z, Z form of DNA.

DNAase or DNase abbr. sometimes used for deoxyribonuclease; DNase is more usual.

DNA-binding protein FIG see matrin.

DNA blot transfer see blot-transfer technique.

DNA chip see SOH.

DNA cloning see molecular cloning.

DNA cycle see cell-division cycle.

DNA-dependent DNA polymerase see DNA polymerase.

DNA-dependent RNA polymerase see RNA polymerase.

DNA-directed DNA polymerase recommended name for DNA polymerase, EC 2.7.7.7.

DNA-directed RNA polymerase recommended name for RNA polymerase, EC 2.7.7.6.

DNA fingerprinting a term sometimes used to refer to genetic profiling.

IDNA) glycosylase or DNA glycosidase any of a group of glycohydrolases that initiate repair of DNA by hydrolysing N-glycosyl bonds linking deoxyribose residues with modified or incorrect bases to generate apurinic or apyrimidinic sites in the DNA and release the bases. They include DNA-3-methyladenine glycosidase I (EC 3.2.2.20), DNA-3-methyladenine glycosidase II (EC 3.2.2.21), and formamidopyrimidine-DNA glycosidase (EC 3.2.2.23). The enzymes form part of the pathway of base-excision repair, which acts on oxidative or non-oxidative damage, as determined by the specificity of individual enzymes. Sequences tend to be related; examples from *Escherichia coli*: DNA-3-methyladenine glycosidase I is constitutive and specific to the named base: database code 3MGI\_ECOLI, 187 amino acids (21.08 kDa); DNA-3-methyladenine glycosidase II is inducible and releases any of 3-methyladenine, 3-methylguanine, 7-methylguanine, 0-2-methylthymine, and 0-2-methylcytosine: database code 3MG2\_ECOLI, 282 amino acids (31.36 kDa).

DNA gyrase see type II DNA topoisomerase.

DNA helicase an enzyme that catalyses unwinding of the DNA double helix during DNA replication and repair. It requires ATP. Example, rep gene product from *Escherichia coli*: database code REP\_ECOLI, 673 amino acids (76.85 kDa).

(DNA) joinase an alternative name for DNA ligase.

DnaK or heat-shock protein 70 abbr.: hsp70; a heat-shock protein that plays an essential role in the initiation of DNA replication in lambda phage and, in combination with DnaJ protein, acts to release proteins O and P. Example from *Escherichia coli*: database code DNAK\_ECOLI, 637 amino acids (68.98 kDa).

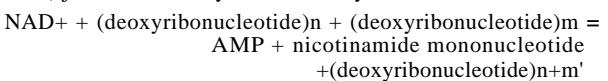

DNA ligase or (DNA) joinase or DNA repair enzyme either of two enzymes that restore broken phosphodiester bonds in deoxyribonucleic acids. (1) DNA ligase (ATP) EC 6.5.1.1; systematic name: poly(deoxyribonucleotide):poly(deoxyribonucleotide) ligase (AMP-forming); other names: polynucleotide ligase; DNA repair enzyme; (DNA) joinase; former name: sealase. An enzyme that catalyses the reaction:

## DNA polymerase

Example from phage T4: database code DNLI\_BPT4, 487 amino acids (55.23 kDa). (2) DNA ligase (NAD+) EC 6.5.1.2; systematic name: poly(deoxyribonucleotide):poly(deoxyribonucleotide) ligase (AMP-forming, NMN-forming); other names: polynucleotide ligase (NAD+); DNA repair enzyme; (DNA) joinase. An enzyme that catalyses the reaction:

Example from *Escherichia coli*: database code DNLJ\_ECOLI, 671 amino acids (73.61 kDa).

DNA-like RNA abbr.: D-RNA or dRNA; a minor fraction of eukaryotic cellular RNA that has a base composition much closer to that of DNA than the bulk of RNA. It is mainly of high molecular mass, short half-life, and confined to the nucleus, and is probably the same as giant messenger-like RNA and pre-messenger RNA.

DNA-3-methyladenine glycosidase see (DNA) glycosylase. DNA methylase either of two enzymes involved in modification and other roles. (1) Site-specific DNA-methyltransferase (adenine-specific) EC 2.1.1.72; other names: N-6 adenine-specific DNA methylase; modification methylase; restriction-modification system; it catalyses the reaction:

Example from *Escherichia coli*: database code DMA\_ECOLI, 278 amino acids (32.06 kDa); it recognizes the base sequence GATC and is part of the system for postreplicative mismatch repair. (2) Site-specific DNA-methyltransferase (cytosine-specific) EC 2.1.1.73; other names: C-5 cytosine-specific DNA methylase; modification methylase; restriction-modification system; it catalyses the reaction between S-adenosyl-L-methionine and DNA-cytosine to form S-adenosyl-L-homocysteine and DNA-5-methylcytosine. Example from *E. coli*: database code DCM\_ECOLI, 472 amino acids (53.40 kDa); it recognizes the base sequence CCWGG and methylates both strands. IDNA) nicking-closing enzyme or nicking-and-closing enzyme alternative names for type I DNA topoisomerase.

DNA nucleotidylexotransferase recommended name for terminal deoxynucleotidyltransferase.

DNA photolyase EC 4.1.99.3; recommended name: deoxyribodipyrimidine photo-lyase; other name: photoreactivating enzyme. An enzyme that splits cyclobutadipyrimidine (in DNA) into two pyrimidine residues (in DNA), thereby repairing the DNA after light-induced pyrimidine dimer formation. It is light dependent, requiring the cofactors reduced flavin and either (in different enzyme types) a folate coenzyme or a modified flavin. Example, *Escherichia coli* enzyme required for 'light repair': database code PHR\_ECOLI, 472 amino acids (53.61 kDa); four motifs.

DNA polymerase common name for either of two categories of enzymes that catalyse the synthesis of DNA from deoxyribonucleoside triphosphates in the presence of a nucleic-acid primer. Based on structural similarities, DNA polymerases have been grouped in two families. In family A are *Escherichia coli* and various other bacterial polymerases I, *Thermus aquaticus* Taq polymerase, some bacteriophage polymerases, and yeast mitochondrial polymerase γ. In family B are many polymerases of higher eukaryotes, yeast polymerases I to III, and polymerase REV3, *E. coli* polymerase II, archaebacterial polymerases, and many viral polymerases.

(1) DNA-directed DNA polymerase EC 2.7.7.7; other name: DNA nucleotidyltransferase (DNA-directed); it is required for DNA replication and repair and has 3'-exonuclease activity (see proofreading). Eukaryotic DNA-directed DNA polymerases are of five types:

(a) DNA polymerase-a (also called DNA polymerase I or Kornberg enzyme) is a high-molecular-mass (>100 kDa) en-

**DNAprimase**

dNTP

zyme that was first detected in *E. coli*; in association with DNA primase it is replicative. Example (human): database code DPOA\_HUMAN, 1462 amino acids (165.67 kDa) belongs to polymerase family B, with six conserved regions, four of which are involved in substrate binding. Several DNA viruses have type B polymerases; examples include adenoviruses and herpesviruses.

(b) DNA polymerase- $\beta$  (*or* DNA polymerase II) is a low-molecular-mass (<50 kDa) enzyme recovered almost entirely in nuclear extracts.

(c) DNA polymerase- $\gamma$  (*or* DNA polymerase III) is an enzyme of high molecular mass (>100 kDa) that copies synthetic polyribonucleotides with high efficiency, but does not copy DNA well. Examples from *E. coli*:  $\alpha$  chain: database code DP3A\_ECOLI, 1160 amino acids (129.76 kDa);  $\beta$  chain: database code DP3B\_ECOLI, 366 amino acids (40.54 kDa);  $\epsilon$  chain: database code DP3E\_ECOLI, 243 amino acids (27.07 kDa). The protein at database code DP3X\_ECOLI, 643 amino acids (71.06 kDa) represents  $\epsilon$  and  $\tau$ ; the production of the two protein products from this region is due to programmed ribosomal frameshifting.

(d) DNA polymerase- $\sigma$  is a zinc finger protein with both polymerase and 3'-exonuclease activities; it is a heterodimer of 125 kDa and 50 kDa subunits.

(e) DNA polymerase-mt is the mitochondrial DNA polymerase.

*E. coli* has three DNA polymerases: (a) pol I, database code DPOI\_ECOLI, 928 amino acids (103.00 kDa); this has 5'- and 3'-exonuclease activities; the 5'-exonuclease activity is involved in DNA replication; the polymerase activity is employed during DNA repair; 3-D structures are known for parts of the enzyme (database codes NRL\_IDPII and NRL\_IDPI2). (b) pol II, database code DP02\_ECOLI, 782 amino acids (89.82 kDa); is regulated by lexA and belongs to family B (above). (c) pol III, the major replication polymerase, has an  $\alpha$  subunit with polymerase activity, database code DP3A\_ECOLI, 1160 amino acids (129.76 kDa) and a total subunit composition of  $(\alpha, \epsilon, \theta)_2 \cdot \tau_2 \cdot (\gamma, \delta, \delta', \psi, \chi)_2 \cdot \beta_4$ . The complex ( $\alpha, \epsilon, \theta$ ), the 'core', is assembled first.

(2) RNA-directed DNA polymerase is the EC recommended name for reverse transcriptase.

DNA primase a DNA-directed RNA polymerase (EC 2.7.7.-) of the bacterial primosome. It associates transiently with the primosome and synthesizes short RNA primers for the Okazaki fragments on both template strands at replication forks. Example from *Escherichia coli*: database code PRIM\_ECOLI, 581 amino acids (65.49 kDa).

DNA print the pattern formed by denaturing the DNA in colonies of bacteria grown on a support and fixing the DNA to the support.

DNA provirus *see* provirus.

DNA repair enzyme any of the various enzymes involved in the different stages of DNA repair. Three steps are involved, each catalysed by a different set of enzymes: (1) the altered portion of DNA is removed by repair nucleases; (2) DNA polymerase fills the gap with a complementary copy; (3) the break is sealed by DNA ligase. There are two other related repair pathways, called (base-)excision repair and nucleotide-excision repair. *See a/so* repair enzyme.

DNA replication *see* replication of DNA.

DNA-RNA hybrid a double helix consisting of one DNA chain and one complementary RNA chain, the two chains being held together by hydrogen bonds between the complementary base pairs.

DNA-RNA hybridization *or* DNA-RNA hybridisation the formation of a duplex (def. 2) nucleic-acid structure that occurs when DNA and RNA molecules that have complementary base sequences are brought together. This phenomenon is exploited in a technique used to localize genes in a chromosome that depends on allowing radioactively labelled RNA to hybridize with denatured, single-stranded DNA from which the

RNA was transcribed and then determining the position on the DNA where hybridization has taken place by autoradiography. It also forms the basis of Northern blotting.

DNase *usual abbr.* for deoxyribonuclease. Compare DNAase. (DNA) sealase *an alternative name* for polynucleotide ligase (def. 1).

DNA sequencing determination of the order in which bases occur in DNA. Usually the DNA is cut with restriction enzymes and subjected to either the chemical cleavage method or the chain-termination method.

DNA superhelix *see* supercoil.

(DNA) swivelase *a former name* for type I DNA topoisomerase. DNA topoisomerase any enzyme that alters superhelix density in supercoiled DNA. Topoisomerases are found in all cell types, from microorganisms to those of humans, and in some viruses e.g. bacteriophage T4 and vaccinia. All topoisomerases isolated so far have the ability to relax negatively supercoiled DNA, converting it to a less supercoiled form. They have been divided into type I, which make a transient single-strand break, and type II, which make a transient double-strand break. Type I DNA topoisomerase, EC 5.99.1.2; *other names*: DNA topoisomerase, relaxing enzyme, untwisting enzyme, swivelase, nicking-closing enzyme, ro-protein; it catalyses the ATP-independent breakage of a single strand of DNA, which may be followed by passage (i.e., in the case of duplex DNA, transfer of the unbroken strand through the broken strand) and rejoining. This has the effect of relaxing one negative supercoil. Example from *Escherichia coli*: database code TOPI\_ECOLI, 864 amino acids (97.29 kDa). This enzyme can relax only negatively supercoiled DNA, whereas some enzymes, e.g. that from calf thymus, can relax both negatively and positively supercoiled DNA. Type II DNA topoisomerase, EC 5.99.1.3; *other name*: DNA topoisomerase (ATP-hydrolysing); it catalyses ATP-dependent breakage, passage (in this case, of a double-strand through a double-strand break) and rejoining of the double-stranded DNA. This enzyme can thus decatenate circular duplex DNA. All type II enzymes can relax both positively and negatively supercoiled DNA. Bacterial DNA gyrase is a special example of this class of enzyme. In addition to the properties of the other type II enzymes, it catalyses the ATP-dependent introduction of negative superhelical turns into a closed circular DNA. It is an A<sub>2</sub>B<sub>2</sub> tetramer. The energy-free topoisomerase activity of the A subunit, which breaks the DNA, is inhibited by 4-quinolone antibiotics such as nalidixic acid and ciprofloxacin. The energy-transducing activity of the B subunit is inhibited by novobiocin and other coumarin antibiotics. Example, subunit A: database code GYRA\_ECOLI, 875 amino acids (96.85 kDa); subunit B: database code GYRB\_ECOLI, 803 amino acids (89.72 kDa). The breaking and rejoining of DNA is catalysed by the A subunit; the B subunit is the ATPase. A distinctive property of this particular enzyme is that it can introduce negative superhelical turns into a closed circular DNA molecule with the coupled hydrolysis of ATP. *See a/so* linkage number, supercoil, winding number, writhing number.

(DNA) untwisting enzyme *an alternative name* for (DNA) swivelase.

DNA virus *or* deoxyribovirus any virus in which the genome consists of DNA, either double-stranded (in class I viruses) or single-stranded (in class II viruses). *See* Baltimore classification of viruses.

DNFB *abbr.* for (2,4-dinitrofluorobenzene). *See* Sanger's reagent.

Dnp *symb/for* dinitrophenyl group.

DNP *abbr.* for 1 (2,4-dinitrophenol). 2 deoxyribonucleoprotein (use deprecated).

Dns *symbol* for 5-(dimethylamino)naphth-1-ylsulfonyl; *see a/so* dansy!.

dNTP *abbr.* for any deoxynucleoside (5')-triphosphate (the deoxynucleoside being either unspecified or unknown).

## dolichyl-diphosphooligosaccharide-protein

**DOC** abbr. for (use discouraged) 1 deoxycholate (*see* deoxycholic acid). 2 deoxycorticosterone.

**doca or DOCA** abbr. for deoxycorticosterone acetate (*see* deoxycorticosterone).

**Docetaxel** a proprietary name for a semisynthetic analogue of taxol.

**docking** the binding of any macromolecule or part of such a molecule to its specific harbouring site on another molecular structure. *See also* signal recognition particle receptor.

**docking protein** another name for signal recognition particle receptor.

**docos+ or (before a vowel) docos+** prefix indicating twenty-two or twenty-two times.

**docosadienoic acid** any straight-chain fatty acid having 22 carbon atoms and two double bonds. The (5Z,13Z)-form has been reported to occur in *Limnanthes douglasii*.

**docosahexaenoic acid** any straight-chain fatty acid having 22 carbon atoms and six double bonds. Only the (all-Z)-4,7,10,13,16,19-isomer, of the *n*-3 family, occurs naturally, being present in substantial amounts (10-15% of total fatty acids) in fish oils, and in variable amounts (a few percent of total) in animal glycerophospholipids. It can be formed metabolically from *a*-linolenic acid.

**docosanoic acid or behenic acid** a straight-chain saturated fatty acid having 22 carbon atoms that occurs as a constituent of cerebrosides and some seed oils (especially of *Lophira* spp.); in some of the latter it accounts for 20-30% of total fatty acids.

**docosapentaenoic acid** any straight-chain fatty acid having 22 carbon atoms and five double bonds. The (all-Z)-4,7,10,13,16-isomer is a member of the *n*-6 family and can be formed metabolically from linoleic acid; it is a constituent of animal glycerophospholipids. The (all-Z)-7,10,13,16,19-isomer, of the *n*-3 family, can be formed metabolically from *a*-linolenic acid; it is a precursor of 4,7,10,13,16,19-docosahexaenoic acid, and is present in small amounts (a few percent) in animal glycerophospholipids and in larger amounts (up to 10%) in fish oils.

**docosatetraenoic acid** any straight-chain fatty acid having 22 carbon atoms and four double bonds. Adrenic acid is found in animal glycerophospholipids, especially in brain and heart of animals fed sunflower or corn oil, and is presumed to be the (all-Z)-7,10,13,16-isomer.

**docosatrienoic acid** any straight-chain fatty acid having 22 carbon atoms and three double bonds. The (all-Z)-7,10,13-isomer occurs in animal lipids, especially during essential fatty acid deficiency.

**docosenoic acid** any straight-chain fatty acid having 22 carbon atoms and one double bond. The (1IZ)-isomer, cetoleic acid, occurs in marine oils and rapeseed oil. The (13Z)-isomer, erucic acid, is an important constituent of rapeseed and other oils of plants belonging to the family Cruciferae. The possibility that it may be harmful has prompted efforts to breed crop varieties that yield oils containing low levels or none of this fatty acid.

**Dod** symbol for the dodecyl group.

**dodeca+ or (before a vowel) dodec+** prefix indicating twelve.

**dodecandrin** a type I ribosome-inactivating protein.

**dodecanoic acid** systematic name for lauric acid, a straight-chain saturated fatty acid having 12 carbon atoms. *See also* laurate.

**dodecanoyl** symbol Lau; systematic name for lauroyl.

**dodecanoic acid** any straight-chain fatty acid having 12 carbon atoms and one double bond.

**dodecenoyl** the acyl group derived from any dodecanoic acid.

**dodecenoyl-CoA  $\Delta$ -isomerase** EC 5.3.3.8; systematic name: dodecenoyl-CoA *LJ3-cis-LJ2-trans*-isomerase; other names:  $\Delta^3$ -*cis*- $\Delta^2$ -*trans*-enoyl-CoA isomerase; acetylene-allene isomerase; 3,2 *trans*-enoyl-CoA isomerase. An enzyme that is involved in unsaturated fatty acid oxidation; it catalyses the isomerization of 3-cis-dodecenoyl-CoA to 2-trans-dodecenoyl-

CoA, thereby producing a substrate for enoyl-CoA hydratase. Example from rat: database code 521091, 298 amino acids (32.86 kDa). *See also* peroxisomal bifunctional enzyme.

**dodecyl symbol:** Dod; preferred name for the alkyl group,  $\text{CH}_3\text{---}[\text{CH}_2]_{10}\text{---CH}_2\text{-}$  (also known as lauryl), derived from dodecane.

**n-dodecyl-N,N-dimethylglycine** lauryldimethylbetaine; a zwitterionic betaine detergent, CMC 1.6-2, I mM, Proprietary name: Empigen BB.

**n-dodecyl-j3-D-glucopyranoside** a water-soluble nonionic detergent, CMC 0.13 mM.

**n-dodecyl-j3-D-maltoside** a water-soluble nonionic detergent, aggregation number 98, CMC 0.1-0.6 mM.

**dodecylsulfate** the  $\text{CH}_3\text{---}[\text{CH}_2]_{10}\text{---CH}_2\text{---O---SO}_3^-$  anion. *See* sodium dodecyl sulfate.

**doghouse configuration** (of a cyclobutadipyrimidine) *see* pyrimidine dimer.

**Doisy**, Edward Adelbert (1893-1986), US chemist, biochemist, and endocrinologist remembered for the isolation of the female sex hormones estradiol, estriol, and estrone, and especially for his isolation (from putrified fish meal) of a second antihemorrhagic principle named vitamin K<sub>2</sub> (now termed menaquinone) (*see also* Dam) and for his subsequent structural characterization of vitamins K<sub>1</sub> and K<sub>2</sub>. Nobel Laureate in Physiology or Medicine (1943) 'for his discovery of the chemical nature of vitamin K' [prize shared with H. C. P. Dam].

**dolichol** the recommended term for any 2,3-dihydriodolyprenol derived from four or more linked isoprene units, i.e. any prenol derivative of general structure H-[CH<sub>2</sub>-C(CH<sub>3</sub>)=CH-CH<sub>2</sub>-]<sub>n</sub>-CH<sub>2</sub>-CH(CH<sub>3</sub>)-CH<sub>2</sub>-CH<sub>2</sub>-OH where *n* is greater than 3; in naturally occurring dolichols *n* is commonly in the range 13-23, (Note: Because the isoprene unit carrying the hydroxyl group is saturated in dolichols, they are not true prenols or polyprenols, though often classed as such. It is therefore recommended that, unless qualified, these collective terms are not used to include dolichols.) The phosphoric esters of dolichol (dolichol phosphate or phosphodolichol or dolichyl phosphate) and the diphosphoric esters (dolichol diphosphate or diphosphodolichol or dolichyl diphosphate) function in eukaryotes as carriers of mono- and oligosaccharide residues in the glycosylation of lipids and proteins within intracellular membranes. First, glycosyl groups are transferred from soluble nucleoside-diphosphosugars such as GDPmannose, UDP-N-acetylglucosamine, UDPglucose, or UDPxylose to form dolichyl phospho- or diphosphosugars. Then dolichyl diphosphooligosaccharides are built up from these by stepwise transfer of additional sugar residues. Finally the completed oligosaccharide moiety is transferred to a lipid or to a growing polypeptide chain with release of dolichyl diphosphate.

**dolichol kinase** EC 2.7.1.108; an enzyme that catalyses the formation of dolichyl phosphate from CTP and dolichol with release of CDP. Dolichyl phosphate is a precursor of dolichyl diphosphooligosaccharides, dolichyl phosphoglucose, and dolichyl phosphomannose, intermediates in N-linked glycoprotein oligosaccharide biosynthesis. Example from yeast: database code SC59\_YEAST, 519 amino acids (58.84 kDa).

**dolichol o-acyltransferase** EC 2.3.1.123; an enzyme that catalyses the formation of dolichyl palmitate from palmitoyl-CoA and dolichol with release of CoA. Acylated dolichols are found in some cell membranes, though their function is obscure.

**dolichyl** the alkyl group derived from a dolichol by loss of its hydroxyl group,

**dolichyl diphosphooligosaccharide** a precursor for the transfer of N-linked oligosaccharide chains to protein in the synthesis of glycoproteins. It consists of dolichol esterified to diphosphate with an oligosaccharide chain linked to the diphosphate by the C-1 of the sugar at the reducing end of the chain.

**dolichyl-diphosphooligosaccharide-protein glycosyl-**

**dolichyl-phosphate  $\beta$ -D-glucosyltransferase**

transferase EC 2.4.1.119; an enzyme that catalyses the reaction of dolichyl diphosphooligosaccharide with protein L-asparagine to form a glycoprotein with the oligosaccharide chain attached by glycosylamine linkage to protein L-asparagine, with release of dolichyl phosphate. Example from chicken: database code GSBP\_CHICK, 508 amino acids (56.90 kDa).

**dolichyl-phosphate  $\beta$ -D-glucosyltransferase** EC 2.4.1.117; an enzyme that catalyses the reaction of UDPglucose with dolichyl phosphate to form dolichyl ft-o-glucosyl phosphate (an intermediate in the biosynthesis of N-linked glycoprotein oligosaccharides) and UDP. It is a type II membrane protein of the endoplasmic reticulum involved in the glycosylation pathway. Example from yeast: database code ALG5\_YEAST, 334 amino acids (38.30 kDa).

**dolichyl-phosphate-mannose-protein mannosyltransferase** EC 2.4.1.109; an enzyme that catalyses the reaction of dolichyl phosphate o-mannose with protein to form O-o-mannosylprotein and dolichyl phosphate. Two examples from yeast: database code PMTLYEAST, 817 amino acids (92.57 kDa); and database code PMT2\_YEAST, 758 amino acids (86.75 kDa). See also dolichyl-phosphate p-O-mannosyltransferase.

**domain** 1 any topological region having specific characteristics, contained within certain limits, and/or under individual control. 2 or structural domain a compact, globular region in the structure of a single protein molecule, which may consist of several such globular regions held together by more flexible parts of the polypeptide chain. It has been suggested that the word be reserved for large subassemblies that would be stable if the polypeptide chain connecting them to the rest of the protein molecule were to be cleaved and that the term folding unit be used to define small assemblies of secondary structure segments in a protein molecule. 3 a region of a protein molecule delimited on the basis of function without knowledge of and relation to the molecular substructure, as, e.g., the part of a protein molecule that binds to a receptor, that binds a substrate and possesses a catalytic function forming a catalytic domain, or that, in a membrane protein, passes through the membrane from one face to the other, forming a transmembrane domain. Such a region may contain more than one structural domain (see def. 2). 4 a poorly characterized length of chromosomal DNA, of the order of 50–200 kilobase pairs, that comprises all the (coding or noncoding) sequences required for the formation of mRNA for anyone (specified) protein. 5 a zone within a cellular membrane consisting of one class of component, e.g. lipid. 6 a diverse set of cellular events, processes, and metabolic reactions controlled or affected by a specific agent, e.g. a hormone or another messenger. See metabolic code. 7 a mathematical aggregate to which a variable is confined. 8 (in physics) any region in a ferromagnetic solid in which all the atoms have the spins of their unpaired electrons aligned in the same direction: magnetic domain. See also Appendix E.

**domain of bonding** the two linked binding sets through which a pair of associated protomers are associated.

**dominant** (in genetics) describing a gene that produces the same character whether present in the homozygous state or in the heterozygous state (i.e. together with a different specified allele). The ineffective heterozygous allele is described as recessive to the dominant one. Dominant inherited diseases fall into one of three categories: (1) 'change of function' in which the abnormal protein acquires a novel activity that is deleterious to the cell, (2) 'dominant negative' in which the abnormal

**dopamine**

protein forms heterooligomeric complexes with the protein from the normal allele thereby knocking out the function of the entire protein complex, (3) 'haplo-insufficiency' in which a single copy of the gene has lost function and the 50% of the normal amount of protein that is produced from the non-mutated allele is not adequate to preclude clinical symptoms. Examples: type (1), sodium channel disorders; type (2), mutations in collagen genes which lead to osteogenesis imperfecta; type (3), loss of function in one copy of the low-density-lipoprotein receptor gene resulting in familial hypercholesterolemia.

**Donnan effect** or **Douman** (membrane) equilibrium the effect of the presence of charged macromolecules upon one side of a semipermeable membrane on the distribution of small, permeable ions across the membrane. At equilibrium, the small counterions will be more concentrated on the macromolecules' side of the membrane and the small ions of the same charge as the macromolecules will be less concentrated there, whereas on the side of the membrane with no macromolecules the concentrations of the small ions of opposite charge will be equal. It can be shown that, if the small ions are A<sup>+</sup> and B<sup>-</sup>,

$$[A^+]_{(1)}/[A^+]_{(2)} = [B^-]_{(2)}/[B^-]_{(1)} = r_D,$$

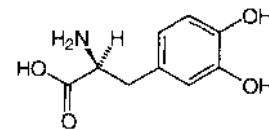

where  $r_D$  is the Donnan ratio and the subscripts 1 and 2 indicate the two sides of the membrane. [After Frederick George Donnan (1870–1956), British physical chemist.]

**donor** (in chemistry) any chemical species that is able to donate one or more electrons, atoms, or groups to another species, the acceptor.

**donor atom** 1 an atom that supplies two electrons in forming a dipolar bond. 2 an atom, added as an impurity to a semiconductor, that provides additional electrons in the conduction band. See also electron donor.

**donor cell** any living cell that contributes genetic information to another, recipient cell. See conjugation (def. 3), transduction, transformation.

**dopa** or **DOPA** abbr. for 3-hydroxytyrosine; 3,4-dihydroxyphenylalanine; 2-amino-3-(3,4-dihydroxyphenyl)propanoic acid; the naturally occurring enantiomer is 3-hydroxy-L-tyrosine (abbr.: L-dopa, also known as levodopa because it is levorotatory;  $[\alpha]_{D}^{20} \approx 13.0$ ). L-Dopa is formed from L-tyrosine by tyrosine 3-monooxygenase, EC 1.14.16.2, and is an immediate metabolic precursor of the neurotransmitter dopamine and other catecholamines. L-Dopa is used in the treatment of Parkinson's disease.

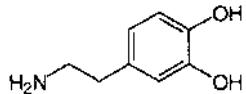

**dopac** or **DOPAC** abbr. for dihydroxyphenylacetate.

**dopachrome  $\Delta^7$ - $\Delta^2$ -isomerase** EC 5.3.3.12; systematic name: dopachrome  $\Delta^7$ - $\Delta^2$ -isomerase; an enzyme that catalyses the conversion of dopachrome (2-carboxy-2,3-dihydroindole-5,6-quinone) to 5,6-dihydroxyindole-2-carboxylate. Dopachrome is formed non-enzymatically from dopaquinone, the product of monophenol monooxygenase. These are reactions in the pathway of melanin synthesis. A deficiency in the enzyme results from a mutation in mice known as *slaty*. The enzyme contains zinc. Example from *Mus musculus*: database code TYR2\_MOUSE, 517 amino acids (58.57 kDa).

**dopa decarboxylase** see aromatic-L-amino-acid decarboxylase. **dopamine** an alternative name for 3,4-dihydroxyphenylethylamine; 3-hydroxytyramine; 3,4-dihydroxyphenylethylamine; 4-(2-aminoethyl)-1,2-benzenediol; a catecholamine neurotransmitter formed by aromatic-L-amino-acid decarboxylase, EC 4.1.1.28, from 3,4-dihydroxy-L-phenylalanine. A metabolic

## dopamine $\beta$ -hydroxylase

precursor of norepinephrine and epinephrine, it is found in dopaminergic nerves in the brain and in the adrenal medulla. See also Parkinson's disease.

**dopamine  $\beta$ -hydroxylase** EC 1.14.17.1; recommended name: dopamine ft-monoxygenase; systematic name: 3,4-dihydroxyphenethylamine,ascorbate:oxygen oxidoreductase (ft-hydroxylating). An enzyme that catalyses hydroxylation of dopamine to norepinephrine in aminergic neurons releasing norepinephrine and epinephrine; ascorbate is simultaneously oxidized to dehydroascorbate. The enzyme is a copper protein, stimulated by fumarate. It is absent from dopaminergic neurons. Example, homotetramer, human precursor, database code DOPO\_HUMAN, 603 amino acids (67.62 kDa).

**dopamine JJ-monoxygenase** see dopamine JJ-hydroxylase, dopamine receptor any of several membrane proteins that bind dopamine and mediate its intracellular effects. Types  $D_1$  to  $D_5$  have been recognized;  $D_1$  and  $D_5$  (also called  $D_{1A}$  and  $D_{1B}$ ) comprise one subfamily;  $D_2$ ,  $D_3$  and  $D_4$  (also called  $D_{2A}$ ,  $D_{2B}$ , and  $D_{2C}$ ) comprise a second subfamily.  $D_3$  receptors seem to be insensitive to guanine nucleotides and regulate conductance of  $Ca^{2+}$ . All are seven-transmembrane-domain receptors that couple to G-proteins.  $D_1$  and  $D_5$  elevate cyclic AMP, but vary in binding characteristics;  $D_2$  has a short and a long form originating from alternative splicing; in humans, the short form ( $D_{2S}$ ) has 414 amino acids, and the long form ( $D_{2L}$ ) has 443 amino acids.  $D_2$  lowers cyclic AMP levels and regulates ion channels, opening  $K^+$  and inhibiting  $Ca^{2+}$  channels.  $D_3$  and  $D_4$  have binding characteristics similar to, but distinct from  $D_2$ ; their action is not mediated by G-protein interaction with adenylate cyclase. Examples, all human;  $D_1$ : database code DADR\_HUMAN, 446 amino acids (49.29 kDa);  $D_2$ : database code D2DR\_HUMAN, 443 amino acids (50.62 kDa);  $D_3$ : database code D3DR\_HUMAN, 400 amino acids (44.22 kDa);  $D_4$ : database code D4DR\_HUMAN, 387 amino acids (40.89 kDa);  $D_5$ : database code DBDR\_HUMAN, 477 amino acids (52.95 kDa).

**dopaminergic** describing a nerve that is activated by dopamine. The term is applied to nerves that act by releasing dopamine at their nerve endings. Compare adrenergic, aminergic, cholinergic, peptidergic, purinergic, serotonergic.

**Doppler effect** the apparent change in the frequency of acoustic or electromagnetic waves due to relative motion between the source and the observer. The frequency appears to increase when the source and the observer move towards each other, and to decrease when they move away from each other. [After Christian Johann Doppler (1803–53), Austrian mathematician and physicist.]

**dorsal protein embryonic developmental morphogenetic nuclear protein**; a protein whose concentration in the nucleus of a cell during the blastoderm stage of development determines the cell's lateral or ventral identity. It is similar to the product of the vertebrate proto-oncogene *corel*. Example from *Drosophila melanogaster*: database code DORS\_DROME, 678 amino acids (75.39 kDa).

**dose** 1 a measured quantity of a drug, microorganism, radiation, etc. administered to an organism, often at specified intervals. In experimental pharmacology, the units and routes of administration should be specified and the quantity of the drug expressed per unit of animal mass, e.g. mol kg<sup>-1</sup>, mg kg<sup>-1</sup>, mg min<sup>-1</sup> kg<sup>-1</sup>. 2 to prescribe or administer a dose or doses. - dosage *n.*

**dose equivalent symbol:** *H*; a measure of the biological effects of ionizing radiation upon humans (or other mammals)

## double helix

used in radiation dosimetry and health physics. It is usually equal to the absorbed dose multiplied by the **quality** factor. In the case of radiation arising from radioactive material within a person's body, the absorbed dose must be multiplied also by a distribution factor (normally unity, but in certain instances given a value of 5) in order to take account of any nonuniform distribution of radioactivity. The CGS unit of dose equivalent is the rem; the corresponding SI derived unit is the sievert (def. I).

**dose rate** in radiation dosimetry, the amount of ionizing radiation (expressed in grays, rads, rems, roentgens, or sieverts) received or receivable by an irradiated object or organism in unit time. For personnel, it is usually expressed in sieverts per hour. (There is no separately named unit of dose rate.)

**dose ratio** an older name for concentration ratio. dose-response curve any graphical representation of the relationship between the size of an administered dose and the extent of the response of the organism, or other test system, to the dose. The response may be some biochemical or physiological change in one or more organisms, tissue samples etc., or the proportion of organisms in a group that show a response.

**dosimeter** or **dose meter** an instrument for measuring the quantity of ionizing radiation administered to an organism or an object, or the intensity of a source of such radiation.

**dosimetry** the process of measuring administered quantities of ionizing radiation, drugs, microorganisms, etc.

**dot hybridization** or **dot hybridisation** or **dot blotting** a development of blotting or blot transfer, in which as little as 1 pg of a specific nucleic-acid sequence, bound to nitrocellulose as a small spot, can be detected using a 32P-labelled probe as a 'dot blot'.

**double-antibody method** any technique in which a specific antibody, used to detect or measure its corresponding antigen, as in immunoassay, is isolated from the reaction mixture by combination with heterologous antibody to the specific antibody. Compare antiglobulin test.

**double-beam spectrophotometer** a spectrophotometer in which the incident light beam is split into two halves, one half passing through the sample and the second half passing through the reference so that direct measurement of the difference in absorption can be made. In one type the two emergent beams fall on different detectors and the resulting signal is a direct current; in another type the incident beam passes alternately through the sample and the reference, and the two emergent beams fall on the same detector resulting in an alternating current signal.

**double-blind testing** a method of evaluating the efficacy of a substance (e.g. a drug) in which neither the subjects nor the experimenter knows the identity of the samples at the time of the evaluation.

**double bond** a covalent bond that consists of two electron pairs shared by two atoms.

**double-displacement (enzyme) mechanism** or **ping-pong mechanism** or **substituted-enzyme mechanism** any enzymic mechanism in which an enzyme reacts with one substrate to give a covalently modified enzyme together with the release of one product, and the modified enzyme then reacts with the second substrate with the subsequent release of the second product and the return of the enzyme to its initial state.

**double helix** or Watson-Crick model of DNA; the main features of this model are that DNA consists of two antiparallel helical polynucleotide chains coiled around the same axis to form a double helix. Deoxyribose-phosphate backbones are on the outside of the helix and purine and pyrimidine bases lie approximately at right angles to the axis on the inside of the helix. The diameter of the helix is 2.0 nm and there is a residue on each chain every 0.34 nm. The angle between each residue on the same chain is 36°, so that the structure repeats after 10 residues (3.4 nm) on each chain. The two chains are held together by hydrogen bonds between pairs of bases, each mem-

## double immunodiffusion

ber of the pair belonging to a different polynucleotide chain. Adenine is always paired with thymine and guanine with cytosine. The two chains are therefore complementary.

**double immunodiffusion or double diffusion** a technique of immunodiffusion in which both the antibody and the antigen diffuse towards each other through a gel to form lines of precipitation. *See Ouchterlony technique.*

**double labelling** an experimental strategy in which either a single chemical compound is labelled with two different nucleides or two compounds are each labelled with a different nucleide. It is used to follow the simultaneous transformations of two substances or two parts of one substance, or to distinguish identical molecules synthesized at different times. **-doubly labelled adj.**

**double layer** *see electric double layer.*

**double membrane** *see unit membrane.*

**double-reciprocal plot** a plot of  $\text{II}_x$  versus  $\text{II}_y$ , where  $x$  and  $y$  are two variables. If the plot of  $y$  versus  $x$  has the shape of a rectangular hyperbola the corresponding double-reciprocal plot will be a straight line. Note: The  $x$  and  $y$  axes are not the asymptotes of the rectangular hyperbola. The Lineweaver-Burk plot is a double-reciprocal plot. *See also hyperbolic kinetics curve.*

**double refraction** *see birefringence.*

**double refraction of flow** *see flow birefringence.*

**double-sector cell** a cell (def. 2), used in analytical ultracentrifugation experiments, with two radial sector-shaped cavities, allowing the concentration distribution of a solute in one sector to be related to that of the solvent alone in the other sector: i.e. the second sector provides a reference for the first.

**double-sieve hypothesis** a hypothesis invoked to account for the unexpectedly low level of error (misreading) observed in protein biosynthesis. According to this hypothesis, the discrete synthetic and hydrolytic sites that exist on certain aminoacyl-tRNA synthetases provide a two-stage stereochemical sorting mechanism - likened in action to a pair of sieves - for the elimination of inappropriate amino acids. The synthetic site first rejects amino acids larger than that genetically specified; the hydrolytic site then preferentially destroys reaction products of amino acids smaller than, or isosteric with, the one specified. The second process has also been termed **editing** or proofreading. Such a mechanism would have particular importance in discriminating between a pair of very similar amino acids such as isoleucine and valine. *Compare kinetic proofreading.*

**double-stop terminator** two consecutive termination codons in a molecule of mRNA.

**double-stranded or double-strand** describing a duplex form of a nucleic acid. *See double-stranded RNA, duplex DNA.*

**double-stranded RNA** abbr.: dsRNA; a structure that occurs when complementary base sequences in single-stranded RNA form a duplex (def. 2). The RNA may fold back on itself to generate an antiparallel duplex structure, known as the stem, with a loop of unpaired bases at the end. The loop and stem together are called a hairpin. The two complementary sequences can result from an inverted repeat. *See also palindrome.*

**doublet** 1 any sequence of two nucleotides in a polynucleotide strand. 2 a closely spaced pair of spectral lines or peaks. *Compare twin.*

**doubling dilution** a serial dilution effected so that the concentration in each tube of the particular cell, substance, etc. of interest is half that in the preceding tube of the series.

**doubling time** the average time taken for the number of cells in a population to double. It will equal the **generation time** only if every cell in the population is able to form two daughter cells and there is no cell lysis.

**Dounce homogenizer or Dounee homogeniser** a hand-operated tissue homogenizer, usually of glass, consisting of a ball that is operated as a piston in a tube. The clearance is adjusted to give a fine particle size reduction without damage to cell

nuclei or mitochondria. [After Alexander Latham Dounce, US biochemist (1909- ).]

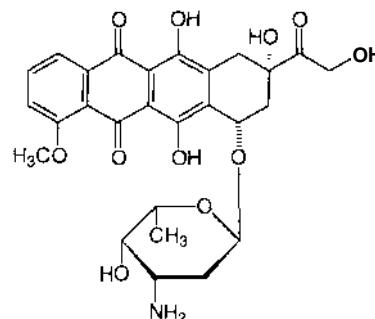

**Dowex** proprietary name for a group of synthetic ion-exchange resins made by Dow Chemical Company. *See also cholestyramine resin.*

**down regulation** 1 a decrease in response of a cell to a hormone brought about either by a decrease in receptor number or by the uncoupling of an effector component. 2 a decrease in the activity of an enzyme or the amount of a protein resulting from the action of an effector molecule on gene expression or protein synthesis. **--down-regulated adj.**

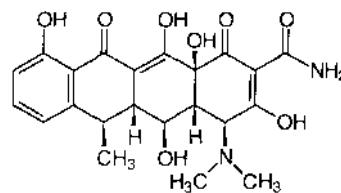

**Down's syndrome or (formerly) mongolism** a type of mental abnormality frequently associated with trisomy of chromosome 21. The condition is characterized by a small stature, a rounded head with obliquely slanted ('Mongol-like') eyes and high cheekbones, a fissured tongue with enlarged papillae, and a characteristic palmprint. The degree of mental defect varies considerably. [First described in 1866 by John Langdon Down (1828-96), British physician.]

**downstream** 1 (*in molecular biology*) that part of a strand of DNA lying towards the 3' end from the recognition sequence for a particular restriction enzyme. 2 towards the end of a multistage process, or at a stage nearer to the endpoint of the process than a key stage or one under consideration. *Compare upstream.*

**doxorubicin** a cytotoxic anthracycline antibiotic from *Streptomyces peucetius* var. *caesius*; its carbohydrate is daunosamine. It intercalates with DNA and prevents the actions of type II DNA topoisomerase. It also inhibits reverse transcriptase and acts on cell membranes. It has anti-tumour activity and has been used to treat some forms of cancer.

**doxycycline** 5-hydroxy-6-deoxytetracycline; an antibiotic having a wide range of activity against both Gram-positive and Gram-negative organisms. It is closely similar to **tetracycline** in structure and mechanism of action. One proprietary name is Vibramycin.

**DPG or 2,3-DPG** abbr. for (2,3)-diphosphoglycerate (former name for 2,3-bis(phospho)-n-glycerate).

**DPG pocket** abbr. for diphosphoglycerate pocket. *See bisphosphoglycerate pocket.*

**dpm or d.p.m.** abbr. for disintegrations per minute.

Dpm *see Azpm.*

DPN *abbr. for diphosphopyridine nucleotide when its oxidation state is unknown or unspecified (obsolete; NAD now used).*

DPN+ *abbr. for diphosphopyridine nucleotide (oxidized) (obsolete name for NAD+).*

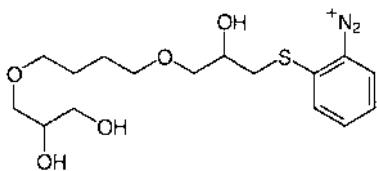

DPNH *abbr. for reduced diphosphopyridine nucleotide (obsolete; NADH now used).*

DPP *abbr. for dipeptidyl peptidase.*

Dpr *see Azpr.*

dps *abbr. for disintegrations per second.*

DPT *abbr. for 2-diazophenylthioether, the short name of the group  $-\text{O}-\text{CH}_2-\text{CH}(\text{OH})-\text{CH}_2-\text{O}-[\text{CH}_2]_4-\text{O}-\text{CH}_2-\text{CH}(\text{OH})-\text{CH}_2-\text{S}-\text{C}_6\text{H}_4-\text{N}_2^+$ , used to introduce reactive diazonium groups into cellulose or paper, forming DPT-cellulose or DPT-paper. These are used in blottransfer of proteins or nucleic acids. DPT is formed by diazotization of 2-aminophenylthioether (abbr.: APT) groups previously coupled to the support.*

D region the (third) hypervariable region occurring between the V region and the J region in the heavy chains (but not in the light chains) of immunoglobulin molecules. It is coded for by the D (for 'diversity') gene segment.

dRib *symbol for the monosaccharide deoxyribose, 2-deoxy-D-ribose.*

Drk *abbr. for 1 a small protein that bears SH2 domains (see SH domain) and acts as a link between sevenless protein and son of sevenless protein in the *Drosophila* photoreceptor system (downstream of receptor kinases). 2 Drkl a mammalian integral membrane protein forming a voltage-dependent potassium channel of the delayed rectifier class. The voltage sensor, probably segment S4, is characterized by a series of positively charged amino-acid residues at every third position. Example from rat: database code CIKA\_RAT, 853 amino acids (95.17 kDa).*

D-RNA or dRNA *abbr. for DNA-like RNA.*

dropping-mercury electrode *an electrode used in polarography in which mercury drops from a reservoir through a capillary tube into the solution under study. It has the advantage of constantly presenting a clean, unpolarized mercury surface to the solution.*

*Drosophila* a genus of small dipterous insects that includes the fruit fly, *D. melanogaster*, also known as vinegar fly or banana fly. This is much used in genetic research because of the giant chromosomes, which occur in the cells of its salivary glands, and because of its short life cycle.

Drude equation *an equation describing the variation of optical rotation with wavelength of light. It is useful in the interpretation of measurements of optical rotatory dispersion, when it may be expressed in the form:*

$$\{\bar{m'}\}_{\lambda} = \frac{96nNA}{hc} \times \frac{R\lambda_0^2}{\lambda^2 - \lambda_0^2}$$

where  $N_A$  is the Avogadro constant,  $h$  is the Planck constant,  $c$  is the speed of light,  $R$  is the rotational strength,  $\lambda_0$  is the wavelength of the centre of an absorption band,  $\lambda$  is the wavelength of the observation, and  $\{\bar{m'}\}_{\lambda}$  is the reduced mean residue rotation at that wavelength, as defined at molar optical rotation. *See also Moffitt-Yang equation. [After Paul Karl Ludwig Drude (1863-1906), German physicist, noted for, inter alia, his work on refraction of light.]*

drug any naturally occurring or synthetic substance, other than a nutrient, that, when administered or applied to an organism, affects the structure or functioning of the organism; in particular, any such substance used in the diagnosis, prevention, or treatment of disease.

drug-metabolizing enzyme or xenometabolic enzyme any enzyme that acts on a drug or other foreign compound but is not known to have any action on a normal metabolite. Many enzymes previously included in this category have subsequently been found to act also on normally occurring substrates.

drug resistance the relatively enhanced resistance of an organism to the action of a drug. It may be caused by induction of an enzyme acting on the drug, by mutation, or by the acquisition of a plasmid coding for drug resistance.

dry ice solid carbon dioxide. It is a convenient cooling agent because, at ordinary atmospheric pressures, heat converts it directly to the gaseous form (sublimation point 194.65 K at 101 325 Pa; -78.5 °C at 760 Torr).

DsbA a 21 kDa protein that is the bacterial functional equivalent in *Escherichia coli* of protein disulfide-isomerase in eukaryotes. There is little similarity in the primary structure of the two proteins. The structure of DsbA has been determined by X-ray crystallography and part of the structure shown to be similar to thioredoxin.

DSC *abbr. for differential scanning colorimetry or differential scanning calorimeter.*

dsDNA *abbr. for double-strand(ed) DNA (see duplex DNA).*

DSPD *abbr. for disalicylidene propanediamine.*

dsRNA *abbr. for double-strand(ed) RNA.*

DSS *abbr. for 2,2-dimethylsilapentane 5-sulfonic acid; a compound used as a water-soluble reference substance in nuclear magnetic resonance spectroscopy.*

dsx *abbr. for the doublesex gene in *Drosophila melanogaster*. Alternative splicing of the same transcript yields the male-specific protein (database code DSXM\_DROME, 549 amino acids (57.35 kDa); and the female-specific protein (database code DSXF\_DROME, 427 amino acids (44.72 kDa)). They are transcription factors that bind to the fat body enhancer.*

dT symbol for a residue of the deoxynucleoside thymidine (alternative to dThd).

dTDP *abbr. for deoxyribosylthymine diphosphate or thymidine diphosphate, the common names for 2'-deoxyribosylthymine-5'-diphosphate; thymidine 5'-diphosphate; 5'-thymidylyl phosphate; thymine 2'-deoxyriboside 5'-diphosphate.*

DTE *abbr. for 1,4-dithioerythritol.*

dThd symbol for a residue of the deoxynucleoside thymidine; 2'-deoxyribosylthymine; thymine 2'-deoxyriboside (alternative to dT).

dThd5'P symbol for thymidine 5'-phosphate.

dThd5'PP symbol for thymidine 5'-diphosphate (alternative to ppdT).

dThd5'PPP symbol for thymidine 5'-triphosphate (alternative to pppdT).

dTMP *abbr. for deoxyribosylthymine monophosphate or thymidine monophosphate, the common names for 2'-deoxyribosylthymine 5'-phosphate, thymidine 5'-phosphate, 5'-thymidylic acid, thymine 2'-deoxyriboside 5'-phosphate.*

DTNB *abbr. for 5,5'-dithiobis(2-nitrobenzoic acid); see Ellman's reagent.*

DTT *abbr. for 1,4-dithiothreitol.*

dTTP *abbr. for deoxyribosylthymine triphosphate or thymidine triphosphate, the common names for 2'-deoxyribosylthymine 5'-triphosphate; thymidine 5'-triphosphate; 5'-thymidylyl diphosphate; thymine 2'-deoxyriboside 5'-triphosphate.*

dU symbol for a residue of the deoxynucleoside 2'-deoxyuridine (alternative to dUrd).

dual specificity mitogen-activated protein kinase kinase *see MAP kinase kinase.*

Dubnoff shaker a controlled-temperature water bath with a uniformly oscillating load platform and facilities for main-

## Duboscq colorimeter

## dynactin

taining a controlled atmosphere. It is used for studies of the metabolism of tissues and microorganisms and for enzyme and blood-coagulation studies. [After Jacob William Dubnoff (1909- ), US biochemist.]

**Duboscq colorimeter** an early, accurate visual colorimeter for determination of small quantities of substances in solution, in which the intensities of colour of two solutions, standard and unknown, were compared by varying the path-lengths of light passing through them from a single source until their apparent colours matched. This was achieved by placing the solutions in flat-bottomed vessels (termed cups) and adjustment of their positions in relation to two identical, fixed, transparent plungers through which the light passed, via prisms, to a divided-field eyepiece. The path-length in each solution was then read from a vernier scale. [After Jules Duboscq (1817-86), French optician.]

**Duchenne muscular dystrophy** see *dystrophin*.

**ductless gland** *an alternative name for* endocrine gland.

**DUDP** *abbr. for* deoxyuridine diphosphate, the common name for 2'-deoxy-5'-uridylyl phosphate; 2'-deoxyuridine 5'-diphosphate; uracil 2'-deoxyriboside 5'-diphosphate.

**Duffy system** *symbol:* Fy; a blood-group system for which the antigenic determinant depends on the structure of an erythrocyte membrane glycoprotein, of molecular mass 35-55 kDa, the structural details of which are lacking.

**Dulbecco, Renato** (1914- ), Italian-born US virologist notable for demonstrating how certain viruses are able to transform some cells into a cancerous state; Nobel Laureate in Physiology or Medicine (1975) jointly with D. Baltimore and H. M. Temin 'for their discoveries concerning the interaction between tumour viruses and the genetic material of the cell'.

**dulcitol** *another (older) name for* galactitol.

**DUMP** *abbr. for* deoxyuridine monophosphate, the common name for 2'-deoxyuridine 5'-phosphate; 2'-deoxy-5'-uridylic acid; uracil 2'-deoxyriboside 5'-phosphate.

**duodenum** that part of the small intestine extending from the pylorus of the stomach to the jejunum. In mammals it lies around the head of the pancreas and receives the duct from the exocrine pancreas and the gall bladder. -duodenal *adj.*

**Duolite** *proprietary name for* a group of ion-exchange resins. It includes those formerly known by the names Biodemirrolit, De-Acidite, Zeo-Karb, and Zerolit.

**duplex** 1 having two parts or elements, especially of similar form or function. 2 describing a molecular structure (or part of one) in which two polynucleotide strands lie side by side in a head-to-tail orientation and are linked together along their length; *see duplex DNA*. 3 describing a telegraphic system, computer channel, etc. that permits two messages to be sent simultaneously in opposite directions.

**duplex DNA** double-stranded DNA in which the two polynucleotide chains are linked together by hydrogen bonds between complementary base pairs along their lengths, with the 3'→5' phosphodiester bonds of the two chains running in opposite directions. Such a molecule is usually coiled into a double helix and it may not be covalently closed into a circular molecule and/or formed into superhelical DNA (*see supercoil*) *See also double helix*.

**duplicate (in biology)** to reproduce by division into two equal parts; *see binary fission*.

**duplication** *see gene duplication*.

**Durd** *symbol for* a residue of the deoxynucleoside deoxyuridine; 2'-deoxyribosyluracil; uracil 2'-deoxyriboside (*alternative to* dU).

**Durd5'P** *symbol for* deoxyuridine 5'-phosphate.

**Durd5'PP** *symbol for* deoxyuridine 5'-diphosphate (*alternative to* ppdU).

**Durd5'PPP** *symbol for* deoxyuridine 5'-triphosphate (*alternative to* ppdU).

**dUTP** *abbr. for* deoxyuridine triphosphate, the common name for 2'-deoxyuridine 5'-triphosphate; 2'-deoxy-5'-uridylyl diphosphate; uracil 2'-deoxyriboside 5'-triphosphate.

**dUTPase** EC 3.6.1.23; *recommended name:* dUTP pyrophosphatase; *systematic name:* dUTP nucleotidohydrolase; *other name:* deoxyuridine-triphosphatase. An enzyme of nucleotide metabolism in eukaryotes that prevents the incorporation into DNA of deoxyuridyl residues from dUTP by catalysing the hydrolysis of the latter to dUMP and pyrophosphate. Genes for dUTPase are found in several viruses, e.g. herpes simplex type I: database code DUT\_HSVII, 371 amino acids (39.08 kDa).

**Duve** *see de Duve*.

**du Vigneaud, Vincent** (1901-78), US biochemist distinguished for the synthesis of the posterior pituitary hormones oxytocin and vasopressin, for establishing the structure of biotin, and for his contributions to the synthesis of penicillin; Nobel Laureate in Chemistry (1955) 'for his work on biochemically important sulphur compounds, especially for the first synthesis of a polypeptide hormone'.

**dwarfism** underdevelopment of the body due to hyposecretion of somatotropin. Affected humans typically attain adult heights of less than 1.25 m.

**Dy** *symbol for* dysprosium.

**dyad** 1 two units treated as one. 2 a meiotic chromosome in which the two homologous members of the tetrad have separated. 3 a pair of cells resulting from the first meiotic division. 4 a bivalent atom, molecule, or group. *See also dyad symmetry, dyad axis*.

**dyad-related** describing a phenomenon that occurs at a specific position with respect to a dyad axis.

**dyad symmetry** 1 the type of symmetry occurring in molecular structures in which there is repetition after every 180° rotation around a dyad axis. 2 (*in molecular biology*) the formal description of a palindromic sequence in which the axis of symmetry is at the centre of the palindromic sequence. *See palindrome*.

**dye** a natural or synthetic substance that strongly absorbs certain wavelengths of visible or near ultraviolet light and is used to colour material by becoming firmly attached to it. *See also stain*.

**dye-exclusion test** a test for cell viability based on the phenomenon that living cells exclude some dyes, e.g. Eosin and Trypan Blue, whereas dead cells take them up and become stained.

**dye-laser** a device for obtaining high-intensity light of chosen wavelength by passing the monochromatic emission beam of a laser through a stream of liquid containing a fluorescent dye, and then passing the emitted broad-band fluorescent light through a monochromator. By variation of the dye employed a wide range of wavelengths of high-intensity light can be obtained from the single-wavelength laser emission. The light obtained by this device is necessarily of longer wavelength than that of the laser emission.

**dye-ligand chromatography or pseudo-affinity chromatography or pseudo-ligand affinity chromatography** a technique similar to affinity chromatography in which the immobilized ligand is anyone of certain reactive dyes (coupled usually to cross-linked agarose), the dye commonly being a triazinyl compound, e.g. Reactive Blue 2 or Reactive Red 120. The technique is thus sometimes referred to (inappropriately) as triazine-dye affinity chromatography. The fixed dye molecules selectively bind particular enzyme or other protein molecules; the specificity of the interaction varies widely with both protein and dye, although frequently the dye appears to mimic a natural ligand of the protein. Examples of use are the isolation of nucleotide-requiring enzymes (*see also nucleotide-binding fold*) and the removal or purification of albumin from serum. The underlying mechanism is not fully understood but appears to involve both hydrophobic (Le. apolar) and strongly ionic interactions. Many uses may in reality be examples of affinity-elution chromatography.

**dynactin** the largest protein component of the dynactin complex, a 20S multiprotein assembly of total mass about 1.2

**dynamic**

MDa, that activates dynein-based activity *in vivo*. A large structural component of the complex is an actin-like 40 nm filament composed of actin-related protein, to which other components attach. Vertebrate dynactin is a ubiquitously expressed cytoplasmic protein; several isoforms of mass ranging from 117 kDa to 160 kDa are produced by alternative splicing. It has a high degree of homology with the product of the *Drosophila* gene *glued*, essential during embryogenesis, some mutations of which kill homozygous embryos. Example from rat: database code DYNA\_RAT, 1325 amino acids (146.05 kDa).

**dynamic** of, or concerned with, motion or force, or with dynamics.

**dynamics** 1 the branch of a science, especially mechanics, concerned with the motions of objects and the forces that produce such motions. It includes **kinetics**. 2 those forces that produce change or movement in a system or molecule; the motions (e.g. of residues within a macromolecule) so resulting.

**dynamic state of body constituents** the phenomenon, discovered in the early 1940s, that body components, especially proteins, are in a state of continuous degradation and resynthesis (i.e. of dynamic equilibrium). It was subsequently found to be applicable to other body constituents, although genomic DNA is a notable exception.

**dynamin** a microtubule-associated protein able to bind and hydrolyse GTP. The dynamin family includes two types, neuron-specific dynamin 1, and the widely expressed dynamin 2, which exhibit a high degree of sequence similarity in the 300 amino acid N-terminal region containing the GTP-binding site, but show divergence in a 100 amino acid proline-rich C-terminal region that in dynamin 1 but not dynamin 2 is a site for regulation of GTPase activity by phosphorylation-dephosphorylation. Dynamins are activated by protein kinase C and have a **pleckstrin homology domain** which binds acidic (especially inositol-) phospholipids with activation of the GTPase activity. Dynamins are involved in formation of microtubule bundles and in vesicular trafficking; purified dynamin 2 in solution forms helical structures that *in vivo* may facilitate the pinching off of vesicles budding from the plasma membrane and accelerate endocytic recycling. The *Drosophila* protein (a dynamin 2) is a product of *shibire*, a gene known to be involved in endocytosis. Examples, rat dynamin 1: database code DYNLRAT, 851 amino acids (95.93 kDa); *Drosophila* product of *shibire*: database code DYN\_DROME, 883 amino acids (98.54 kDa).

**dyne symbol:** dyn; the CGS unit of force, defined as the force required to give one gram an acceleration of one centimetre

**dystrophy**

per second per second. A gram weight thus represents a force of about 980 dyn. 1 dyn =  $10^{-5}$  N.

**dynein** a large, multisubunit protein complex with ATPase activity, that is associated with microtubules and functions as a molecular motor to drive the movement of a diverse range of intracellular structures, such as endosomes, lysosomes, and mitochondria, along microtubules towards the centrosome. It is also attached to the peripheral fibrous components of eukaryotic flagella and cilia and is responsible for their movement; it may also play a role in the separation of chromosomes at cell division. The complex consists of two heavy chains ( $\sim$ 500 kDa), three or four intermediate chains ( $\sim$ 70 kDa) and four light chains ( $\sim$ 50 kDa). Example: cytoplasmic dynein heavy chain (MAP-1C) from rat: database code RAT-DYNEINC, 4644 amino acids, (531 kDa); intermediate chain from *Chlamydomonas reinhardtii*: database code DY06\_CHLRE, 567 amino acids (63.52 kDa).

**dynorphin** an opioid tridecapeptide of high potency found in pig brain, duodenum, and pituitary, having the structure

Tyr-Gly-Gly-Phe-Leu-Arg-Arg-Gln-Phe-Lys-Val-Val-Thr, the N-terminal pentapeptide sequence of which is identical with **[5-leucine]enkephalin**. It is synthesized as **preprodynorphin** (also called preproenkephalin B), from which its precursor protein **prodynorphin** (also called  $\beta$ -neoendorphin or proenkephalin B), a 236-residue polypeptide, is formed. See also **endorphin**.

**dys+** prefix indicating abnormal, diseased, impaired, painful, or difficult.

**dysfunction** any abnormality or disturbance in the function of an organ, tissue, cell, or part of a cell. -**dysfunctional ad.**

**dysgenic** genetically deleterious.

**dystroglycan** a protein precursor yielding a 43 kDa transmembrane glycoprotein and an extracellular 156 kDa dystrophin-associated glycoprotein in skeletal muscle; the 156 kDa component binds **laminin**, acting as a laminin receptor that links the extracellular matrix and **sarcolemma** in skeletal muscle. Example (precursor) from human: database code DSG1\_HUMAN, 1049 amino acids (113.59 kDa).

**dystrophin** a protein present in small amounts in normal muscle but absent or abnormal in patients with **Duchenne muscular dystrophy**. It may play a role in anchoring the cytoskeleton to the plasma membrane. Example from human: database code OMD\_HUMAN, 3685 amino acids (426.19 kOa). See also **dystroglycan, utrophin**.

**dystrophin-related protein** (abbr ORP) see **utrophin**.

**dystrophy** any disorder, sometimes genetic, of the structure and functions of an organ or a tissue, as of muscle or bone. -**dystrophic ad.**

# Ee

**e** symbol for 1 electron; it may be written as e- to indicate its charge; e+ denotes a positron. 2 (in mathematics) the transcendental number equal to the limiting value of the series  $[1 + (ln!)^n]$  for  $n = 1$  to infinity; its value is 2.718 281 82846. It is used as the base of natural (Napierian) logarithms. 3 equatorial; see conformation.

**e'** symbol for pseudo-equatorial; see conformation.

**e** symbol for 1 elementary charge (or proton charge) 2 efficacy (of a drug).

**E** symbol for 1 a residue of the α-amino acid L-glutamic acid (alternative to Glu). 2 elimination reaction. 3 electromeric effect (in electron displacement). 4 exa+ (SI multiplicative prefix denoting  $10^{18}$ ).

**IE<sub>lo</sub>** or **[E]t<sub>o</sub>** or **IE<sub>stoich</sub>** (in enzyme kinetics) symbol for the total or stoichiometric concentration of active (catalytic) centres.

**E**, abbr. for estrone.

**E<sub>Z</sub>** abbr. for estradiol.

**E74** a protein, expressed during development of *Drosophila*, that correlates with an ecdysone-induced activity of puff 74EF. It is encoded by *Drosophila EIP74Ej*, an ecdysone-inducible gene that encodes two *ETS-related* protein products, E74A and E74B, that differ mainly in their N-terminal regions, and have substantial poly-Ala, poly-Asn, poly-Gin, poly-Gly, and poly-Ser domains.

**E** symbol for 1 (in chemical nomenclature) a specific configuration around a double bond; see *Ell* convention. 2 electromotive force. 3 electric potential difference (of a galvanic cell). 4 energy; kinetic energy and potential energy may be denoted by the symbols  $E_k$  and  $E_p$  respectively. 5 extinction coefficient (no longer recommended). 6 (bold italic) electric field strength (see electric field).

**E**- prefix (in chemical nomenclature) denoting a geometric isomer in which the highest priority ligands according to the Cahn-Ingold-Prelog rules (see sequence rule) are located on opposite sides of a double bond. See also *Ell* convention.

**-E** conformational descriptor denoting the envelope conformation of a monosaccharide or monosaccharide derivative.

**$E^\ominus$  or  $E^\oplus$**  symbol for standard electrode potential.

**$E'$  or  $E^\ominus'$**  symbol for standard electrode potential at a specified pH.

**E**, or  **$E_A$**  symbol for (Arrhenius) activation energy.

**E<sup>•</sup>** symbol for electron affinity (def. 2).

**Eadi&-Hofstee plot** a graphical representation of enzyme kinetic data in which the reaction velocity divided by the substrate concentration,  $v/[S]$ , is plotted as ordinate against the reaction velocity,  $v$ , as abscissa. If a straight line is obtained, the intercept on the abscissa gives the maximum velocity,  $V$ , and that on the ordinate  $V/K_m$ . The slope is  $-1/K_m$ . [After George Sharpe Eadie (1895-1976) and Barend Hendrik Jan Hofstee (1912-80). US biochemists, who independently described it in 1942 and 1952, respectively.]

**Eagle's medium** any of various growth or maintenance media used in tissue culture and essentially comprising a balanced salt solution, usually Earle's balanced salt solution or Hanks's balanced salt solution, supplemented with amino acids, vitamins, serum, and antibiotics.

**EAR-3** see COUP.

**Earle's balanced salt solution** a solution used in tissue culture to provide a normal ionic, pH, and osmotic environment for cell growth. It contains, per 100 ml distilled water, 0.68 g NaCl, 0.04 g KCl, 0.02 g CaCl<sub>2</sub>, 0.02 g MgSO<sub>4</sub>·7H<sub>2</sub>O, 0.0125 g NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O, 0.22 g NaHCO<sub>3</sub>, 0.1 g glucose, and 0.002 g Phenol Red; it has a pH of 7.6-7.8.

**early enzyme** an enzyme that is transcribed from an early gene (def. 2) of a virus. Compare late enzyme.

**early gene** 1 or immediate gene any of a number of genes in-

volved in the earliest responses of cells to factors that initiate the transition from quiescence to proliferation. Early genes include those that encode transcription factors, such as the *c-JUN*, *c-FOS*, and *c-EGR* genes, and those coding for structural proteins such as actin. Early genes are further subdivided into immediate-early and delayed-early genes. 2 any viral gene that is transcribed early after the virus infects a host cell. Such genes probably code for proteins that are necessary for viral nucleic acid replication. Compare late gene.

**early growth response protein** any of a family of proteins that are expressed early in response to growth factors and function as transcriptional regulators, binding to the DNA sequence 5'-CGCCCCGC-3'. Example, early growth response protein 1 from human (other names: krox24, TF ETR103); database code EGRI\_HUMAN, 543 amino acids (57.51 kDa).

**early protein** a protein that is transcribed from an early gene (def. 2) of a virus. Compare late protein.

**early quitter** any incomplete polypeptide formed in an *in vitro* translation system.

**Easson-Stedman model** a model to explain the differences in biological activity of two enantiomeric molecules; it assumes that three of the groups attached to an asymmetric carbon atom in an agonist (or substrate) are involved in its attachment to a specific receptor (or enzyme), one enantiomer will therefore be a better agonist (or substrate) than the other. The concept is similar to, but considerably pre-dates, that developed by Ogston (see Ogston concept).

**EBV or ED virus** abbr. for Epstein-Barr virus.

**EC** abbr. for 1 Enzyme Commission; it is used as a prefix in the numerical designation of an enzyme (see enzyme classification).

2 electron capture. 3 enterochromaffin (as in EC cell).

**EC<sub>50</sub>** abbr. for half effective concentration; the molarity of an agonist that produces 50% of the maximal possible effect of that agonist. Other percentage values ( $EC_{20}$ ,  $EC_{40}$ , etc.) can be specified. The action of the agonist may be stimulatory or inhibitory.

**EC cell** abbr. for enterochromaffin cell.

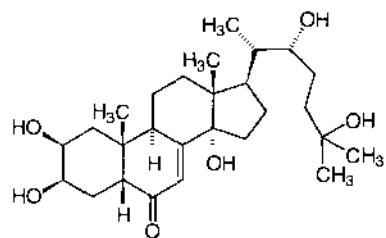

**Eccles**, (Sir) John Carew (1903-97), Australian neurophysiologist; Nobel Laureate in Physiology or Medicine (1963) jointly with A. L. Hodgkin and A. F. Huxley 'for their discoveries concerning the ionic mechanisms involved in excitation and inhibition in the peripheral and central portions of the nerve cell membrane'.

**eccrine** 1 describing a secretory cell that discharges its product without loss of cytoplasm. 2 describing a gland made up of such cells. Compare apocrine, holocrine, merocrine.

**ECD** abbr. for 1 electron capture detector. 2 electrochemical detection. See polarography.

**ecdysis** the periodic shedding of the exoskeleton and construction of a new cuticle, as in insects and crustaceans, or the shedding of the outer layer of the skin, as in reptiles. -ecdysial ad.

**ecdysone** 1 ex-ecdysone (22R)-2P,3P,14,22,25-pentahydroxycholest-7-en-6-one; the ecdysteroid that is synthesized in and

## ecdysone receptor

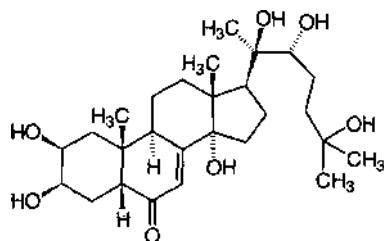

ED<sub>so</sub>

secreted by the prothoracic glands of immature insects and the ovaries of the adult females. First isolated from the silkworm moth (*Bombyx mori*), it is the inactive prohormone of the moulting hormone ecdysterone; it may also have intrinsic hormonal activity at other stages of insect development. 2  $\beta$ -ecdysone *an alternative name for ecdysterone. 3 a former name for ecdysteroid.*

**ecdysone receptor** a receptor for ecdysone, located in the cell nucleus and related to the steroid/thyroid/retinoic acid family of nuclear hormone receptors. It consists of a heterodimer of a subunit named EcR (ecdysone receptor) and another named USP (ultraspiracle), the insect homologue of vertebrate retinoid X receptor. The heterodimer binds ecdysone with high affinity, and the ternary complex binds to DNA. Example: database code ECR\_DROME, 878 amino acids (93.85 kDa).

**ecdysteroid or (formerly) ecdysone** any of a group of polyhydroxylated ketosteroids of which  $\alpha$ -ecdysone is the parent substance for the purpose of nomenclature (*see ecdysone*). They are almost invariably C<sub>27</sub> steroids, differing only in the number and/or steric arrangement of their hydroxyl groups. Ecdysteroids are ubiquitous in insects and other arthropods, in which they initiate postembryonic development, including the metamorphosis of immature forms and the development of the reproductive system and the maturation of oocytes in adult females. They have been found also in annelids, molluscs, and nematodes. Cognate substances, often known as phytoecdysterones, have been identified in plants. The principal ecdysteroids in insects are  $\alpha$ -ecdysone (*see ecdysone (def. 1)*) and ecdysterone.

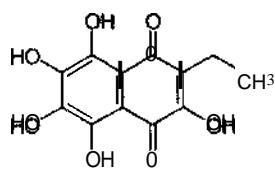

**ecdysterone or 13-ecdysone or crustecdysone or (insect) moulting hormone 20-hydroxyecdysone; (22R)-2*i*,3*i*,14,20,22,25-hexahydroxycholest-7-en-6-one;** the ecdysteroid isolated both from insects and from crustaceans. In insects, ecdysterone is formed in peripheral tissues from  $\alpha$ -ecdysone through the action of ecdysone 20-monoxygenase (EC 1.14.99.22). The hormone causes puffing of polytene chromosomes, and initiates moulting of larval and pupal forms by stimulating the epidermal cells to enlarge, divide, and secrete degradative enzymes that dissolve the protein and chitin components of the cuticle. Moreover, in the adult females of certain insects, e.g. mosquitoes (*Aedes* spp.) and *Drosophila melanogaster*, ecdysterone formed from  $\alpha$ -ecdysone in the ovaries stimulates vitellogenin synthesis in the fat body.

**ECF** abbr. for extracellular fluid.

**ECG or (US) EKG** abbr. for 1 electrocardiograph. 2 electrocardiogram.

**echinochrome A** 2-ethyl-3,5,6,7,8-pentahydroxy-1,4-naphthalenedione; a red pigment of sea urchin eggs.

**echinoderm** any of the phylum Echinodermata of marine invertebrates that contains sea urchins, sea cucumbers, starfish, etc. They are more or less radially symmetrical, with calcareous skeletal plates in their skin and a well-developed coelom. Locomotion and gaseous exchange are accomplished by means of retractable tube feet. They are related to the same ancestral stock that gave rise to the vertebrates.

**eclipsed conformation** *see torsion angle.*

**eclosion hormone** any peptide hormone that programmes the death of certain muscles and neurons during metamorphosis of insects.

**ecology** the branch of biology dealing with the relations of living organisms to their surroundings. -ecological *adj.*; ecologically *adv.*; ecologist *n.*

**ecomone** any nontrophic molecule that ensures a flux of information between organisms in an ecosystem.

**ecosystem** a unit of the environment together with the organisms it contains. There is a constant interchange between living organisms and their chemical and physical environment.

**ecotin** a monomeric periplasmic protein of *Escherichia coli* that inhibits the pancreatic serine proteases chymotrypsin, trypsin, and elastases, enabling the organism to survive in the presence of these enzymes. It also inhibits blood coagulation factors Xa and XIIa and kallikrein, thereby having anticoagulant effects. Example from *E. coli*: database code ECOT\_ECOLI, 162 amino acids (18.17 kDa).

**ECP** abbr. for eosinophil cationic protein.

**ecstasy** *see* 3,4-methylenedioxymethamphetamine.

**ECTEOLA cellulose** abbr. for a weakly basic ( $pK \approx 7.5$ ) anion-exchange material of uncertain structure, prepared by the condensation of epichlorohydrin, triethanolamine (hence e.c + t,e,ola), and cellulose. It is useful for separations of proteins, nucleoproteins, and nucleic acids.

**ecto+ comb. form** indicating external, outer.

**ectocrine** describing or relating to a metabolite that, when released from the organism in which it was made, differentially affects other organisms of the same or a different species. Such a metabolite might be harmful to some members of a community and beneficial to others. The term includes allomone, ectohormone, kairomone, and pheromone. *Compare endocrine (def. 1), exocrine (def. 1).*

**ectoenzyme** any enzyme that is attached to the external surface of the plasma membrane of a cell.

**ectohormone** any ectocrine substance whose production and release benefits either the organism producing it or other members of the same species. *Compare endohormone.*

**ectoparasite** any parasite that lives on the exterior of its host organism.

**ectopic** occurring in an unusual place or in an unusual form or manner. For example, an ectopic protein is a protein produced by a neoplasm derived from a tissue that does not normally produce that protein. An example is the production of vasopressin and corticotropin by small cell lung cancer. Ectopic pregnancy occurs when the fertilized ovum implants outside the uterus e.g. in a fallopian tube. *Compare entopic.*

**ectoplasm** the outer, relatively rigid part of the cytoplasm. *Compare endoplasm. -ectoplasmic adj.*

**ectoplast** the part of the plasma membrane of a plant cell that is in contact with the cell wall.

**ectoprotein** any individual protein found on the exterior of cells. Such proteins may function, e.g., as mediators of cell-cell or cell-surface interactions, or as receptors for substances with regulatory actions on cells.

**ectosymbiont** a partner in a symbiotic relationship that remains outside the tissues and cells of the other partner, often occupying a body cavity; e.g. one of the cellulose-metabolizing microorganisms occurring in the digestive tract of ruminants. *Compare endosymbiont. See also symbiosis.*

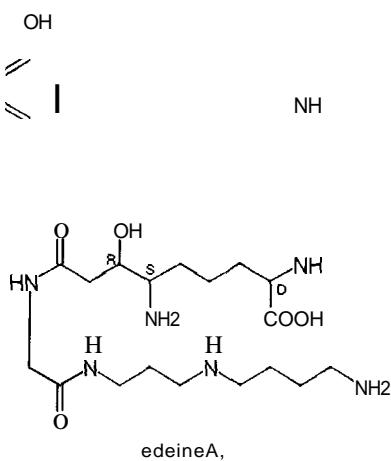

**ED<sub>50</sub>** abbr. for median effective dose; i.e. the dose of a drug or other agent that produces, on average, a specified all-or-none response in 50% of a test population, or, if the response is

## edeine

EF.<sup>1</sup>

graded, the dose that produces 50% of the maximal response to that drug or agent.

**edeine** any of several pentapeptide-amide antibiotics elaborated by a strain of *Bacillus brevis* and effective against Gram-positive and Gram-negative bacteria, some fungi and other eukaryotic cells, and some neoplastic cells. Edeine AI, *N*[(*N*<sup>2</sup>-[*N*-(*f*3-tyrosyl)isoseryl]-2,3-diaminopropionyl)-2,6-diamino-7-hydroxyazela-9-yl]glycyl]spermidine, and its *NW*-amidinospermidine analogue, edeine B<sub>1</sub>, are highly active; their respective constitutional isomers, edeines A<sub>2</sub> and B<sub>2</sub>, have low intrinsic activity. In intact bacteria, low concentrations of edeine reversibly inhibit DNA synthesis and enhance RNA synthesis but do not affect protein synthesis. In cell-free systems, edeine AI interacts with both ribosomal subunits (preferentially the smaller one) and strongly inhibits translation.

**Edelman, Gerald Maurice** (1929- ), US biochemist; molecular biologist, and neuroscientist; Nobel Laureate in Physiology or Medicine (1972) jointly with R. R. Porter 'for their discoveries concerning the chemical structure of antibodies'.

**edema** or (esp. Brit.) oedema swelling of an organ or tissue due to the accumulation of fluid. -edematous or (esp. Brit.) oedematous *ad*.

**edestin** a 300 kDa globulin obtained from hemp seed, castor-oil beans, and certain other seeds. It readily forms polymorphic crystals and will support the growth of animals in the absence of other dietary proteins. [From Greek *edestos*, edible.]

**edetate** see EDTA.

**EDF** abbr. for erythroid differentiation protein; *see* activin.

**editing** 1 the process or act of altering or adapting erroneous molecular structures, especially nucleotide sequences in polynucleotides, so as to preserve fidelity in the transfer and expression of genetic information. For example, the 3'→5' exonuclease activity of DNA polymerase I has an editing function in DNA polymerization by removing mismatched residues at the primer terminus of the growing chain. Another editing function is shown by aminoacyl-tRNA synthetases. In the presence of ATP and the 'wrong' amino acid, these enzymes do not catalyse the formation of the incorrect aminoacyl-tRNA but act as ATP pyrophosphatases, hydrolysing ATP to AMP and pyrophosphate. The term is applied also to the processes of conversion of RNA precursors, e.g. hnRNA, to the mature form, mRNA. 2 the insertion, deletion, or substitution of nucleotides within nascent RNA transcripts to produce RNA molecules with sequences that differ from those coded genetically. Most examples have been found in organelle-encoded RNAs, e.g. mitochondrial RNAs, and include

ApoB, several glutamate receptor mRNAs, and Wilms tumour susceptible gene mRNA. In the case of ApoB, a cytidine residue is deaminated to a uridine residue so that the codon for glutamine (CAA) becomes a stop codon (UAA); hence, translation results in a shortened form of the protein.

**editosome** a macromolecular complex involved in the editing of RNA transcripts. Specific ribonucleotide complexes include guide RNA (*see* gRNA), which specifies the edited sequence.

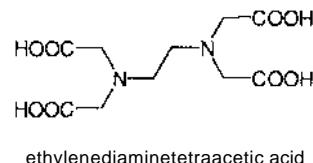

**Edman degradation** a procedure used in sequencing (poly)peptides in which amino-acid residues are removed stepwise from the N terminus by reaction with phenylisothiocyanate, C<sub>6</sub>H<sub>5</sub>-N=C=S, to form the phenylthiocarbamyl-peptide (*abbr.*: PTC-peptide). This is then cleaved in anhydrous acid (which favours attack by the sulfur atom on the carbonyl carbon of the terminal peptide) to give a thiazolinone intermediate and the release of the remainder of the peptide chain. The thiazolinone intermediate is hydrolysed to the phenylthiocarbamyl derivative of the N-terminal amino acid, which then cyclizes to form the phenylthiohydantoin derivative (*abbr.*: PTH-amino acid). The PTH-amino acid is extracted into organic solvents and identified by chromatography. These derivatives have a strong UV-absorption at about 259 nm, which permits them to be visualized against a fluorescent screen using an ultraviolet light source. As the remainder of the peptide chain is liberated intact, the procedure may be repeated - up to about ten amino-acid residues may be sequenced in this way, or more in favourable cases. The procedure may be automated, e.g. in a sequenator. [After Pehr Victor Edman (1916-77), Swedish protein chemist, who described the method in 1956.]

**Edman reagent** phenylisothiocyanate; C<sub>6</sub>H<sub>5</sub>-N=C=S. *See* Edman degradation.

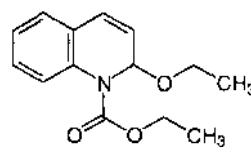

**EDR** *abbr.* for equi-effective dose ratio.

**EDRF** *abbr.* for endothelium-dependent releasing factor (*see* nitric oxide).

**EDTA** ethylenediaminetetraacetate; edetate; any anion or salt, esp. the (hydrated) disodium salt, of edetic acid, ethylenediamine-*N,N,N',N'*-tetraacetic acid, (ethylenedinitrilo)tetraacetic acid. Commonly used as the disodium salt, it is a powerful chelating agent for divalent metal ions.

**EEDQ** *abbr.* for N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline; an agent for peptide condensation that causes little or no racemization; it is useful in coupling ligands to insoluble polymers. It also causes progressive and irreversible inhibition of mitochondrial F,-ATPase.

**eEF-2** a eukaryotic elongation factor that is equivalent to the prokaryotic EF-G.

**EET** (*formerly*) *abbr.* for epoxyeicosatetraenoate.

**EF** *abbr.* for elongation factor.

**EF-1** *see* EF-T, elongation factor.

**EFE**

**EFE** abbr. for ethylene-forming enzyme.

**effective dose** see **ED<sub>50</sub>**.

**effective theoretical plate number symbol:** *N*; a number indicative of chromatographic column performance when resolution is taken into account:  $N = 16R_s^2/(1 - a)^2$ , where  $R_s$  is the peak resolution and  $a$  the separation factor (i.e. the ratio of the distribution ratios or coefficients for the two substances being resolved when measured under identical conditions); by definition  $a$  is greater than unity. Compare **height equivalent to an effective theoretical plate**. See also **theoretical plate**.

**effectomer** the part of a two-component agonist that brings about the biological effect but only when bound to a **haptomer**, which enables it to interact with the cell membrane and exert its toxic action on intact cells. For example, the A fragment of diphtheria toxin can only exert its toxic effects on a target cell when bound to the B fragment.

**effector 1 or modifier or modulator** (in molecular biology) any small molecule or ligand that interacts with an enzyme thereby changing its catalytic behaviour but that is not itself changed during the enzyme action. A **positive effector** enhances catalytic activity while a **negative effector** reduces it. See also **allosteric effector**. 2 (in physiology) a cell or organ that produces a physiological response when stimulated by the nervous system.

**effector site or regulatory site** any site on an enzyme molecule that binds an **effector**.

**efferent 1** conveying outwards from a part, organ, or centre; e.g. of a blood vessel, nerve, or duct. 2 an efferent part, e.g. a blood vessel or nerve. Compare **afferent**.

**efficacy symbol:** *e*; a quantitative index of drug action related to the magnitude of a tissue response generated at a given level of receptor occupancy with (full) agonists (of high efficacy) generating the maximum possible response. Drugs with lower efficacy that cannot generate a maximal response even when all receptors are occupied are known as **partial agonists**; **antagonists** have an efficacy of zero. The overall response to a drug will be a function of its efficacy and receptor binding affinity, which determines the proportion of receptors occupied at a given concentration of drug. It may be formulated as the combination of an agonist with its receptors that results in a signal or a **stimulus**, *S*, equal to the product of the efficacy of the agonist, *eA*, and the proportion of receptors occupied, *PAR*; i.e.  $SA = eAPAR$ . See also **intrinsic efficacy**, **maximal agonist effect**.

**efficiency** the ratio of the useful output of a machine, device, system, etc. to the input, whether in terms of thermal, mechanical, or radiation energy, or of biological or chemical conversions.

**efficiency of counting** see **counting efficiency**.

**efficiency of plating abbr.:** EOP; a quantification of the relative efficiencies with which different cells can be infected by viruses, and support viral replication. It is the ratio of the plaque count to the number of virions in the inoculum.

**efflux** see **lux**.

**EF-G or translocase abbr.** for an **elongation factor** of *Escherichia coli* that promotes the GTP-dependent translocation of the nascent protein chain from the A-site to the P-site of the ribosome. Database code EFG\_ECOLI, 703 amino acids (77.36 kDa). An equivalent factor in eukaryotes is named eEF-2.

**EF-hand a helix-turn-helix motif** that binds  $\text{Ca}^{2+}$ ; it is found in many  $\text{Ca}^{2+}$ -binding membrane proteins and also in certain others, e.g. **myosin** light chain. It was first recognized in parvalbumin, in which it involves helices E and F. To envisage the motif, use the right hand with thumb and forefinger extended at  $\approx 90^\circ$  with the remaining three fingers clenched. The thumb will then point towards the C terminus of helix F and the forefinger will point along helix E in the N-terminal direction, the clenched fingers tracing the course of the E-F loop about the bound calcium ion. Two apposed right-hands, representing the E and F and the C and D helices of the molecule, are related by a 2-fold axis of symmetry.

**efrapeptin or efrastatin or A23871** a hydrophobic peptide fun-

**Ehlers-Danlos syndrome**

gal antibiotic that inhibits oxidative phosphorylation by binding to the soluble component,  $F_1$ , of mitochondrial  $\text{H}^+$ -transporting **ATP synthase**.

**EF-T or transfer factor** a cytoplasmic protein of *Escherichia coli* and other prokaryotes which functions in protein synthesis to promote the GTP-dependent binding of aminoacyl-tRNAs to the A-site of the ribosome during protein chain elongation. EF-T can be dissociated into two polypeptides, EF-Tu (EF-IA) and EF-Ts (EF-IB), the complex being the main form in bacterial cells. These are so described since on their initial isolation one was heat-labile, or unstable, (Tu) and one was heat-stable (Ts). Only Tu functions directly in the GTP-dependent binding of the aminoacyl-tRNA to the A-site of the ribosome but Ts is required for regenerating Tu-GTP after the binding reaction which results in the hydrolysis of GTP to GDP. The factors were originally isolated from both *E. coli* and *Pseudomonas fluorescens*. The structures from *E. coli* are known, database code EFTS\_ECOLI, 283 amino acids (30.39 kDa), EFTU\_ECOLI, 393 amino acids (43.13 kDa). The 3-D structure of Tu shows high alpha-helix content with identified binding sites for GTP and aminoacyl-tRNA. The Tu from *E. coli* is also a subunit of RNA polymerase of phage Q $\beta$  (Q beta). See also **elongation factor**.

**EF-Ts now designated EF-IB; see EF-T.**

**EF-Tu now designated EF-IA; see EF-T.**

**egasyn** an amphipathic glycoprotein, found in microsomal (i.e. endoplasmic reticulum) membranes of mouse liver, that forms a complex with microsomal (but not lysosomal) **P-D-glucuronidase** (EC 3.2.1.31) and thereby anchors it to the microsomal membranes. It may similarly anchor other polar proteins. It hydrolyses carboxylic esters to an alcohol and carboxylic anion. It has a C-terminal consensus sequence, HXEL, that retains the proteins in the endoplasmic reticulum. Example from *Mus musculus*: database code A55281, 562 amino acids (61.51 kDa). [From e (endoplasmic) + g (glucuronidase) + Greek syn, with.]

**EG cell or L cell** an **enteroglucagon-producing** endocrine cell. Such cells are found in the basal part of the mucosal glands in the lower intestine; the highest concentrations occur in the terminal ileum and colon. They contain large, dense, secretory granules and are easily distinguishable from other endocrine cells in the same area.

**EGF abbr.** for epidermal growth factor.

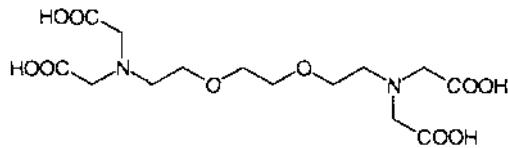

**egg** the reproductive structure of certain animals, e.g. reptiles, birds, and insects, consisting of an **ovum** together with nutritive and protective tissues, and from which, when fertilized, a young offspring emerges.

**egg albumin** the common name for **ovalbumin**.

**egg cell** an alternative name for **ovum**.

**egg white** the white part of an egg (especially a bird's egg) surrounding the yolk. Its principal organic constituent is egg albumin (see **ovalbumin**).

**EGTA abbr.** for ethylene glycol-O,O'-bis(2-amino-ethyl)-N,N,N',N'-tetraacetic acid, [ethylenebis(oxyethylenetrinitrilo)]tetraacetic acid; also for any anion or salt thereof. It is a chelating agent with a high affinity for  $\text{Ca}^{2+}$  ions.

**Ehlers-Danlos syndrome** a heterogeneous group of inherited human disorders sharing many phenotypic features. Classically the clinical picture includes hyperelastic, fragile skin, poor wound healing, hyperextensible joints, and easy bruising. Seven distinct genetic forms have been described. Type I,

which is severe, is inherited as an autosomal dominant; the biochemical lesion is unknown. Types II and III are inherited as autosomal dominants; the biochemical lesions are unknown. Type IV is inherited as an autosomal dominant, but X-linked inheritance is not excluded; patients lack type III collagen and analysis has shown that skin collagen from these patients lacks a peptide of about 100 amino-acid residues that is characteristic of type III collagen. Type V shows X-linked inheritance and fibroblast cultures from a patient show a diminished lysyl oxidase activity, both in the cells and the medium. Type VI is inherited as an autosomal recessive, and collagen from such patients is deficient in hydroxylysine; fibroblast cultures from these patients contain an abnormal lysyl hydroxylase (EC 1.14.11.4). Type VII is presumed to be inherited as an autosomal recessive and the biochemical lesion is a deficiency of procollagen peptidase, with a consequent failure to normally convert procollagen to collagen. [After Edvard Ehlers (1863-1937), German dermatologist, and Henri Alexandre Danlos (1844-1932), French dermatologist, whose respective descriptions of the disorders were published in 1901 and 1908.]

Ehrlich, Paul (1854-1915), German medical scientist famous for his work in chemotherapy, especially for his demonstration of the efficacy of synthetic arsenicals in spirochaetal infections, and notable also for his studies of the interaction of dyes with living tissues, for his work on the assay of antisera, and for advancing the side-chain theory of immunity; Nobel Laureate in Physiology or Medicine (1908) jointly with I. I. Mechnikov 'in recognition of their work on immunity'.

Ehrlich's reagent a solution of p-dimethylaminobenzaldehyde in cone. HC!. It forms coloured complexes with a number of compounds, such as indoles, aromatic amines, ureides, and hydroxyproline, and is useful in the detection and estimation of these compounds.

EIA abbr. for enzyme immunoassay.

eicos+ or (before a vowel) eicos+ a variant spelling (esp. US) of icosa+ (comb. form denoting twenty or twenty times). This spelling is universally used in naming eicosanoids, although not officially recommended (but see Appendix B).

eicosadienoic acid any straight-chain fatty acid having twenty carbon atoms and two double bonds per molecule. The all-Z-(8,11)-isomer is a normally minor metabolite of oleic acid in mammals, but is important as an intermediate in the pathway synthesizing all-Z-eicosa-5,8,II-trienoic acid (Mead acid) during essential fatty acid deficiency. The (5,1 I)-isomer occurs in gymnosperms, and several others have been synthesized. The (IIZ,14Z)-isomer occurs as an intermediate in the synthesis of arachidonate from linoleate via dihomo-y-linoleate, but this is not the major pathway for this biosynthesis.

eicosanoic acid the systematic name for arachidic acid. eicosanoid any of various agents that are C<sub>20</sub> polyunsaturated fatty acids, commonly arachidonic acid (see eicosatetraenoic acid), or an eicosapentaenoic acid, or their skeletal derivatives. They include the leukotrienes and the prostanoids and are noted for their widespread biological activity, such as contraction or relaxation of smooth muscle, platelet aggregation, and the inflammatory response.

eicosapentaenoic acid any straight-chain fatty acid having twenty carbon atoms and five double bonds per molecule. The most noteworthy is the all-Z-(5,8,11,14,17)-isomer, which occurs in animal phospholipids, especially those of many marine species; fish oils are a good source, with eicosapentaenoic acids often representing up to 10% of total fatty acids. Eicosapentaenoic acids act as precursors of the PG<sub>3</sub> series of prostaglandins. The suggestion has been made that a higher than normal content of this acid in the diet can protect against heart disease.

eicosatetraenoic acid any straight-chain fatty acid having twenty carbon atoms and four double bonds per molecule. The all-Z-(5,8,11,14)-isomer is arachidonic acid. The (8,11,14,17)-isomer is an important intermediate in the formation of long-

chain n-3 fatty acids from (9,12,15)-linolenic acid, being formed from that acid by desaturation at C-6 and chain elongation. The (5,11,14,17)-isomer is another naturally occurring form.

eicosatetraynoic acid any straight-chain fatty acid having twenty carbon atoms and four triple bonds per molecule. eicosa-5,8,II,14-tetraynoic acid (abbr.: ETYA) is a relatively nonspecific inhibitor of reactions involving arachidonate, including phospholipase A<sub>2</sub>, prostaglandin-endoperoxide synthase, and lipoxygenase.

eicosatrienoic acid any straight-chain fatty acid having twenty carbon atoms and three double bonds per molecule. The all-Z-(5,8,II)-isomer (Mead acid) is synthesized in mammals in essential fatty-acid deficiency. The all-Z-(8,II,14)-isomer, known also as dihomo-(6,9,12)-linolenic acid (or dihomo-y-linolenic acid), is a precursor of arachidonic acid and of the PG<sub>1</sub> series of prostaglandins. The (5,11,14)-isomer has been found in higher plants and algae, cats, marine organisms, and insects.

eicosatriynoic acid any straight-chain fatty acid having twenty carbon atoms and three triple bonds per molecule. 5,8,II-eicosatriynoic acid (abbr.: ETI) is an agent that selectively inhibits 5- and 12-lipoxygenase without inhibiting prostaglandin-endoperoxide synthase.

eicosenoic acid any straight-chain fatty acid having twenty carbon atoms and one double bond per molecule. The 9E-isomer is gadelaic acid (see gadelaide); the 9Z-isomer is gadoleic acid (see gadoleate), a constituent of fish oils; and the IIZ-isomer is gondoic acid, present in seeds and fish oils.

EID abbr. for electroimmunodiffusion.

eIF abbr. for eukaryotic initiation factor (see initiation factor).

Eigen, Manfred (1927- ), German physical chemist noted for developing techniques for the study of rapid reactions and applying them to problems of molecular biology; Nobel Laureate in Chemistry (1967), the prize being shared with R. G. W. Norrish and G. Porter 'for their studies of extremely fast chemical reactions, effected by disturbing the equilibrium by means of very short pulses of energy'.

eigenfunction a solution of a differential equation that has solutions only for particular values of some parameters.

eigenvalue anyone of the possible values for a parameter of an equation for which the solution will be compatible with the boundary conditions.

Eijkman, Christiaan (1858-1930), Dutch physician, bacteriologist, and nutritionist noted for observing that unpolished rice grains contained an antiberiberi principle (later recognized as a vitamin and named vitamin B) or thiamine) and for being the first to produce a dietary deficiency disease experimentally; Nobel Laureate in Physiology or Medicine (1929) 'for his discovery of the antineuritic vitamin' [prized shared with F. G. Hopkins].

einstein a non-SI unit used to express the energy associated with one mole of photons during a photochemical reaction. I einstein = N<sub>A</sub>hν, where N<sub>A</sub> is the Avogadro constant, h is the Planck constant, and ν is the particular frequency of the electromagnetic radiation effecting the reaction.

Einstein, Albert (1879-1955), German-born Swiss then US patent examiner and mathematical physicist famous above all for his formulation of both the special theory of relativity (in 1903) and the general theory of relativity (in 1916); Nobel Laureate in Physics (1921) 'for his services to Theoretical Physics, and especially for his discovery of the photoelectric effect'.

Einstein-Sutherland relation a relation between the diffusion coefficient at infinite dilution, D<sub>0</sub>, and certain molecular parameters. D<sub>0</sub> = kTlf, where T is the thermodynamic temperature, k is the Boltzmann constant, and f is the frictional coefficient of the diffusing particle.

EKG abbr. (US) for 1 electrocardiograph. 2 electrocardiogram. elafin another name for SKALP. [From elastase f inhibitor. The

'f' was inserted to avoid confusion with elastin and gives an association to the *Latinfinire*, to terminate.]

**elaideate** 1 numerical symbol: 18:1(9); the trivial name for (*E*)-octadec-9-enoate;  $\text{CH}_3-\text{[CH}_2]_7-\text{CH}=\text{CH}-\text{[CH}_2]_7-\text{COO}^-$  (*trans* isomer); the anion derived from elaidic acid, (*E*)-octadec-9-enoic acid, a monounsaturated straight-chain higher fatty acid. 2 any mixture of free elaidic acid and its anion. 3 any salt or ester of elaidic acid. *Compare* oleate.

**elaidinization** or **elaidinisation** the *cis* to *trans* isomerization of mono- and polyunsaturated fatty acids, as in the isomerization of oleic acid to elaidic acid brought about by treatment with nitrous acid or by the action of rumen bacteria.

**elaidoyl** the trivial name for (*E*)-octadec-9-enoyl;  $\text{CH}_3-\text{[CH}_2]_7-\text{CH}=\text{CH}-\text{[CH}_2]_7-\text{CO}^-$  (*trans* isomer); the acyl group derived from elaidic acid, (*E*)-octadec-9-enoic acid. It occurs in acylglycerols to an appreciable extent in the body fats of ruminants, possibly having arisen from oleic acid by elaidinization. *Compare* oleoyl.

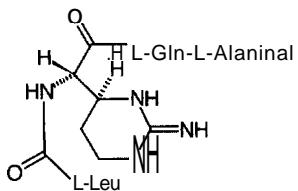

**elaioplast** any oil-storing leukoplast that occurs in plant cells.

**ELAM abbr.** for endothelial leukocyte adhesion molecule; i.e. E-selectin (see selectin).

**elasmobranch** 1 any member of the subclass Elasmobranchii, comprising fishes with cartilaginous skeletons such as sharks, skates, and rays. 2 of, pertaining to, or relating to the Elasmobranchii.

**elastase** historically, any proteinase that hydrolyses elastin. However, the name is now applied to a group of enzymes that vary in specificity. Pancreatic elastase, EC 3.4.21.36 (*other names*: pancreatic peptidase E; pancreatic elastase I), catalyses the hydrolysis of proteins, including elastin, with preferential cleavage at Ala-I-Xaa. Example (domestic pig): database code NRL\_3EST, 240 amino acids (25.88 kDa); 3-D structure known. Pancreatic elastase II, EC 3.4.21.71, preferentially cleaves the carbonyl side of Leu, Met, and Phe. Leukocyte elastase EC 3.4.21.37 (*other names*: lysosomal elastase; neutrophil elastase; bone marrow serine protease; medullasin), catalyses the hydrolysis of proteins, including elastin, with preferential cleavage at Val-I-Xaa > Ala-I-Xaa. Pancreatic elastase and leukocyte elastase, in common with most elastases, are serine proteinases, but others, e.g. elastase (EC 3.4.24.26) from *Pseudomonas aeruginosa*, are zinc-containing metalloproteinases. Elastase III is pancreatic endopeptidase E (EC 3.4.21.70; *other name*: cholesterol-binding proteinase); it shows preferential cleavage at Ala-I-Xaa, but does not hydrolyse elastin.

**elastatinal** a peptide produced by actinomycetes that inhibits serine proteinases, particularly elastase.

**elastic** (*of a body or a substance*) capable of returning to its original shape after deformation. -elasticity *n*.

**elasticity coefficient** symbol:  $\xi_S^e$ ; for a metabolic system in a steady state, the fractional change in the velocity,  $v$ , of an enzyme step caused by a fractional change in substrate, effector, or product concentration,  $S$ . It is given by:

$$\xi_S^e = \frac{S(aV)}{v} \cdot \frac{\partial S}{\partial S} \Big|_{y,z,\dots} = \frac{alny}{alns}$$

Since the elasticity coefficient is defined as the partial derivative of a velocity,  $v$ , with respect to  $S$  (multiplied by the scaling factor,  $S/v$ ) all other variables that are able to influence the rate through the enzyme are held constant. There are, for any

reaction, as many elasticity coefficients as there are metabolites and effectors that interact with the enzyme in question. See also controllability coefficient, response coefficient, sensitivity coefficient.

**elastin** a major structural protein of mammalian connective tissues, especially elastic fibres, and found at sites such as the aorta, nuchal ligament, and lung. Glycine makes up one third of the amino-acid residues in elastin; glycine, proline, alanine, and valine together account for over 80% of its residues. The polymeric chains are cross-linked together into an extensible 3-D network, lysinonorleucine and desmosine cross-links being formed between allysine and lysine residues. A soluble precursor of elastin, proelastin, has been isolated from copper-deficient pigs in which the formation of allysine is blocked. Example (precursor) from human: database code ELS\_HUMAN, 730 amino acids (63.19 kDa).

**elastonectin** a protein,  $M_r$  120 000, from human skin fibroblasts and associated with adhesion of mesenchymal cells to elastic fibres.

**elective theory of immunity** *an alternative name for* selective theory of immunity

**electrical coupling** the phenomenon of ion transport across a membrane, in the absence of a cation-anion cotransport system, when the movement of anions and cations, following the law of electroneutrality, is governed only by the passive permeabilities of the membrane to the ions in question.

**electric birefringence** a form of birefringence, also known as the Kerr effect, caused by the alignment of (macro)molecules in an electric field.

**electric capacitance** *see* capacitance.

**electric cell** an apparatus consisting of two reversible electrodes dipping into the same solution, or into separate solutions electrically connected through an electrolyte bridge. It is used to generate an electromotive force, for electrolysis, or to measure the chemical activity of a chemical species in one of the solutions. *See also* half-cell.

**electric charge** or **quantity of electricity** symbol:  $Q$  or  $q$ ; the attribute of certain elementary particles that is responsible for electric phenomena. Electric charge may be of two kinds, positive or negative, which interact electromagnetically such that like charges repel one another while unlike charges are attracted one to another. The SI derived unit of electric charge is the coulomb. *See also* charge (def. 3).

**electric conductance** or **conductance** symbol:  $G$ ; a measure of the readiness with which an electric current can flow through a given component of a circuit. For a direct-current circuit it is equal to the reciprocal of the resistance; for an alternating-current circuit it is equal to the resistance divided by the square of the impedance. The SI derived unit of conductance is the siemens. *See also* mho.

**electric current** or **current** symbol:  $I$  or  $i$ ; one of the seven SI base physical quantities - flow of electric charge through a conductor. The magnitude of a current is given by the amount of charge flowing per unit time. The SI base unit of electric current is the ampere.

**electric dichroism** the form of dichroism (def. 1) caused by orientation of (macro)molecules in an electric field.

**electric dipole moment** *see* dipole moment.

**electric double layer** *an alternative name for* electrochemical double layer.

**electric field** a field in which a stationary electric charge,  $Q$ , experiences a force,  $F$ , proportional to the magnitude of the charge. The electric field strength,  $E$ , is given by:  $E = F/Q$ ; it is expressed in  $\text{V m}^{-1}$ . If the field is produced by other stationary charges it is called an electrostatic field. *Compare* Coulomb's law.

**electricity** 1 any of the forms of energy associated with moving or stationary electrons, protons, or other charge-bearing entities (whether molecular or otherwise). Static electricity is associated with stationary charges, current electricity with moving charges. 2 the science dealing with electricity.

## electric potential

**electric potential or potential symbol:**  $V$  or  $\phi$ ; the work done in bringing unit electric charge from infinity to a specified point in an electric field. The SI derived unit of electric potential is the volt.

**electric potential difference or potential difference symbol:**  $E$  or  $U$  or  $\Delta V$  or  $\Delta\phi$ ; abbr.: pd; the work done when a unit electric charge is moved between two points having different electric potentials. If the points are joined by a conductor an electric current will flow between them. The SI derived unit of electric potential difference is the volt. Compare electromotive force.

**electric resistance or resistance symbol:**  $R$ ; the impediment to the flow of an electric current through a component of a circuit, a medium, or a substance. The SI derived unit of resistance is the ohm.

**electro+** or (sometimes before a vowel) **electr+** comb. form indicating electric, electrically, electrolytic.

**electroblot** see electrophoretic transfer.

**electroblotting** an alternative name for electrophoretic transfer.

**electrochemical analysis or electrochemical assay** a chemical analysis or assay performed by means of electrolysis or electrodeposition.

**electrochemical double layer** any double layer of charges formed in a solution by the adsorption of a layer of ions of opposite charge at the surface of another charge-carrying phase, e.g. the walls of the vessel or the surface of a macromolecule.

**electrochemical equivalent** the mass of an ion deposited or liberated by the passage of 1 coulomb of electricity. In grams it is 1/96487 of the chemical equivalent.

**electrochemical potential symbol:**  $\tilde{\mu}$ ; the change in free energy occurring when a charged solute is transported either up or down a concentration gradient. It is the sum of the free energy changes due both to the concentration gradient and to the electric potential. It is expressed in J mol<sup>-1</sup>.

**electrochemical series** an alternative name for electromotive series.

**electrochemistry** the branch of science concerned with the study of electrolysis, electrolytic cells, and the applications and properties of ions in solution. -electrochemical adj.

**electrochromatography** the form of chromatography in which separation of the constituents of a mixture is due to the effect of a constant electric field. See also zone electrophoresis.

**electrochromism** any reversible change in optical absorption or emission spectra of a molecule in the condensed phase due to an external electric field. Compare photochromism, thennochromism. -electrochromic adj.

**electrocortin** the former name for aldosterone (before establishment of its structure).

**electrocrySTALLIZATION or electrocrystallisation** electrodeposition that results in crystal formation.

**electrode** any conductor, such as metal, metal covered with one of its salts, carbon, or a thin glass or other membrane, used to establish electric contact with a solution or other non-metallic part of an electric circuit. The potential assumed by the electrode may depend on the (thermodynamic) activity of one of the solutes in the solution with which it is in contact. See also anode, calomel electrode, cathode, enzyme electrode, hydrogen electrode, ion-selective electrode, oxygen electrode, quinhydrone electrode, reference electrode.

**electrodecantation or electrophoresis convection** a technique for separating and fractionating proteins and other sols that exploits local differences in concentration and density that may occur during electrodialysis. Under the influence of gravity such density differences lead to large-scale separation of sols of high and of low concentrations. This results in a gradual increase in the concentration of a sol in the lower layers of the solution and a decrease in the upper layers.

**electrodeposition** the deposition of material from a dissolved or suspended state onto an electrode by the application of an electric field; it includes electrocrystallization.

**electrode potential symbol:**  $E$ ; the electric potential between

## electrolytic conductivity

a reversible electrode and the solution in which it is immersed. It may be due to the loss or gain of electrons, if the solution contains a redox couple, or to the formation of ions from unchanged atoms or of atoms from ions, if the solution contains ions of a chemical element present as uncharged atoms in the electrode.

**electrodialysis** a form of dialysis conducted in the presence of an electric field across the membrane(s). It is useful for quickly removing ionic microsoluteS from a solution containing nondiffusible material.

**electroelution** a technique in which application of an electric potential causes biomolecules to be transferred from an electrophoresis gel to a membrane during blotting procedures. See also transfer membrane.

**electroendosmosis** a former term for electroosmosis. -electroendosmotic adj.

**electrofocusing** a newer name for isoelectric focusing.

**electrofuge** (in chemistry) a leaving group in a reaction that does not carry away the bonding electron pair.

**electrogenesis** the generation of an electrochemical potential gradient, esp. across a membrane.

**electrogenic pump** any biological system that generates an electrochemical potential across a membrane by pumping one ion across the membrane without the concomitant movement of another ion of the same charge in the opposite direction.

**electroimmunoassay** the original name for rocket immunoelectrophoresis.

**electroimmunodiffusion** abbr.: EID; any technique for the analysis of antigenic macromolecules in which a combination of electrophoresis and immunodiffusion is employed. Four types may be distinguished: (1) one-dimensional single, i.e. rocket immunoelectrophoresis; (2) one-dimensional double, i.e. counter immunoelectrophoresis; (3) two-dimensional single, i.e. crossed immunoelectrophoresis; and (4) two-dimensional double, not so far individually named or much used.

**electroimmunodiffusogram** the immunoprecipitation pattern produced by any type of electroimmunodiffusion.

**electrokinetic potential or zeta potential symbol:**  $\zeta$ ; the potential drop across the mobile part of an electrochemical double layer that is responsible for electrokinetic phenomena. The electrokinetic potential is positive if the potential increases from the bulk of the liquid phase towards the interface.

**electrolectin** a lectin of the galatin family from *Electrophorus electricus*, and the name of a group of p-D-galactoside-binding lectins found in teleosts, amphibians, and mammals. Example from *E. electricus*: database code LEG\_ELEEL, 129 amino acids (14.44 kDa).

**electrolysis** the chemical change produced by passing a direct electric current through a solution of an electrolyte, or through a fused electrolyte. Positively charged ions (cations) move towards the cathode and negatively charged ions (anions) move towards the anode, thus carrying the electric current. At the electrodes the positively charged ions gain electrons and negatively charged ions give up electrons, forming uncharged atoms, molecules, or radicals, which may either be deposited on the electrode or react with the electrode, the solvent, or each other. Alternatively, atoms of the electrode material may ionize and go into solution.

**electrolyte** any substance that, when in solution or molten, can undergo (partial or complete) dissociation into ions and hence is able to conduct an electric current by the movement of the ions.

**electrolyte balance** (in physiology) the sum total of the reactions and processes concerned with the maintenance of a constant internal environment in the body with respect to the distribution of ions between the various fluid compartments and excretions.

**electrolytic** 1 of, pertaining to, or produced by electrolysis. 2 of or pertaining to an electrolyte.

**electrolytic conductivity or (formerly) specific conductance symbol:**  $K$ ; the ability of an electrolyte to permit the flow of

## electromagnetic

electric current, defined by the equation:  $\kappa = j/E$ , where  $j$  is the electric current density and  $E$  is the electric field strength. In SI units,  $\kappa$  is in  $\text{S m}^{-1}$ ,  $j$  in  $\text{A m}^{-2}$ , and  $E$  in  $\text{V m}^{-1}$ . Electrolytic conductivity is usually measured in a rigid conductivity cell whose cell constant has been determined by means of a reference potassium chloride solution.

**electromagnetic** 1 of, relating to, or involving both electricity and magnetism; having both electrical and magnetic properties. 2 of or relating to electromagnetic radiation. 3 a of, relating to, containing, or operated by an electromagnet. b of or relating to electromagnetism.

**electromagnetic radiation** abbr.: emr or EMR; radiation consisting of transverse waves of energy with associated electric and magnetic fields that can be represented by vectors at right angles to each other and to the direction of its propagation. The radiation results from the acceleration of electric charges and can be propagated through free space (i.e. it requires no supporting medium). The characteristics of the radiation vary with the frequency (or the wavelength) of the wave motion, the range of possible frequencies constituting the electromagnetic spectrum. From the low-frequency end of the spectrum to the high end are ranged: radiofrequency radiation, infrared radiation, visible radiation or light, ultraviolet radiation, X-rays, and gamma-radiation. Radiation of all frequencies travels at the same velocity through space. The speed of light in vacuum,  $c_0$ , is defined as 299 792 458 m s $^{-1}$ .

**electromagnetic unit** abbr.: emu or EMU; any of the electrical units based on the magnetic properties of electric currents. The force,  $F$ , between two magnetic poles of strength  $m_1$  and  $m_2$  placed a distance  $d$  apart in a medium of permeability  $\mu$  is given by  $F = m_1 m_2 \mu d^2$ . If  $F$ ,  $\mu$ , and  $d$  each be unity and if  $m_1 = m_2 = m$ , then  $m$ , and  $m_2$  are poles of unit strength. Units based on this definition of  $m$  are electromagnetic units and are denoted by the prefix 'ab+'.

**electromeric effect** an obsolescent term for a molecular polarizability effect occurring by intramolecular electron displacement characterized by the substitution of one electron pair for another in the same atomic octet of electrons.

**electrometer** any instrument of very high input impedance that is used for detecting or measuring (changes in) the magnitude of an electric potential difference or electric charge esp. if of small value. Hence it is useful also for the (indirect) measurement of a very low electric current or a very high electric resistance, and for the detection or measurement of ionizing radiation. -electrometric adj.

**electrometric titration** 1 an alternative name for potentiometric titration. 2 a name sometimes used generically for conductometric titration and potentiometric titration.

**electromotive force** abbr.: emf or EMF; symbol:  $E$ ; the energy supplied by a source of electric current in driving unit electric charge through an electric circuit. The SI derived unit of electromotive force is the volt. Compare electric potential difference.

**electromotive series** or **electrochemical series** a series in which the metals are arranged in decreasing order of their tendency to form cations by a reaction of the type:  $M \rightleftharpoons M^+ + e^-$ .

**electromyogram** abbr.: EMG; the tracing produced by an electromyograph.

**electromyograph** an instrument for detecting and recording the electrical activity of a muscle or group of muscles.

**electron** 1 symbol:  $e$  or  $e^-$  or  $\beta^-$ ; a negatively charged elementary particle of rest mass,  $m_e$ ,  $\approx 9.109\ 39 \times 10^{-31}$  kg and electric charge  $1.602\ 177\ 33(49) \times 10^{-19}$  C. It is sometimes termed a negatron, especially to distinguish it from its antiparticle, the positron. Electrons are present orbiting in all atomic nuclei and are involved in the formation of bonds between atoms. Specific designations of electrons in atoms and molecules include: u-electrons, which participate in single bonds;  $\pi$ -electrons, which participate in double or triple bonds; and p-electrons, which participate in unshared electron pairs. 2 (sometimes) either a negatron (i.e. electron (def. 1)) or a positron. See also beta-particle.

## electron equivalent

electron acceptor 1 any substance to which an electron may be transferred. 2 an alternative name for Lewis acid (use discouraged). Compare electron donor.

**electron affinity** 1 the degree to which any molecular entity attracts one or more additional electrons. 2 symbol:  $E_{ea}$ ; the minimum energy, expressed in joules, needed to remove an electron from a negatively charged molecular entity, or the reciprocal of the energy required to introduce an electron into a molecular entity.

**electron-affinity spectroscopy** a sensitive ionization method for the qualitative analysis of small quantities of organic compounds separated by gas chromatography, based on the differences in electron-capture ability that exist between the principal classes of organic compounds. The substances to be detected are passed through an ionized gas; the detector is sensitive to the resulting reduction in current.

**electron capture** 1 or K-capture abbr.: EC; a mode of decay of radionuclides in which an electron from an inner orbit of a decaying atom is absorbed into its nucleus, wherein a proton is converted to a neutron. Rearrangement of the orbital electrons then leads to the emission of characteristic X-radiation (see X-radiation). Generally the captured electron is derived from the K-shell, hence the alternative name. 2 see electron-affinity spectroscopy.

**electron-capture detector** abbr.: ECD; the type of detector used in electron-affinity spectroscopy.

**electron carrier** any molecular entity that serves as an electron acceptor and electron donor in an electron transport system.

**electron-dense** describing any structure, material, or compound that scatters an impinging electron beam, thus becoming apparent in electron microscopy, etc.

**electron-dense label** any atom group or substance (e.g. ferritin) that is electron-dense and that has been or may be attached in a specific manner to compounds or structures so as to show them up by electron microscopy, etc.

**electron density** the electron probability distribution in any molecular entity. If  $P(x,y,z)$  is the electron density at the point with coordinates  $x,y,z$ , then the probability of finding an electron in the volume element  $dx dy dz$  is  $P(x,y,z) dx dy dz$ . In, e.g., X-ray scattering experiments the scattering at this position is proportional to this probability. The term is often wrongly applied to negative charge density.

**electron-density map** a three-dimensional representation of the structure of a molecule or substance derived from X-ray diffraction data and made by the superposition of the electron-density contours of a series of imaginary parallel planes through the specimen being examined.

**electron diffraction** an effect observed when a narrow beam of electrons passes through a layer of material, e.g. a crystal, and is deflected by this material. The effect is due to the wave-like nature of electrons.

**electron donor** 1 any substance that is able to transfer an electron to another chemical species. 2 an alternative name for Lewis base (use discouraged). Compare electron acceptor. See also donor atom.

**electron donor-acceptor chromatography** see charge-transfer chromatography.

**electron donor-acceptor complex** (sometimes) an alternative name for 1 charge-transfer complex (use not recommended). 2 Lewis adduct (use not recommended).

**electronegative** 1 describing an atom or a group of atoms that tends to attract electrons, especially in the formation of a covalent bond. 2 describing any chemical or other entity that carries a negative charge and hence tends to move to the anode in electrophoresis.

**electronegativity** a measure of the power of an atom or group of atoms to attract electrons to itself from other parts of the same molecular entity.

**electron equivalent** the equivalent of any oxidizing (or reducing) agent that is equivalent to one entity of electrons.

## electroneutrality condition

**electroneutrality condition** the condition that in any solution the sum of the negative electric charges on ions must be equal to the sum of the positive charges on ions.

**electron-exchange resin** any synthetic resin containing groups able to undergo reversible oxidation-reduction reactions; such resins are useful as insoluble oxidizing or reducing agents.

**electron gun** a device used in electron microscopes, mass spectrometers, and other instruments to generate a beam of high-velocity electrons. It consists of a white-hot tungsten filament, as the electron source, and an anode kept at a potential of several tens of kilovolts above that of the filament. The electrons are accelerated towards the anode, which contains a small orifice through which some of the fastest electrons pass to form the electron beam.

**electron hole** the hole in the valency structure of an atom created by the absence of an electron when the energy level of an electron is raised from the valency band to the conduction band. The hole has a great tendency to recapture an electron. *See also hole.*

**electronic** 1 of or relating to an electron or electrons. 2 of, relating to, or operated by electronics (def. 2).

**electronics** 1 (*functioning as sing.*) the branch of science and technology concerned with electronic devices and circuits and with their development and applications. 2 (*functioning as pl.*) the circuits, devices, and equipment that function by the passage of electrons through semiconductors, transistors, and thermionic valves.

**electronic transition** the passage of an electron in a chemical entity from one energy level to another.

**electron lens** any arrangement of coils and/or electrodes producing a magnetic and/or an electric field used to focus an electron beam, e.g. in an electron microscope.

**electron micrograph** any photograph of an object taken with an electron microscope.

**electron microscope** abbr.: EM or e.m.; an instrument in which a magnified image of a sample is produced using a beam of high-energy electrons. The electrons are accelerated by means of an electron gun, using voltages in the range 40-100 kV, and the apparatus is evacuated to minimize electron scatter by air. In the transmission electron microscope (abbr.: TEM) the electron beam is focused onto a thin sample by a combination of magnetic and electric lenses and, after passing through the sample, the electrons are focused onto a fluorescent screen or photographic plate. The resolving power can be as great as 0.2-0.5 nm. In cryo-electron microscopy, lightly fixed frozen sections are employed. If these are used for the detection of antigens with antibodies coupled to colloidal gold, the technique is called cryoimmuno-electron microscopy. In the scanning electron microscope (abbr.: SEM) a narrow beam of electrons is made to scan to and fro across the sample by a varying field, and emitted secondary electrons are focused onto a screen to produce an image of the specimen. The specimen may be thicker than in the transmission electron microscope and, though resolution is lower with the scanning instrument, the depth of field is greater and the image gives a three-dimensional effect.

**electron multiplier** an electronic device for detecting, and counting, electrons, using secondary emission. It consists of an evacuated tube containing a series of electrodes, each held at a higher positive electric potential than the preceding one. When an electron hits the first electrode two or more secondary electrons are emitted; these are accelerated to the second electrode, where more electrons are produced, and so on.

**electron nuclear double resonance** abbr.: ENDOR; a phenomenon in nuclear magnetic resonance spectroscopy in which saturation of an electron resonance by the simultaneous application of a microwave field causes, under appropriate conditions, an improvement of the resolution of nuclear hyperfine structures.

**electron optics** the branch of science concerned with the effects of electric and magnetic fields on the movement of elec-

## electron trap

trons, especially with the focusing and deflection of electron beams in cathode-ray tubes, electron microscopes, and similar devices.

**electron paramagnetic resonance spectroscopy** *an alternative name for* electron spin resonance spectroscopy.

**electron probe X-ray microanalysis** a highly sensitive technique for elemental microanalysis based on the frequencies and/or intensities of the characteristic X-rays emitted by each element present in a sample when it is excited by a beam of accelerated electrons.

**electron sink** or **electron trap** an electrophilic atom or group of atoms that can capture an electron from another part of a molecular system.

**electron spectroscopy for chemical analysis** abbr.: ESCA; *see* photoelectron spectroscopy.

**electron spin** *see* spin (def. 3).

**electron spin-echo spectroscopy** a technique giving precise values for electron spin relaxation times, in which intense microwave pulses at a frequency satisfying the resonance condition are applied to a paramagnetic sample in a magnetic field. Phase coherence in the spins is lost through relaxation when the pulse is switched off but can be restored by a second pulse 180° out of phase. The restoration of phase coherence gives rise to a nuclear induction signal (the echo).

**electron spin-lattice relaxation time** (*in* electron spin resonance spectroscopy) a measure of the time taken for the spin population to return to its equilibrium value by interaction with the fluctuating internal electric fields surrounding it.

**electron spin resonance spectroscopy** abbr.: ESR (spectroscopy); a technique, also called electron paramagnetic resonance spectroscopy (abbr.: EPR (spectroscopy)) and analogous to nuclear magnetic resonance spectroscopy, that is used to investigate paramagnetic centres in the system under study; only electrons whose spin is not paired with the oppositely directed spin of another electron give an ESR signal. Useful information is obtained by this technique about certain transition-metal ions (notably Cu<sup>2+</sup>), (free) radicals, and free electron centres such as may be produced by X-irradiation of (macro) molecules. A probe (def. 2) giving an ESR signal may be incorporated into membrane lipids or attached to proteins to enable otherwise inaccessible systems to be studied by this technique.

**electron spin-spin relaxation time** (*in* electron spin resonance spectroscopy) a measure of the time taken for phase coherence to be lost and equilibrium to be re-established through interaction with neighbouring spins. It is inversely proportional to the line width of the signal.

**electron-transfer flavoprotein** or **electron-transferring flavoprotein** abbr.: ETF; a protein containing flavin adenine dinucleotide (FAD) that together with an acyl-CoA dehydrogenase (EC 1.3.99.3) forms a system that oxidizes an acyl-CoA molecule and reduces ubiquinone and other acceptors in the mitochondrial electron transport system.

**electron-transferring flavoprotein dehydrogenase** abbr.: ETF dehydrogenase EC 1.5.5.1; an enzyme that catalyses the oxidation of reduced ETF by ubiquinone to form ETF and ubiquinol. The ubiquinol is then oxidized by ubiquinol-cytochrome c reductase. It is an iron-sulfur flavoprotein involved in coupling the beta-oxidation system to the respiratory chain. *See also* electron-transferring flavoprotein.

**electron-transferring fluoroprotein** *see* azurin.

**electron transport** 1 respiratory electron transport; the process by which pairs of electrons derived from intermediates of the tricarboxylic-acid cycle and other substrates flow down the respiratory chain to dioxygen, the ultimate electron acceptor in respiration. 2 photosynthetic electron transport; the process by which pairs of electrons are transported from H<sub>2</sub>O to NADP<sup>+</sup> in the light phase of photosynthesis during noncyclic photophosphorylation.

**electron-transport chain** *an alternative name for* respiratory chain.

**electron trap** *an alternative name for* electron sink.

## electronvolt

**electronvolt or electron volt symbol:** eV; a non-SI unit of energy equal to the kinetic energy acquired by an electron when accelerated through an electric potential difference of 1 volt.  $I\text{ eV} = e \times V \approx 1.602 \times 10^{-19} \text{ J}$ , where  $e$  is the elementary charge and  $V$  is the volt.

**electroosmosis or (formerly) electroendosmosis** the motion of a liquid through a membrane (or plug or capillary) consequent upon the application of an electric field across the membrane. A similar phenomenon may occur in electrophoresis, where many of the supporting media used, e.g. paper or agar, acquire negative charges during electrophoresis at alkaline pHs and, since the medium cannot move,  $\text{H}_3\text{O}^+$  ions move towards the cathode, giving the effect of an osmotic movement of solvent towards the cathode and making electrically neutral molecules appear to be cationic. -electroosmotic *adj.*

**electropherogram a variant spelling of** electrophoretogram.

**electrophile or electrophilic reagent** any chemical species that is preferentially attracted to a region of high electron density in another species during a chemical reaction. Such reagents normally are positively charged or contain electron-deficient chemical groups. They tend to react with electron-rich or negatively charged chemical species. Compare nucleophile.

**electrophilic** 1 of, pertaining to, or being an electrophile; having or involving an affinity for regions of high electron density in a chemical reactant. 2 describing a chemical reaction in which an electrophile participates.

**electrophilic catalysis** catalysis by a Lewis acid, i.e. any chemical species that abstracts an electron pair from the reactant.

**electrophilic displacement** an alternative term for electrophilic substitution reaction.

**electrophilicity** the relative reactivity of an electrophile, measured by the relative rate constants of different electrophiles towards a common reactant.

**electrophilic reagent** an alternative name for electrophile.

**electrophilic substitution reaction or electrophilic displacement** a chemical reaction in which an electrophile effects heterolytic substitution in another reactant, both bonding electrons being supplied by that other reactant.

**electrophoresis** 1 the phenomenon of the movement of ions (including macromolecular ions) or charged particles or ions through a fluid under the influence of an electric field applied to the fluid. A number of different media have been used as the fluid support, including paper, cellulose acetate, starch gel, and polyacrylamide gel. Ions or particles bearing a net positive charge tend to move towards the negative pole of the electric field and vice versa, the rate of movement of a particular variety of ion or particle depending, *inter alia*, on its charge-to-mass ratio. The phenomenon has been widely applied in separating proteins, nucleic acids, and other charged molecular species for analytical or preparative purposes, and also in the analytical or preparative fractionation of heterogeneous populations of dispersed cells or other types of macroscopic particles. 2 the act or process of causing ions or charged particles so to migrate; any technique based upon such a phenomenon, e.g. continuous flow electrophoresis, immunoelectrophoresis, moving boundary electrophoresis, paper electrophoresis, polyacrylamide gel electrophoresis, zone electrophoresis. See also electrodecantation. -electrophoretic *adj.*

**electrophoresis convection** an alternative term for electrodecantation.

**electrophoretic effect** the phenomenon of decreased electrophoretic mobility of a charged macromolecule caused by the movement of counter ions and/or solvent molecules in the opposite direction to that of the macromolecule.

**electrophoretic mobility symbol:**  $u$ ; the electrophoretic velocity,  $v$ , of a charged particle expressed per unit field strength; hence,  $u = viE$ , where  $E$  is the field strength. The value of  $u$  is positive if the particle moves towards the pole of lower potential and negative in the opposite case. The electrophoretic mobility depends only on molecular parameters.

## eleetrostriction

**electrophoretic molecular sieving (sometimes) an alternative term for** polyacrylamide (gel) electrophoresis.

**electrophoretic titration curve** the pH-mobility curve of an ampholyte, e.g. a protein, generated by subjecting a zone of it to electrophoresis in a gel slab at right angles to a preformed, stationary pH gradient. Compare isoelectric focusing.

**electrophoretic transfer or electroblotting** a development of the technique of blot transfer, in which proteins or nucleic acids are transferred from a separation gel to nitrocellulose or diethylaminoethyl- (DEAE-)cellulose membranes or to diazo-benzoyloxymethyl- (DBM)- or diazophenylthioether- (DPT-) paper by electrophoresis, rather than by capillary flow, with a consequent decrease in the time required for the transfer. The membrane or paper bearing a resultant pattern of separated substances has been termed an electroblot. See blotting.

**electrophoretic velocity symbol:**  $v$ ; the velocity of a charged particle during electrophoresis. It is normally proportional to the electric field strength. Compare electrophoretic mobility.

**electrophoretogram or electropherogram** the result of a zone-electrophoretic separation, either directly visible or after staining or processing to produce a graph.

**electrophysiology** the part of physiology concerned with the electrical phenomena associated with bodily processes, such as nervous and muscular activity.

**electroporate** to create momentary pores in the membranes of living cells, without loss of their viability, by exposing them to a sequence of brief electrical pulses of high field strength. The reversible breakdown of the cell membranes thus caused enables treated cells to take up exogenous material (e.g. drugs or foreign DNA). -electroporated *adj.*; electroporation *n.*

**electroporator** an apparatus or device for effecting electroporation.

**electropositive** 1 describing an atom or group of atoms that tends to give up electrons, especially in the formation of a covalent bond. 2 describing any chemical or other entity that carries a positive charge and hence tends to move to the cathode in electrophoresis.

**electropositivity** a measure of the power of an atom or group of atoms to give up electrons to other parts of the same molecular entity.

**electrospray** a technique used in mass spectrometry in which a dilute acidic solution of the macromolecule is sprayed from a metal syringe needle maintained at +5000 V, forming fine highly charged droplets from which the solvent rapidly evaporates.

**electrostatic** of or pertaining to static electricity or electrostatics.

**electrostatic bond** any valency linkage between atoms arising from the transfer of one or more outer-shell electrons of one atom to the outer shell of another atom, leading to more complete outer shells in both atoms. The dissociation of an electrostatic bond leads to the production of ions.

**electrostatic field** any electric field produced by stationary charges.

**electrostatic interaction** any of the attractive or repulsive forces between atoms and/or groups of atoms and/or molecules that are due to the presence of ionized chemical entities and to the electronegative and electropositive properties of these atoms, groups, or molecules. Compare electric field.

**electrostatic precipitation** the removal of small particles suspended in a gas by electrostatic charging followed by precipitation onto a highly charged collector.

**electrostatics** the branch of physics concerned with static electricity.

**electrostatic units abbr:** esu or ESU; a system of electrical units, used in the cgs system, based upon the electrostatic unit of electric charge, i.e. the quantity of electricity that will repel an equal quantity of electricity, 1 em distant from it in a vacuum, with the force of 1 dyne.

**electrostriction** the reversible change in dimensions of a dielectric when an electric field is applied to it. For example, the

## electrotaxis

electrostatic field associated with a dissolved electrolyte causes a shrinkage in the volume occupied by the solvent.  
electrotaxis the directional movement of an organism in an electric field. -electrotactic *adj.*

electrotropism any orientation response of a sessile organism to an electrical stimulus.

electrovalency or (*esp. US*) electrovalence 1 the type of valency characterized by the transfer of one or more electrons from one atom to another atom, with the formation of ions. 2 the number of negative or positive charges acquired by an atom by the respective gain or loss of electrons. -electrovalent *adj.*; electrovalently *adv.*

electrovalent bond *an alternative term for* ionic bond.

electroviscosity the, usually minor, change in viscosity that occurs when an electric field is applied to some polar liquids.

elodoisin a tachykinin with the structure Glp-Pro-Ser-Lys-Asp-Ala-Phe-Ile-Gly-Leu-Met-NH<sub>2</sub>; it is obtained from the posterior salivary glands of small octopus (*Eledone* spp.). It is more potent than physalaemin and substance P in some assay systems. It is useful as a lachrymal and salivary secretagogue and in the study of receptors for substance P.

element any basic and distinct component of matter that is not resolvable into simpler components with differing chemical properties. Each consists exclusively of atoms with the same unique proton number (although such atoms may not necessarily have the same nucleon number or relative atomic mass). Ninety-three chemical elements are known to occur naturally, either in the free state or in combination with others; to date, a further 16 have been produced artificially. -elemental or elementaryad).

elementary analysis any quantitative chemical analysis of the amounts of different chemical elements present in a sample.

elementary charge or proton charge symbol: *e*; a fundamental physical constant representing the electric charge on one electron (or proton). Its recommended value is 1.602 177 33 (49) × 10<sup>-19</sup> C.

elementary particle 1 or fundamental particle any of the particles that form the base units of which all matter is composed. The stable elementary particles are protons, electrons, and neutrinos; they combine with neutrons to form stable atoms. Other, short-lived elementary particles are known. 2 or Fernández-Morán particle or oxysome or stalked particle any of the knoblike structures, 8–9 nm in diameter, seen in the electron microscope on the inner surface of the inner membrane of unfixed mitochondria negatively stained with phosphotungstate.

elementary rest mass symbol: *m<sub>e</sub>*; the mass of an electron, it is a fundamental atomic constant, 9.109 389 7(54) × 10<sup>-31</sup> kg. eleostearate 1 numerical symbol: 18:3(9,11,13); the trivial name for octadeca-9,11,13-trienoate; CH<sub>3</sub>—[CH<sub>2</sub>]<sub>3</sub>—[CH=CH—[CH<sub>2</sub>—COO—; the anion derived from eleostearic acid, octadeca-9,11,13-trienoic acid, a triunsaturated straight-chain higher fatty acid. It is a constitutional isomer of (6,9,12)-linolenate with conjugated double bonds. 2 any mixture of free eleostearic acid and its anion. 3 any salt or ester of eleostearic acid. See also eleostearoyl.

eleostearoyl symbol: eSte; the trivial name for octadeca-9,11,13-trienoyl; CH<sub>3</sub>—[CH<sub>2</sub>]<sub>3</sub>—[CH=CH]<sub>3</sub>—[CH<sub>2</sub>]<sub>7</sub>—CO—; the acyl group derived from eleostearic acid. The 9<sub>2</sub>,11E,13E-isomer occurs naturally as acylglycerols in some seed oils, especially tung oil.

*ELF1* a gene encoding transcription factors, related to the protooncogene *ETS* and named from E74-like factor (*see E74*), a *Drosophila* protein that binds a regulatory element of the dopa decarboxylase gene. Example from *Drosophila melanogaster*: database code ELFLDROME, 1063 amino acids (116.15 kDa).

elimination reaction a chemical reaction in which two groups are removed from a molecule of an organic compound without being replaced by other groups. In most such reactions the groups are lost from adjacent carbon atoms: one of the groups

## ellipticity

eliminated is commonly a hydron and the other a nucleophile, and the elimination results in the formation of a multiple bond. The reverse process is an addition reaction.

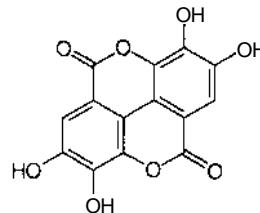

Elion, Gertrude Belle (1918–99), US chemist, biochemist, and pharmacologist distinguished for her introduction, largely in collaboration with her colleague G. H. Hitchings, of a range of widely used synthetic drugs designed as antimetabolites, including the antifolate bactericidal agent co-trimoxazole, the immunosuppressants mercaptopurine and its derivative azathioprine, and the antiviral compound acycloguanosine; Nobel Laureate in Physiology or Medicine (1988) jointly with J. W. Black and G. H. Hitchings 'for their discoveries of important principles for drug treatment'.

ELISA abbr. for enzyme-linked immunosorbent assay.

Elk a family of cell-surface proteins similar to those encoded by the protooncogene *ETS* and with presumed similar function (named from Eph-like kinase); they are protein tyrosine kinases, restricted to brain and testis, having a single transmembrane domain and two fibronectin-like domains. Example from rat (precursor): database code KELK\_RAT, 984 amino acids (109.88 kDa).

Elk-1 a gene-regulating protein, found in lung and testis, that binds to DNA at purine-rich sites. It is a substrate for a MAP kinase in the phosphorylation cascade originating with activated protein kinase C or Ras; on phosphorylation it forms with the transcription factor SRF a ternary complex, which binds to the serum response element of DNA, turning on *FOS* transcription. Example (human): database code ELK1\_HUMAN, 428 amino acids (44.86 kDa).

ellagic acid 4,4',5,5',6,6'-hexahydroxydiphenic acid 2,6,2',6'-dilactone; a commonly occurring plant polyphenol that inhibits glutathione S-transferase.

ellipse any closed plane figure whose perimeter is the locus of a point that moves so that the sum of its distances from two fixed points, the foci, is constant. An ellipse has two axes of symmetry, the major axis at the furthest distance between opposing points on its circumference and the minor axis at the nearest distance.

ellipsoid any surface or solid figure whose plane sections are all either ellipses or circles. -ellipsoidal *adj.*

ellipsoid of rotation or ellipsoid of revolution a solid figure generated by the rotation of an ellipse about one of its axes. If the rotation is about the major axis the ellipsoid of revolution is said to be prolate, whereas if the rotation is about the minor axis it is said to be oblate. See also equivalent ellipsoid of rotation, spheroid (def. 2).

ellipsosome a compartment in the retinal cones of fish that contains cytochrome-like pigment.

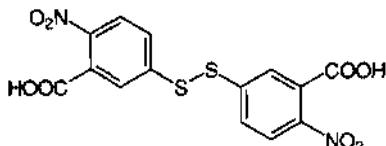

elliptical of, relating to, or having the shape of an ellipse or ellipsoid. -elliptically *adv.*

elliptically polarized or elliptically polarised describing light (or other electromagnetic radiation), whose electric vector appears to follow an elliptical path when viewed along the light beam. See also polarized light.

ellipticity 1 the ratio of the lengths of the major to the minor axis of an ellipse or ellipsoid. 2 the arc tangent of the ratio of the lengths of the minor to the major axis of an ellipse. See also circular dichroism, Cotton effect, molecular ellipticity.

## Ellman's reagent

Ellman's reagent 5,5'-dithiobis(2-nitrobenzoic acid) (*abbr.*: DTNB); a reagent used for labelling thiol (SH) groups in protein side-chains. The reagent reacts quantitatively with thiol groups, forming mixed disulfides and releasing the anion 5-sulfido-2-nitrobenzoic acid; this absorbs light at 412 nm, thus permitting the determination of the number of thiol groups in the protein sample. [After George Leon Ellman (1923- ).]

elongase any of the long-chain fatty-acyl-coenzyme A elongating enzymes, found in mammalian microsomes, that act on saturated and unsaturated fatty-acyl derivatives having 16 or more carbon atoms per molecule of fatty acid.

elongation factor *abbr.*: EF; any of a group of soluble proteins required for chain elongation during polypeptide synthesis at the ribosome. In *Escherichia coli* there are three elongation factors: EF-Tu, EF-Ts (*see* EF-1), and EF-G. EF-Tu helps to bind aminoacyl-tRNA, via a tertiary complex, aminoacyl-tRNA'EF-Tu'GTP, to the ribosomal A-site. After EF-Tu-dependent GTP hydrolysis, the EF-Tu·GDP complex dissociates from the ribosome and is recycled to EF-Tu'GTP, probably via an EF-Tu'EF-Ts intermediate. *E. coli* EF-Tu and GTP form ternary complexes with all aminoacyl-tRNAs except the initiator, tRNA<sup>Met</sup>. EF-G catalyses the GTP-dependent movement of the ribosome and the codon-anticodon-linked mRNA-peptidyl-tRNA complex relative to each other, resulting in the removal of a deacylated tRNA and the location of peptidyl-tRNA from the ribosomal A-site to the P-site. In eukaryotes three proteins, EF-1 $\alpha$ , EF-1 $\beta$ , and EF-2, are required for the elongation events. EF-1 $\alpha$ , which occurs in different tissues as aggregates of varying size of a polypeptide chain of  $M_r$  53 000, functions during chain elongation, like EF-Tu, to bring the aminoacyl-tRNA to the ribosomal A-site in a reaction in which GTP is hydrolysed. EF-1 $\beta$ , of  $M_r$  30 000, functions as EF-Ts. EF-2, like EF-G, catalyses the translocation of the peptidyl-tRNA from the ribosomal A-site to the P-site in a GTP-dependent reaction. Rat liver EF-2 has an  $M_r$  of 110 000, while wheatgerm EF-2 has an  $M_r$  of 70 000. *Compare* initiation factor, release factor.

Eison-Morgan reaction a colorimetric reaction for the estimation of combined and free hexosamines. The specimen is heated in alkaline solution with acetylacetone to form a pyrrole derivative, which then gives a red colour with p-dimethylaminobenzaldehyde on acidification. [After Leslie Alderman Elson and Walter Thomas James Morgan (1900- ), British biochemist, who together described the reaction in 1933.]

eluant *a variant spelling of eluent*.

eluate 1 (*in chromatography*) the solution flowing from a chromatographic column; the desired material in such a solution. 2 (*in immunology*) a solution of material derived from an insoluble or particulate antigen-antibody complex, e.g. by heating or by treatment with an appropriate buffer solution. eluent or eluant, a liquid used in elution, particularly in chromatography.

eluent strength function (*in chromatography*) the order of an eluotropic series defined as the adsorption energy per unit area of standard activity of the solvent:

$$\log K = \log V_a + a(SO - A_e O),$$

where  $K$  is the distribution coefficient in mass/volume of adsorbent and is independent of the solute concentration,  $V_a$  is the adsorbent surface volume,  $a$  is an adsorbent function proportional to the average surface energy of the adsorbent,  $S_0$  is a solute parameter equivalent to the adsorption energy of the

solute from solution,  $A$ , the area of adsorbant occupied by solvent, and  $\ell O$  is a solvent strength parameter; the larger  $\ell O$ , the stronger the solvent.

eluotropic series a series of solvents arranged in the order of their relative abilities to effect elution.

elute to wash out or extract retained material, particularly from a chromatography column.

eluting 1 of or relating to elution, e.g. an eluting solvent. 2 the process of carrying out an elution.

elution the process of washing out or extracting adsorbed material from a chromatographic column.

elution volume (*in chromatography*) the volume of mobile phase that must pass through a chromatographic column, after sample application, to produce a peak in the concentration of a particular solute in the effluent or eluate.

elutriation the process of separating and purifying particles in a powder or suspension according to their rates of sedimentation. It may be effected by repeatedly washing, decanting, and settling, or by allowing a liquid or gas containing the particles to flow upwards (against gravity), when particles whose sedimentation rates are less than the rate of upward flow are washed away from the larger, heavier particles. *Compare* centrifugal elutriation, electrodecantation.

elutriator a device for grading finely divided material according to the sizes and weights of the particles by means of a stream of liquid or gas.

elymoclavine an ergot alkaloid produced by *Claviceps purpurea* and other fungi.

em+ prefix; *a variant of en+ (sometimes before b, m, and p)*.

EM or e.m. *abbr.* for electron microscope (*or* electron microscopy).

Embden-Meyerhof pathway or Embden-Meyerhof-Parnas pathway alternative names for glycolytic pathway. [After Gustav Embden (1874-1933) and Otto Meyerhof (1884-1951), German biochemists, and Jacob Karol Parnas (1884-1949), Polish biochemist.]

EMBL *abbr.* for European Molecular Biology Laboratory; an international research facility based at Heidelberg in Germany. The initials are also used as the name of a major database of nucleic acid and protein sequences maintained by EMBL.

EMBO *abbr.* for European Molecular Biology Organization.

embolus (*pl.* emboli) a thrombus fragment that is transported in the circulation to distant tissues, where it can cause ischaemic tissue damage.

embryo the structure that develops from a zygote, up to the time of birth or hatching in eutherian animals, or of germination in plants. In mammals the term is restricted to the structure present in the early part of gestation that develops into a fetus. -embryonic *adj.*

embryogenesis or embryogeny the formation of an embryo from an ovum and the processes of its development. -embryogenic *adj.*

embryology the branch of biology concerned with the study of embryos and their development. -embryological or embryologic *adj.*; embryologically *adv.*; embryologist *n.*

embryonated differentiated into, or having an embryo, e.g. an embryonated hen's egg.

embryonic stem cell *abbr.*: ES cell; a totipotent cell that can be cultured from an early embryo.

embryonin another name for bovine  $\alpha_2$ -macroglobulin.

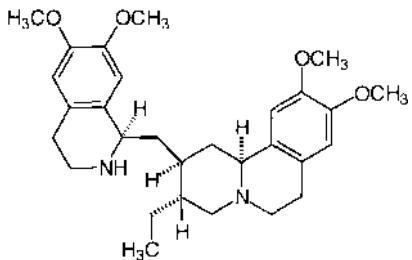

emerimycin *see* peptaibiotics.

Emerson enhancement the phenomenon in photosynthesis in which the quantum yield of light in the far-red region of the spectrum is enhanced by weak background illumination with shorter wavelength light. *Compare* enhancement spectrum. [After Robert Emerson (1903-59).]

emetin 1 having the power to cause vomiting. 2 any compound with emetic properties.

emetine 6',7',10,11-tetramethoxyemetan; an alkaloid from *Cephaelis ipecacuanha* that is a gastrointestinal irritant and

potent emetic and used as an expectorant and antiamoebic agent. It inhibits protein synthesis by preventing translocation of peptidyl-tRNA from the A- to the P-site on the ribosome.

**emf** or **EMF** abbr. for electromotive force.

**EMG** abbr. for electromyogram.

+emia or (esp. Brit.) +aemia suffix denoting blood, especially some abnormal condition of the blood.

**elinilin** abbr. for elastin microfibril interface located protein; an extracellular matrix glycoprotein, gp115. It is a component of elastin fibres, preferentially located at the elastin-microfibril interface.

**emiocytosis** a process whereby a secretory substance is released from a cell; a form of exocytosis. A secretory granule moves to the cell surface, where the membrane sac enclosing the granule fuses with the plasma membrane, ruptures, and liberates the granule into the extracellular space.

**emission** (in physics) the release of energy in the form of radiation or particles.

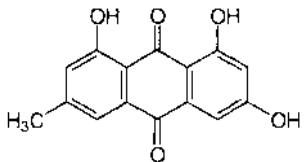

**emission spectrophotometry** or **emission photometry** the processes of measuring an emission spectrum, either photometrically or photographically.

**emission spectroscopy** the spectroscopy of an emission spectrum. This differs from emission spectrophotometry in being a generic term. Thus measurement may be photometric or photographic, for example.

**emission spectrum** any spectrum of emitted electromagnetic radiation produced by a sample after its atoms or molecules have been put into excited states by the absorption of energy, each line in the emission spectrum being produced by the decay of a particular species of excited atom or molecule to some lower energy level. The exciting energy may be supplied as heat, bombardment by particles, or irradiation with other electromagnetic radiation. Compare absorption spectrum, excitation spectrum.

**EMIT** abbr. and trademark for enzyme-multiplied immunoassay technique; see homogeneous enzyme immunoassay.

**emodin** 1,3,8-trihydroxy-6-methylanthraquinone; a compound found (as its rhamnoside) in rhubarb root and other plants.

**EMPIGEN BB** proprietary name for dodecyl-N,N-dimethylglycine. **EMR** abbr. for 1 equi-effective molarity concentration ratio.

2 or **emr** electromagnetic radiation.

**emu** or **EMU** abbr. for electromagnetic unit.

**emulsifier** 1 an alternative name for emulsifying agent. 2 a machine for making emulsions.

**emulsify** to form or to convert into an emulsion. -emulsifiable or **emulsible** adj.; emulsification n.

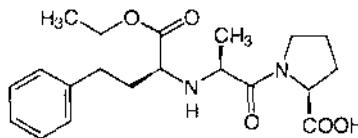

**emulsifying agent** or **emulsifier** any amphiphile or surfactant, such as a phospholipid or a soap, small quantities of which promote the formation of, and stabilize, an emulsion.

**emulsin** a ferment (i.e. an enzyme preparation) obtained from sweet or bitter almonds and originally studied in 1837 by the German chemists Justus von Liebig (1803-73) and Friedrich Wohler (1800-82) for its ability to degrade amygdalin. Together with invertin, it played an important role in Fischer's work on enzyme specificity leading to his lock and key model. In modern terms, it was an enzyme mixture containing mainly  $\beta$ -glucosidase activity (EC 3.2.1.21).

**emulsion** 1 a temporary or permanent dispersion of an oil or other hydrophobic material in an aqueous solution, or vice versa, forming an oil-in-water emulsion or a water-in-oil emulsion respectively. 2 short for photographic emulsion.

**en+** or (sometimes before b, m, and p) **em+** prefix 1 (forming verbs) put in or into, e.g. encapsulate, encode; surround or cover with, e.g. enmesh; to make into a certain condition, e.g. enrich. 2 (forming nouns and adjectives) in, into, e.g. endemic.

**enalapril** (S)-I-[N-{1-(ethoxycarbonyl)-3-phenylpropyl]-L-alanyl]-L-proline; an inhibitor of angiotensin converting enzyme (ACE) and a valuable antihypertensive drug. It has the advantage over captopril that it is more easily absorbed and has fewer side effects, and also that enalapril, to which it is converted after absorption by removal of the ethyl ester group, is a much more potent ACE inhibitor than captopril. ACE inhibitors were developed from compounds such as succinylproline, an early inhibitor. Conversion of the free succinyl carboxyl group to a sulphydryl, and addition of a methyl group, yielded captopril with greatly enhanced binding properties. In enalaprilate there was addition of further binding affinity by a phenylethyl group, restoration of carboxyl in place of sulphydryl and introduction of a secondary amino group. These drugs lower angiotensin II levels which lowers blood pressure, both because of a reduction in direct action of angiotensin as a vasoconstrictor and also by reducing its actions in stimulating aldosterone and norepinephrine release, both of these latter substances having hypertensive effects.

**enamel** the hard, white, calcified material that forms the outer covering of the crown of a tooth.

**enamilin** see tuftelin.

**enamine** or **alkenylamine** any organic molecule having the general structure  $R_1R_2NCR_3=CR_4R^5$  (where the R groups may be any hydrocarbyl group or H, and the same or different).

**enanthate** see heptanoate.

**enantiomer** either of a pair of stereoisomers whose molecules as a whole display chirality, i.e. are mirror images of each other and thus not superposable. They are sometimes referred to as optical isomers or optical antipodes; these terms are not recommended. See also enantiomorph (def. 2), racemate (def. 1). Compare diastereoisomer.

**enantiomeric** of, or pertaining to, an enantiomer; pertaining to the phenomenon of, or displaying enantiomerism. Chiral groups that are mirror images of one another are termed enantiomeric groups. See also enantiomorphic, racemic.

**enantiomeric purity** a measure of the proportion of one enantiomer in an enantiomeric mixture expressed as either a fraction or a percentage. Distinguish from optical purity.

**enantiomerism** the phenomenon of the existence of enantiomers in general, or the existence of enantiomeric molecules in a particular instance; it includes optical isomerism.

**enantiomorph** 1 either of two objects, especially crystals, that

**enantiomorphic**

are mirror images of each other and thus are not superposable. 2 either of the two crystalline forms exhibited by a pair of enantiomers. Use of the term to mean enantiomer is deprecated.

**enantiomorphic** or enantiomorphous of, or pertaining to, an enantiomorph; pertaining to the phenomenon of, or displaying enantiomorphism. The term is often used synonymously with enantiomeric (enantiomeric molecules frequently form enantiomeric crystals).

**enantiomorphism** the phenomenon of being related as between an object and its nonsuperposable mirror image. The term is used especially in relation to enantiomeric crystals.

**enantiomorphous** see enantiomorphic.

**enantiotopic** 1 when chemically-like ligands in constitutionally equivalent locations (generally the two *a* ligands in *Caabc*) are related by a centre or plane of symmetry, or by an alternating axis of symmetry (but not by a simple axis of symmetry), they are enantiotopic. The two ligands are in a stereochemically different, mirror-image environment. If each *a* ligand of *Caabc* is replaced separately by a different, achiral ligand, *d*, the products are the two enantiomers of *Cabcd*. Example: the methylene hydrogens of ethanol are enantiotopic; if ethanol is written as a Fischer projection structure with OH at the top, H-C-H in the middle, and CH<sub>3</sub> at the bottom, the left-hand hydrogen of the central methylene is H<sub>O*i*</sub>, while that at the right is H<sub>R</sub> (see pro-R/pro-S convention). Replacement of IH<sub>R</sub> by 2H yields (+)-(R)-[1-<sup>2</sup>H]ethanol and the same replacement of IH<sub>S</sub> yields the enantiomer, (-)-(S)-[1-<sup>2</sup>H]ethanol. In another important compound, citric acid, the two CH<sub>2</sub>COOH groups are also enantiotopic. 2 the two faces of a double bond or of a planar cyclic ring system that are related by a symmetry plane but not by a C<sub>2</sub> axis (i.e., a two-fold axis of symmetry) are enantiotopic; the two faces show stereochemically different, mirror-image related environments. Separate addition of the same achiral reagent to the two faces (see *Re/Si* convention) gives enantiomeric products. Example: the simple addition of HCN to CH<sub>3</sub>-CHO yields a racemic mixture of the (*R*) and (*S*) cyanohydrins, CH<sub>3</sub>-CH(OH)-CN, with both faces of C=O being involved. The reduction of the C=O bond of CH<sub>3</sub>-CHO to form ethanol by alcohol dehydrogenase requires addition of a hydride ion from NADH at the C atom and a hydron at the O atom. Thus, reduction of CH<sub>3</sub>-CHO with NADH at its A face (see diastereotopic (def. 2») yields (*R*)-[1-<sup>2</sup>H]ethanol and reduction of CH<sub>3</sub>-C<sup>2</sup>HO with A-NADH yields (*S*)-[1-<sup>2</sup>H]ethanol. The enzymatic reduction is stereospecific and only one of the enantiotopic faces of C=O is attacked; it is the same one (the *Re* face) in both of these situations. Compare diastereotopic.

**encapsidate** to surround (a particle of viral nucleic acid) with a capsid. -encapsidation *n*.

**encapsis** the association of myofibrils into bundles and the further association of these bundles into larger bundles, etc.

**encephalin** a variant spelling of enkephalin.

**encephalitis** inflammation of the brain.

**3'** end the end of a linear polynucleotide strand at which the 3'-hydroxyl group of the terminal nucleoside residue is normally not phosphorylated.

**5'** end the end of a linear polynucleotide strand at which the 5'-hydroxyl group of the terminal nucleoside residue is normally phosphorylated.

**end+** a variant form of *endo+* (sometimes before a vowel).

**end capping** (in chromatography) the blocking of residual silanol groups on the surface of silica where these remain exposed after the bonding of C<sub>18</sub> or other alkyl chains to the silica in the formation of reversed-phase stationary phases for column chromatography. For this purpose hydrocarbyl silanes (see silane (def. 3») having small alkyl (usually methyl) groups are used so that they can penetrate between the main bonded-phase groups.

**endemic** present in or peculiar to a more or less localized area, e.g. an endemic disease. Compare enzootic.

**endohydrolysis**

endergonic describing a process or reaction on which work must be done, i.e. one requiring an energy input, for it to take place. At constant pressure and temperature the free energy content of such a system increases. Compare exergonic. [From *endo+* plus Greek *ergon*, work.]

**end group** any residue at an extremity of a branched or linear macromolecule.

**end-group analysis** determination of both the nature and the number of terminal groups in a macromolecule, e.g. in proteins, the N- and C-terminal amino-acid residues; in polynucleotides, the 3'- and 5'-terminal nucleotide residues.

**endo+** or (sometimes before a vowel) *end+* comb. form meaning within, inner, absorbing, containing. Compare *exo+*. See also *intra+*.

**endo-** prefix (in *chemical nomenclature*) denoting insertion (of the additional constituent(s) specified) into the structure of (a named compound); e.g. *endo*-4a-glycine-[5-leucine]enkephalin; *endo*-Gly4a-[Leu<sup>5</sup>]enkephalin; Tyr-Gly-Gly-Phe-Gly-Leu; a synthetic polypeptide in which a glycine residue has been inserted between residues 4 and 5 of [5-leucine]enkephalin.

**endo-** prefix (in *stereochemistry*). See conformation.

**endoamylase** any amylase that hydrolyses nonterminal glycosidic linkages; it is a subcategory of *endoglycosidase*.

**endocrine** 1 describing or relating to any gland or other group of cells that synthesizes hormones and secretes them directly into the blood, lymph, or other intercellular fluid. 2 describing or relating to a secretion of endocrine tissue. 3 a secretory product of endocrine tissue; a hormone. Originally known as internal secretion. Compare *exocrine*.

**endocrine gland** or *ductless gland* any of the ductless glandular structures that secrete (one or more) hormones directly into the bloodstream.

**endocrinology** the science concerned with the endocrine organs, their products, and the effects of these products. -endocrinological *adj.*

**endocytic** 1 situated within a living cell but not belonging to the cell itself; intracellular. 2 an alternative term for endocytosis (see *endocytosis*).

**endocytosis** the uptake of external materials by cells through the mechanism of phagocytosis or pinocytosis. The term is often used interchangeably with pinocytosis. Compare exocytosis, transcytosis. See also internalize, viropexis. -endocytic or endocytotic *adj.*; -endocytose *vb*.

**endocytotic vesicle** see pinocytotic vesicle.

**endodeoxyribonuclease** see deoxyribonuclease.

**endoenzyme** 1 any intracellular enzyme. Compare ectoenzyme, exoenzyme (def. 1). 2 any enzyme that catalyses *endohydrolysis*. It may be an *endoglycosidase*, an *endonuclease*, or an *endopeptidase*. Compare *exoenzyme* (def. 2).

**endogenous** arising or developing within an organism, tissue, or cell, and excluding any consequences of externally added agents or materials. -endogenously *adv.*

**endoglin** a major glycoprotein of vascular endothelium that may be important in the binding of endothelial cells to integrins. It forms a heteromeric complex with the signalling receptors for transforming growth factor  $\beta$  (TGF- $\beta$ ). It has an RGD integrin-recognition motif and is a homodimer of disulfide-linked subunits. Example (precursor) from *Sus scrofa*: database code EGLN\_PIG, 653 amino acids (70.20 kDa).

**endoglycosidase** any enzyme within subclass EC 3.2, glycosidases, that hydrolyses nonterminal glycosidic linkages in oligo- or polysaccharides. Many activities of this type are known, e.g. from *Flavobacterium meningosepticum*.

**endohormone** any hormone acting within the individual organism that produces it. Compare *ectohormone*.

**endohydrolysis** the hydrolysis, esp. by an *endoenzyme*, of any linkage between residues in a biopolymer. For example, endopeptidases attack neither the C-terminal nor the N-terminal peptide linkages of an oligo- or polypeptide, and *endoglycosidases* attack the terminal glycosidic linkages at either the reducing or nonreducing end of an oligo- or polysaccharide.

endolyn-78 a glycoprotein, M<sub>r</sub> 78 000, present in substantial amounts in membranes of endosomes and lysosomes, but occurring only at low levels in plasma membrane and the peripheral tubular endosomal compartment.

**endomembrane system** a hypothetical integrated membrane system of eukaryotic cells, proposed by Morré and Mollenhauer, that represents a developmental and functional continuum. It comprises the endoplasmic reticulum, nucleus, Golgi apparatus and vesicles, plasmalemma, tonoplast, and outer membranes, but not the inner membranes of the mitochondria and chloroplasts.

**endometrium** the mucous membrane that lines the uterus. It becomes progressively thicker and more glandular in the later stages of the estrous (menstrual) cycle, which prepares it for embryo implantation. If pregnancy occurs the endometrium becomes the decidua, which is shed after birth. If pregnancy does not occur the endometrium returns to its original state; in primates, including humans, much of the endometrium breaks down and is lost in menstruation. -endometrial *ad.*

**endomitosis** the replication of chromosomes without cellular or nuclear division. It is a form of polyploidization that is fairly common in differentiated or differentiating tissues. It is characterized by an increase in nuclear DNA content.

**endonuclease** any enzyme of a large group of phosphoric diester hydrolases, forming sub-subclasses EC 3.1.21-31, that catalyses the hydrolysis of nonterminal diester linkages in polynucleotides to yield oligonucleotides. Examples include certain of the deoxyribonucleases and ribonucleases. Compare exonuclease. See also restriction endonuclease.

**endopeptidase** or **endoproteinase** or (formerly) **proteinase** any enzyme within subclass EC 3.4, peptide hydrolases, that hydrolyses nonterminal peptide linkages in oligopeptides or polypeptides, and comprising any enzyme of sub-subclasses EC 3.4.21-99. They are classified according to the presence of essential catalytic residues or ions at their active sites. Four distinct sub-subclasses are: (1) serine proteinases (EC 3.4.21); (2) cysteine proteinases (EC 3.4.22); (3) aspartic proteinases (EC 3.4.23), and (4) metalloproteinases (EC 3.4.24). There are two major families of serine proteinases, the chymotrypsins and the subtilisins. Aspartic proteinases contain two aspartic residues at their active site. The metalloproteinases contain metal ions, usually zinc. The proteinases can be distinguished by inhibitors, which are usually specific for a particular class or type.

**endopeptidase La** the enzyme EC 3.4.21.53; other names: ATP-dependent serine proteinase; ATP-dependent protease La; a serine proteinase that catalyses the hydrolysis of large proteins such as globin, casein, and denatured serum albumin in the presence of ATP. It is seemingly the sole member of its own superfamily. Example from *Escherichia coli*: database code JN0303, 784 amino acids (87.35 kDa).

**endoperoxide** a cyclic peroxide formed from a long-chain polyunsaturated fatty acid, especially arachidonic acid, through the action of prostaglandin-endoperoxide synthase.

**endoplasm** the inner, relatively fluid, part of the cytoplasm. Compare ectoplasm. -endoplasmic *ad.*

**endoplasmic reticulum** abbr.: ER; the irregular network of unit membranes, visible only by electron microscopy, that occurs in the cytoplasm of many eukaryotic cells. The membranes form a complex meshwork of tubular channels, which are often expanded into slitlike cavities called cisternae. The ER takes two forms, rough (or granular), with ribosomes adhering to the outer surface, and smooth (with no ribosomes attached). When cells are disrupted by homogenization, the cisternae of rough ER break up into small closed vesicles called rough microsomes. Similarly the smooth ER may give smooth microsomes. The functions of the two forms of the ER differ. The ribosomes attached to the rough ER are the site of translation of the mRNA for those proteins which are either to be retained within the cisternae (ER-resident proteins), the proteins of the lysosomes, or the proteins destined for export from

the cell. Glycoproteins also undergo their initial glycosylation within the cisternae. The smooth ER has several distinct roles. It is the recipient of the proteins synthesized in the rough ER. Those proteins to be exported are passed to the Golgi complex (see Golgi apparatus), the resident proteins are returned to the rough ER and the lysosomal proteins after phosphorylation of their mannose residues are passed to the lysosomes. Glycosylation of the glycoproteins also continues. The smooth ER is the site of synthesis of lipids, including the phospholipids. The major membrane phospholipids are phosphatidylcholines, phosphatidylethanolamines, phosphatidylserines, and sphingomyelins. The ER also produces cholesterol, triacylglycerols, and ceramides. The membranes of the smooth ER also contain enzymes that catalyse a series of reactions to detoxify both lipid-soluble drugs and harmful products of metabolism. Large quantities of certain compounds such as phenobarbital cause an increase in the amount of the smooth ER.

**endoproteinase** or (formerly) **proteinase** an alternative name for endopeptidase.

**ENDOR** abbr. for electron nuclear double resonance.

**endorphin** any endogenous peptide with morphine-like activity. The term was originally applied to a general class of substances of morphine-like activity postulated to occur in the brain; 'endogenous opioid' is now used to denote any peptide, found in higher organisms, that has morphine-like activity. The group includes the pentapeptide enkephalins, but the term is most often applied to the endogenous opioid peptides of the pituitary gland, including α-endorphin, which has the structure Tyr-Gly-Gly-Phe-Met-Thr-Ser-Glu-Lys-Ser-Gln-Thr-Pro-Leu-Val-Thr; β-endorphin has the same structure but with an additional Leu at the C terminus; γ-endorphin has the same structure as α-endorphin with additionally -Leu-Phe-Lys-Asn-Ala-Ile-Ile-Lys-Asn-Ala-His-Lys-Gly-Gln-OH at the C terminus. Endorphins have the same N-terminal tetrapeptide sequence as the enkephalins. Tissue endorphins are larger polypeptides (about 7 kDa) found in pancreas, placenta, and adrenal medulla. The members of this group of peptides originate from large precursor molecules: preproopiomelanocortin is the precursor of β-endorphin, both in brain and other tissues, and [Met<sup>5</sup>]enkephalin; preprodynorphin (preproenkephalin B) is the precursor of dynorphin; [Leu<sup>5</sup>]enkephalin is formed from preproopiomelanocortin and from preproenkephalin A. Compare exorphin. [From endo(genous) + morphine.]

**endo-a-sialidase** EC 3.2.1.129; other names: endo-N-acetylneuraminidase; endoneuraminidase; poly(a-2,8-sialosyl) endo-N-acetyleneuraminidase; an enzyme that catalyses the endohydrolysis of a-2,8-sialosyl linkages in oligo- or poly(sialic) acids. Example from bacteriophage kif: database code ENAN\_BPKIF, 919 amino acids (101.77 kDa).

**endoskeleton** any skeleton lying within an organism, such as the axial skeleton of vertebrates. Compare exoskeleton.

**endosmosis** the osmotic flow of water or of an aqueous solution into a cell, organism, or vessel from a surrounding aqueous medium. Compare exosmosis. -endosmotic *ad.*

**endosome** a membrane-bound organelle in animal cells that carries materials newly ingested by endocytosis. It passes many of the materials to lysosomes for degradation.

**endosperm** the nutritive tissue, found in the seeds of most angiosperms, that surrounds and nourishes the embryo.

**endosperm albumin** the proteins occurring in the endosperm of, e.g. barley; see protein Z.

**endospore** 1 an asexual spore formed within a cell, especially one produced by some bacteria and algae. 2 or **endosporium** the innermost coat of the wall of a spore or pollen grain.

**endosymbiont** a partner in a symbiotic relationship that penetrates the tissues or cells of the other partner; e.g. any of the nitrogen-fixing species of bacteria that occur in the root nodules of legumes. See symbiosis. Compare ectosymbiont.

**endosymbiotic infection** an infection of cells by viruses that replicate without cytopathic effect.

## endothelial leukocyte adhesion molecule

engrailed

**endothelial leukocyte adhesion molecule abbr.:** ELAM; another name for selectin.

**endothelin abbr.:** ET; anyone of three 21-residue peptides, called endothelins I, 2, and 3 (abbr.: ET-1, ET-2, ET-3). Endothelins 2 and 3 are so named because of homology with ET-I, which is known to be made by the endothelial cell. ET-I is the most potent vasopressor compound yet discovered, being ten times more potent than angiotensin II. All three compounds have two disulfide bridges, between cysteine residues I and 15, and 3 and II; these hold the structure in a conical spiral shape. The amino-acid sequence of ET-I is {bicyclic(I $\rightarrow$ 15, 3 $\rightarrow$ II)} [Cysl-Ser-Cys3-Ser-Ser-Leu-Met-Asp-Lys-Glu-Cys11-Val-Tyr-Phe-Cys15-His-Leu-Asp-Ile-Ile-Trp]; ET-2 differs in having -Trp-Leu- at positions 6,7; ET-3 has the substitutions (position in parentheses) Thr(2), Phe(4), Thr(5), Tyr(6), Lys(7), and Tyr(14). The endothelins are products of three distinct genes, and are synthesized as part of a large precursor molecule, preproendothelin (prepro-ET), which is then proteolytically processed. The 2.2 kb mRNA for human prepro-ET-I is encoded in five exons, the 5'-flanking region containing response elements for phorbol ester (Fos/Jun-inducible) and nuclear factor I (TGF- $\beta$ -induced expression; see transforming growth factor), and its expression is stimulated by vasopressor hormones such as epinephrine, angiotensin II, and arginine vasopressin, as well as TGF- $\beta$  (from aggregating platelets), thrombin, and interleukin-1. Prepro-ET-I is a 203-residue peptide, which is cleaved to the 92-residue pro-ET (big endothelin), from which ET-I is formed by endothelin converting enzyme. Related peptides are vasoactive intestinal contractor and sarafotoxin, a peptide produced by *Atractaspis engaddensis*. Only ET-I is detected in vascular endothelial cells; it is also expressed in nonvascular cells in other tissues, including brain, kidney, and lung. ET-2 and ET-3 are expressed in tissues such as brain, kidney, adrenal, and intestine.

**endothelin receptor** any of several membrane proteins that bind endothelins and mediate their intracellular effects. They are G-protein-coupled seven-transmembrane-domain receptors. The structures of two types have been predicted from human, rat, and bovine cDNA. ETA (human, 427 amino acids) has affinity ET-I  $\geq$  ET-2  $\gg$  ET-3, while ET<sub>B</sub> (human, 442 amino acids) is equipotent for all three.

**endothelium** the single layer of thin, flattened cells of mesoblastic origin that lines the blood vessels and some body cavities, e.g. those of the heart. Compare epithelium, mesothelium. -endothelial adj.

**endothelium-derived relaxing factor abbr.:** EDRF; see nitric oxide.

**endothermic** describing a process or reaction that absorbs heat, i.e. a process or reaction for which the change in enthalpy,  $\Delta H$ , is positive at constant pressure and temperature. Compare exothermic.

**endothiapepsin EC 3.4.23.22; other name: Endothia aspartyl proteinase.** An enzyme that catalyses the hydrolysis of proteins with broad specificity similar to that of pepsin A; it prefers hydrophobic residues at PI and PI', but does not cleave the Ala-Leu linkage in the B chain of insulin or the protected dipeptide Cbz-Glu-Tyr; it clots milk. Example from *Cryptocnectria parasitica* (*Endothia parasitica*; chestnut blight fungus); database code NRL\_4APE, 330 amino acids (33.76 kDa); 3-D structure known; it is similar to other aspartic proteases.

**endotoxin** any microbial toxin that cannot easily be separated from the structure of the cell. Compare exotoxin.

**end point or endpoint** the point in a titration that should (but may not always) correspond to the theoretical equivalence point.

**end product** the final chemical substance formed in a sequence of metabolic (or chemical) reactions.

**end-product inhibition** the inhibition of a sequence of metabolic reactions by the end product of the sequence, usually by action on a reaction which is often at the beginning of the sequence.

**end-window counter** a Geiger counter or proportional counter so constructed that its base is relatively transparent to the radiation to be detected.

**+ene suffix (in chemical nomenclature)** indicating the presence of one or more carbon-carbon double bonds in an organic compound.

**enediol** any acyclic organic compound in which there is a hydroxyl group attached to each of two carbon atoms that are linked by a double bond. Compare enol.

**energy symbol:** E; the capacity of a system for doing work. There are various forms of energy - potential, kinetic, electrical, chemical, nuclear, and radiant - which can be interconverted by suitable means. The SI unit of energy is the joule.

**energy balance** the algebraic balance of the various energy inputs versus energy outputs of a system; it is positive if energy is released and negative if it is absorbed. In physiology it is the relation of the amount of energy taken into the organism to the amount used for internal work, external work, and for the growth and repair of tissues.

**energy barrier** see potential energy barrier.

**energy charge** see adenylate energy charge.

**energy coupling** the coupling of ATP synthesis to electron transport in the respiratory chain.

**energy diagram** a diagram representing the energy contents of various states of the reactants, activated complexes, and products in a chemical reaction; or of the nuclear energy levels of an atom; or of the electronic energy levels of an atom or molecule.

**energy flow (in ecology)** the transfer of energy between organisms in an ecosystem.

**energy level** any of the stable energy states that a molecular entity can take up. In quantum mechanics only certain discrete energy levels are possible and continuous variation of the energy level of a molecular entity is excluded.

**energy metabolism** the metabolic reactions of a cell or organism concerned with energy transformations.

**energy of activation** see activation energy.

**energy-poor term sometimes used to describe** 1 a compound whose hydrolysis under standard conditions manifests a small negative free energy change. See also low-energy compound. 2 a chemical group with a low group potential. 3 the linkage of such a chemical group to some other group.

**energy requirement** the amount of energy needed to maintain a cell or organism.

**energy sink** a molecule or a group in a molecule that is able easily to accept energy transferred to it from another component of the system.

**energy transduction** see transduction (def. 2).

**energy transfer** the transfer of excitation energy from one chromophore or one molecular entity to another by a process not involving radiation; the energy may then be dissipated in a variety of ways, e.g. by fluorescence. Such energy transfer is very dependent on the distances involved and is useful in studies of structural relationships between groups on a macromolecule.

**energy trapping** the processes by which energy released in a catabolic reaction is coupled to the synthesis of another compound, often a nucleoside triphosphate such as ATP.

**engineered** 1 (of a cell or organism, or a strain of cells or organisms) colloquial term for genetically engineered. 2 (of a nucleotide sequence) jargon term, usually followed by 'into' artificially inserted (into a longer sequence, such as a vector). 3 (of a protein) jargon term describing an altered protein synthesized by a cell or organism (or a strain of cells or organisms) whose genetic material has been manipulated to that end.

**engrailed** any of various protein products of the homeotic gene *engrailed*; in *Drosophila* this is a segment-polarity gene. Examples: engrailed-1 and engrailed-2 (human) respectively; database codes HMELHUMAN and HME2\_HUMAN, 391 amino acids (40.00 kDa) and 332 amino acids (34.12 kDa); en-

## enhancement

grailed chain C, *Drosophila melanogaster*, database code NRL\_IHDDC, 57 amino acids (6.94 kDa); 3-D structure of complex with DNA known; one motif.

**enhancement** 1 the improvement of the effects of ionizing radiation on tissue by dioxygen or other chemical agents. 2 the increased yield of one virus from cells infected by another virus; the term is often used when the mechanism of the process is not known. *Compare* complementation (def. 2), interference. 3 see Emerson enhancement. 4 see fluorescence enhancement.

**enhancement of fluorescence** *an alternative term/or* fluorescence enhancement.

**enhancement spectrum** a spectrum showing the enhancement of photosynthetic quantum yield from that produced at a fixed-wavelength background illumination to that produced by illumination with a variable-wavelength beam. Such spectra show peaks that can sometimes be reasonably well identified with specific pigments in the system. *Compare* Emerson enhancement.

**enhancer** (*in molecular biology*) a eukaryotic control element that can increase expression of a gene. Enhancers may be located some distance from the gene and may be either upstream or downstream.

**enhancesome** a dislike structure, formed by a 180 bp loop of DNA and dimers of the *Xenopus* transcription factor xUBF, that is involved in rRNA transcription.

**enkephalin** any pentapeptide endorphin with the sequence Tyr-Gly-Gly-Phe-Xaa. There are two similar naturally occurring enkephalins, present in brain, spinal cord, and gut; their recommended trivial names are: [5-leucine]enkephalin (*abbr.:* [Leu<sup>5</sup>]enkephalin or [Leu]enkephalin), Tyr-Gly-Gly-Phe-Leu (I); and [5-methionine]enkephalin (*abbr.:* [Met<sup>5</sup>]enkephalin or [Met]enkephalin), Tyr-Gly-Gly-Phe-Met (II). (II has the same sequence as residues 61-65 of  $\beta$ -lipotropin.) The common precursor of I and II, proenkephalin - itself formed from preproenkephalin by removal of the signal peptide - contains four copies of II and one each of I, the heptapeptide [Met<sup>5</sup>]enkephalin-Arg-Phe, and the octapeptide [Met<sup>5</sup>]enkephalin-Arg-Phe-Leu. (*Note:* Designations such as Leu-, leucyl-, or leucine-enkephalin have commonly been given to I, with corresponding terms for II, but all of these incorrectly imply N-terminal extension with a residue of leucine or methionine, respectively.)

enkephalinase *see* carboxypeptidase H.

**enkephalin convertase** a specific carboxypeptidase that converts enkephalin precursors into enkephalin in adrenal chromaffin granules. It is now known as carboxypeptidase H.

**enniatin** any of various antibiotics from *Fusarium* spp. that function as ionophores. They are cyclodepsipeptides (*see* depsipeptide).

**enol** any acyclic organic compound with a hydroxyl group attached to either of two carbon atoms that are linked by a double bond. *Compare* enediol. *See also* keto-enol tautomerism.

**enolase** EC 4.2.1.11; *recommended name:* phosphopyruvate hydratase; *other name:* 2-phosphoglycerate dehydratase. An enzyme that catalyses the conversion of 2-phospho-D-glycerate to phosphoenolpyruvate and H<sub>2</sub>O; magnesium is a cofactor. Example from *Saccharomyces cerevisiae*: database code NRL\_7ENL, 436 amino acids (46.58 kDa); 3-D structure known; six motifs.

**enology** or (*esp. Brit.*) oenology the study of wines.

**5-enolpyruvylshikimate-3-phosphate phospholyase** *see* chorismate synthase.

**eNOS** *see* nitric-oxide synthase.

**enoyl** an acyl group derived from any alkenoic acid.

**enoyl-[acyl-carrier protein] reductase** (NADPH, A-specific) EC 1.3.1.39; *other name:* acyl-ACP dehydrogenase; an enzyme of the fatty acid synthase complex in liver. It catalyses the reduction by NADPH of trans-2,3-dehydroacyl-[acyl-carrier protein] to form acyl-[acyl-carrier protein] and NADP<sup>+</sup>.

**enoyl-CoA hydratase** 1 EC 4.2.1.17; *systematic name:* (3S)-3-

## enteroglucagon

hydroxyacyl-CoA hydro-lyase; *other names:* enoyl hydrase, unsaturated acyl-CoA hydratase; an enzyme of the beta-oxidation system, present in mitochondria and peroxisomes. It catalyses the hydration of (3S)-3-hydroxyacyl-CoA to *trans*-2(or 3)-enoyl-CoA. It is a mitochondrial matrix protein, a homohexamer; a characteristic transit peptide sequence is found in the precursor. Example (precursor) from rat: database code ECHM\_RAT, 290 amino acids (31.48 kDa). 2 EC 4.2.1.74; *recommended name:* 10ng-chain-enoyl-CoA hydratase; an enzyme that catalyses a similar reaction to the above; it does not act on crotonoyl-CoA. *See also* beta-oxidation system.

**enoyl-CoA isomerase** *see* dodecenoyl-CoA  $\Delta$ -isomerase.

**3,2-trans-enoyl-CoA isomerase** *see* dodecenoyl-CoA  $\Delta$ -isomerase.

**enrich** to increase in content or abundance; e.g. to increase the abundance of one (usually stable) nuclide of an element above its naturally occurring level; to increase the content in a foodstuff of one or more specific nutrients (such as vitamins or minerals) above the natural level. -enrichment *n.*

**enrichment medium** a selective culture medium that favours the growth of a desired microorganism.

**entactic** describing an enzyme poised for catalytic action in the absence of substrate.

**entactin** or nidogen a sulfated Ca<sup>2+</sup>-binding protein occurring in basement membrane and involved in cell adhesion; it binds laminin and type IV collagen. The protein has two globular domains, an EF-hand domain, EGF-like domains and a thyroglobulin type I domain. Example (precursor) from human: database code NIDO\_HUMAN, 1247 amino acids (136.34 kDa).

**enteric** or enteral of or pertaining to the intestine or gut.

**enteric-coated** describing a drug or medicament that is prepared in a form enabling it to pass through the stomach unaltered and be released in the intestine.

**entero+ or (before a vowel) enter+** *comb. form* denoting the intestine.

**enterobactin** or enterochelin N',N,N"-tris(2,3-dihydroxybenzoyl)-2,6,10-trioxo-1,5,9-trioxacyclododecane-3,7,11-triamine; a siderochrome of the catechol-derivative variety produced by certain members of the Enterobacteriaceae, e.g. *Escherichia coli*, *Salmonella* spp. It is the cyclic self-triester (trilactide) of N-(2,3-dihydroxybenzoyl)-L-serine, and a product of the shikimate pathway.

**enterochelin** *an alternative name for enterobactin.*

**enterochromaffin cell** *abbr.:* EC cell; any gut endocrine cell containing biogenic monoamines that gives a positive chromaffin reaction and displays a characteristic yellow formaldehyde-induced fluorescence. Such cells may be divided immunocytochemically and ultrastructurally into functionally distinct types.

**enterocrinin** a putative peptide hormone, crystallizable from extracts of intestine of certain mammals, that is held to stimulate duodenal and jejunal secretion of digestive enzymes.

**enterocyte** any of the columnar epithelial cells on the luminal surface of the villi of the small intestine. Enterocytes are immature in the crypts, mature in the middle of the villi, and senile at the exfoliation area at the villous tips. They have numerous microvilli on their luminal surface (the brush border) and are responsible for the synthesis of digestive enzymes and for the absorption of materials from the gut.

**enterogastrone** the putative hormone from the duodenum that inhibits gastric activity. Some or all of the actions attributed to enterogastrone are probably due to glucose-dependent insulinotropic peptide.

**enterogastrone effect** *see* gastric inhibitory peptide.

**enteroglucagon** a collective term for a small family of peptides derived from proglucagon by post-translational processing in the L cells (or G cells) of the distal small intestine and colon. One component is GLP-1<sup>7-37</sup> (*see* GLP).

**enteroglucagon** or glucagon-37 or oxyntomodulin a peptide isolated from porcine jejunum-ileum that interacts with glucagon receptors and activates adenylate cyclase in hepat-

## enterohepatic recirculation

cytes. It has a specific action on the acid-secreting area of gastric mucosa. It has 37 residues, of which the sequence of the N-terminal 29 is identical with that of pancreatic glucagon. **enterohepatic recirculation** the cycle of secretion from the gall bladder into the upper intestinal tract with reabsorption in the lower tract and transport to the liver followed by resecretion. *See* bile acids.

**entero-insular axis** the interrelationship of endocrine function between the gastrointestinal tract and the pancreatic islets in which signals arising in the gut after ingestion of nutrients effect endocrine responses by the islets.

**enterokinase** *a former name for* enteropeptidase.

**enteropeptidase or (formerly) enterokinase** the enzyme EC 3.4.21.9; a serine proteinase enzyme of the brush border of the upper small intestine that activates trypsinogen by the selective cleavage of the Lys<sub>6</sub>-Ile<sup>7</sup> bond in the latter. Example (precursor) from *Bos taurus*: database code ENTK\_BOVIN, 1035 amino acids (114.89 kDa); residues 1-800 form the non-catalytic heavy chain, 801-1035 the catalytic light chain.

**enterotoxin** any bacterial exotoxin, whether ingested or produced within the intestine, that has an action upon the intestinal mucosa, usually giving rise to diarrhoea and other unpleasant symptoms. Cholera toxin is an example. Other enterotoxins are produced by *Escherichia coli* and some Staphylococci. Of the *E. coli* enterotoxins, LT (from labile, i.e. heat-labile, toxin) is similar in structure to cholera toxin and has a similar mode of action. ST (from heat-stable toxin) has an effect similar to atrial natriuretic peptide, activating guanylate cyclase. It has 13 amino acids. Other enterotoxins produced by *E. coli* include hemolysin and vero toxin, a Shiga-like toxin similar to that of *Shigella dysenteriae* that has N-glycosidase activity, and cleaves an adenine residue from the 28S rRNA of the 60S ribosome subunit.

**enthalpimetry** the measurement of the enthalpy of a body or system.

**enthalpy or heat content symbol:** *H*; a physical quantity and a thermodynamic property defined as the sum of the internal energy of a system, *U* and the product of the volume, *V*, multiplied by the pressure, *p*, i.e.  $H = U + pV$ . Enthalpy is related to the Gibbs energy, *G*, by the equation  $G = H - TS$ , where *T* denotes the thermodynamic temperature and *S* denotes entropy.

**Entner-Doudoroff enzyme** the 'catabolic' o-glucose-6-phosphate dehydrogenase (EC 1.1.1.49) from *Pseudomonas fluorescens*. It is a 220 kDa protein composed of four, apparently identical, polypeptide chains. *See also* Entner-Doudoroff pathway.

**Entner-Doudoroff pathway** a metabolic pathway occurring in *Pseudomonas* spp. in which o-glucose 6-phosphate is first oxidized to 6-phospho-o-gluconate, which is then acted on by 6-phosphogluconate dehydratase (EC 4.2.1.12) to form 2-dehydro-3-deoxy-6-phospho-o-gluconate. This is then split by 2-dehydro-3-deoxypyrophosphogluconate aldolase (EC 4.1.2.14) to give pyruvate and o-glyceraldehyde 3-phosphate. [After Nathan Entner (1920-) and Michael Doudoroff (1911-).]

**entomology** the science of the study of insects.

**entopic** occurring in the usual place. *Compare* ectopic.

**ENTREZ** a suite of computer programs accessible via the Internet that links MEDLINE with genome and sequence databases.

**entropic union** a polymerization, or other reaction, resulting from an energetically unfavourable interaction of a surface of the molecule in question with water molecules; the polymerization causes the removal of water from the molecules' surfaces and hence a decrease in the free energy content of the system.

**entropy symbol:** *S*; a physical quantity and a thermodynamic property indicating the amount of disorder in a system; i.e. the amount of energy in a system that is unavailable for doing work. In any irreversible process the total entropy of all systems concerned is increased. In a reversible process the total increase in entropy in all systems concerned is zero, while the increase in entropy, *dS*, of any individual system, or part of a

## enzyme I

system, is equal to the heat that it absorbs, *dq<sub>rev</sub>* divided by the thermodynamic temperature, *T*; i.e.  $dS = dq_{rev}/T$ . Entropy is related to Gibbs energy, *G*, and enthalpy, *H*, by the equation  $G = H - TS$ . The SI unit for entropy is J K<sup>-1</sup> -entropic adj.

**entry exclusion** the phenomenon in which a resident plasmid interferes with the entry of genetic material to a cell by (bacterial) conjugation (def. 4).

**enucleate** 1 to remove the nucleus from (a cell). 2 (of a cell) deprived of its nucleus. -enucleation n.

**enuresis** the involuntary passing of urine. -enuretic adj.

**enva** viral gene for envelope protein.

**envelope** 1 any covering or enclosing structure, e.g. a membrane, capsule, shell, or skin. 2 the cell membrane of a bacterium, together with all the structures external to it including the cell wall and, sometimes, the capsule. 3 or peplos an outer lipoprotein coat of a virion that occurs in an enveloped virus. 4 see nuclear envelope.

**envelope conformation** any conformation of a nonplanar five-membered saturated ring compound when four of its ring atoms lie in one plane and the remaining atom lies outside that plane. For a monosaccharide or monosaccharide derivative the conformational descriptor -E may be added to its name.

**enveloped virus** any virus in which a nucleoprotein core is surrounded by a lipoprotein envelope consisting of a closed bilayer of lipid derived from that of the host cell's membrane(s), with glycoprotein on the outside and matrix protein or nucleocapsid protein on the inside. Enveloped viruses include herpesviruses, negative-strand RNA viruses, retroviruses, and togaviruses.

**envelope protein** any protein (usually a glycoprotein) of the envelope of a virus. Example: envelope polyprotein gp160 precursor of human immunodeficiency virus (HIV) type I; database code ENV\_HVIA2, 855 residues (97.33 kDa). Residues 1-29 are the signal peptide; 30-509 form exterior membrane glycoprotein gp120; 510-855 form transmembrane glycoprotein gp41. The variable (very rapidly evolving) antigenic regions of HIV are in the gp120 sequence.

**envelysin** EC 3.4.24.12; *other names:* sea-urchin-hatching proteinase; hatching enzyme; an enzyme so named because it dissolves (lyses) the fertilization envelope of the sea-urchin embryo. It is a metalloendopeptidase that catalyses the preferential cleavage of proteins on the amino side of bulky hydrophobic residues, Leu, Ile, Phe, and Tyr. The enzyme requires zinc and calcium. Example (precursor) from the sea urchin *Paracentrotus lividus*: database code HE\_PARLI, 587 amino acids (65.14 kDa).

**Enzacyrl** the proprietary name for a group of synthetic carriers for the immobilization of enzymes and other organic biomolecules that are copolymers of acrylamide and various derivatives of *N,N'*-methylene diacrylamide.

**enzootic** present in or peculiar to animals in a more or less localized area; e.g. an enzootic disease. *Compare* endemic.

**enzyme** any naturally occurring or synthetic macromolecular substance composed wholly or largely of protein, that catalyses, more or less specifically, one or more (bio)chemical reactions at relatively low temperatures. The action of RNA that has catalytic activity (*see* ribozyme) is often also regarded as enzymic. Nevertheless, enzymes are mainly proteinaceous and are often easily inactivated by heating or by protein-denaturing agents. The substances upon which they act are known as substrates, for which the enzyme possesses a specific binding or active site. *See also* enzyme classification, isoenzyme. [From German *enzym*, possibly from modern Greek *enzumos*, leavened, or more probably from Greek *en*, in, + *zumiē*, leaven, yeast.] -enzymic or enzymatic adj.

**enzyme I** EC 2.7.3.9; enzyme I of the phosphotransferase system; phosphoenolpyruvate-protein phosphotransferase; systematic name: phosphoenolpyruvate:protein-L-histidine *Nn*-phosphotransferase. A soluble bacterial enzyme, part of a system for the transport of hexoses across the cell membrane, that cata-

## enzyme II

lyses the phosphorylation by phosphoenolpyruvate of a low  $M_r$ , heat-stable protein, HPr. *Compare* enzyme II (def. I). enzyme II 1 EC 2.7.1.69; enzyme II of the phosphotransferase system; protein-N"-phosphohistidine-sugar phosphotransferase; systematic name: protein-N"-phosphohistidine:sugar N"-phosphotransferase. Any of a group of related membrane-bound bacterial enzymes, part of the system for the transport of hexoses across the cell membrane, that catalyse the phosphorylation of hexoses by phospho-HPr (see enzyme I). Enzyme II is responsible for the specificity of the transport process with respect to the sugar. 2 *an former name for acyl-carrier protein.*

enzyme-activated irreversible inhibitor *an alternative name for suicide inhibitor.*

enzyme activation the generation of a catalytically active enzyme from an inactive or poorly active form or from a biosynthetic precursor (proenzyme). Activation may be by enzymic or chemical covalent modification or by addition of a specific activator.

enzyme adaptation *see inducible enzyme.*

enzyme cascade *see cascade sequence.*

enzyme classification the systematic arrangement and naming of enzymes by the Enzyme Commission. Each enzyme is denoted by the abbreviation EC followed by a set of four numbers separated by stops. The first number denotes one of the six main divisions: EC 1, oxidoreductases; EC 2, transferases; EC 3, hydrolases; EC 4, lyases; EC 5, isomerases; and EC 6, ligases. The second number denotes the subclass, the third number denotes the sub-subclass; the fourth number is the serial number of the particular enzyme. The most recent edition of the classification, *Enzyme Nomenclature 1992* (IUB/Academic Press; San Diego, London), lists 3196 enzymes.

enzyme cluster or (sometimes) multienzyme cluster 1 any physiologically significant system of two or more enzymes in physical (i.e. noncovalent) association. The term embraces any enzyme complex, multienzyme complex, or membrane-bound enzyme array. Clustered enzymes usually display different kinetic and/or regulatory features from their unassociated counterparts; they may be encoded in a cluster-gene. *See also* multienzyme system. 2 *an alternative term for cluster (def. 2).*

Enzyme Commission or the International Commission on Enzymes; a body established in 1956 by the International Union of Biochemistry (IUB) to consider the classification and nomenclature of enzymes and coenzymes, their units of activity and standard methods of assay, together with the symbols used in the description of enzyme kinetics. The Commission, which worked closely with the Biological Chemistry Nomenclature Commission of the International Union of Pure and Applied Chemistry (IUPAC), was dissolved in 1961 and its work has been carried on in turn by the Standing Committee on Enzymes of IUB, by the IUPAC/IUB Joint Commission on Biochemical Nomenclature (JCBN), by an Expert Committee on Enzymes, and most recently by the Nomenclature Committees of IUB (NC-IUB) or the International Union of Biochemistry and Molecular Biology (NC-IUBMB). *See also* enzyme classification.

enzyme complex an operational term for any structural and functional entity composed of a number of dissociable enzymes that catalyse a sequence of closely related chemical reactions. *Compare* multienzyme.

enzyme detergent any detergent preparation incorporating an enzyme to assist its cleansing action. The enzymes used in such detergents are usually proteinases of high thermal and alkaline stability, e.g. Alcalase.

enzyme differentiation the process whereby, during the development of an organism, each tissue acquires its own characteristic quantitative pattern of enzymes, which underlies the physiological functions and morphological features of the tissue. From a fairly uniform enzymic make-up in the cells of the early embryo, the enzyme patterns of different tissues become progressively more differentiated as development into the mature organism proceeds.

## enzymic activity

enzyme electrode any electrode, incorporating an enzyme into its structure, that responds to the concentration of one of the substrates or products of the reaction catalysed by the enzyme. The enzyme is trapped within a gel matrix surrounding the electrode or is kept in contact with the electrode by a semi-permeable membrane.

enzyme engineering or enzyme technology the branch of biomolecular engineering concerned with processes designed to produce, isolate, purify, and immobilize enzymes and to use them for the catalysis of specific chemical reactions.

enzyme immunoassay or enzymoimmunoassay abbr.: EIA; any immunoassay in which an enzyme-catalysed reaction is used as the indicator. *See also* heterogeneous immunoassay, homogeneous immunoassay.

enzyme induction the synthesis of an enzyme in a cell or organism at a markedly increased rate in response to the presence of an inducer. The inducer is thought to combine with a repressor thereby preventing the latter from blocking an operator, which controls the translation of the structural gene for the enzyme.

enzyme-inhibition immunoassay a variation of enzyme immunoassay in which the inhibition of an enzyme-catalysed reaction is used as the indicator.

enzyme labelling a method used to detect or locate (and sometimes estimate) an antigen in, e.g., a tissue section. The section is exposed to a complementary antibody that has been covalently linked to an enzyme; the antibody binds to the antigen, and its location (and its amount) is determined by an assay dependent on the catalytic activity of the linked enzyme. *See also* enzyme immunoassay.

enzyme-linked immunosorbent assay abbr.: ELISA; a form of quantitative immunoassay based on the use of antibodies (or antigens) that are linked to an insoluble carrier surface, which is then used to 'capture' the relevant antigen (or antibody) in the test solution. The antigen-antibody complex is then detected by measuring the activity of an appropriate enzyme that had previously been covalently attached to the antigen (or antibody).

enzyme membrane any (semipermeable) membrane to which an enzyme has been covalently bound. Such membranes are useful in constructing enzyme electrodes.

enzyme-multiplied immunoassay technique abbr. and proprietary name: EMIT; *an alternative name for homogeneous enzyme immunoassay.*

enzyme-paper graft an enzyme immobilized on (filter) paper, which is frequently impregnated with indicators. It is useful for making analytical devices.

enzyme reactor a device for using immobilized enzymes or enzyme systems for synthetic or other processing reactions, especially on an industrial scale.

enzyme recruitment the exploitation of substrate-ambiguous enzymes or transport proteins in the evolution of new biochemical pathways.

enzyme repression inhibition of the formation of an enzyme by a compound formed in or taken in by a cell or organism.

enzyme specificity *see* specificity.

enzyme-Substrate complex abbr.: ES; the stoichiometric complex of an enzyme molecule and a substrate molecule bound at the enzyme's active site.

enzyme technology *an alternative term for enzyme engineering.*

enzyme unit symbol: U; abbr.: EU; an obsolete unit of activity of enzymes, defined as the amount of enzyme that will catalyse the transformation of one micromole of the substrate per minute under standard conditions. It has now been superseded by the kata!

enzymic or enzymatic by, of, involving, or relating to an enzyme or enzymes; catalysed by an enzyme or by enzymes. - enzymically or enzymatically adv.

enzymic activity the rate of reaction of substrate that may be attributed to catalysis by an enzyme. The concept is now obsolete, having been superseded by catalytic activity. The unit of

**enzymic cycling**

enzymic activity was initially the enzyme unit and subsequently the katal (as originally defined). The derived quantity concentration of enzymic activity was defined as activity divided by volume and was expressed as katalas per litre. See also catalytic activity concentration, molar (enzymic) activity, specific (enzymic) activity.

**enzymic cycling** a form of catalytic assay in which there is no coupled indicator reaction; instead, the regenerating system is allowed to cycle for a set time, after which the reactions are stopped by destruction of all enzymes and the most easily determined product is measured in a separate assay. The coupled system thus acts as a chemical amplifier in the determination of the intermediate catalyst.

**enzymo+ comb. form** denoting an enzyme or enzymic activity.

**enzymoimmunoassay** *an alternative name for enzyme immunoassay.*

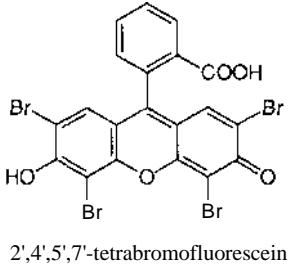

**enzymology** the science of the study of enzymes and enzyme-catalysed reactions. -enzymological *adj.*; enzymologist *n.*

**enzymolysis** the enzyme-catalysed splitting of a chemical compound into smaller ones. The term commonly refers to enzymic hydrolysis. -enzymolytic *adj.*

**eobiogenesis** the first occurrence of the formation of living matter from nonliving material.

**eobiont** any system showing some characteristics of living systems but not enough to be generally accepted as living.

**eosin** any of a number of similar red acidic dyes, derivatives of fluorescein, especially Eosin Y (yellowish), 2',4',5',7'-tetrabromofluorescein disodium salt, Acid Red 87 (CI 45380), or Eosin B (bluish), 4',5'-dibromo-2',7'-dinitrofluorescein disodium salt, Acid Red 91 (CI 45400). They are widely used as stains in histology and hematology.

**eosinophil** (el 1 or eosinophil leukocyte or eosinophilic leukocyte a polymorphonuclear leukocyte, present in blood and other connective tissues, that has numerous large cytoplasmic granules that stain readily with eosin. The granules contain numerous hydrolytic enzymes including acid phosphatase, arylsulfatase, cathepsins, glucuronidase, peroxidase, and ribonuclease. The relative number of eosinophils in the blood, normally low, rises markedly in certain allergic conditions and parasitic infections but their function is poorly understood. 2 any cell whose cytoplasm stains readily with eosin, especially an eosinophilic cell of the anterior pituitary that secretes prolactin and somatotropin.

**eosinophil cationic protein abbr.: ECP** a highly basic zinc-containing ribonuclease that binds avidly to negatively charged surfaces and is particularly effective at damaging the tegument of schistosomes.

**eosinophilic** having an affinity for eosin.

**eosinotactic** having an attractive or repulsive action on eosinophils. [A contraction of eosinophil + chemotactic.]

**eosome** the suggested primary particulate biogenetic precursor, via the neosome, of the ribosome. Eosomes of *Escherichia coli* have an average sedimentation coefficient of 14S.

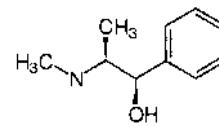

**EPA abbr. for 1 eicosapentaenoic acid.** Normally indicating the (all-Z)-5,8,11,14,17 isomer. 2 erythroid potentiating activity (see TIMP).

**epidermal growth factor receptor**

**EpETrE abbr. for epoxyeicosatrienoate.**

**EPH** a gene encoding a subfamily of protein tyrosine kinases. It is named from erythropoietin-producing hepatocellular carcinoma cell line, from which the probe used to isolate the gene was obtained. Related proteins are Elk (Eph-like kinase), Eek (Eph and Elk-related kinase), Eck (epithelial cell kinase), and Erk (Elk-related kinase). Overexpressed EPH has tumorigenic potential; the ligand of Eph is unknown; database code for the expressed protein: KEPH\_HUMAN, 984 amino acids (108.80 kDa); residues 1-23 are the signal 24-984 Eph.

**ephedrine** (IR,2S)-1-phenyl-1-hydroxy-2-methylaminopropane; an alkaloid obtained from several species of gymnosperm shrubs belonging to the genus *Ephedra*. A structural analogue of epinephrine, it mimics central and peripheral effects of noradrenergic and adrenergic neurons through direct and indirect actions, hence its CNS-stimulant effects and its use as a decongestant in upper respiratory tract infections.

**epi+** or (*before a vowel*) **ep+** prefix denoting 1 on, upon, over, beside, near, close to, in addition to. 2 a chemical compound or group related in some way to a specified chemical compound or group, e.g. an epimer. 3 a chemical compound or group distinguished from a specified chemical compound or group by having a bridge connection in the molecule, e.g. an epoxide.

**epiarginase** see epiprotein.

**epichlorohydrin** 3-chloropropylene oxide; chloromethyloxirane; 1-chloro-2,3-epoxypropane; a colourless liquid widely used in industry as a solvent and an intermediate in the manufacture of glycerol, glycerol ethers and epoxy resins. In the presence of potassium hydroxide it reacts with compounds containing alcoholic hydroxyl groups to form diethers of glycerol and hence finds application in the manufacture of cross-linked derivatives of polysaccharides such as the proprietary materials Sephacel, Sephadex, and Sepharose.

**epidemic** 1 describing a disease that affects many persons simultaneously in a more or less restricted area. 2 the widespread occurrence of a disease in a human population. Compare endemic.

**epidemiology** the study of the nature and spread of a disease in a human population.

**epidermal growth factor abbr.: EGF** any member of a group of heat-stable, hormonal,  $\approx 6$  kDa proteins that consist of a single polypeptide chain of 49-53 residues with three intra-chain disulfide bonds; they are classified as cytokines. One form (mEGF), originally known as tooth-lid factor, can be isolated from submaxillary glands of the male mouse (see nerve growth factor). A similar protein (hEGF), extracted from human pregnancy urine and named urogastrone, is now known to be highly homologous to EGF (37 of 53 residues identical, disulfide bonds preserved). The main effects of EGF *in vivo* are to stimulate the growth of epidermal and epithelial cells, and to inhibit the secretion of gastric acid. It also has a potent mitogenic action on many types of cultured mammalian cells and displays a number of insulin-like properties towards them (see insulin-related growth factors). It is synthesized as a large preprotein, EGF membrane glycoprotein precursor, which contains, as well as the mature EGF protein, nine EGF-like repeats and urogastrone. Example (precursor) from human: database code EGF\_HUMAN, 1207 residues (133.79 kDa). The action of EGF is mediated by the epidermal growth factor receptor.

**epidermal growth factor receptor** or EGF receptor the mediator of the biological signal of epidermal growth factor (EGF)

and also of transforming growth factor-a (TGF-a). It is a membrane protein with a single transmembrane domain, and a tyrosine kinase activity in the cytoplasmic domain; the extracellular domain, which binds EGF, is highly glycosylated. The *v-erbB* oncogene codes for a protein highly homologous to a truncated EGF receptor, and the gene that codes for the receptor is now regarded as the protooncogene *c-erbB* (*see erbS*). Binding of EGF to the receptor leads to the induction of tyrosine kinase activity, and formation of dimers, as a result of which autophosphorylation occurs; stimulation of cell DNA synthesis and cell proliferation follows. Internalization of the EGF-receptor complex occurs subsequent to binding EGF. Example (precursor) from human: database code EGFR\_HUMAN, 1210 amino acids (134.14 kDa).

**epidermis** the outermost layer of cells of an animal or plant. -epidermal *adj.*

**epienzymatic control** a form of control of arginine metabolism, occurring in some *Saccharomyces* spp., in which arginases bind stoichiometrically to ornithine carbamoyltransferase (EC 2.1.3.3), inhibiting the latter's activity but without substantially modifying the arginase activity. *See also epiprotein.*

**epigenesis** the concept that an organism develops from an originally undifferentiated mass of living material through the appearance of structures and functions not originally present. **epigenetic** describing any of the mechanisms regulating the expression and interaction of genes, particularly during the development process. These include changes that influence the phenotype but have arisen as a result of mechanisms such as inherited patterns of DNA methylation rather than differences in gene sequence: imprinting is an example of this.

**epigenetics** the branch of biology dealing with the analysis of the mechanisms causing phenotypic effects to be produced by the genes of a genotype.

**epiligrin** an extracellular matrix protein, secreted by cultured epidermal keratinocytes. It is found in epithelial basement membranes but not membranes of endothelia, nor in muscle or nerve cells. It is a ligand for cell adhesion via integrins, with three chains linked by disulfide bonds, and is also an adhesive ligand for T lymphocytes. Example from the gene sequence of human epiligrin *a3*: database code HUMLAMAB, 145 amino acids (15.77 kDa). *See also laminin.*

**Epilim** a proprietary name for sodium valproate (*see valproic acid*).

**epimer** (*in stereochemistry*) either of two diastereoisomers that differ in configuration at only one chiral centre. The term includes anomer.

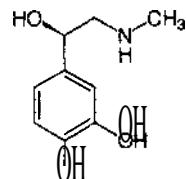

**epimerase** any enzyme within subclass EC 5.1, that catalyses epimerization (note that subclass EC 5.1 also includes racemases). Some epimerases, e.g. UDParabinose 4-epimerase (EC 5.1.3.5), contain tightly bound NAD, which undergoes oxidation and reduction during the reaction.

**epimeric** of or relating to an epimer or the chiral centre that specifies an epimer.

**epimerization** or **epimerisation** the process of converting an epimer into its diastereoisomer by altering the configuration at the epimeric chiral centre. -epimerize or epimerise *vb.*

**epimino+** an alternative term for imino+ (def. 2).

**epinephrine** or **adrenaline** (-)-I-(3,4-dihydroxyphenyl)-2-(methylamino)ethanol; a hormone secreted by the adrenal medulla and a neurotransmitter secreted by neurons in the brainstem. It is synthesized by the methylation of norepinephrine. It is an agonist for adrenoceptors, through which it has powerful glycogenolytic and lipolytic effects (both of which are mediated by cyclic AMP) and also affects the activity of smooth muscle (notably of the cardiovascular system and bronchi) and glandular tissue. Its mode of action critically depends on whether it acts through  $\alpha$  or  $\beta$  adrenoceptors. The BP official name for this substance is Adrenaline; the USP official name for this substance is Epinephrine; Adrenalin is a USA trademark name. It was named adrenalin by Takamine in 1901.

epinephrine

**epiphase** the upper, less dense layer of a two-phase system. *Compare hypophase. -epiphasic adj.*

**epiplasm** a membrane skeleton of certain protists, that contributes to cell shape and patterning of the species-specific cortical architecture. This cytoskeleton contains proteins known as articulins.

**epiprotein** a specific protein, produced in certain circumstances in some *Saccharomyces cerevisiae* strains, that binds stoichiometrically to ornithine carbamoyltransferase (EC 2.1.3.3), thereby inhibiting its activity. It has subsequently been shown to have arginase activity and so is sometimes known as epiarginase. *See also epienzymatic control.*

**episemantic molecule** any molecule that is synthesized under the control of a tertiary semantide. All molecules built by enzymes in the absence of a template are included because, although they do not express extensively the information contained in the semantide, they are a product of this information. *See also asemantic molecule.*

**episome** 1 a genetic element that is sometimes found in cells, especially those of bacteria, and that can replicate either when integrated into or independently of the host chromosome. 2 any fragment of DNA that exists in a cell as an extrachromosomal element. This DNA may not be replicated and passed to daughter cells. The plasmid is an example of an episome. DNA elements that use transposases involved in phage lambda integration are also examples of episomes.

**epithelium** 1 (*in animal anatomy*) a sheet of closely packed cells, arranged in one or more layers, that covers the outer surfaces of the body or lines any internal cavity or tube (except the blood vessels, heart, and serous cavities). *Compare endothelium, mesothelium.* 2 (*in plant anatomy*) any of certain layers of parenchymal cells that line an internal cavity or tube. -epithelial *adj.*

**epitope** any immunological determinant group of an antigen. -epitopic *adj.*

**epitype** any class or group of related epitopes.

**epoprostenol** international nonproprietary name for prostaglandin *I<sub>2</sub>*; *see prostacyclin.*

**epothilone** *see taxol!*

**epoxidation** the formation of an epoxide by addition of an oxygen atom as a bridge across the double bond of an alkene.

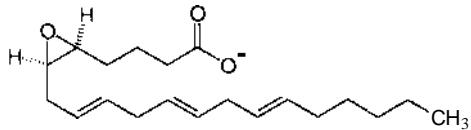

**epoxide** any compound where molecules contain an epoxy group attached to adjacent carbon atoms to form a saturated three-membered ring system.

**epoxy+** prefix (*in chemical nomenclature*) indicating the presence in a molecule of an oxygen atom directly attached (by single covalent bonds) to two (adjacent or nonadjacent) carbon atoms of a carbon chain or ring system. Epoxy compounds are cyclic ethers.

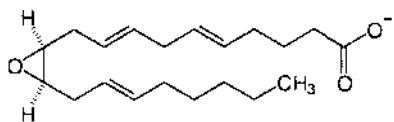

**epoxyeicosatrienoate abbr.: EpETrE or (formerly) EET;** any of various metabolites of arachidonate that contain an epoxy group. They are formed by the action of cytochrome P450 - this occurs in numerous tissues and has a high degree of stereospecificity. The products are predominantly present esterified to membrane-bound phosphatidylcholine. They have a wide spectrum of biological activities, including stimulation of peptide hormone release, inhibition of Na<sup>+</sup>,K<sup>+</sup>-ATP-

## epoxy resin

ase, mobilization of microsomal Ca<sup>2+</sup>, and inhibition of prostaglandin-endoperoxide synthase. Examples are (all-Z)-5S,6R-epoxyeicosa-8,11,14-trien-1-oate and (all-Z)-11S,12R-epoxyeicosa-5,8,14-trien-1-oate. EpETrEs can be further metabolized to vic-diols, diepoxides, and other products.

(all-2)-5S,6R-epoxyeicosa-8,11,14-trien-1-oate

(all-2)-11S,12R-epoxyeicosa-5,8,14-trien-1-oate

**epoxy resin** or **epoxide resin** any of a class of synthetic resins, containing ether linkages and epoxy groups, formed by the copolymerization of an epoxide (e.g. 1-chloro-2,3-epoxypropane) and a polyphenol (e.g. 2,2-bis(4-hydroxyphenyl)-propane). When mixed with certain accelerators, e.g. an amine or an anhydride, such resins produce hard, clear, resistant, thermosetting polymers that are used as adhesives and coatings and for embedding materials for microscopy, especially electron microscopy.

**Eppendorf pipette** any of a range of push-button, plunger-operated, precalibrated, dispensing micropipettes with disposable polypropylene tips. [After the name of the manufacturer.]

**EPPS** *an alternative name for Hepps.*

**EPR** or **epr** *abbr. for* electron paramagnetic resonance spectroscopy (*see* electron spin resonance spectroscopy).

**epsilon symbol:**  $\epsilon$  (lower case) or  $E$  (upper case); the fifth letter of the Greek alphabet. For uses *see* Appendix A.

**epsilon chain** or  **$\epsilon$  chain** the heavy chain of IgE immunoglobulin molecules.

**EPSP** *abbr. for* 5-enolpyruvylshikimate phosphate; an intermediate in aromatic amino-acid biosynthesis by the shikimate pathway (*see* shikimate).

**EPSP synthase** *an alternative name for* 3-phosphoshikimate 1-carboxyvinyltransferase. *See also* shikimate.

**Epstein-Barr virus** human (gamma) herpesvirus 4; a DNA virus, first isolated from specimens of tumour tissue obtained from African children affected by Burkitt's lymphoma, that causes infectious mononucleosis (glandular fever) in young adult humans. [After (Sir) Michael Anthony Epstein (1921-), British pathologist and immunologist, and Yvonne M. Barr.]

**eq.** or **Eq.** *abbr. for* equivalent (def. 4).

**equation of state** any equation connecting the pressure, volume, and temperature of a substance or a mixture.

**equatorial** 1 of, relating to, or being an equator; located at or near an equator. *Compare* axial (def. 1). 2 (*in stereochemistry*) symbol:  $e$ ; *see* conformation.

**equi+** *comb. form* denoting equal or equality.

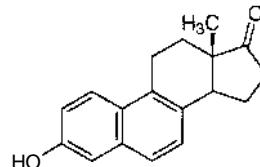

**equi-effective dose ratio abbr.:** EDR; the ratio of the doses of test and reference substances that produce the same biological effect (whether activation or inhibition).

**equi-effective molarity ratio abbr.:** EMR; the ratio of the molarity of test and reference substances that produce the same biological effect (whether activation or inhibition).

**equilenin** *the trivial name for* 3-hydroxyestra-1,3,5(10),7-tetraen-17-one; a weakly estrogenic steroid hormone isolated from the urine of pregnant mares. *Compare* equilin.

## equilin

taen-17-one; a weakly estrogenic steroid hormone isolated from the urine of pregnant mares. *Compare* equilin.

**equilibrate** to bring to equilibrium, or cause (something) to be in equilibrium (with some other thing), especially with the environment or with a (specified) system. -equilibration n.

**equilibrium** 1 a state of balance between or among opposing forces or processes that results in the absence of net change. 2 (*in chemistry*) a state of dynamic balance in a reversible chemical reaction when the reaction velocities in both directions are equal.

**equilibrium assay** a type of radioimmunoassay in which the reagents used are allowed to reach thermodynamic equilibrium. *Compare* disequilibrium assay.

**equilibrium constant symbol:**  $K$ ; an expression of the position of the equilibrium (def. 2) of a reversible chemical reaction under specified physical conditions (e.g. temperature, pressure, nature of solvent, ionic strength, etc.). For a reaction of the generalized form:

when the thermodynamic activity of each of the components A, B, M, N, etc. is written as (A), (B), (M), (N), etc., and  $a$ ,  $b$ ,  $m$ ,  $n$ , etc. are the respective numbers of molecular entities participating in the reaction, the equilibrium constant is given by:

$$K = \{ (M)m(N)n \dots \} / \{ (A)^a(B)^b \dots \}$$

Frequently in biochemical systems it is not possible to evaluate the activities of all the components; the concentration equilibrium constant (*symbol:*  $K_a$ ) rather than the true or thermodynamic equilibrium constant is then calculated,  $K$  being expressed in terms of the molarities of each of the components in place of their activities. When the specified concentration of a component includes more than one chemical species (e.g. ionized plus un-ionized forms, or chelated plus unchelated metal ion) in unknown proportions, an apparent (concentration) equilibrium constant (*symbol:*  $K'$ ) constrained with respect to certain variables (e.g. pH, or total concentration of metal ion), is written. *See also* affinity constant, association constant, dissociation constant,  $pK$ .

**equilibrium density-gradient centrifugation** a method for the separation of cells, cell organelles, macromolecules, or other particles of different densities by centrifugation in a solution that increases in solute concentration, and hence in density, from the top to the bottom of the centrifuge tube. At equilibrium, particles of the same density are found as a band or zone in the density gradient. *Compare* differential centrifugation.

**equilibrium dialysis** a technique used to measure the binding of a microsolute or ions to a macrosolute. A solution of the macrosolute is placed inside a dialysis bag (through which the macromolecules will not pass); this represents phase a. The bag is suspended in a solution containing the microsolute (phase  $\beta$ ). At equilibrium, any excess concentration of the microsolute in phase a is taken as evidence for binding. From a measurement of the excess concentration of the microsolute and knowledge of the concentration of the macrosolute the extent of the binding may be determined.

**equilin** *the trivial name for* 3-hydroxyestra-1,3,5(10),7-tetraen-17-one; a weakly estrogenic steroid hormone isolated from the urine of pregnant mares. *Compare* equilenin.

## equimolar

**equimolar** of equal molarity.

**equimolecular** containing equal numbers of molecular entities. **equine** of, relating to, or being a member of the family Equidae (horses, zebras, and asses); of, belonging to, characteristic of, obtained from, or relating to, a horse or horses; resembling a horse.

**equiv.** *abbr.* for equivalent (def. 3).

**equivalence** 1 the state of being equal, equivalent, or interchangeable. 2 equivalency. 3 the point or zone in a precipitin test at which antigen and antibody are present in optimal proportions for combination and precipitation.

**equivalence factor symbol** (for a chemical species X):  $feq(X)$ ; a number pertaining to a given reacting component of a specified titrimetric reaction derived from consideration of the overall stoichiometry of the reaction. For a reaction of the following type:  $\nu A + \nu B \rightarrow \text{products}$ , where  $\nu A$  and  $\nu B$  are the respective numbers of reacting entities, then the equivalence factor of species B is given by:  $feq(B) = \nu B / \nu A$ . When  $\nu A > \nu B$  and  $feq(A)$  is taken as unity, then  $feq(B)$  is unity or less than unity. In the case of a reaction that can be clearly identified as acid-base or oxidation-reduction, the equivalence factor must be related to one entity of titratable hydrons or of transferable electrons, respectively.

**equivalence point** or **stoichiometric point** or **theoretical end point** the point in a titration at which the amount of titrant added is chemically equivalent to the amount of substance titrated.

**equivalency** or **equivalence** 1 the state of having equal valencies. 2 the state of having equal equivalence factors.

**equivalent** 1 equal or interchangeable in amount, importance, meaning, or value. 2 (*in chemistry*) having equal valencies. 3 something that is equivalent (to something else). 4 (*in chemistry*) a *abbr.*: equiv. or eq. or Eq.; a unit of amount of substance, defined as the entity of a chemical species that in a specified reaction would combine with, displace, or in any other appropriate way be equivalent to, one entity of titratable hydrons (in an acid-base reaction) or one entity of electrons (in an oxidation-reduction reaction). It is the arithmetic product of the molar mass of the chemical species and its equivalence factor. b (*formerly*) equivalent weight.

**equivalent activity** a measure of the radiation output of a real radiation source containing a particular radionuclide, defined as being equal to the activity (def. 1b) of a hypothetical point source of the same radionuclide that would give the same exposure rate at the same distance from the centre of the source. It is customarily used to express the strengths of most sources emitting high-energy gamma radiation.

**equivalent ellipsoid of rotation** the ellipsoid of rotation having the same volume as an actual hydrodynamic unit of a macromolecule in solution (which consists of the macromolecule and tightly bound solvent).

**equivalent weight** *abbr.*: equiv. wt.; an obsolete term defined as the weight in grams of an element, compound, or group that, in a specified reaction, will combine with or displace 8 grams of oxygen, or the equivalent weight of another chemical species. *See also* equivalent (def. 4).

**ER** *abbr.* for endoplasmic reticulum.

**erbA** an oncogene (*v-erbA*) originally found in avian erythroblastosis virus; the corresponding protooncogene (*c-erbA*) encodes thyroid hormone receptor. Example, product of *v-erbA* from avian erythroblastosis virus: database code ERBA\_AVIER, 385 amino acids (43.98 kDa); it requires the activity of other oncogenic agents for tumorigenesis. *See also* erbS.

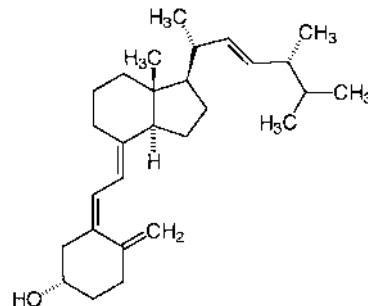

**erbB** an oncogene (*v-erbB*) from avian erythroblastosis virus; the corresponding protooncogene (*c-erbB*) encodes the epidermal growth factor receptor. In tumours the extracellular ligand-binding domain and the C terminus are deleted, contributing to a system with a constitutively active receptor protein. Example of protein product of *v-erbB* from avian erythroblastosis virus: database code ACBERBBH, 31 amino acids (3.50 kDa). The erb oncogene system is complicated; the transform-

er90+

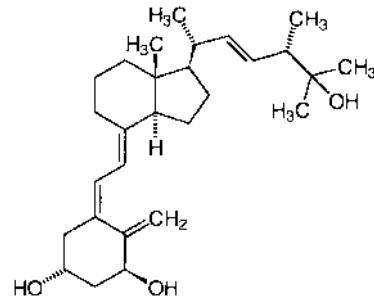

ing protein from the virus is a polyprotein product from *gag*, *erbA*, and *erbB*.

**ercalcidiol** or (*formerly*) 25-hydroxyergocalciferol *the recommended trivial name for* (52,7E,22E)-(3S)-9,10(19),22-ergostatetraene-3,25-diol; a secosteroid with vitamin D<sub>0</sub> activity. It is formed in the liver from ercalcidiol and converted to ercalcitriol in the kidney.

**ercalcidiol** or ergocalciferol *the recommended trivial name for* calciferol, vitamin D<sub>2</sub>, (52,7E,22E)-(3S)-9,10-seco-5,7,10(19),22-ergostatetraen-3-ol; a secosteroid with vitamin D<sub>0</sub> activity, obtained synthetically by UV-irradiation of ergosterol. It is the form of vitamin D most commonly used as a dietary supplement and for treatment of vitamin D deficiency. *International nonproprietary name:* ergocalciferol.

**ercalcitriol** or (*formerly*) 1a,25-dihydroxyergocalciferol *the recommended trivial name for* (52,7E,22E)-(1S,3R)-9,10-seco-5,7,10(19),22-ergostatetraene-1,3,25-triol; a secosteroid with vitamin D<sub>0</sub> activity. It is the biologically active metabolite of ercalcidiol and ercalcidiol.

**ERE** *abbr.* for estrogen response element (*see* response element). **erepsin** a once-supposed single enzyme secreted by the mucosa of the small intestine and thought to be responsible for completing the breakdown in the gut of partially digested proteins into amino acids. It is now known to be a mixture of peptidases.

**erg** the cgs unit of work, defined as the work done by a force of 1 dyne acting over a distance of 1 cm; equivalent to  $10^{-7}$  J.

**ERG** a gene encoding a family of transcription factors and related to the protooncogene *ETS*; it is named from '*ETS-related gene*'. It is expressed in some tumour-derived cell lines. Database code for expressed protein: ERG\_HUMAN, 462 amino acids (52.03 kDa).

**ergastoplasm** a term formerly applied to the basophilic, fibrillar structures seen especially in pancreatic secretory cells; now termed rough endoplasmic reticulum.

**+ergic suffix** (*in pharmacology*) indicating agonist activity on a receptor in a neuron. *See, e.g.* adrenergic.

**ergo+** (*comb. form*) 1 or (*before a vowel*) erg+ denoting work. 2 or (*before a vowel*) ergot+ denoting obtained from ergot or derived from a substance occurring naturally in ergot.

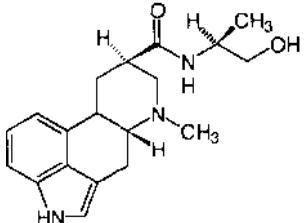

## ergocalciferol

**ergocalciferol** the alternative recommended trivial name and the international nonproprietary name for ercalcidiol.

**ergoflavin** the major pigment from ergot.

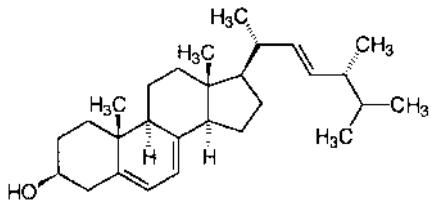

**ergometrine** see ergonovine.

**ergonovine** D-lysergic acid L-2-propanolamide; ergometrine; an ergot alkaloid noted for inducing sustained uterine contractions and used in the treatment of postpartum hemorrhage.

**ergosome (sometimes)** a polyribosome.

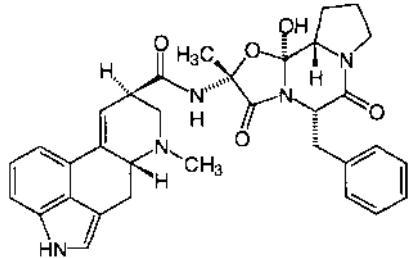

**ergosterol** trivial name for (22E)-ergosta-5,7,22-trien-3 $\beta$ -ol; (22E)-(24R)-24-methylcholesta-5,7,22-trien-3 $\beta$ -ol; a sterol found in ergot, yeast, and moulds. It is usually obtained industrially from yeast, which synthesizes it from simple sugars. It is the most important of the provitamins D. On irradiation with ultraviolet light it is converted to ercalcidiol (vitamin D<sub>2</sub>).

**ergot** the common name for the sclerotial phase of the fungus *Claviceps purpurea*, which parasitizes the ovaries of cereals such as rye, and other grasses, leading to ergot-contaminated seeds. Ergot yields various medically useful alkaloids, including ergotamine and ergometrine, and is a source of lysergic acid. However, ingestion of contaminated seeds by livestock or humans can result in poisoning (ergotism).

**ergot alkaloid** any of a group of about 30 indole alkaloids obtainable from ergot. All are derivatives of lysergamide and are biosynthesized from L-tryptophan.

**ergotamine** 12'-hydroxy-2'-methyl-5'a-(phenylmethyl)ergotam-3',6',IS-trione; an ergot alkaloid with vasoconstrictor activity, used in the treatment of migraine.

**ERIC** abbr. for enterobacterial repetitive intergenic consensus sequence; any of a number of highly conserved partly palindromic sequences. They are reminiscent of REPs but are longer (120 bp) and are in extragenic sites.

**ERK** abbr. for from extracellular signal-regulated kinase; any of a sub-subclass (EC 2.7.-), protein kinases, also (more fre-

## erythro+

quently) known as MAP kinases. Examples (all human): ERK1 (*or* insulin-stimulated MAP2 kinase) phosphorylates MAP2 and myelin basic protein; database code ERK1\_HUMAN, 379 amino acids (43.09 kDa); ERK2 (*or* mitogen-activated protein kinase 2 *or* MAP kinase 2) is similar; database code ERK2\_HUMAN, 360 amino acids (41.34 kDa); ERK3 (*or* MAP kinase isoform p63) has similar activity; database code ERK3\_HUMAN, 557 amino acids (62.55 kDa).

**ER mannosidase** EC 3.2.1.1.; *other name*: Man(9)-a-mannosidase; a glycoprotein enzyme of the N-glycosylation pathway of the endoplasmic reticulum that catalyses the removal of just one mannose residue from the core oligosaccharide of glycoproteins (Man<sup>9</sup>) to produce a specific isomer of Man(S)GlcNAc. Example (precursor) from human: database code MAN9\_HUMAN, 625 amino acids (70.74 kDa). See mannosidase.

**Ernst, Richard Robert** (1933– ) Swiss physical chemist noted for the application of pulsed radiofrequency radiation in nuclear magnetic resonance spectroscopy and the resultant extension of the technique to biological macromolecules; Nobel Laureate in Chemistry (1991) 'for his contributions to the development of the methodology of high resolution nuclear magnetic resonance (NMR) spectroscopy'.

**erp60** see calreticulin.

**ER-resident protein** any protein that is retained by the endoplasmic reticulum. Their retention is regulated by the heterotetramer of a phosphoprotein (calnexin), a phosphoglycoprotein (see **Ssr $\alpha$** ), and two glycoproteins (see **Ssr $\beta$** ). See also KDEL.

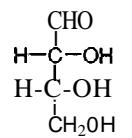

**'error catastrophe'** hypothesis a hypothesis stating that since the protein synthetic machinery of the cell is itself made of protein, any imprecision in protein synthesis will lead to the formation of protein synthetic machinery of lowered accuracy, which will lead in turn to the production of even less precise machinery. If this positive feedback of error into the protein synthetic machinery is sufficiently high it will cause instability and an accelerating deterioration of the cell, resulting in cell death or loss of function.

**error-prone repair** the processes of DNA repair, following damage, that give rise to 'fixed' mutations. Whether or not a particular damaged site will eventually lead to a mutation is dependent both on the genetic constitution of the cell and on environmental factors. It has been suggested that such mutations are due to errors in filling gaps in daughter DNA strands.

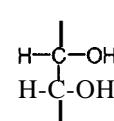

**ERYF1** see GALA-1.

**erythritol** i-erythritol; meso-erythritol; ms-1,2,3,4-tetrahydroxybutane; erythro-1,2,3,4-butanetetrol; a polyol configurationally isomeric with (active) threitol but optically inactive through internal compensation. It occurs in certain fungi (where it appears to act as a storage carbohydrate), and is found also (as an ester of orsellinic acid) in some green algae and lichens. It is about twice as sweet as sucrose.

**erythro-** the configurational prefix to the systematic name of a polyhydric alcohol, especially of a monosaccharide, used to indicate the particular stereochemical configuration of a set of two contiguous CHOH groups that occurs in D- or L-erythrose; e.g. *D*-erythro-2-pentulose for *D*-ribulose. Compare *threo*-.

*D*-erythrose

*D*-erythro

**erythro+** or (before a vowel) erytr<sup>b</sup>+ or (sometimes) eryth-  
comb. form 1 indicating red-coloured. 2 pertaining to red blood cells.

**erythroblast**

**erythroblast** any of the nucleated red blood cells that are intermediates in the formation of a nonnucleated erythrocyte from a hemocytoblast. *-erythroblastic adj.*

**erythrocruorin** any of a group of respiratory pigments of invertebrates in the range of 0.4–6.7 MDa and containing 30–400 heme groups per molecule.

**erythrocuprein** *an alternative name for superoxide dismutase.*

**erythrocyte** a mature red blood cell; in mammals it is non-nucleated and lacks mitochondria. Erythrocytes contain, but are no longer capable of synthesizing, hemoglobin and they function in the transport of oxygen. Mammalian erythrocytes obtain energy from anaerobic glycolysis and also metabolize glucose via the phosphogluconate pathway. *-erythrocytic adj.*

**erythrocyte sedimentation rate abbr.:** ESR; the rate at which erythrocytes sediment as measured under defined conditions. An increased ESR is almost always indicative of organic disease and is associated with an increased concentration of fibrinogen,  $\gamma$ -globulin, u<sub>2</sub>-macroglobulin, or  $\gamma$ -macroglobulin in the plasma.

**erythrodextrin** any of the larger dextrans that give a red colour with diiodine.

**erythropoiesis** *an alternative term for erythropoiesis.*

**erythro-,6-hydroxyaspartic acid** an amino acid formed by post-translational modification of an aspartyl residue at position 41 of the light chain of protein C.

**erythroid** 1 red or reddish in colour. 2 of or relating to erythrocytes or their precursors.

**erythroid differentiation factor** *see inhibin.*

**erythrolabe** a pigment that is sensitive to red light (570 nm) and is found in some retinal cones of the mammalian eye. It is lacking in subjects with red-blindness but is present in those with green-blindness. *Compare chlorolabe, cyanolabe.*

**erythromycin** any of several wide-spectrum macrolide antibiotics obtained from *Streptomyces erythreus*. Three components, A, B, and C, are produced during fermentation, the major component being erythromycin A. They inhibit protein synthesis in prokaryotes by binding to the 50S ribosomal subunit and inhibiting translocation.

**erythromycin resistance factor** any of several proteins that confer resistance to the antibiotic erythromycin. There are three mechanisms of resistance: (1) erythromycin esterase (EC 3.1.1.-), which is itself of two types (I and II); (2) a transmembrane export system (*e.g. erm* genes of *Arthrobacter* and certain Gram-positive bacteria); (3) rRNA (adenine-N<sup>6</sup>)-methyltransferase (EC 2.1.1.48), an enzyme that catalyses the reaction between S-adenosyl-L-methionine and rRNA to form S-adenosyl-L-homocysteine and rRNA containing N<sup>6</sup>-methyladenine; example from *Staphylococcus aureus*: database code MLS2\_STAAU, 244 amino acids (28.83 kDa); this protein produces a dimethylation of the adenine residue at position 2058 in 23S rRNA, resulting in reduced affinity between ribosomes and all macrolide, lincosamide, and streptogramin B-type antibiotics.

**erythron** *a collective term for the circulating erythrocytes and their precursors.*

**erythrophore** a type of chromatophore, coloured red and found especially in some fishes and crustaceans. The pigment, a carotenoid, is contained in bright red granules, which normally are dispersed throughout the cytoplasm, but which aggregate rapidly in response to epinephrine leading to near discoloration of the cell.

**erythropoiesis** *or erythrogenesis* the formation of red blood cells, in bone marrow or elsewhere. *-erythropoietic or erythrogenetic adj.*

**erythropoietin** a 46 kDa mammalian glycoprotein cytokine, formed in the kidneys and liver of mammals, that stimulates cellular differentiation of bone-marrow stem cells at an early stage of erythropoiesis, accelerates the proliferation and maturation of terminally differentiating cells into erythrocytes, and maintains a physiological level of circulating erythrocyte mass. The protein is now prepared from cDNA expressed in

CRO cells and other cells. It is now established as the accepted treatment of chronic renal failure. Its receptor is a type I membrane protein. Examples (precursors, human): erythropoietin, database code EPO\_HUMAN, 193 amino acids (21.28 kDa); erythropoietin receptor, database code EPOR\_HUMAN, 508 amino acids (55.00 kDa).

**erythrose** *the trivial name for the aldötetrose erythro-tetrose;* it has D and L enantiomers, which are respectively diastereoisomeric with those of threose. *See erythro-* for structure.

**erythrosome** an artificial membrane preparation in which detergent-extracted, glutaraldehyde-fixed erythrocyte ghosts are coated with phospholipid.

**erythrulose** *the trivial name for the ketotetrose glycero-tetrolose;* it has D and L enantiomers.

**ES abbr.** *for enzyme-substrate complex.*

**esc** a regulatory gene in *Drosophila* that controls expression of BX-C genes in embryos. It is named from extra sex combs.

**ESCA abbr.** *for electron spectroscopy for chemical analysis. See photoelectron spectroscopy.*

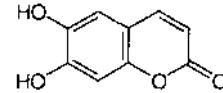

**ES cell abbr.** *for embryonic stem cell.*

**Escherichia** a genus of Gram-negative, rod-shaped, usually motile, chemoorganotrophic bacteria belonging to the family Enterobacteriaceae. It contains a single species, the colon bacillus, *Escherichia coli*. [After Theodor Escherich (1857–1911), German physician, who (in 1885) isolated the colon bacillus and gave it its original name of *Bacterium coli commune*.)

**Escherichia colior** colon bacillus *abbr.:* *E. coli*; the sole member of the bacterial genus *Escherichia* and arguably the most widely used experimental cell system in biochemistry and molecular biology. The cells are straight, round-ended rods, commonly 0.5–1  $\mu\text{m}$  x 1–4  $\mu\text{m}$ , and usually occurring singly or in pairs. The organism is present in the intestinal tract of humans and other animals and is common in soil and water. The numerous strains, some of which are enteropathogenic, are commonly distinguished serologically by their O, K, and H antigens. Strain 0157 is a life-threatening enteropathogen with genes seemingly derived (at least in part) from *Shigella* spp. It produces both hemolysin and enterotoxin. *E. coli* takes part in bacterial conjugation and other forms of genetic transfer, and can be infected with some bacteriophages and plasmids. *See also toxin.*

**Eschweiler-Clarke reaction** *see reductive amination.*

**esculetin** 6,7-dihydroxycoumarin; an agent that selectively inhibits 5- and 12-lipoxygenase, without inhibiting prostaglandin-endoperoxide synthase.

**E-selectin** *see selectin.*

**eserine** *an alternative name for physostigmine.*

**E-site** the deacylated tRNA binding site in ribosomes; in bacteria this involves ribosomal proteins of the large subunit and 23S rRNA.

**ESQL abbr.** *for embedded SQL;* a computer language that allows SQL to interface with other programming languages, *e.g. FORTRAN and C.*

**ESR or esr abbr.** *for 1 electron spin resonance.* 2 erythrocyte sedimentation rate.

**essential** 1 of or being the essence of something; inherent. 2 absolutely necessary, basic, fundamental, indispensable, vitally important. 3 necessary for the normal growth of an organism but either not synthesized by that organism or synthesized at an inadequate rate. 4 (*in pathology*) describing a clinical condition or disorder that is not attributable to any discernible cause; idiopathic (def. 1). 5 relating to or derived from an extract of a plant, especially as an essence.

## essential amino acid

essential amino acid any amino acid that cannot be synthesized by a cell or an organism in an amount corresponding to need. The extent to which a particular amino acid is essential in anyone species of organism depends on the stage of development of the subject and its physiological state. The following L-amino acids are nutritionally essential for the maintenance of nitrogen equilibrium in an adult human: isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, and valine. In addition, arginine and histidine are essential in growing children. The initial letters of the L-amino acids needed for optimal growth of infants or rats may be remembered using the mnemonic 'Many Very Hairy Little Pigs Live In The Torrid Argentine'. *Compare* nonessential amino acid.

essential fatty acid any polyunsaturated fatty acid that cannot be synthesized by a cell or an organism in an amount corresponding to need or from any dietary precursor. For mammals, linoleic acid (*see* linoleate) and (9,12,15)-linolenic acid (*formerly collectively known as* vitamin F) are nutritionally essential. *Compare* nonessential fatty acid.

essential fatty acid deficiency a condition that arises from the absence of essential fatty acids in the diet. A deficiency of fatty acids of the *n*-6 family (e.g. linoleic acid) in the diet of young animals results during growth in decreased body weight and, after some months, in increased skin permeability and capillary fragility, and dermatitis. If prolonged into adulthood, poor litter sizes (e.g. in rats) and infertility can result. Deficiency of fatty acids of the *n*-3 family, in the presence of *n*-6 fatty acids, does not result in such obvious manifestations, partly because these fatty acids are tenaciously retained in tissues, and partly because *n*-6 fatty acids (e.g. 22:5 *n*-6) not normally present in significant amounts are synthesized and appear to compensate for the deficiency of *n*-3 fatty acids of similar length and degree of unsaturation. That the effects of deficiency are not solely due to lack of substrates for prostanoïd synthesis is indicated by the ability of columbinic acid to relieve some of the effects.

essential fructosuria a relatively rare, hereditary, asymptomatic metabolic disorder characterized by the presence of fructose in the urine. In humans it is probably inherited as an autosomal recessive trait. Fructosuria occurs only after ingestion of fructose, which can also cause vomiting and aversion to sweet foodstuffs; long-term consequences can include failure to thrive, renal tubular dysfunction, and cirrhosis. Fructose metabolism involves formation of fructose 1-phosphate by ketohexokinase (EC 2.7.1.3); fructose 1-phosphate is then an (alternative) substrate for fructose-bisphosphate aldolase (EC 4.1.2.13) (I). Of the three isoenzymes of I (A, B, and C), B is much more active than A and C with fructose 1-phosphate as substrate. In essential fructosuria, the B isoenzyme of I is deficient and as a result there is a failure to metabolize fructose.

essential oil any of a group of volatile, odorous, natural oils obtained from plants. Such oils are usually benzene derivatives or terpenes, and are useful as flavouring agents or perfumes.

essential pentosuria *see* pentosuria.

EST abbr. for expressed sequence tag.

EST1 a gene involved in telomere maintenance, possibly coding for telomerase. It is named from 'even shorter telomeres'. It encodes a DNA-binding protein with RNA-directed DNA polymerase activity. Yeast gene product: database code EST1\_YEAST, 699 amino acids (81.62 kDa).

established cell line cultured cells of a single origin that have the potential to be subcultured indefinitely whilst maintaining stable characteristics.

eSte symbol for the eleostearoyl group,  $\text{CH}_3\text{--}[\text{CH}_2]_3\text{--}[\text{CH}=\text{CH}]_3\text{--}[\text{CH}_2]_7\text{--CO--}$ .

ester any organic compound formed, either actually or formally, by the elimination of the elements of water between a hydroxyl group of an oxoacid (def. I) and a hydroxyl group of

## estramustine

either an alcohol or a phenol. Esters formed by condensation of one, two, or three molecular proportions of alcohol or phenol with one of a tribasic oxoacid may be termed monoesters, diesters, or triesters, respectively.

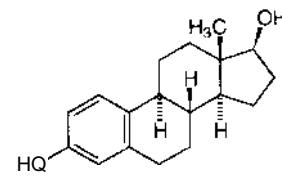

esterase any enzyme that catalyses the hydrolysis of an ester. Esterases form subclass EC 3.1 of the class EC 3, hydrolases, and are divided according to the nature of their substrates into the following sub-subclasses: EC 3.1.1, carboxylic ester hydrolases; EC 3.1.2, thioester hydrolases; EC 3.1.3, phosphatases, phosphoric monoester hydrolases; EC 3.1.4, phosphodiesterases, phosphodiester hydrolases, phosphoric diester hydrolases (other than nucleases; see EC 3.1.11–3.1.31 below); EC 3.1.5, triphosphoric monoester hydrolases; EC 3.1.6, sulfatases, sulfuric ester hydrolases; EC 3.1.7, pyrophosphatases, diphosphoric monoester hydrolases; EC 3.1.8, phosphoric triester hydrolases; EC 3.1.11, exodeoxyribonucleases producing 5'-phosphomonoesters; EC 3.1.13, exoribonucleases producing 5'-phosphomonoesters; EC 3.1.14, exoribonucleases producing other than 5'-phosphomonoesters; EC 3.1.15, exonucleases active with either ribo- or deoxyribonucleic acids and producing 5'-phosphomonoesters; EC 3.1.16, exonucleases active with either ribo- or deoxyribonucleic acids and producing other than 5'-phosphomonoesters; EC 3.1.21, endodeoxyribonucleases producing 5'-phosphomonoesters; EC 3.1.22, endodeoxyribonucleases producing other than 5'-phosphomonoesters; EC 3.1.25, endodeoxyribonucleases specific for altered bases; EC 3.1.26, endoribonucleases producing 5'-phosphomonoesters; EC 3.1.27, endoribonucleases producing other than 5'-phosphomonoesters; EC 3.1.30, endonucleases active with either ribo- or deoxyribonucleic acids and producing 5'-phosphomonoesters; EC 3.1.31, endonucleases active with either ribo- or deoxyribonucleic acids and producing other than 5'-phosphomonoesters.

esteratic of, by means of, or having the activity of an esterase. esterification the act or process of forming an ester from an oxoacid by condensing it with an alcohol or a phenol, or vice versa.

esterify to effect or to undergo esterification.

ester value *an alternative term for saponification number.*

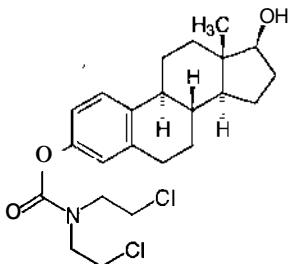

1713-estradiol or (*esp. Brit.*) 1713-oestradiol 1,3,5-estratriene-3,17P-diol; the most potent of the major estrogens. It is synthesized by the ovary, from which it is secreted directly into the circulation. Its formation depends on the presence of both luteinizing hormone and FSHRH; it is synthesized from testosterone by the aromatase complex, which is localized in ovarian granulosa cells, and is stimulated by follitropin; lutropin, on the other hand, stimulates production of testosterone, the aromatase substrate, by ovarian thecal cells. Apart from being important during development in inducing female characteristics, 17p-estradiol is important during the first half of the menstrual cycle (i.e. before ovulation) in stimulating proliferation of the epithelial and stromal layers of the endometrium in preparation for ovulation; it also stimulates production by the liver of proteins that bind steroids and thyroxine. During pregnancy, synthesis of estrogens is greatly increased, most of this increase being due to synthesis by the fetal adrenal gland of the precursors dehydroepiandrosterone and 16-hydroxy-dehydroepiandrosterone.

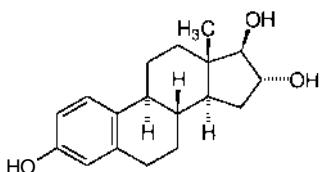

estramustine or (*esp. Brit.*) oestramustine estradiol 3-bis(2-chloroethyl)carbamate; an ester formed between estradiol and

## estriol

the carbonic-acid analogue of nitrogen mustard (mustine); it has antineoplastic activity.

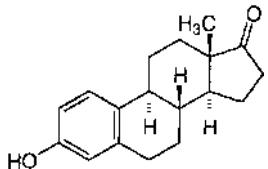

**estriol or (esp. Brit.) oestriol** 16 $\alpha$ -estradiol; 1,3,5-estratriene-3,16 $\alpha$ ,17 $\beta$ -triol; a relatively weak estrogen produced mainly during pregnancy. It is synthesized by the placenta from 16 $\alpha$ -hydroxydehydroepiandrosterone sulfate, which is formed in fetal liver from dehydroepiandrosterone sulfate secreted by the fetal adrenal gland. Urinary estriol is measured to monitor fetal well-being in high-risk pregnancies. Low levels are also associated with the inherited X-linked disorder, placental sulfatase deficiency.

**estrogen or (esp. Brit.) oestrogen** any substance, natural or synthetic, that produces changes in the female sexual organs similar to those produced by 17 $\beta$ -estradiol, the principal hormone of the vertebrate ovary. Naturally occurring estrogens are C18-steroid hormones; they are produced also by the placenta, adrenal cortex, and testis, as well as by many species of plants. *Compare* androgen. -estrogenic or oestrogenic adj.

**estrone or (esp. Brit.) oestrone** 1,3,5-estratrien-3-01-17-one; a major estrogen, also called folliculin, synthesized and secreted by the ovary, in which it is formed from androstenedione by the aromatase complex. However, estrone is mainly synthesized in peripheral tissues, from androstenedione taken up from the circulation. Its actions are similar to those of 17 $\beta$ -estradiol.

**estrone sulfotransferase** EC 2.8.2.4; an enzyme involved in the inactivation of estrogens. It catalyses the reaction of 3'-phosphoadenylylsulfate with estrone to form the inactive estrone 3-sulfate with release of adenosine 3',5'-bisphosphate. Example from *Bos taurus*: SUOE\_BOVIN, 295 amino acids (34.60 kDa).

**estrophile** (sometimes) estrogen receptor.

**estrous cycle or (esp. Brit.) oestrous cycle** the hormonally controlled cycle of activity of the reproductive organs of iON-

## ethereal sulfate

pregnant, sexually mature females of many species of mammal. It may be continuous or seasonal, depending on species. There are four principal phases. (1) Follicular phase or estrus-ovarian Graafian follicles mature, estrogen secretion by the ovary is at its highest, and the endometrium proliferates; the phase culminates in ovulation; in seasonal animals it is the time of sexual receptivity. (2) Luteal phase or metestrus - the corpus luteum develops in the ovary, estrogen secretion diminishes, and progesterone secretion reaches its maximum. (3) Diestrus - the corpus luteum and endometrium regress, new follicular growth begins, and progesterone secretion diminishes. (4) Proestrus - the corpora lutea involute, Graafian follicles re-emerge, and gonadal hormone secretion is at its lowest. The cycle then recommences.

**estrus or (esp. Brit.) oestrus** the first phase of the estrous cycle.

-estrous or (esp. Brit.) oestrous adj.

**esu or ESU abbr.** for electrostatic unit.

**Et symbol** for the ethyl group, CH<sub>3</sub>-CH<sub>2</sub>-.

**ET abbr.** for endothelin.

**eta 1 symbol:** η (lower case) or H (upper case); the seventh letter of the Greek alphabet. For uses see Appendix A. 2 (in chemical nomenclature) a less common alternative name for hapt.

**ETF abbr.** for electron-transfer flavoprotein or electron-transferring flavoprotein.

**ethambutol** (+)-N,N'-bis(I-hydroxymethylpropyl)ethylenediamine; an antitubercular drug.

**ethanol or (formerly) ethyl alcohol** CH<sub>3</sub>-CH<sub>2</sub>-OH; a colourless, water-miscible, flammable liquid. It is produced by alcoholic fermentation and is thereby probably the single most important product of bioindustry in economic terms. However, most ethanol (not destined for human consumption) is now manufactured from ethylene as a by-product in the petroleum industry. Commonly known as alcohol.

**ethanolamine-phosphate cytidylyltransferase** EC 2.7.7.14; other name: phosphorylethanolamine transferase; an enzyme that catalyses the reaction of CTP and ethanolamine phosphate to form CDPEthanolamine with release of pyrophosphate.

**ethanolaminophotransferase** EC 2.7.8.1; an enzyme of the pathway for *de novo* synthesis of phosphatidylethanolamines. It catalyses the reaction of CDPEthanolamine with 1,2-diacylglycerol to form phosphatidylethanolamine with release of CMP. Example from yeast: database code EPTI\_YEAST, 391 amino acids (44.51 kDa). *Compare* phosphatidylserine decarboxylase.

**ethanol fermentation** an alternative term for alcohol fermentation.

**ethanolic** of, containing, or derived from ethanol; dissolved in pure or aqueous ethanol.

**ethanolysed cellulose** a powdered and highly purified form of cellulose, formerly in use as a supporting medium in preparative zone electrophoresis of proteins, e.g. serum proteins. It is prepared by heating fibrous cotton (cotton wool) under reflux for approximately 24 h with acid-ethanol (absolute ethanol made 1 molar with respect to HCl either by introduction of dry hydrogen chloride gas or by reaction with acetyl chloride). By this means, partial alcoholysis of the cellulose occurs and acidic groups are neutralized by esterification, the cotton fibres being partially degraded into nonclumping particles; at the same time, light-absorbing and other interfering impurities are extracted from the cellulose.

**ether 1** any anhydride, of general formula RI-O-Rz, formed between two (identical or nonidentical) organic hydroxy compounds. 2 the common name for diethyl ether (or ethyl ether or ethoxyethane), C<sub>2</sub>H<sub>5</sub>-O-C<sub>2</sub>H<sub>5</sub>.

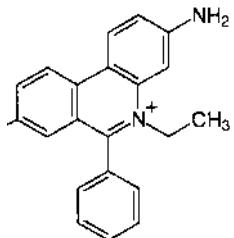

**ethereal** (in chemistry) of, containing, or dissolved in an ether, especially diethyl ether.

**ethereal sulfate** an obsolete term for any biogenic half-ester of sulfuric acid with an aromatic hydroxy compound. Ethereal sulfates are found in the urine as end products of sulfur metabolism and metabolism of some aromatic compounds.

## ether lipid

**ether lipid** any lipid that contains (normally) one fatty alcohol in ether linkage to one of the carbon atoms (normally C10) of glycerol. They are found in low concentrations in glycerophospholipid fractions, the constituent at C-2 of the glycerol moiety then being an acyl group. Platelet-activating factor is an important physiologically active ether glycerophospholipid. Ether linkages in neutral acylglycerols are known, and contain one fatty alcohol linked to glycerol by an ether linkage (usually at C10), with fatty acids in ester linkage at the other two positions. The ether linkage resists hydrolysis, and typical hydrolysis products are the glycerol ethers such as batyl alcohol, chimal alcohol, and selachyl alcohol.

**ethidium** the 3,8-diamino-5-ethyl-6-phenylphenanthridinium cation, usually used as the bromide salt. It binds by intercalation to double-stranded regions of DNA and RNA molecules with marked enhancement of fluorescence. It is used as a trypanocide and to reveal double-stranded DNA and RNA in gel electrophoresis.

**ethinylestradiol** the international nonproprietary name for ethinylestradiol; 17a-ethynyl-1,3,5(10)-estratriene-3,17P-diol]; [17a]-19-norpregna-1,3,5(10)-trien-20-yne-3,17-diol; a synthetic steroid with potent estrogenic activity, commonly used in oral contraceptive preparations.

**ethionine** S-ethyl-L-homocysteine; a synthetic, carcinogenic analogue of methionine. Its toxicity is due to the fact that it competes with methionine for the enzyme methionine adenosyl-transferase, with the result that S-adenosylmethionine is formed. This leads to a deficiency of ATP.

**ethoxy symbol:** OEt or Eto; the alkoxy group, CH<sub>3</sub>-CH<sub>2</sub>-O-, derived from ethanol by loss of a hydrogen atom.

**ethyl symbol:** Et; the CH<sub>3</sub>-CH<sub>2</sub>- alkyl group, derived from ethane.

**ethyl alcohol** the former name for ethanol.

**ethylene** CH<sub>2</sub>=CH<sub>2</sub>; a colourless gas and the first member of the olefin (or alkene) series of hydrocarbons. It occurs naturally as a phytohormone, with a number of physiological effects, the most important being stimulation of ripening of fleshy fruit and stimulation of abscission of leaves. See also ethylene-forming enzyme.

**ethylenediaminetetraacetate** see EDTA.

**ethylene-forming enzyme abbr.:** EFE; *other name:* 1-aminocyclopropane-l-carboxylate (ACe) oxidase. An enzyme component of the biosynthetic pathway for the formation of the plant hormone ethylene; it catalyses a reaction between 1-aminocyclopropane-l-carboxylate and O<sub>2</sub> to form ethylene, HCN, CO<sub>2</sub> and two molecules of 2H<sub>2</sub>O; iron and ascorbate are cofactors. The enzyme is a dioxygenase but structurally unrelated to other examples of these. Example from tomato: database code ACC1\_LYCES, 316 amino acids (35.93 kDa).

**ethylenic** containing one or more aliphatic carbon-carbon double bonds, as in ethylene.

**N-ethylmaleimide** abbr.: NEM; an agent that reacts irreversibly with thiol groups in proteins; it is useful as an inhibitor in transport studies and of thiol enzymes.

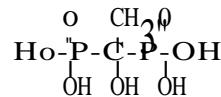

**N-ethylmaleimide-sensitive fusion protein abbr.:** NSF protein; a homotetrameric cytoplasmic protein required for

vesicle-mediated transport and transport from the endoplasmic reticulum to the Golgi stack. Example from Chinese hamster: database code SCI8\_CRIGR, 744 amino acids (82.44 kDa). See also SNAP (def. 3).

**ethynylestradiol** see ethinylestradiol.

**ETI** see eicosatrienoic acid.

**etidronate** any anion of etidronic acid, (l-hydroxyethylidene)bisposphonic acid, an analogue of diphosphoric acid in which the latter's bridging oxy group is replaced by a l-hydroxyethylidene group. Disodium etidronate is useful clinically for reducing the turnover rate of bone, e.g. in osteoporosis or in Paget's disease of bone.

etidronic acid

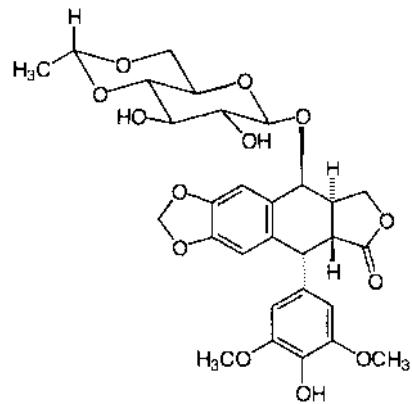

**etiology or (esp. Brit.) aetiology** the cause or causes of disease and their study.

**Etn** symbol for a residue of ethanolamine, H<sub>2</sub>N-CH<sub>2</sub>-CH<sub>2</sub>-O-.

**EtO or OEt** symbol for the ethoxy group, CH<sub>3</sub>CH<sub>2</sub>O-.

**ES cell abbr.** for embryo-derived stem cell.

**Etoposide** a semisynthetic lignan derivative prepared from podophyllotoxin. It is useful as an antitumour agent in multi-drug therapies, exerting its effect probably through interaction with topoisomerase II, which it inhibits; it also inhibits nucleoside transport in mammalian cells.

**ETS abbr.** for expression tagged site; a jargon phrase from genome mapping projects, etc. meaning a DNA database code (usually short) corresponding to an actively transcribed gene (i.e. cDNA from mRNA) of known sequence but, in general, of unknown function. Large ETS libraries are used in the Human Genome Project and similar projects on other organisms.

**ETS** a protooncogene related to v-ets, one of the oncogenes of the acutely transforming avian erythroblastosis virus E26; is named from 'E twenty-six specific'. It encodes a family of transcription factors: Ets 1 activates stromelysin and collagenase genes and binds to the enhancer sequence of the TCRA gene; it is expressed in tumours of the peripheral nervous system and in Ewing's sarcoma; Ets1 and Ets2 are kinase substrates. Example of expressed protein: database code ETS1\_HUMAN, 441 amino acids (50.41 kDa).

**ETYA** 5,8,11,14-eicosatetraynoic acid (see eicosatetraynoic acid).

**eu+ prefix** 1 indicating well, pleasant, good. 2 indicating normal, true, typical. In medicine, sometimes used interchangeably with normo+.

e.u. symbol for entropy unit.

Eu symbol for europium.

EU abbr. for enzyme unit (obsolete).

Eubacteria a name suggested for one of three major lineages of cellular organisms, the others then being Archaeabacteria and eukaryotes, defined when organisms are classified on the basis of sequence homologies of their ribosomal RNA. It comprised all typical bacteria, the major subdivisions being the cyanobacteria, the Gram-positive bacteria, and the Gram-negative bacteria. This classification has now been superseded: see Archaea, Bacteria, and Eukarya.

eucaryon a variant spelling of eukaryon.

eucell any cell of a eukaryote.

euchromatin the dispersed less dense form of chromatin in the interphase nucleus. It exists in at least two forms, about 10 per cent being in the form of transcriptionally active chromatin which is the least condensed, while the rest is inactive euchromatin which is more condensed than active chromatin but less condensed than heterochromatin which represents about 10 per cent of the chromatin in the interphase nucleus.

eucollagen 1 a highly modified form of collagen that can be easily and completely transformed into gelatin. 2 a hypothetical limiting structure for collagen in which Gly occurs at intervals of three residues and Hyp at intervals of ten residues; it is considered to be responsible for the 28.6 repeat distance in the X-ray diffraction pattern.

eugenics (functioning as sing.) the study of methods of improving the hereditary characters of the human race, especially by selective breeding. -eugenic adj.

*Euglena* a genus of fusiform, photosynthetic protozoa (sometimes classified as algae) of the division Euglenophyta. They are useful in biochemical research as unicellular photosynthetic organisms.

euglobulin any 'true' globulin of blood plasma that is soluble in isotonic salt solutions, insoluble at low ionic strengths (or in pure water), and precipitated by addition of saturated ammonium sulfate solution to a final concentration of 33%. Compare pseudoglobulin.

euglycemia or normoglycemia the condition or state in which the blood glucose level is within the normal range. See also glycemia. -euglycemic adj.

Eukarya one of the three major kingdoms of cellular organisms, the others being Archaea and Bacteria. The eukarya are characterized by the presence of a eukaryon.

eukaryon or (sometimes) eucaryon (pl. eukarya or eucarya) the type of cell nucleus bounded by a nuclear membrane and containing true chromosomes. It is characteristic of all multicellular and unicellular organisms except bacteria, actinomycetes, and cyanobacteria. Compare prokaryon.-eukaryous or eucaryous adj.

eukaryosis or (sometimes) eucaryosis the condition of possessing a eukaryon. -eukaryotic or eucaryotic adj.

eukaryote or (sometimes) eucaryote any organism whose cells contain a eukaryon (or eukarya) and undergo meiosis. Compare prokaryote.

eukaryotic porin see porin.

Euler 1 Hans Karl August Simon von Euler-Chelpin (1873-1964), father of U.S. von Euler (see von Euler (def. 2)) and generally known as Hans von Euler or Euler, German-born Swedish chemist and biochemist distinguished for his work on the enzymic mechanism of fermentation and in particular for his isolation, naming, and study of the chemical nature and functions of cozymase (now known as NAD); Nobel Laureate in Chemistry (1929), the prize being shared with A. Harden 'for their investigations on the fermentation of sugar and fermentative enzymes'. 2 V/C Svante von Euler see von Euler (def. 2). Euler-Chelpin see Euler (def. 1).

eumelanins see melanin.

eueptide a name suggested for any physiologically active gastrointestinal polypeptide.

eueptide bond a name suggested for a peptide bond formed

specifically between C-1 of one amino-acid residue and N-2 of another residue. Compare isopeptide bond.

euploid having a chromosome number that is an exact multiple of the monoploid number; i.e. each chromosome of the set is present in the same number. Compare aneuploid. -euploidy n.

euthyroid having a normally functioning thyroid gland and normal levels of thyroid hormones.

eutopic binding (sometimes) an alternative term for productive binding.

eutrophic describing a habitat, esp. a lake or other mass of water, that contains abundant nutrients, both organic and inorganic, and hence favours excessive growth of aerobic plants and microorganisms. Such growth results in depletion of dissolved dioxygen and, ultimately, extinction of aerobic life. Compare dystrophic (def. 2), oligotrophic.

eutrophication the process of becoming or rendering eutrophic. eV symbol for electronvolt.

event marker a feature of some chart recorders by means of which a mark is made on the chart to record the occurrence of a specifiable event or series of events, e.g. the stepwise operation of a fraction-collecting device.

evolution 1 (in biology) the process of cumulative change occurring in the form and mode of existence of a population of organisms in the course of successive generations related by descent. 2 (in chemistry) the liberation of a gas, or of heat, in the course of a chemical reaction. -evolutionary or evolutionary ad.

evolve 1 to develop gradually; to cause to develop. 2 (in biology) to undergo evolution (def. 1). 3 (in chemistry) to give off a gas or heat.

ex+ 1 prefix indicating out of, away from, outside of; without, lacking; former. 2 comb. form a variant of exo+ (sometimes before a vowel).

exa symbol: E; the SI prefix denoting  $10^{18}$  times.

EXAFS abbr. for extended X-ray absorption fine structure (spectroscopy).

excelsin a crystallizable globulin of  $\approx 290$  kDa obtained from the seed of the brazil-nut tree, *Bertholletia excelsa*. It structurally resembles arechin, edestin, and glycinin.

exchange 1 to cause two different objects to change places with each other. 2 the act or process of exchanging. 3 (in genetics) the reciprocal exchange of chromatid segments between chromosomes at meiosis or mitosis that results in genetic recombination.

exchange diffusion the exchange of ions or molecules across a (biological) membrane; it can be by simple diffusion or be carrier-mediated.

exchange labelling the catalysed exchange of one nuclide for another radioactive or stable nuclide of the same element in a chemical compound in order to produce an isotopically labelled form. The procedure is useful esp. in the preparation of tritium-labelled compounds.

exchanger a substance upon which, or a device by which, an exchange (def. 2) can be effected; e.g. an ion exchanger, or a heat exchanger.

exchange reaction a chemical reaction that results in the production of a substance that is chemically identical with the starting material. It is not detectable by traditional chemical analysis but (often) is demonstrable with the help of (radio)isotopes.

excimer an adduct formed between a molecular entity that has been excited by a photon and an identical unexcited molecular entity; the adduct exists until it fluoresces by emission of a photon. An excimer is recognized by the production of a new fluorescent band at a longer wavelength than that of the usual emission spectrum. Its formation is distinguishable from resonance energy transfer in that the excitation spectrum is identical with that of the monomer.

excitation:  $A + \text{photon} \rightarrow A^*$

excimer formation:  $A^* + A \rightarrow D^*$

excimer fluorescence:  $D^* \rightarrow A + A + \text{photon}$

## excinuclease

excinuclease a DNA-repair endonuclease. An example is the ABC excision nuclease of *Escherichia coli*; this comprises three subunits, named from the corresponding *uvr* genes. UvrA is an ATPase and DNA-binding protein that preferentially binds single-stranded or UV-irradiated double-stranded DNA; it belongs to the ABC transporter family; database code UVRA\_ECOLI, 940 amino acids (103.75 kDa). UvrB stimulates the activities of UvrA; database code UVRB\_ECOLI, 673 amino acids (76.14 kDa). UvrC is a nuclease component; database code UVRC\_ECOLI, 588 amino acids (65.64 kDa).

excisase an enzyme involved in lambda phage induction. *See* integrase.

excise to cut out or remove, as of a tumour, organ, or part of a linear polymer.

excision 1 the act or process of excising, especially the enzymic removal of an oligonucleotide segment from a nucleic-acid molecule. 2 (*in genetics*) the separation of one or more replicons from a cointegrate.

excisionase *see* Xis protein.

excision repair one of the intracellular mechanisms for the repair of DNA lesions (single-strand breaks, damaged bases, etc.). It occurs in the following stages: (1) recognition of the damaged region; (2) removal of the damaged oligonucleotide by two enzymic nucleolytic reactions (excision); (3) synthesis by DNA polymerase of the excised oligonucleotide using the second (intact) DNA strand as template; and (4) covalent joining by DNA ligase of the newly synthesized segment to the existing ends of the originally damaged DNA strand. The process is light-independent. *Compare* photoreactivation, post-replication repair. *See also* short-patch repair.

excitability proteins a collective name for intrinsic membrane proteins that are ion channels, receptors, and ion pumps.

excitable capable of responding to a stimulus; used especially of a biological membrane, neuron, or other living matter. -excitability *n.*

excitable membrane any biological membrane capable of responding to a specific chemical or physical stimulus. Such membranes are commonly characterized by: (1) the presence of a highly specific, integral protein receptor; (2) the occurrence of a conformational change in the receptor in response to the specific stimulus with a consequential change in membrane permeability or in the activity of a membrane-bound enzyme; and (3) reversibility of the alterations in conformation of the receptor and functional activity of the membrane.

excitation-contraction coupling a general term often used to refer to the coupling of an excitatory stimulus to the contraction of muscle; the process by which the fibres of a muscle are caused to contract by the stimulation of a neuron.

excitation spectrum any spectrum of electromagnetic radiation that, when applied to a sample, causes the atoms and molecules of the sample to become excited by the absorption of energy and, when reverting to their normal energy levels, to emit radiation of different frequencies to that of the absorbed radiation. *Compare* absorption spectrum, emission spectrum.

excitatory able to excite; stimulatory.

excitatory amino-acid receptor a receptor for any excitatory amino-acid in the central nervous system. These comprise two main groups: ionotropic, regulating an intrinsic ion channel, or metabotropic, coupled to either the cAMP or inositol phospholipid second messenger systems. The three main types of ionotropic receptors all have four transmembrane domains and are characterized pharmacologically by selective agonists: N-methyl-D-aspartate (NMDA), L-amino-3-hydroxy-5-methylisoxazole (AMPA), and kainate. NMDA receptors have a further binding site for glycine, which modulates receptor activation. All such ionotropic receptors regulate Na<sup>+</sup> and K<sup>+</sup> conductance; NMDA receptors additionally regulate Ca<sup>2+</sup> conductance. Seven subtypes of metabotropic receptor have been cloned, all with seven transmembrane domains (mGlu1 to mGlu7): mGlu1 and mGlu5 modulate inositol phospholipid

## exocytic

turnover while mGlu2, mGlu3, mGlu4, mGlu6, and mGlu7 are all negatively coupled to adenylate cyclase.

excite 1 to raise a molecular entity from its ground state to an excited state by the input of energy. 2 to cause an increase in activity or other response in an organism or part of an organism. -excitation *n.*

excited state any state of a molecular entity that has a higher energy level than its ground state.

exciter any device that excites, or raises a substance to an excited state.

exciton any nonconducting nonlocalized neutral entity that occurs in semicrystalline semiconductors, consisting of an excited electron bound to a positive hole, the combination forming a concentration of energy with certain properties characteristic of a particle.

exciton splitting the splitting of electronic absorption bands of a population of identical chromophores that are arranged in space such that sets of two or more are in close proximity. The splitting arises from electronic interactions between excited and nonexcited chromophores within the sets.

exclusion chromatography *an alternative name for* permeation chromatography.

exclusion limit an attribute of a specific gel used in gel-permeation chromatography. It is the relative molecular mass of the largest molecule of a particular shape that can be effectively fractionated by its use.

exclusion principle *see* Pauli exclusion principle.

exclusion reaction the reaction of a phage-infected bacterium that prevents the entry of additional phages. It is brought about by the strengthening of the bacterial cell envelope.

exclusion volume the volume of solvent retained by the column bed in gel-permeation chromatography that is outside the gel particles. *Compare* void volume.

excrete to eliminate waste materials (from a body or organism). -excretion *n.*; excretive or excretory *adj.*

exendin any of several peptides belonging to the glucagon family that have been isolated from *Heloderma* spp., exendin-1 (*or* helospectin 1), exendin-2 (*or* helodermin) and exendin-4 from *Heloderma suspectus* and exendin-3 from *Heloderma horridus horridus*. They have biological activity similar to vasoactive intestinal peptide and secretin. Exendin-4 shares 53 per cent similarity in its primary structure with glucagon-like peptide I (GLP-I) (7-36) amide. The latter binds to exendin receptors on pancreatic acinar cells, and exendin (9-39) (from exendin-3 or -4) is a GLP-1 receptor antagonist which blocks the inhibitory effect of GLP-1 on food intake of fasted rats. Exendin-4 is

(database code EXE4\_HELSU, 4,188 kDa); exendin-3 is similar except for residues 1-3 which are HSD.

exergonic describing any process or reaction that can produce work; i.e. one that, at constant pressure and temperature, results in a negative change in free energy content. *Compare* endergonic.

exhaustive methylation the maximal methylation of all groups in a substance that are capable of being methylated; it is useful in structural studies of carbohydrates, alkaloids, etc. exo+ or (*sometimes before a vowel*) ex+ comb. form indicating outside, external, outer. *Compare* endo+. *See also* exo-, exo- prefix (*in stereochemistry*) *see* conformation.

exocellular describing cellular components that are external to the cell membrane but attached to its outer surface. *Compare* extracellular.

exocrine 1 describing or relating to a gland or other group of cells that discharges its secretion through a duct. 2 relating to a secretion of exocrine tissue. 3 a product of exocrine tissue. *Compare* endocrine.

exocytic 1 situated outside a living cell and not belonging to

the cell itself; extracellular. 2 *an alternative term for exocytotic (see exocytosis).*

**exocytose** to effect exocytosis. -*exocytosed adj.*

**exocytosis** the discharge by a cell of intracellular materials to the exterior by emiocytosis or reverse pinocytosis. *Compare endocytosis, transcytosis. See also externalize. -exocytic or exocytotic adj.*

**exodeoxyribonuclease** *see deoxyribonuclease.*

**exodeoxyribonuclease I** EC 3.1.11.1; *other names:* exonuclease I; *Escherichia coli* exonuclease I. An enzyme that catalyses exonucleolytic cleavage of DNA in the 3'- to 5'- direction, releasing 5'-phosphomononucleotides. It shows a preference for single-stranded DNA. Database code EX1\_ECOLI, 475 amino acids (54.44 kDa).

**exodeoxyribonuclease V** EC 3.1.11.5; *other names:* exonuclease V; *Escherichia coli* exonuclease V; RecBC. An enzyme that catalyses exonucleolytic cleavage of DNA (in the presence of ATP), in either the 5'- to 3'- or the 3'- to 5'-direction, to yield 5'-phosphooligonucleotides. Database codes of the subunits (products of genes *recA*, *recB*, and *recC*): RecA: EX5A\_ECOLI, 608 amino acids (66.89 kDa); RecB: EX5B\_ECOLI, 1180 amino acids (133.81 kDa); RecC: EX5C\_ECOLI, 1122 amino acids (128.70 kDa).

**exodeoxyribonuclease VII** EC 3.1.11.6; *other names:* exonuclease VII; *Escherichia coli* exonuclease VII. An enzyme that catalyses exonucleolytic cleavage of DNA, in either the 5'- to 3'- or the 3'- to 5'-direction, to yield 5'-phosphomononucleotides.

**exodeoxyribonuclease (phage SP3-induced)** EC 3.1.11.4; *other names:* phage SP3 DNase; DNA 5'-dinucleotidohydrolase. An enzyme that catalyses exonucleolytic cleavage of DNA in the 5'- to 3'-direction to yield 5'-phosphodinucleotides.

**exoenzyme** 1 any enzyme that occurs attached to the outer surface of a cell (i.e. an ectoenzyme) or in the periplasmic space, or one that is secreted by a cell into the medium. *Compare endoenzyme (def. 1).* 2 any enzyme that cleaves a linkage to the terminal residue of a biopolymer. *Compare endoenzyme (def. 2).*

**exogenous** originating outside an organism, tissue, or cell, e.g. nutrients; of or pertaining to external factors that affect an organism, e.g. light. -*exogenously adv.*

**exomorphin** *see casomorphin.*

**exon** 1 any coding or messenger sequence of deoxynucleotides; Le. any intragenic region of DNA in eukaryotes that will be ultimately expressed in (mature) mRNA or rRNA residues. An arrangement of exons alternating with introns constitutes a transcriptional unit. 2 ordinary title of any of the four most junior officers of the Yeomen of the Guard (Beefeaters, Warders of the Tower of London, appointed by the monarch) who in turn act as resident commanders in the absence of superior officers. -*exonic adj.*

**exon shuffling** the recombination of different coding regions of eukaryotic structural genes (i.e. exons) through crossing-over, a mechanism proposed to explain the mosaic structure of eukaryotic genes. Such a mechanism is also responsible for the generation of, e.g., antibody diversity.

**exonuclease** any enzyme of a group of phosphoric diester hydrolases, forming sub-subclasses EC 3.1.11-16, that catalyses the hydrolysis of terminal diester linkages in polynucleotides to yield mononucleotides, the degradation of the chain occurring sequentially from one end. *Compare endonuclease. See also deoxyribonuclease, nuclease, ribonuclease.*

**exopeptidase** any enzyme of a group of peptide hydrolases within subclass EC 3.4 that catalyses the hydrolysis of peptide bonds adjacent to the terminal amino or carboxyl group of an oligo- or polypeptide. They include: EC 3.4.11, aminopeptidases; EC 3.4.13, dipeptidases; EC 3.4.14, di- and tripeptidyl peptidases; EC 3.4.15, peptidylpeptidases; EC 3.4.16, serine-type carboxypeptidases; EC 3.4.17, metallocarboxypeptidases; EC 3.4.18, cysteine-type carboxypeptidases; and EC 3.4.19, omega peptidases.

**exophthalmic goitre or Graves' disease** a form of hyperthyroidism characterized by enlargement of the thyroid gland and protrusion of the eyeballs.

**exopolysaccharide** any of a range of extracellular homo- or heteropolysaccharides produced by microorganisms, either as insoluble capsules or as soluble slimes. They serve for protection and possibly also in recognition by host organisms.

**exoribonuclease** *see ribonuclease.*

**exorphin** any peptide with morphine-like activity (*see opioid peptide*) that originates from outside the body. Such substances occur, e.g., in proteolytic digests of certain dietary proteins. *Compare endorphin.*

**exo-a-sialidase** EC 3.2.1.18; *other names:* sialidase; neuraminidase; N-acylneuraminate glycohydrolase; a-neuraminidase; an enzyme that catalyses the hydrolysis of a-2,3-, a-2,6-, and a-2,8-glycosidic linkages joining terminal nonreducing N- or O-acylneuraminy1 residues to galactose, oligosaccharides, glycoproteins or glycolipids. Examples: hemagglutinin-neuraminidase from measles virus (strain aik-c) (subacute sclerosing panencephalitis virus); database code HEMA\_MEASA, 617 amino acids (69.24 kDa); sialidase (neuraminidase) from *Clostridium perfringens*; database code NANH\_CLOPE, 382 amino acids (42.76 kDa).

**exoskeleton** any skeleton covering the outside of an organism or lying in the skin, such as the hard chitinous cuticle of an arthropod or the shell of a mollusc. *Compare endoskeleton.*

**exosmosis** the osmotic flow of water or of an aqueous solution from a cell, vessel, or organism into the surrounding aqueous medium. *Compare endosmosis. -exosmotic adj.*

**exosome** a fragment of exogenous DNA that, when taken up by a cell, is not readily integrated into the chromosome but can replicate, and be expressed.

**exothermic** describing a process or reaction that is accompanied by the evolution of heat; i.e. a process or reaction for which the change in enthalpy,  $\Delta H$ , is negative at constant pressure and temperature. *Compare endothermic.*

**exotic** describing an introduced (i.e. foreign), nonendemic, nonacclimatized organism.

**exotoxin** any toxin formed by a microorganism and secreted into the surrounding medium. *Compare endotoxin.*

**exp** (*in mathematics*) symbol for exponential; *see exponential function.*

**expansin** any of a group of proteins, located within the cell walls of plants (both dicotyledons and grasses), that play an essential role in loosening cell walls during cell growth. They are hydrophobic, nonglycosylated proteins of  $M_r \approx 30$  kDa.

**experiment abbr.:** expt.; 1 any procedure or series of procedures, carried out in defined conditions and designed to obtain new information about substances, materials, organisms, or natural phenomena, or to test or confirm a hypothesis. 2 *an alternative term for experimentation.* 3 to carry out an experiment or experiments. -*experimenter n.*

**experimental abbr.:** exptl.; 1 of, relating to, or based on the results of, an experiment or experimentation. 2 describing a disease produced deliberately in laboratory plants or animals for the purposes of study or as a model for the natural disease condition. 3 any particular object or system in an experiment that includes, or is subjected to, one of the variables. *Compare control (def. 1). -experimentally adv.*

**experimentation** the act, process, or practice of carrying out an experiment or experiments.

**explant** 1 to transfer a piece of living tissue from its normal situation to a culture medium. 2 any piece of tissue treated in this way. -*explanted adj.*

**exponent or index** (*in mathematics*) any number (or expression, or symbol for a number) indicating the power to which another number (or expression or symbol) is raised; e.g., in the expression  $a^n$ ,  $n$  is the exponent, indicating that  $a$  is multiplied by itself  $n$  times.

**exponential** (*in mathematics*) 1 of, containing, or involving one or more exponents, e.g. an exponential equation. 2 de-

## exponential function

## extracellular space

scribing something approximately expressible by an exponential equation.

**exponential function** (*in mathematics*) any function of the type  $a^x$  or  $Ae^{ax}$ , where  $A$  and  $a$  are constants,  $e$  is an irrational number that is the base of natural logarithms, and  $x$  is a variable;  $e^x$  is sometimes written  $\exp x$ .

**exponential growth** *an alternative term for* logarithmic growth.

**exponential phase** *an alternative term for* logarithmic phase.

**export** *informal term* describing a substance synthesized in, and then secreted from, a cell or type of cell in a multicellular organism; e.g. export protein.

**exposure** 1 (*in photography or radiography*) the act or process of exposing sensitized photographic material, e.g. a film or plate, to light or to ionizing radiation. 2 (*in photography*) a measure of the amount of light admitted into a photographic device expressed in terms of the lens aperture (f number) and time. b *or* light exposure symbol:  $H$ ; a physical quantity equal to the product of the illuminance and the time,  $\Delta t$ , for which the area is exposed. The SI unit is the lux second. 3 (*in radiation dosimetry*) a measure of the amount of X- or gamma radiation to which a subject or object is exposed, expressed in terms of the quantity of electric charge of the ions of one sign produced when all the electrons of both signs liberated in a volume of air of unit mass are completely stopped. The SI unit is C kg<sup>-1</sup>, which has replaced the rontgen. *Compare* absorbed dose.

**express** 1 (*in genetics*) a to allow or cause the information in a gene to become manifest. b to activate the cellular functions involved in gene expression. c (*in cDNA technology*) to effect the synthesis of protein from the corresponding cloned gene using an expression vector in an expression system. 2 (*in mathematics*) to indicate by means of a symbol, formula, or equation. 3 to force or squeeze out a liquid from an object.

**expressed sequence tag** abbr.: EST; a partial sequence of a clone picked at random from a cDNA library and used in the identification of genes being expressed in a particular tissue. The technique exploits recent advances in automated DNA sequencing and sequence data handling, and a remarkably high number of ESTs turn out to represent previously unknown genes. These are identified by the predicted primary structure of the proteins that would be expressed and their relation to proteins of known structure. ESTs have proved extremely valuable in mapping the human genome, and there has been controversy surrounding attempts to patent them.

**expression** 1 the act or process of allowing information to become manifest. *See* gene expression, expression vector, expression system. 2 (*in mathematics*) a variable function or some combination of constants, variables, and/or functions. 3 the act or process of forcing or squeezing fluid from or out of something.

**expression system** a cell system into which an expression vector has been introduced and that contains all the enzyme systems needed for translation of messenger RNA. Ideally, it also contains the enzymes needed for post-translational modification of the synthesized protein. Expression in *Escherichia coli* or other bacterial cells may be inadequate for eukaryotic protein expression, but expression in mammalian cell lines may be inconvenient. Use of a baculovirus expression vector in insect cells is one technique that has been used successfully for eukaryotic protein expression.

**expression tagged site** *see* ETS.

**expression vector** (*in cDNA technology*) a vector that promotes transcription of a cloned gene, leading to synthesis of protein in a suitable expression system. An expression vector carries a promoter, e.g. *EcoRI(UV5)*, which includes the regulatory region of the *lac* operon and the UV5 mutation, so that the system is insensitive to catabolite repression.

**expressor** a chemically undefined positive regulator of eukaryotic gene expression.

**expt.** abbr. for experiment (def. I).

**exptl.** abbr. for experimental (def. I, 2).

**extein** a peptide counterpart of an exon. *See* intein, splicing.

**extended X-ray absorption fine structure (spectroscopy)** abbr.: EXAFS (spectroscopy); a method for determining short-range order and local structure around specific atoms in noncrystalline materials. In this technique the X-ray absorption spectrum of the material is measured over an extended energy range near the absorption edge of one particular element in the material and structural details may be obtained from the observed modulation of the X-ray absorption on the high-energy side of the absorption edge. It is useful for elucidating the environment of metal ions in biological macromolecules.

**extensin** a glycoprotein found in plant cell walls in association with pectin. It resembles collagen of animal cells in being rich in trans-4-hydroxy-L-proline residues, and it contains L-arabinofuranose and D-galactopyranose residues attached in oligosaccharide units to the hydroxyl groups of the protein.

**extension sequence** a terminal sequence of amino-acid residues that is present in a nascent polypeptide as generated by translation of mRNA but is absent from any mature polypeptide or protein formed from it. An N-terminal extension sequence may be a signal sequence.

**extensive property** any of the properties of a substance or object that depend on the amount of the substance or the size of the object being considered, e.g. internal energy, mass, volume. *Compare* intensive property.

**externalize** or **externalise** to render external, especially to secrete a substance from a cell or organism. -externalization or externalisation n.

**external standard** any standard that is added to a sample at some point in an assay and serves as a reference by which the unknown being investigated can be quantified or identified.

**external-standard method of quench correction** or **external standardization** a method for correcting for quenching in liquid scintillation counting in which a source of gamma radiation external to the sample is brought into proximity with it after the sample has been counted and the sample is then counted again. The observed increase in count rate is correlated with that obtained using a set of differently quenched standards and the appropriate correction to the sample-count rate obtained. The method is simple and can be automated but on its own is less accurate than other methods. *Compare* internal-standard method of quench correction.

**extinction** *an older term (no longer recommended) for absorbance.*

**extinction angle** in flow birefringence between concentric cylinders, with polarizer and analyser at right angles, the angle between the cross of isocline and the cross formed by the polarizer and the analyser. It ranges from 45° (no orientation) to zero (complete orientation).

**extinction coefficient** symbol  $E$ ; *an alternative term (no longer recommended) for molar (decadic) absorption coefficient. See absorption coefficient.*

**extra+** prefix signifying outside or beyond.

**extra arm** or **variable arm** the base-paired segment of variable length in the cloverleaf model of some tRNA molecules. *See* transfer RNA.

**extracellular** present outside a cell, expelled from a cell, or happening outside a cell. *Compare* exocellular, intracellular.

**extracellular fluid** abbr.: ECF; the portion of the total liquid content that occurs outside the cells, esp. as distinct from intracellular fluid. In higher animals it comprises the interstitial fluid, the lymph, and the blood plasma. In a 70 kg man the volume of ECF is approximately 15.5 L and it represents approximately 22% of body mass. *Compare* intracellular fluid.

**extracellular matrix** a layer consisting mainly of proteins (especially collagen) and glycosaminoglycans (mostly as proteoglycans) that forms a sheet underlying cells such as endothelial and epithelial cells. The constituent substances are secreted by cells in the vicinity, especially fibroblasts.

**extracellular space** that part of a multicellular organism outside the cells proper - usually taken to be outside the plasma membranes - and occupied by fluid.

**extrachromosomal**

**extrachromosomal** describing structures, including DNA molecules, that are not part of a chromosome, or processes that proceed *outside* the chromosomes.

**extrachromosomal inheritance** inheritance controlled by extrachromosomal genes, such as those in mitochondrial or chloroplast DNA or in plasmids.

**extract** 1 to remove from or separate; to obtain a substance from a material, mixture, organism, or part of an organism by some chemical and/or physical process. 2 something extracted; a solution containing an active principle that has been extracted from plant or animal material.

**extraction** 1 the act or process of extracting. 2 something that has been extracted. *Compare extract* (def. 2).

**extra piece** *an alternative name for* signal peptide.

**extrapolate** (*in mathematics*) to estimate a value or the value of a function beyond the data values already obtained by either extending a graph or by calculation. *Compare interpolate.* -*extrapolation n.*

**extremophile** an organism that requires extreme physicochemical conditions for its optimum growth and proliferation. Such organisms include thermophiles or psychrophiles, halophiles, alkaliphiles or acidophiles, osmophiles, and barophiles, based on their growth at extremes of temperature, salt concentration, pH, osmolarity, or pressure, respectively.

**extrinsic** originating or acting from the *outside*. -*extrinsically adv.*

**extrinsic factor** *a former name for* vitamin B<sub>12</sub>.

**extrinsic fluorescence** fluorescence caused by a molecule of a fluor of small molar mass attached by either chemical coupling or simple binding to a (macro)molecule under study.

**extrinsic pathway** (of blood coagulation) *see* blood coagulation.

**extrinsic protein** *an alternative name for* peripheral (cell membrane) protein.

**extrude** to squeeze or force out; used especially of a solid or *semisolid* material. -*extrusion n.*

**extrusome** an organelle excreted as an anterior vacuole by a parasitic protist. It contains substances used for penetration of host cells.

**ex vivo** describing any biological process, reaction, or experiment in which the nature or magnitude of a change occurring

in living tissues in intact organisms is subsequently measured *in vitro* following the excision of affected tissues. *Compare in vivo* [Latin, meaning from life.]

**eye** (*in molecular biology*) a region of DNA undergoing replication, in which the separated strands give the appearance of an eye.

**E/Z convention** a convention of stereochemical descriptors for an unsaturated compound showing *cis-trans* isomerism that indicate unequivocally the steric relations around a (given) double bond. The sequence rule is applied in turn to the pair of atoms or groups attached to one of the doubly bonded atoms and to the pair attached to the other doubly bonded atom, and the order of preference in each case is established. If the two preferred atoms or groups are on opposite sides of the reference plane of the molecule the arrangement is called *E* [from German *entgegen*, opposite], and if they are on the same side of the plane it is called *Z* [from German *zusammen*, together]. For use as a prefix (in chemical nomenclature) the descriptor is placed in parentheses and connected with a hyphen, e.g. (*E*)-butenedioate and its stereoisomer (*Z*)-butenedioate (the respective systematic names for *trans*-I,2-ethylenedicarboxylate (= fumarate) and for *cis*-I,2-ethylenedicarboxylate (= maleate). When a molecule of an unsaturated compound contains more than one double bond the prefix is composed of multiple symbols, each preceded if appropriate by the lower-numbered locant of the relevant double bond; e.g. (*2E,4Z*)-2,4-hexadienoate. The convention is now generally preferable to that using the structural prefixes *cis*- and *trans*-, especially for olefinic compounds having more than two substituents at a double bond (where it avoids possible ambiguity as to which pair of substituents is being designated). *See also pro-E,pro-Z convention.*

**ezrin** or *cytovillin* or *villin-2* or *PSI* a protein involved in connections of major cytoskeletal structures to the plasma membrane, having domains in common with talin. It undergoes tyrosine phosphorylation after activation of specific growth factor receptors, and functions as a membrane-to-cytoskeleton linker that is involved in assembly of apical microvilli in parietal cells. It participates in the regulation of acid secretion. Example from human: database code EZRI\_HUMAN, 585 amino acids (69.19 kDa).

# Ff

*f symbol for* femto+ (SI prefix denoting  $10^{-15}$  times).

*I symbol for* 1 frequency (alternative to  $\nu$ ). 2 activity coefficient referenced to Raoult's law. 3 fugacity (alternative to  $\tilde{p}$ ). 4 frictional coefficient. 5 furanose form (added after the symbol for a monosaccharide, e.g. *Ara* for arabinofuranose). 6 (*in mathematics*) function.

*F symbol for* 1 a residue of the a-amino acid L-phenylalanine (alternative to Phe). 2 fluorine. 3 the fluoro group in an organic compound. 4 (*in genetics*) filial generation. 5 farad. 6 Fick unit. 7 *abbr. for* fertility; *see* Fplasmid. 8 *abbr. sometimes used* (not recommended) to designate folate or folic acid or their reduced derivatives.

F1, F2a1, F2a2, F2b, F2c, F3 *older nomenclature for* histones. F signifies fraction; in early work, the histones were extracted from the nuclei with sulfuric acid solutions, and separated according to their solubility.

F<sub>420</sub> *see* coenzyme F<sub>420</sub>'

F<sub>430</sub> *see* coenzyme F<sub>430</sub>.

OF *symbol for* degree Fahrenheit. *See* Fahrenheit temperature scale.

F<sup>+</sup> *symbol for* a donor bacterial cell containing an F plasmid; F denotes a recipient bacterial cell lacking an F plasmid.

F *symbol for* 1 Faraday constant. 2 force (bold italic in vector equations). 3 fluence (alternative to H).

FA *abbr. for* 1 fatty acid. 2 folic acid or folate (not recommended). 3 filtrable agent.

Fab fragment a  $\approx$ 45 kDa protein fragment obtained (together with Fe fragment and Fc' fragment) by papain hydrolysis of an immunoglobulin molecule. It consists of one intact light chain linked by a disulfide bond to the N-terminal part of the contiguous heavy chain (the Fd fragment). Two Fab fragments are obtained from each IgG antibody molecule; each fragment contains one antigen-binding site. The term Fab is derived from ['fragment antigen-binding']. *Compare* F(ab)zfragment. *See also* Fv fragment.

F(ab')<sub>2</sub> fragment a  $\approx$ 90 kDa protein fragment obtained (together with pFc' fragment) by pepsin hydrolysis of an immunoglobulin molecule. It consists of that part of the immunoglobulin molecule N-terminal to the site of pepsin attack and contains both Fab fragments held together by disulfide bonds in a short section of the Fc fragment (the hinge region). One F(ab')<sub>2</sub> fragment is obtained from each IgG antibody molecule; it contains two antigen-binding sites but not the site for complement fixation. *Compare* Fab fragment.

FABP *abbr. for* fatty acid binding protein (e.g. albumin, etc.); four motifs are characteristic of this function.

Fabry's disease an X-linked inborn error of human metabolism due to defective lysosomal a- $\alpha$ -galactosidase A activity. It is a sphingolipidosis or sphingolipid lysosomal storage disease. The enzyme defect leads to the progressive deposition in most visceral tissues of neutral glycosphingolipids with terminal  $\alpha$ -D-galactosyl residues, principally globotriaosylceramide, Gal(α-4)Gal(pl-4)Glc(pI-I)Cer. [After Johannes Fabry (1860-1930), German physician.]

facilitated diffusion diffusion (def. 2) across a biological membrane through the participation of specific transporting agents (transporters) or carriers. The equilibrium distribution reached is the same as that achieved by simple diffusion but at anyone site facilitated diffusion is mediated by a transport protein that exhibits specificity for the transported species. The existence of the transporter mediates passage across the membrane of molecules to which it would otherwise be impermeable. *Sometimes termed* mediated transport to distinguish it from active transport.

FACIT *abbr. for* fibril-associated collagens with interrupted triple helices; a group of collagens (types IX, XII, and XIV)

composed of triple-helical regions interrupted by non-triple-helical regions of 8-42 amino acids.

FACS *abbr. for* fluorescence-activated cell sorter.

F-actin the form of actin found in filaments.

factor 1 any component or cause that contributes to an effect or result; a term often used to denote an uncharacterized (or incompletely characterized) component of a biological system. 2 (*in mathematics*) any integer or polynomial that can be divided exactly into another integer or polynomial.

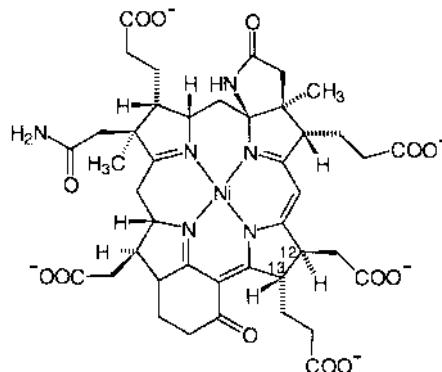

factor I to factor XIII, factor Va, etc. names of the blood coagulation factors.

factor B a component of complement.

factor D a component of complement.

factor F *an alternative name for* initiation factor.

factor F<sub>430</sub> a nickel-containing tetrapyrrole compound involved in the terminal reductive step of methanogenesis in methanogenic bacteria, in which methane is formed from methyl-coenzyme M (*see* coenzyme M). It exists both as the protein-bound and free forms. The free form has an absorption maximum at 430 nm, which shifts to 421 nm in the bound form.

factor G *an alternative name for* EF-G; *see also* elongation factor.

factor H a component of complement.

factor I a component of complement.

factorial symbol: !; the product of all positive integers from 1 up to and including the integer in question, n; hence

$$n! = n(n - 1)(n - 2)(n - 3)\dots 3 \times 2 \times 1.$$

factor IF *an alternative name for* initiation factor.

factor R *an alternative name for* release factor.

factor S a tetrapeptide, of unknown structure, isolated from cerebrospinal fluid of goats, that slowly induces delta (slow wave) sleep in rats on infusion into the cerebral ventricles.

factor T *an alternative name for* EFT; *see also* elongation factor.

facultative able to live under more than one set of environmental conditions.

facultative aerobe *see* aerobe.

facultative anaerobe *see* anaerobe.

FAD *abbr. for* flavin-adenine dinucleotide.

fade the waning of a response in the continued presence of an agonist. *Compare* desensitization.

FADH<sub>2</sub> *abbr. for* flavin-adenine dinucleotide (reduced).

F agent *see* sex factor.

Fahrenheit temperature scale a temperature scale in which 32 OF is set equal to 273.15 K and 212 OF is set equal to 373.15 K. Thus 1 Fahrenheit degree = 5/9 x K, and Fahrenheit tem-

## fall curve

perature (OF) =  $9/5 \times (\text{Celsius temperature}) + 32$ . [After G. D. Fahrenheit (1686-1736), German scientist.]

**fall curve** the curve describing the decrease in the colour intensity of a sample with time, obtained in a colorimetric analysis using an autoanalyser.

**falling-drop method** a method for the accurate determination of relative densities of liquids in which a drop of the liquid is allowed to fall to its equilibrium position in a column containing a defined density gradient of an immiscible liquid. It was formerly used for determination of the deuterium oxide content of samples of water.

**falling-mercury electrode** *an alternative term for dropping-mercury electrode.*

**falling-sphere viscometer** an instrument for measuring the viscosity of a liquid from the time taken for a solid sphere to fall through a given distance in a column of the liquid compared with the time taken for it to fall through the same distance in a liquid of known viscosity.

**Fallopian tube** an oviduct of a mammal.

**familial** 1 or of pertaining to a given family. 2 describing something transmitted between members of a family, especially a familial character, condition, or disease.

**family** 1 (*in taxonomy*) a taxonomic category of related organisms ranking below the order and above the genus. 2 (*in chemistry and biochemistry*) *an imprecise term for* a group of substances closely related structurally. See also superfamily. 3 (*in molecular biology*) see Appendix E.

**Fanconi syndrome** an inherited human disorder characterized by glycosuria, amino aciduria, phosphaturia, and acidosis. It is due either to functional deficiency of the proximal renal tubules or to abnormalities in amino-acid metabolism. See also renal rickets. [After Guido Fanconi (1892-1979), Swiss pediatrician.]

**farad symbol:** F; the SI derived unit of electric capacitance. A capacitor has a capacitance of one farad when a charge of one coulomb raises the potential between its plates to one volt: i.e.  $1\text{ F} = 1\text{ C V}^{-1}$ . [After Michael Faraday (1791-1867), British physicist.]

**faradaic current** an electric current flowing through an electrode that corresponds to the electrolytic oxidation or reduction of one or more chemical species.

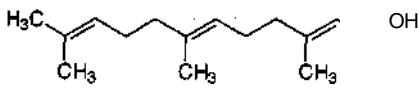

**Faraday constant symbol:** F; a fundamental constant, defined as the quantity of electricity required to deposit one mole of a univalent ion from a solution of an electrolyte. It is the arithmetic product of the Avogadro constant, L (or NA), and the elementary charge, e; hence

$$F = Le \quad (\text{or } F = NAe) = 9.6485309(29) \times 10^4 \text{ C mol}^{-1}$$

**Faraday effect** the rotation of the plane of vibration of polarized light, or of other polarized electromagnetic radiation, when passing through an isotropic, transparent medium in a magnetic field that has a component in the direction of the radiation.

**Farber's disease or Farber's lipogranulomatosis** *an alternative name for ceramidase deficiency.*

**farnesol** *the trivial name for* any of four possible stereoisomers of 3,7,II-trimethyl-2,6,10-dodecatrien-1-ol; a sesquiterpene alcohol. The 2E,6E-isomer is found in many essential oils. The 2Z,6E-isomer is a minor constituent of some essential oils.

2E,6E-isomer

**farnesyl** the (2E,6E)-3,7,II-trimethyl-2,6,10-dodecatrien-1-yl group; the alkenyl group derived from the sesquiterpene alcohol farnesol. 2E,6E-Farnesyl diphosphate (= *trans.trans-farne-*

## fast reaction

syl diphosphate) is an intermediate in carotenoid, sesquiterpene, squalene, and sterol biosynthesis and is also a substrate in the addition of the farnesyl group to proteins (*see prenylation*).

**farnesyltransferase** EC 2.5.1.21; *recommended name:* farnesyl-diphosphate farnesyltransferase; *systematic name:* farnesyl-diphosphate:farnesyl-diphosphate farnesyltransferase; *other name:* presqualene-diphosphate synthase. An enzyme that catalyses the formation of presqualene diphosphate from two molecules of farnesyl diphosphate with release of pyrophosphate. It occurs in the pathway for the synthesis of squalene and derivatives (cholesterol, sesquiterpenes). In eukaryotes it is a monomeric microsomal enzyme. Example from yeast: database code ERG9\_YEAST, 444 amino acids (51.61 kDa).

**farnesyltransferrase** EC 2.5.1.29; *systematic name:* trans,trans-farnesyl-diphosphate:isopentenyl-diphosphate farnesyltranstransferase; *other name:* geranylgeranyl-diphosphate synthase. An enzyme that catalyses the formation of geranylgeranyl diphosphate from *trans,trans-farnesyl* diphosphate and isopentenyl diphosphate with the release of pyrophosphate. It occurs in the pathway for sesquiterpene and cholesterol synthesis and forms the prenyl derivative geranylgeranyl diphosphate. In some fungi and plants this activity is part of a multifunctional protein that also has the activities of geranylgeranyl-diphosphate synthase (*see dimethylallylBR-transferase*) and geranylBRtransferase. Example from *Neurospora crassa*: database code GGPP\_NEUCR, 428 amino acids (47.83 kDa).

**farnoquinone** *an alternative name for* menaquinone-6; *see menaquinone.*

**Farr test** a radioimmunoassay technique for measuring the absolute antigen-binding capacity of an antiserum. The antibody is allowed to react with radiolabelled antigen and the antigen-antibody complex is then precipitated by addition of saturated ammonium sulfate solution to a final concentration of 40% w/v. The antigen that has reacted can be determined in the precipitate.

**far ultraviolet** *see ultraviolet.*

**fascicle or fibre tract** a tight parallel bundle of nerve fibres that are either axons or dendrites. It is formed during the growth of nerves, and is mediated in part by cell adhesion molecules.

**'asciclin** any of the proteins of a related group that are involved in nerve fascicles (bundles). They include fasciclin I, a neuronal cell adhesion molecule; example (precursor) from *Drosophila melanogaster*: database code FAS1\_DROME, 652 amino acids (72.52 kDa); and fasciclin II, which is a neuronal recognition molecule related to NCAM (*see adhesion molecules*): database code FS2LDROME, 873 amino acids (96.82 kDa).

**fascin** a protein involved in the formation of actin bundles and actin polymerization. Example from *Strongylocentrotus purpuratus*: database code SUSFASCIN, 496 amino acids (54.88 kDa).

**fast** 1 (*of a component of a mixture or specified substance*) one that migrates further or furthest from the origin in chromatography or electrophoresis. 2 uninfluenced by a specified agent, e.g. by light, acid, etc. See also acid-fast bacilli. 3 to abstain from, or to be prevented from, taking nourishment for at least 24 hours (in the case of laboratory animals). In clinical chemistry, the requirement is often for an overnight fast, normally at least 10 hours. -fasted *adj.*; -fasting *n.*

**FASTA or FASIN** a computer program used for searching and analysing protein and nucleic acid sequences.

**fast component** an unusual component of a mixture, e.g. a hemoglobin variant, that moves in a specified buffer system more rapidly in chromatography or electrophoresis than does the normal component.

**fast reaction** any reaction, or step in a reaction sequence, that has a large rate constant and proceeds rapidly. In a reaction sequence, a fast reaction is not the rate-limiting step.

## fat

fat 1 any triacylglycerol or mixture of triacylglycerols that is solid below 20°C; those that are liquid at such temperatures are usually referred to as oils. 2 an alternative name for lipid. 3 an alternative name for adipose tissue; see brown adipose tissue, white adipose tissue.

**fatal familial insomnia** a rare inherited neurological disease, first described in 1986 among inhabitants of mountainous regions of Italy. It is characterized by intractable insomnia and other neurological abnormalities. It is one of three familial forms of human prion disease. Neuropathologically, there is neuronal loss with associated gliosis. It is associated with a pathogenic mutation of the prion gene at codon Asn<sup>178</sup> (shared with Creutzfeldt-Jakob disease, but for unknown reasons of different phenotype) linked to codon Met<sup>129</sup>, a site that exhibits Met1Val polymorphism.

**fat body** any of the fat-containing cellular structures that serve as energy reserves in amphibians, insects, and reptiles.

**fat cell or fat-cell or lipocyte or (in animals) adipocyte** any living cell containing noticeable amounts of lipid, primarily as fat or oil.

**fat index** the mass of diethylether-extractable fat per unit mass of nonfat material (on a dry-weight basis) in, e.g., a foodstuff or tissue.

**F<sub>1</sub>-ATPase** see W-transporting ATP synthase.

**fat-soluble vitamin** any of a diverse group of vitamins that are soluble in organic solvents and relatively insoluble in water. The group includes vitamins A, D, E, and K.

**fat solvent** any lipid solvent e.g. chloroform or diethylether, that will extract triacylglycerols from biological or other materials.

**fatty** derived from or containing fat.

**fatty acid** any of the aliphatic monocarboxylic acids that can be liberated by hydrolysis from naturally occurring fats and oils. Fatty acids are predominantly straight-chain acids of 4 to 24 carbon atoms, which may be saturated or unsaturated; branched fatty acids and hydroxy fatty acids also occur, and very long chain acids of over 30 carbons are found in waxes. See also fatty-acid nomenclature, polyunsaturated fatty acid.

**fatty-acid activation** the conversion of a fatty acid molecule to its fatty acyl-coenzyme A thioester, the first step in the reactions of beta oxidation. Fatty acyl-coenzyme A can be formed in a reaction catalysed by the acid-thiol ligases EC 6.2.1.1, 6.2.1.2, and 6.2.1.3, or by a CoA-transferase of sub-subclass EC 2.8.3.

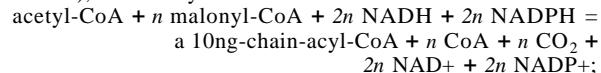

**fatty-acid nomenclature** a system of symbols for describing fatty acids. The basic symbolism comprises the number of carbon atoms in the molecule, followed by the number of double bonds; the two numbers are separated by a colon. Thus, 16:0 represents palmitic acid, 16:1 palmitoleic acid, etc. To avoid ambiguity, double bond positions in unsaturated fatty acids should be indicated; 18:3 (9,12,15) represents α-linolenic acid, 18:3 (9,11,13) represents eleostearic acid. These symbols may also include the E/Z configurational descriptors (see E/Z convention). Although not now recommended, a still used system numbers the first double bond from the carboxyl group using the Greek letter Δ. Thus, oleic acid is 18:1 Δ9 or 18:1 Δ<sup>9</sup>. This system persists in some enzyme names; e.g., the systematic name for linoleate isomerase (EC 5.2.1.5) is linoleate Δ<sup>12</sup>-cis-LΔΔ-trans-isomerase. See also fatty acid oxidation complex. Double bonds may also be designated from the end of the chain remote from the carboxyl group. If n is the total number of carbons, n-3 represents CH<sub>3</sub>-CH<sub>2</sub>-CH=CH-, etc. Since in many unsaturated fatty acids the double bonds are successively separated by methylene groups, only the position of the first double bond may be given. Thus linoleic acid [18:2 (9,12)] is also represented as 18:2 n-6. The Greek letter ω has also been used in the same way; e.g. for linoleic acid, 18:2 ω-6. However, it is not recommended that a double bond position, e.g. that of oleic acid, should be designated as ω9. See also fish oil, linoleic family, linolenic family, oleic family, palmitoleic family.

**fatty-acid oxidation complex** a bacterial multifunction pro-

## fatty-acid thiokinase

tein complex that catalyses the **β** oxidation of fatty acids. The example from *Escherichia coli* comprises α and β subunits. The α subunit contains decenoyl-CoA **Δ-isomerase**, enoyl-CoA hydratase, 3-hydroxyacyl-CoA dehydrogenase, and 3-hydroxybutyryl-CoA epimerase; database code FADB\_ECOLI, 729 amino acids (79.50 kDa). The β subunit contains 3-ketoacyl-CoA thiolase; database code THIK\_ECOLI, 387 amino acids (40.84 kDa). For a mammalian system see beta-oxidation system.

**fatty acid synthase complex** a large, well-defined multienzyme complex found in eukaryotes. These enzyme complexes, which are cytoplasmic, catalyse a cyclic set of reactions whereby fatty acids are synthesized from one molecule of acetyl coenzyme A and successive molecules of malonyl coenzyme A. In *Escherichia coli* and most bacteria the activities are in separate proteins. In animals, the enzyme complex (EC 2.3.1.85) produces a long-chain fatty acid (typically palmitate), whereas in yeast the product is a long-chain-fatty-acyl-CoA. The synthase complex of yeast has a mass of 2300 kDa and appears in the electron microscope as an ellipsoid, 25 μm long and 21 μm in cross section. The yeast enzyme comprises α and β subunits. It is termed fatty-acyl-CoA synthase (EC 2.3.1.86), and catalyses the overall reaction:

To synthesize palmitoyl-S-[acyl-carrier protein] requires seven repetitions of the following set of reactions, where X = -S-[acyl carrier protein]:

- (1) R-CH<sub>2</sub>-CO-X + -OOC-CH<sub>2</sub>-CO-X → R-CH<sub>2</sub>CO-CH<sub>r</sub> CO-X + CO<sub>2</sub> + H-X
- (2) R-CH<sub>2</sub>-CO-CH<sub>2</sub>-CO-X + NADPH → R-CH<sub>2</sub>-CH(OH)-CH<sub>r</sub> CO-X + NADP<sup>+</sup>
- (3) R-CH<sub>2</sub>-CH(OH)-CH<sub>2</sub>-CO-X → R-CH<sub>2</sub>-CH=CH-CO-X + H<sub>2</sub>O
- (4) R-CH<sub>2</sub>-CH=CH-CO-X + NADH → R-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CO-X + NAD<sup>+</sup>

The hydroxacyl product of reaction (2) has the 3R configuration and the enoylacyl product of reaction (3) has E configuration. Before the assembly begins, acetyl and malonyl units are transferred from their CoA derivatives to acylcarrier protein (ACP) by the activities of two transferases, EC 2.3.1.8 and EC 2.3.1.9. Representative enzyme activities for the four reactions are named as follows: reaction (1), EC 2.3.1.41, 3-oxoacyl-[ACP] synthase; reaction (2), EC 1.1.1.100, 3-oxoacyl-[ACP] reductase; reaction (3), EC 4.2.1.61, 3-hydroxypalmitoyl-[ACP] dehydratase; reaction (4), EC 1.3.1.9, enoyl-[ACP] reductase (NADH).

Similar enzymes with different chain length specificities may also be involved. For the first round, R = H, the two synthase substrates thus being acetyl-[ACP] and malonyl-[ACP]; the product is 3-oxobutanoyl-[ACP]. After seven repetitions of the four reactions, R = C<sub>12</sub>H<sub>25</sub>, and the product is palmitoyl-[ACP]. The yeast α subunit catalyses reactions (1) and (2); database code FAS2\_YEAST, 1894 amino acids (207.86 kDa). The yeast β subunit catalyses the two acyl transfer reactions and reactions (3) and (4); database code FASI\_YEAST, 2051 amino acids (228.43 kDa).

The mammalian complex is a dimer of identical subunits (260 kDa). Since the product is palmitic acid itself a further enzyme is present: EC 3.1.2.14 (oleoyl-[ACP] hydrolase). Each polypeptide chain is folded into three domains: domain I contains the acyltransferase activities and catalyses reaction (1); domain 2 catalyses reactions (2), (3), and (4); domain 3 catalyses the hydrolysis of palmitoyl-[ACP] to palmitate. In liver, reaction (4) is catalysed by EC 1.3.1.39, enoyl-[acyl-carrier-protein] reductase (NADPH, A-specific).

**fatty-acid thiokinase** an alternative name for 1 butyryl-CoA

## fatty-acyl-CoA dehydrogenase

feedback

ligase (EC 6.2.1.2). 2 10ng-chain-fatty-acid-CoA ligase; *see* fatty-acyl-CoA ligase.

**fatty-acyl-CoA dehydrogenase** any of the acyl-CoA dehydrogenase components of the beta-oxidation system.

**fatty-acyl-CoA desaturase** *see* stearoyl-CoA desaturase.

**fatty-acyl-CoA ligase** either of two enzymes involved in fatty-acid activation.

(1) Long-chain-fatty-acid-CoA ligase (EC 6.2.1.3); *other names:* acyl-activating enzyme; acyl-CoA synthetase; fatty acid thio kinase (long-chain); lignoceroyl-CoA synthase. It catalyses a reaction between ATP, a long-chain carboxylic acid, and CoA to form an acyl-CoA and pyrophosphate. In mammals there are tissue isoforms. Example from rat liver: database code LCFA\_RAT, 699 amino acids (78.09 kDa).

(2) Medium-chain-fatty-acid-CoA ligase (EC 6.2.1.-); *other name:* medium-chain-fatty-acid-CoA synthase. It catalyses the same reaction as above but with medium-chain fatty acids. Example from *Pseudomonas oleovorans*: database code ALKK\_PSEOL, 546 amino acids (59.19 kDa).

**fatty-acyl-CoA synthase** 1 the multifunctional protein responsible for the synthesis of long-chain fatty acyl moieties in some eukaryotes, e.g. yeast. *See* fatty acid synthase complex. 2 an enzyme of the endoplasmic reticulum, EC 6.2.1.3, long-chain-fatty-acid-CoA ligase, that carries out a reaction between ATP, CoA, and a long-chain fatty acid to form the corresponding fatty-acyl CoA, AMP, and pyrophosphate.

**fatty-acyl group** any acyl group derived from a fatty acid.

**fatty alcohol** *an alternative term for* long-chain alcohol.

**fatty degeneration** or fatty infiltration the deterioration of a tissue due to the deposition of abnormally large amounts of fat, usually as globules, in its cells.

**fatty liver** a pathological condition of liver tissue that has undergone fatty degeneration. It results from administration of various poisons, especially chlorinated hydrocarbons, or as a result of a dietary deficiency of choline or threonine.

**favism** a disease of humans in which hemolysis is caused by eating fava beans (*Vicia faba*) or by certain drugs, e.g. sulfonamides, primaquine, and nitrofuran antibiotics. The basic defect is an inherited deficiency of glucose-6-phosphate dehydrogenase in the red blood cells; about 70 variants are known. *See also* glucose-&phosphate dehydrogenase deficiency.

**FBP** *abbr. for* fructose 1,6-bisphosphate.

**FCCP** *abbr. for* carbonylcyanide p-trifluoromethoxyphenylhydrazone; an uncoupling agent.

**F cell** *a former name for* PP cell.

**F<sub>ε</sub>-CF<sub>0</sub>** the ε subunit of the H<sup>+</sup>-transporting ATP synthase complex in the chloroplasts of *Chlamydomonas reinhardtii*, in which the subunit arrangement is different from that in higher plants.

**Fc fragment** a crystallizable protein fragment obtained (together with Fab fragment) by papain hydrolysis of an immunoglobulin molecule. That obtained from human IgG is a 50 kDa protein consisting of the C-terminal halves of two heavy chains linked by two disulfide bonds. The Fc fragment has no antigen-binding activity but carries sites for complement fixation. [Fc is from 'fragment-crystallizable']. *Compare* Fc' fragment, Fd fragment.

**Fc' fragment** a protein fragment obtained in small amounts by papain hydrolysis of an immunoglobulin molecule, in addition to Fab fragments and Fe fragment. That obtained from human IgG is a 24 kDa protein; it forms noncovalently bonded dimers consisting of the C-terminal moieties of two Fc fragments minus their C-terminal tridecapeptide segments. It normally occurs in small quantities in human urine. *See also* pFc' fragment.

**Fc receptor** any of a number of proteins that bind the Fc region of immunoglobulins A, E or G, and facilitate their recognition and uptake, especially by phagocytic cells (*see* phagocyte). Several types have been described; all of the proteins involved have a single transmembrane helical region. Fc receptor I (*abbr.:* FcγRI) or CD64, is a high affinity receptor for IgG, capable of binding monomeric antibody. It is a char-

acteristic marker of mononuclear phagocytes, but may also be expressed on activated neutrophils; example: database code FCGO\_HUMAN, 347 amino acids (42.6 kDa). FcγRII or CD32 is a low affinity receptor for IgG present on monocytes, neutrophils, eosinophils, B cells and platelets. Crosslinking of the surface antibody and the receptor leads to downregulation of the B cell. Binding of immune complexes to this receptor leads to degranulation of platelets and release of inflammatory mediators; example: database code FCGA\_HUMAN, 317 amino acids (34.99 kDa). Another low affinity IgG receptor, FcγRIII or CD16 is found on macrophages, polymorphs, eosinophils and NK cells. On large granular lymphocytes it is a transmembrane glycoprotein that can link the cells to antibody-sensitized target cells, while on macrophages and neutrophils it has a GPI anchor. Two types of IgE receptor are known: (1) a high affinity receptor, FcεRI, found on basophils and mast cells, which on activation leads to the release of histamine and the manifestation of allergy. It is a tetramer of one α chain, one β chain and two disulfide-linked γ chains, examples: α chain, database code FCEA\_HUMAN, 257 amino acids (29.6 kDa); β chain, database code FCEB\_HUMAN, 244 amino acids (26.53 kDa); γ chain, database code FCEG\_HUMAN, 86 amino acids (9.67 kDa). (2) a low affinity receptor, FCERII, found on lymphocytes and monocytes and involved in IgE production and differentiation of B cells. An IgA receptor is found on myeloid cells; example: database code FCAR\_HUMAN, 287 amino acids (32.26 kDa).

**FCS** *abbr. for* fetal calf serum.

**Fd symbol** for ferredoxin.

**Fd<sub>s40</sub> symbol** for a membrane-bound ferredoxin with a redox potential of -0.54 V.

**Fd<sub>s90</sub> symbol** for a membrane-bound ferredoxin with a redox potential of -0.59 V.

**FDA** *abbr. for* Food and Drug Administration (of the USA).

**Fd fragment** a protein fragment obtained by papain hydrolysis of an immunoglobulin molecule followed by reduction of the disulfide bonds. It consists of the part of the heavy chain N-terminal to the papain hydrolysis site. The N-terminal moiety is variable and forms part of the original antigen-combining site; the C-terminal moiety is constant. *Compare* Fe fragment.

**FDNB** *abbr. for* fluorodinitrobenzene; Sanger's reagent.

**FDP** *abbr. for* fructose 1,6-diphosphate (now named fructose 1,6-bisphosphate).

**FdU** *abbr. for* fluorodeoxyuridine (the symbol FdUrd is recommended).

**FdUrd** *symbol for* (a residue of) the deoxyribonucleotide fluorodeoxyuridine (*see* flurouracil).

**Fe symbol** for iron.

**Feln** *symbol for* ferrous (divalent) iron.

**Fehn** *symbol for* ferric (trivalent) iron.

**FEBS** *abbr. for* Federation of European Biochemical Societies. **fecal fat** fat in the feces; the output of fecal fat is normally below about 18 mmol 24 h<sup>-1</sup> in the adult human. Tests that measure the fat content of feces may assist in diagnosis of generalized malabsorption syndrome; an alternative method is the [<sup>14</sup>C]triolein breath-test.

**fed batch process** a process during which one or more nutrients are supplied to a bioreactor, usually without removing biomass and products. *See* batch process.

**Federation of European Biochemical Societies** *abbr.:* FEBS; an international scientific organization founded in 1964 and now representing some 32 countries, including all those of mainland Europe plus Israel. FEBS is governed by a Council composed of one delegate from each of the adhering national biochemical societies plus the members of the Executive Committee. FEBS organizes an annual meeting, advanced courses, and supports fellowships and three annual prizes. It publishes two journals, *FEBS Letters* and *European Journal of Biochemistry*.

**feedback** 1 any feature of a system, e.g. of a metabolic pathway or of an electronic circuit, whereby information about the

## feedback control

## ferrimyoglobin

output of the system is used to influence the input to that system. Such feedback may increase the input to the system – positive feedback – or reduce the input to the system – negative feedback. A cyclic system of components participating in feedback forms a feedback loop, and the system is known as a closed-loop system. *Compare* open-loop system. 2 that part of the output of an electronic, mechanical, or other system that is returned to the input, so modifying its characteristics. *Compare* feedforward. -feed back vb.

**feedback control** control of the activity of any system by a mechanism involving feedback.

**feedback inhibition** or retroinhibition inhibition of the activity of an enzyme by the accumulation of a substance produced further along a metabolic pathway of which the enzyme is a constituent. *Compare* enzyme repression, feedback repression.

**feedback repression** an inhibitory feedback system in which the accumulation of a substance produced in a metabolic pathway represses the synthesis of an enzyme that is required at an earlier stage of the pathway. *Compare* enzyme repression, feedback inhibition.

**feeder cell** an irradiated cell that is capable of metabolizing but not of dividing. Such cells are sometimes added to cultures of unirradiated cells to help in the provision of nutrients.

**feeder layer** a layer of feeder cells in a cell culture.

**feeder pathway** any (minor) metabolic pathway that supplies metabolites to another (major) metabolic pathway.

**feedforward** 1 any feature of a system, e.g. a metabolic pathway, whereby information about the input to the system is used to influence the output of the system. *Compare* feedback (def. 1). 2 that part of the input of a system that influences the output of the system.

**Fehling's solution** a test reagent for glucose and other reducing substances. It is prepared as two solutions: Fehling's solution A containing 0.278 M copper (II) sulfate, and Fehling's solution B containing approximately 1.65 M potassium sodium tartrate and 4.3 M potassium hydroxide; equal volumes of each solution are mixed before a test. When boiled with a reducing substance a yellow or red precipitate of copper (I) oxide is formed. *Compare* Benedict's solution. [After Hermann Christian von Fehling (1812–85), German organic chemist.]

**feline** of, pertaining to, or resembling cats.

**felix** a protein designed for theoretical modelling studies and expressed from a synthetic gene in *Escherichia coli*. Database code NRL\_IFLX, 79 amino acids (8.77 kDa), which also gives the predicted 3-D structure. [From four-helix bundle.]

**female symbol:** ♀; 1 of, pertaining to, or designating the sex that only produces gametes that can be fertilized by male gametes. 2 describing a flower that lacks stamens or has non-functional stamens.

**female sex hormones** any of the estrogens (estradiol-17 $\beta$ , estrone, and estriol) that are concerned with the normal growth and development of the mammalian female reproductive tract and, together with progesterone, control the estrous and reproductive cycles.

**FeMo-co abbr.** for iron-molybdenum cofactor (of component 1 of nitrogenase).

**FeMo protein** any iron-molybdenum-containing protein.

**FEMS abbr.** for Federation of European Microbiological Societies.

**femto+** symbol: f, SI prefix denoting  $10^{-15}$  times.

**femtomolar** (*informal*) describing a solution containing  $10^{-15}$  mol dm<sup>-3</sup> (of a specified solute).

**femtomole symbol:** fmol; one  $10^{-15}$  part of a mole (of a specified substance).

**F episome** an alternative name for F plasmid.

**Fe protein** any iron-containing protein.

**feral** wild; having escaped from cultivation or domestication and reverted to the wild state.

**ferment** 1 any agent or substance that causes fermentation.

2 a former name for **enzyme**. 3 an alternative name for fermenta-

tion. 4 to undergo or to effect fermentation. -fermentable adj.; fermentability n.

**fermentation** 1 (or ferment) the decomposition of chemical substances, brought about by ferments (def. 1), resulting in the production of simpler substances and, often, of energy; an instance of this, especially the anaerobic breakdown of glucose to lactate or ethanol. 2 (*in biotechnology*) the use of microorganisms or cultured cells to produce useful materials, such as antibiotics, beverages, enzymes, and some commodity chemicals.

**fermenter** 1 or fermentor or biofermenter an apparatus or a vessel in which to conduct fermentation under more or less controlled conditions. 2 a person or other agent that causes or is able to cause fermentation. 3 a genus, species, or strain of microorganism that ferments (or does not ferment) glucose or a specified sugar; e.g. lactose fennenter, non-lactose fennenter.

**fermentor** a variant spelling offermenter (def. 1).

**Fernandez-Moran particle** another name for elementary particle (def. 2), attached to the cristae of the mitochondrion.

**ferralterin** a soluble nonheme, iron-sulfur-containing chloroplast protein, mediating the light activation of chloroplast fructose 1,6-bisphosphatase.

**ferredoxin symbol:** Fd; any simple, nonenzymic iron-sulfur protein that is characterized by having equal numbers of atoms of iron and labile sulfur (releasable as hydrogen sulfide by acidification). The iron and sulfur atoms are present in one or two clusters of two or four atoms of each. Ferredoxins are of  $M_r$ , 6000–24 000; many have a particularly low redox potential ( $E^\circ = -0.2$  V to  $-0.6$  V). They act as electron carriers in a variety of oxidation-reduction systems and have been found in a wide range of microorganisms, in chloroplasts, and in mitochondria from adrenal cortex (*see* adrenodoxin) and heart muscle. Example: 2Fe-2S type from *Spirulina platensis*; database code NRL\_3FXC, 98 amino acids (10.49 kDa); three conserved motifs; 3-D structure known. *Compare* rubredoxin. *See also* high-potential iron-sulfur protein, nitrogenase.

**ferredoxin-NADP+ reductase** another name for NADPH:adrenodoxin oxidoreductase.

**ferredoxin-nitrite reductase** see nitrite reductase.

**ferri+** comb. form denoting containing ferric iron.

**ferric** of or containing trivalent iron, Fe<sup>3+</sup> or Fe(m).

**ferrichrome** any of a group of growth-promoting Fe(m) chelates formed by various genera of microfungi, e.g. species of *Aspergillus*, *Neurospora*, and *Ustilago*. They are homodetic cyclic hexapeptides made up of a tripeptide of glycine (or other small neutral amino acids) and a tripeptide of an *N*<sup>4</sup>-acyl-N4-hydroxy-L-ornithine (e.g. the N4-acetyl compound). They are thus siderochromes of the hydroxamic-acid-derivative category.

**ferricytochrome** any cytochrome in which the iron atom is in the ferric form.

**ferriheme** or (*esp. UK*) ferrihaem any Fe(m)-porphyrin coordination complex.

**ferriheme chloride** another name for hemin.

**ferriheme hydroxide** another name for hematin.

**ferrihemochrome** any hemochrome containing Fe(m).

**ferrihemoglobin** or methemoglobin (abbr.: MetHb) an oxidation product of hemoglobin in which all its four iron atoms are in the ferric, Fe(m), state, the sixth coordination valencies of which are occupied, in the acid form, by water molecules, or, in the alkaline form, by hydroxide ions; these two forms have characteristic absorption spectra. Unlike hemoglobin, it cannot bind and transport dioxygen. The 3-D structure is known (Brookhaven file IHGB.PDB). *Compare* ferrimyoglobin.

**ferrimyoglobin** or metmyoglobin (abbr.: MetMb) an oxidation product of myoglobin in which its iron atom is in the ferric, Fe(m), state, the sixth coordination valency of which is occupied, in the acid form, by a water molecule, or, in the alkaline form, by a hydroxide ion. Unlike myoglobin, it cannot bind and store dioxygen. The 3D structure is known (Brookhaven file 1MBC.PDB). *Compare* ferrihemoglobin.

**ferrioxamine** *see* desferrioxamine.

**ferritin** any of a group of electron-dense, major iron-storage proteins that are widely distributed in animal and plant tissues; the iron is stored in a soluble, readily available form. Ferritins consist of a hollow protein shell; the functional molecule, called apoferritin, comprises 24 chains and is roughly spherical, with an external diameter of 12.4–13 nm and an internal diameter of 7–8 nm. The central cavity is able to accommodate a core of up to 4500 Fe(m) atoms, mainly as ferric hydroxide-phosphate,  $(\text{FeO}(\text{OH}))_8(\text{FeO}\cdot\text{PO}_4\text{H}_2)$ . There are two types of ferritin subunits: L (light) and H (heavy); the major chain can be L or H, depending on species and tissue type. In clinical chemistry, low plasma ferritin is an indication of a decrease in the body's iron stores; a concentration of less than  $12 \mu\text{g L}^{-1}$  indicates a complete absence of stored iron. Examples from human: H chain, database code FRIH\_HUMAN, 182 amino acids (21.07 kDa) (3D structure known: database code NRL\_IFHA); L chain, database code FRIL\_HUMAN, 174 amino acids (19.87 kDa).

**ferritin-labelling** the use of ferritin as an electron-dense label by covalently linking ferritin molecules with the aim of making their position in microscopic specimens apparent by electron microscopy.

**ferro+ comb. form** denoting containing ferrous iron.

**ferrochelatase** EC 4.99.1.1; *systematic name*: protoheme ferro-lyase; *other names*: protoheme ferro-lyase; heme synthetase; an enzyme of the pathway for heme biosynthesis. It catalyses the formation of protoheme from protoporphyrin and  $\text{Fe}^{2+}$  with release of 2  $\text{H}^+$ . Hereditary ferrochelatase deficiency occurs in humans and leads to porphyria with accumulation of protopyroxin IX. In bacteria the enzyme is part of siroheme synthase. Example (precursor) from human: database code HEMZ\_HUMAN.

**ferrocytchrome** any cytochrome in which the iron atom is in the Fe(n) state.

**ferroheme** or (*esp. Brit.*) ferrohaem 1 heme. 2 any Fe(n)-porphyrin coordination complex.

**ferrohemochrome** any hemochrome containing Fe(II).

**ferromagnetism** the property displayed by certain substances, typically metallic iron, that have a high magnetic susceptibility and that show increasing magnetization with increasing applied magnetic field strength. Some ferromagnetic materials retain their magnetization in the absence of an applied magnetic field, i.e. they become permanent magnets. Ferromagnetism is due to alignment, temporary or permanent, of the spins of the unpaired electrons in domains in the material. *-ferromagnetic ad.* Compare diamagnetism, paramagnetism.

**ferroprotoporphyrin** *see* heme.

**ferrous** of or containing divalent iron,  $\text{Fe}^{2+}$  or Fe(n).

**ferroxamine** *see* desferrioxamine.

**ferroxidase** *see* ceruloplasmin.

**fertile** 1 capable of producing offspring; capable of producing gametes. 2 capable of undergoing growth and development, e.g. fertile seeds or fertile eggs.

**fertility** the state of being fertile.

**fertility factor** *an alternative name for* Fplasmid.

**fertility vitamin** *a former name for* vitamin E.

**fertilization** or **fertilisation** 1 the fusion of two gametes of opposite sex to form a zygote. 2 the act or process of fertilizing.

**fertilize** or **fertilise** 1 to provide a female gamete with a male gamete to effect fertilization. 2 to supply soil or water with mineral and/or organic nutrients to assist the growth of plants.

**fertilizer** or **fertiliser** 1 any substance or mixture of substances that is added to soil or water to assist the growth of plants. 2 any object or organism, e.g. an insect, that fertilizes an animal or plant.

**fertilizin** a mucopolysaccharide from the jelly-coat of the eggs of some species that plays a part in sperm recognition and attracts sperms of the same species.

**ferulic acid** 4-hydroxy-3-methoxycinnamic acid; 3-(4-hy-

droxy-3-methoxyphenyl)-2-propenoic acid; an aromatic acid widely distributed in plants. It is a component of suberin.

**FES/FPS** a family of genes encoding nonreceptor tyrosine kinases; *v-fps* is an oncogene of Fujinami-PRCII sarcoma, while *v-fes* is a cognate gene of feline sarcoma virus. FES/FPS proteins contain an SH2 domain (*see* SH domain) adjacent to the kinase domain. Overexpression of *c-fes* transforms fibroblasts. Example (human): database code KFES\_HUMAN, 822 amino acids (93.47 kDa).

**Fe-S protein** *abbr. for* iron-sulfur protein.

**fet+** *a variant form of* *offeto+* (before a vowel).

**fetal calf serum** *abbr.:* FCS; a serum prepared from the blood of a fetal calf, widely used in tissue culture media.

**fetal hemoglobin** *an alternative name for* hemoglobin F (*see* hemoglobin).

**fetal-lung maturity test** a test for maturity of the fetal lung based on its content of dipalmitoylphosphatidylcholine (di-palmitoyllecithin). Dipalmitoyllecithin appears in lung surfactant in embryonic life only when the lung reaches maturity. Its concentration in amniotic fluid reflects its production in the lung and can be measured to determine lung maturity as a prenatal test to aid the decision when to induce labour. Formerly, the lecithin/sphingomyelin ratio was measured.

**feto+ or (before a vowel) fet+** *comb. form* denoting fetus.

**fetomodulin** *see* 13-thiomboglobulin.

**a-fetoprotein** *abbr.:* AFP or AFP; a protein formed in fetal liver and found in amniotic fluid. In humans, increased levels in the amniotic fluid between the 14th and 17th weeks of gestation reliably predict most cases of anencephaly and spina bifida cystica, and AFP determination is performed as an antenatal screening test for such defects. Increased serum levels may be found in adults with hepatoma and teratoma; AFP is a valuable marker for liver tumours, blood levels being elevated in about 70% of cases. The normal level in adult human plasma is  $<10 \text{ kU L}^{-1}$ , but rises in normal pregnancy. It is similar to albumin (serum) and vitamin D binding protein. Example (precursor) from human: database code FETA\_HUMAN, 609 amino acids (68.60 kDa).

**fetuin** *see* a2-HS-glycoprotein.

**fetus** or **foetus** the embryo of a mammal in the later stages of development, from the time when the main characteristics of the mature animal can be recognized. In humans the products of conception are termed the fetus from the end of the eighth week of pregnancy until birth. *-fetal or foetal ad.*

**Feulgen reaction** a specific cytochemical reaction to indicate the presence of DNA. It is based on converting DNA, but not RNA, to apurinic acid by acid hydrolysis with release of the aldehyde functions; the aldehyde functions then give a magenta colour on treatment of the specimen with Schiff reagent. Tissue giving such a reaction is termed Feulgen positive, whereas the absence of such a reaction characterizes Feulgen-negative tissues. The reaction is not suitable for living cells. [After Robert Joachim Feulgen (1884–1955), German chemist.]

**FFA** *abbr. for* free fatty acid(s). Compare NEFA.

**F factor** *an alternative name for* Fplasmid.

**F' factor** *an alternative name for* F plasmid.

**F<sub>0</sub>F<sub>1</sub> complex** *see* H<sup>+</sup>-transporting ATP synthase.

**(F<sub>1</sub> + F<sub>2</sub>) fragment** *see* heavy meromyosin.

**F<sub>1</sub> fragment** the separated globular head portion of a myosin molecule.

**F<sub>2</sub> fragment** the separated fibrous part of heavy meromyosin.

**F<sub>3</sub> fragment** *see* light meromyosin.

**FGAM synthase** *see* phosphoribosylformylglycinamide synthase.

**FGAR** *abbr. for* formylglycinamide ribonucleotide; an intermediate in purine biosynthesis.

**FGF** *abbr. for* fibroblast growth factor.

**FGR** a gene encoding a nonreceptor tyrosine kinase and belonging to the *src* family; *v-fgr* is the oncogene of the feline sarcoma virus Gardner-Rasheed. FGR transforms most mammalian

fibroblasts, but not epithelial cells. Example of expressed protein from human: database code KFGR\_HVMAN.

**FH<sub>2</sub>** abbr. (*not recommended*) for dihydrofolate or dihydrofolic acid.

**FH<sub>4</sub>** abbr. (*not recommended*) for tetrahydrofolate or tetrahydrofolic acid.

**FIA** abbr. for fluorescence immunoassay.

**fibre** the US spelling of fibre.

**fibre** or (US) fiber any natural filamentous structure, typically pliable and often strong; by extension the term is applied to filamentous glass or filamentous synthetic polymeric materials. -fibrous adj.

**fibre diagram** the X-ray diffraction pattern obtained from a stretched, hence orientated, sample of an amorphous, solid, naturally occurring or synthetic fibrous linear polymer when analysed by the rotating crystal method.

**fibre optics** 1 a flexible glass or plastic fibre, or a bundle of such fibres, used as a light guide for the transmission of light, especially as images or digitized information. 2 the study of the optical properties of transparent fibres.

**fibriform** having the form of a fibre or fibres.

**fibril** any small thread or fibre, bundles of which may constitute a fibre. -fibrillar, fibrilliform adj.

**fibrillar collagen** see collagen.

**fibrillarin** a component of a nucleolar small nuclear ribonucleoprotein particle (snRNP) thought to participate in the first step in processing pre-rRNA and associated with V3, V8, and V13 snRNP RNAs. It is the nucleolar scleroderma antigen, rich in N<sup>G</sup>,N<sup>G</sup>-dimethylarginine and common to the major family of nucleolar snRNPs. Example from human: database code FBRL\_HVMAN, 321 amino acids (33.78 kDa).

**fibrillin** a large glycoprotein isolated from fibroblast cell cultures. It is a structural Ca<sup>2+</sup>-binding component of connective tissue microfibrils, and contains 34 six-cysteine (EGF-like) repeats and five eight-cysteine (TGF-β1 binding protein-like) repeats. Defects are associated with the autosomal dominant disorder, Marfan's syndrome. Example (fibrillin 1 precursor) from human: 2871 amino acids (311.96 kDa).

**p-fibrillosis** see amyloidosis.

**fibrin** the product(s) formed from fibrinogen when blood plasma clots. The initial stage of this process is the formation of a fibrin monomer (~340 kDa) through the action of thrombin, which cleaves negatively charged fibrinopeptides A and B from fibrinogen. In intact fibrinogen, fibrinopeptides A and B prevent self-association of fibrinogen. Their removal enables the resultant molecule to self-associate readily in a staggered side-by-side arrangement, forming the fibrous soluble fibrin polymer. This in turn is converted into insoluble fibrin polymer (*see* desmofibrin) through the action of plasma transglutaminase (factor XIIIa, EC 2.3.2.13) which, in the presence of calcium ions, creates covalent cross-links between the monomers by transamidating glutamine residues with the amino groups of the side chains of lysine residues in other monomers. *See also* blood coagulation.

**fibrinase** an alternative name for plasmin.

**fibrin monomer** see fibrin.

**fibrinogen** or factor I a highly soluble, 340 kDa, elongated protein of blood plasma concerned in clot formation. It is converted into fibrin monomer by the action of thrombin. Fibrinogen is a hexamer, 46 nm long and 9 nm maximal diameter, containing two sets of three nonidentical chains (u, β, and γ), linked to each other by disulfide bonds. The N termini of all chains are contained in a central nodule, diverging from which are two three-chain coiled coils; these connect the central nodule to the distal nodules containing the distal domains; there are long C termini of the u chains. Thrombin cleaves four Arg-Gly bonds, releasing two each of fibrinopeptides A and B from the α and β chains, and forming fibrin monomer (the intact chains in fibrinogen being referred to as the Au and Bβ chains). This exposes the N-terminal polymerization sites responsible for the formation of the soft clot, which is converted

into the hard clot by factor XIIIa. This catalyses the e-(γ-glutamyl)lysine cross-linking between γ chains (stronger) and between u chains (weaker) of different monomers. Fibrinogen also acts as a cofactor in platelet aggregation (a binding site on the γ chain participates). Example sequences (precursors, human): u, database code FIBA\_HVMAN, 644 amino acids (69.68 kDa); β, database code FIBB\_HVMAN, 491 amino acids (55.87 kDa); γ-A, database code FIBG\_HVMAN, 437 amino acids (49.43 kDa); an alternative (γ-B or γ') is produced by differential splicing; database code FIBH\_HVMAN, 453 amino acids (51.44 kDa). *See also* blood coagulation.

**fibrinogenase** an alternative name for thrombin.

**fibrinolysin** an alternative name for plasmin.

**fibrinolysis** the process of the dissolution of fibrin in blood clots resulting from the proteolytic action of plasmin or other enzymes, e.g. streptokinase or the proteases in snake venom. — fibrinolytic adj.

**fibrinopeptide** either of the types of negatively charged peptide cleaved off fibrinogen when it is converted to fibrin by the action of thrombin. Human fibrinopeptide A is a 16-residue peptide cleaved from each of the fibrinogen Au chains; structure (human): ADSGEGDFLAEGGGVR; fibrinopeptide B is a 14-residue peptide cleaved from each of the Bβ chains.

**fibrin polymer** see fibrin.

**fibrin stabilizing factor** or fibrin stabilising factor abbr.: FSF; an alternative name for factor XIIIa; *see* blood coagulation.

**fibroblast** or fibrocyte a flattened, irregular, branched, motile cell found distributed throughout vertebrate connective tissue. Such cells form, secrete, and maintain the extracellular collagen and mucopolysaccharide of this tissue. Similar cells occur in many invertebrates.

**fibroblast growth factor** abbr.: FGF; any of various growth factors with strong mitogenic potential, characterized by their high affinity for heparin; they are mitogenic for mesodermal and neuroectodermal cells but not for endodermally derived cells. Two major subtypes are recognized, based on their ease of elution from heparin columns: an acidic group (aFGFs), and a less-easily eluted basic group (bFGFs). FGFs have angiogenic properties, may function as inductive agents during embryonic development, and are useful as a partial or total substitute for serum in tissue culture. Those of the acidic group have been isolated mainly from brain or retina; they include acidic brain fibroblast growth factor (brain aFGF), astrogliial growth factor-I (AGF-I), retina-derived growth factor (RDGF), eye-derived growth factor-2 (EDGF-2), endothelial cell growth factor (ECGF), and heparin-binding growth factor (HGF $\alpha$  and HGF $\beta$ ). Those of the basic group have been isolated from brain, retina, and cartilage; they include basic brain fibroblast growth factor (brain bFGF), eye-derived growth factor-I (EDGF-I), astrogliial growth factor-2 (AGF-2), and cartilage-derived growth factor (CDGF). Example, basic fibroblast growth factor (human): database code NRL\_2FGF, 126 amino acids (14.41 kDa); 3-D structure known (beta barrel). FGF-3, so named because aFGF and bFGF had already been identified, a monomer of 239 amino acids, is expressed during embryonic development and by mammary tumour epithelial cells; it is the product of the *int-2* oncogene, and has properties similar to those of basic FGFs. FGF-4 is the product of the *hst1KS3* gene, comprises 205 amino acids, is expressed during development and by some tumours, is mitogenic for fibroblasts and endothelial cells, and is angiogenic *in vivo*. FGF-5 (identified by DNA probes in human bladder carcinoma, hepatoma, and endometrial carcinoma) is a monomer of 267 amino acids; it is expressed by fibroblasts, epithelium, some tumour cells, and during embryonic development, and is mitogenic for fibroblasts and endothelial cells. FGF-6 is the product of *hst-2* (identified by a screen for *hst*-related genes) and is a monomer of 208 amino acids; it is expressed during embryonic development and in adult testis, heart, and skeletal muscle, and is mitogenic for fibroblasts but only weakly for endothelial cells. FGF-7 (ker-

atinocyte growth factor) is a monomer of 194 amino acids; it is expressed by epithelial tissue and is mitogenic for epithelial cells but not for fibroblasts or endothelial cells. *See also KSlhst.*

**fibroblast growth factor receptor abbr.:** FGFR; any of the plasma membrane tyrosine kinase proteins that bind fibroblast growth factors and mediate their intracellular effects. All have a single transmembrane helical domain of 21 amino acids, an extracellular domain of about 350 amino acids with three immunoglobulin domains (but variants with fewer are known), and a cytoplasmic domain of about 410-425 amino acids within which is a tyrosine kinase domain which is activated by ligand binding. Six to nine potential N-linked glycosylation sites are present in the extracellular domain. FGFRs are classified into five types. FGFRI was isolated as a partial cDNA clone encoding anjins-like gene (*j7g*) and is also known as flg. Common variants have only two immunoglobulin (Ig) domains. Example from *Rattus norvegicus* (precursor): database code FGRLRAT, 822 amino acids (91.82 kDa). FGFR2 was isolated as a tyrosine kinase gene encoding a bacterial expressed kinase (*bek*). Common variants of this also have deletion of the first Ig domain. Example from *Xenopus laevis* (precursor): database code FGR2\_XENLA, 813 amino acids (91.34 kDa). FGFR3 is the product of *cek2* (*see cek*); example, human (precursor): FGR3\_HUMAN, 806 amino acids (87.71 kDa). FGFR4 was isolated as a clone from human erythroleukemia cells; example, human (precursor): database code FGR4\_HUMAN, 802 amino acids (87.94 kDa). A fifth type of FGFR is known as flg-2. FGFRI and 2 are expressed by a variety of species, tissues, and cell lines, but FGFR3, FGFR4 and flg-2 have been isolated from a limited number of sources. Heparan sulfate proteoglycans promote binding of FGFs to FGFRs. Binding of ligand to the extracellular domain of FGFRs induces oligomerization of receptors, autophosphorylation, and phosphorylation of intracellular proteins that associate with the activated receptor through their SH2 domains (*see SH domain*). Prominent among these is phospholipase Cyl (*see phospholipase*).

**fibroblast surface antigen** a variant form of surface fibroblast antigen; *see fibronectin.*

**fibrocyte** an alternative name for fibroblast.

**fibroglycan** *see syndecan-2.*

**fibroin** or silk fibroin the protein of the silk fibres that are secreted by the posterior gland of the larva of the silk moth, *Bombyx mori*. It comprises two chains, heavy and light, linked by disulfide bond(s). Both heavy and light chains assembled as a mature protein are needed for efficient intracellular transport and secretion of fibroin; the secondary structure is largely beta sheet. Example (light chain) from *B. mori*: database code FBOL\_BOMMO, 262 amino acids (27.64 kDa).

**fibronectin** any of a group of related adhesive glycoproteins of high molecular mass found on the surface of animal cells, in connective tissue matrices, and in extracellular fluids. They bind to cell surfaces, collagen, fibrin, heparin, DNA, actin, etc. and are involved in cell adhesion, cell motility, opsonization, wound healing, and maintenance of cell shape. Fibronectin is a disulfide-bonded heterodimer. Fibronectins can be classified into two immunologically cross-reacting groups: plasma fibronectins (*also called cold-insoluble globulin or cell attachment protein or cell adhesion factor or cell spreading factor or anti-gelatin factor or opsonic a2"SB-glycoprotein*); and cellular fibronectins (*also called cell surface protein or large external transformation sensitive (LETS) protein or surface fibroblast antigen or galactoprotein A or zeta protein*). Cellular fibronectin (which is the major cell surface protein of cultured fibroblasts) is greatly reduced or even lost when a variety of cell types are transformed by oncogenic viruses, chemical carcinogens, or temperature-sensitive viruses at the permissive temperature and several of the morphological changes associated with transformation can be partially reversed by addition of appropriate amounts of purified cellular

fibronectin. There are three types of fibronectin domain (I, II, III) with several versions in the same protein; extra domains and a connecting strand 3 are present in some forms of fibronectin and absent in others; these differences are due to alternative splicing. Human (precursor): database code FINC\_HUMAN, 2386 amino acids (262.39 kDa). Fibronectin binds to integrins  $\alpha_4\beta_1$ ,  $\alpha_5\beta_1$ ,  $\alpha_5\beta_3$ ,  $\alpha_5\beta_5$ ,  $\alpha_5\beta_6$ , and  $\alpha_4\beta_7$ . [From Latin *fibra*, fibre and *necto*, to attach.]

**fibrosome** an artificial macromolecular complex of fibronectin layered on an agar-coated substrate.

**fibrous protein** any protein able to aggregate into fibres or filaments and serving mainly as a structural protein. The polypeptide chains in such proteins are either extended or coiled in one dimension and their structure is maintained largely by interchain hydrogen bonds.

**fibulin** a Ca<sup>2+</sup>-binding glycoprotein of the extracellular matrix with nine EGF-like repeats. Four forms (A-D) differ only in their C-terminal region and arise by alternative splicing. Example, isoform A precursor from human: database code FBLA\_HUMAN, 566 amino acids (61.53 kDa).

**ficain** or ficin a cysteine endopeptidase, EC 3.4.22.3, from *Ficus* spp. with preferential cleavage at Lys-, Ala-, Tyr-, Gly-, Asn-, Leu-, and Val-. The name is also used for the crude dried latex from *Ficus* spp., but extracts of only a small proportion of these (in one study only 13 out of 43 species) contain proteolytic activity. Its action is similar to that of papain.

**ficin another name for** ficain.

**Fick's first diffusion law** a mathematical description of the physical process of solute diffusion; the flux (mass transferred) of particles, *J*, diffusing across a unit plane in unit time is given by:

$$J = -D(aclax),$$

where the mass concentration gradient at *x* is *aclax* and *D* is the diffusion coefficient for the solute. [After Adolph Eugen Fick (1829-1901), German physiologist.]

**Fick's second diffusion law** a mathematical description of the rate of change in mass concentration, *c*, at point *x* of the diffusing particles with time, (*aclat*), during solute diffusion, for unsteady conditions (*aclax* ≠ 0); it is given by:

$$(aclat) = D(a^2c1ax^2),$$

where *D* is the diffusion coefficient, assumed to be independent of the concentration.

**Fick unit symbol:** F; a non-SI unit sometimes used to express a diffusion coefficient; it is equal to 10<sup>-7</sup> cm<sup>2</sup> s<sup>-1</sup>.

**ficolin** a multimeric protein so named because of its fibrinogen- and collagen-like domains; it was originally isolated as a TGF-β1 binding protein. Recombinant ficolin-α and ficolin-β expressed from cDNA do not bind TGF-β1. Ficolin-α is expressed preferentially in uterus, lung, and placenta whereas ficolin-β RNA is most abundant in skeletal muscle. The function is at present unknown. Example, ficolin-α from pig: database code A47172, 323 amino acids (34.64 kDa).

**Ficoll** or Ficoll 400 a synthetic copolymer of sucrose and epichlorhydrin. It has a branched structure, a high content of hydroxyl groups, which renders it very water-soluble (up to 50% w/v), and a mass average *M<sub>r</sub>* of 400000 ± 100000. Solutions of Ficoll have low osmotic pressures and are useful in preparing density gradients; Ficoll is widely used in preparing continuous or discontinuous gradients for separating cell types. Ficoll 70, with an *M<sub>r</sub>* of 70 000, is useful in perfusion studies.

**Ficoll-Paque** the proprietary name for an aqueous solution of Ficoll and diatrizoate sodium with a density of 1.077 ± 0.001 g cm<sup>-3</sup>. It is useful for the one-step separation of lymphocytes from a sample of anticoagulant-treated blood and for the preparation of other cell types by density-gradient centrifugation.

**fidelity** the degree to which the output of any system accurately describes or reflects the input to the system. The term is used

field

especially of the processes of replication, translation, and transcription, and of electronic amplifiers.

**field** 1 a region of space in which a force is exerted on an object because of its charge (electric field), magnetic dipole (magnetic field), mass (gravitational field), or other attribute. 2 a region of space through which (ionizing) radiation is passing. 3 or field of view the area within which an object is observable with a microscope or other optical instrument.

**Fieser's solution** a solution for removing dioxygen from any other nonacidic, nonoxidizing gas. It contains potassium hydroxide, anthraquinone P-sulfonate, and sodium thiosulfate. Red when fresh, it becomes colourless when exhausted. [After Louis Frederick Fieser (1899-1977), US chemist.]

**FIGLU abbr.** for formiminoglutamate.

**figure of merit** the square of the efficiency divided by the background count for a given liquid scintillation system (see liquid-scintillation counting). It is useful for optimizing the scintillator composition and the discriminator settings for the counting channel(s).

**filaggrin** a protein that aggregates keratin intermediate filaments and promotes disulfide-bond formation amongst them during terminal differentiation of mammalian epidermis. It is initially synthesized as a large, insoluble, highly phosphorylated precursor containing many tandem copies of 324 amino acids, which are not separated by 'large linker' amino-acid sequences. The precursor is deposited as keratohyalin granules; during terminal differentiation it is dephosphorylated and proteolytically cleaved. Example from human (partial sequence): database code FILA\_HUMAN, 416 amino acids (44.06 kDa).

**filament** any very thin, threadlike structure. See also actin, microfilament, thick filament, thin filament. -filamentary or filamentous adj.

**filamin** a protein, extractable from smooth muscle and other tissues, that induces a calcium-ion-insensitive gelation of actin. It promotes orthogonal branching of actin filaments and links actin filaments to membrane glycoproteins. It exists as a homodimer and contains an actin-binding domain. Example, nonmuscle filamin (human): database code ABP2\_HUMAN, 2647 amino acids (280.45 kDa).

**filensin** a membrane- and cytoskeleton-associated protein. It is an intermediate filament type III unique to lens fibre cells. It has primary and secondary structural similarity to other intermediate filament proteins and serves as an anchorage site for vimentin intermediate filaments. Example (bovine): database code S32103, 755 amino acids (82.86 kDa).

**filial generation symbol:** F; any of the generations of living organisms following a particular parental generation. The generation resulting from a mating of the parents is the first filial generation symbol: (F<sub>1</sub>), while that resulting from crossing of F<sub>1</sub> individuals is the second filial generation symbol: (F<sub>2</sub>), and so on.

**filipin** a neutral polyene antibiotic from *Streptomyces filipinensis*. It is similar in action to amphotericin B.

**film badge** a masked photographic film worn by workers exposed to ionizing radiation to indicate the extent of their exposure to radiation.

**filter** 1 any piece or layer of material used or useful for (completely or partially) removing selected components, especially in suspension, from liquid or gaseous mixtures, e.g. a sheet of paper, a stratum of sand (or similar material), or a piece of porous ceramic or plastic. See also membrane filter, ultrafilter. 2 a device incorporating such a piece or layer of material. 3 a block or sheet of material for reducing the intensity of particulate radiation. 4 a screen for selectively absorbing or attenuating electromagnetic radiation or sound waves of some particular or all frequencies. 5 a passive electronic circuit or device that selectively attenuates or allows the passage of certain frequencies of an electrical signal. 6 to remove or separate (suspended particles, macromolecular solutes, selected frequencies of electrical signal or electromagnetic radiation, etc.)

fingerprinting

from (a heterogeneous or composite fluid, beam, signal, etc.) by means of a filter; to pass (something) through a filter. 7 (as modifier) containing or using a filter or filters, or used for filtering, as in a filter fluorometer or filter photometer.

**filterable** or filtrable capable of being filtered; able to pass through a (specified) filter.

**filterable agent** a former name for bacteriophage, virus, or other submicroscopic noncellular microorganism.

**filterable virus** a former name for a virus the particles of which are capable of passing through a filter that will retain bacteria and other cellular microorganisms.

**filter membrane** an alternative term for membrane filter.

**filter paper** porous, unsized paper used for filtration; a disk, piece, or sheet of such paper. Such paper may be chemically treated for special applications, e.g. for use in quantitative analysis; it is also used in paper chromatography.

**filter press** a device for effecting filtration, consisting of a series of (metal, plastic, or wooden) frames the two sides of which are covered with filter cloth. The frames are clamped together and the liquid to be filtered is pumped into them in such a way that the solid residue forms a cake between the cloths and the liquid filtrate is conducted away separately.

**filter pump** a type of vacuum pump used to assist filtration, in which a jet of water forced through a narrow orifice entraps air from the system being evacuated.

**filtrable** a variant spelling of filterable.

**filtrate** the liquid or gas that has passed through a filter (def. 1). **filtration** the act or process of separating or (completely or partially) removing selected components (of a mixture) by means of a filter (def. I), to produce a filtrate. The term includes gel filtration, membrane filtration, and ultrafiltration.

**filtration enrichment** a method for isolating fungal auxotrophs. Mutagenized spores are placed in a minimal medium in which only normal spores germinate and produce a mycelial network. This mycelial network is then removed by filtration and the remaining auxotrophic spores are provided with an enriched medium to allow their germination, growth, and propagation.

**filtration fraction** (in physiology) the fraction of the plasma that is filtered through the renal glomeruli. It is equal to the glomerular filtration rate divided by the renal plasma flow and is frequently taken to be equal to the ratio of the inulin clearance to p-aminohippurate clearance.

**fimbria** (pl. fimbriae) 1 (in botany and zoology) a fringe or fringelike edge or margin, e.g. especially at the opening of a fallopian tube. 2 (in bacteriology) an alternative term for pilus (especially a common pilus). -fimbrial adj.

**fimbriate** or fimbriated characterized by or possessing fimbria; fringed at the edge or margin.

**fimbrin** an actin-binding protein involved in the development and maintenance of cell polarity. Example from *Saccharomyces cerevisiae*: database code FIMB\_YEAST, 642 amino acids (71.69 kDa).

**fine structure** or microstructure any structural detail observable in genetic material, microscopic specimens, spectra, etc. when examined at high magnification or resolution. See also hyperfine structure.

**fingerprinting** any pattern obtained by a variety of means that is characteristic of a biological entity, including 1 the electrophoretic or chromatographic pattern obtained after a process in which a protein is digested, usually enzymically, in defined conditions to produce a mixture of peptides, the nature of the mixture being dependent on the particular protein and the conditions of digestion. The distribution pattern of spots is rarely, if ever, duplicated if a different protein is used. 2 a set of one or more amino-acid motifs (def. 2) obtained by aligning conserved regions of proteins found in protein sequence databases to provide a sequence or set of sequences characteristic of a particular function e.g. the rat metabotropic glutamate receptor 2 precursor fingerprint has seven motifs, the first of which is the 22-residue

## VGPVTIACLGALATLFVTVIFI.

The technique involves alignment followed by maximization of sequence information through iterative scanning, with multiple motifs, of a large composite database. The results are held in the PRINTS database. See also Appendix E. 3 the result of genetic profiling.

**firefly lantern** or lantern the luminescent abdominal organ, or photophore, of the American firefly, *Photinus pyralis*, a common source of the enzyme luciferase and its luminogenic substrate luciferin.

**firefly luciferase** see luciferase.

**firefly luciferin** see luciferin.

**first law of photochemistry** an alternative name for Grothus and Draper law.

**first law of thermodynamics** see thermodynamics.

**first messenger** an alternative term sometimes used for hormone to distinguish it from second messenger. See also chemical messenger, pheromone.

**first-order kinetics** the kinetics of a first-order reaction; see order of reaction.

**first-order reaction** see order of reaction.

**first-pass clearance** or **first-pass elimination** or **first-pass metabolism** the effect of passage of a drug administered by mouth through the liver before it reaches the systemic circulation. Some drugs, in spite of their rapid uptake through the gut mucosal membrane, appear in low concentration in the systemic circulation and hence more has to be administered by mouth than by intravenous injection. As little as 10-20% of the drug may reach the systemic circulation unchanged as a result of their metabolism, mainly by the liver. Some authors extend the term to include metabolism also by the cells of the gut mucosal membrane.

**Fischer** 1 Edmond Henri (1920- ), Swiss-born biochemist; Nobel Laureate in Physiology or Medicine (1992) jointly with E. G. Krebs 'for their discoveries concerning reversible protein phosphorylation as a biological regulatory mechanism'. 2 Emil Hermann (1852-1919), father of H. O. 1. Fischer (see def. 5), German organic chemist, stereochemist, enzymologist, and one of the most famous chemists of the nineteenth century, renowned in particular for his synthetic work on dyes, for elucidating the structures of and synthesizing a wide range of natural products (including sugars, purines, amino acids, and polypeptides), for establishing the steric configurations of all the aldohexoses and aldopentoses (see also Fischer convention), and for recognizing the stereochemical specificity of enzyme action (see lock-and-key model); Nobel Laureate in Chemistry (1902) 'in recognition of the extraordinary services he has rendered by his work on sugar and purine syntheses'. 3 Ernst Otto (1918- ), German inorganic chemist; Nobel Laureate in Chemistry (1973), the prize being shared with G. Wilkinson 'for their pioneering work, performed independently, on the chemistry of the organometallic, so called sandwich compounds'. 4 Hans (1881-1945), German organic chemist noted for his structural and synthetic work on various linear or macrocyclic tetrapyrroles; Nobel Laureate in Chemistry (1930) 'for his researches into the constitution of haemin and chlorophyll and especially for his synthesis of haemin'. 5 Hermann Otto Laurenz (1888-1960), son of Emil H. Fischer (see def. 2), German organic chemist and biochemist noted particularly for his unequivocal chemical syntheses (with E. Baer) of glyceraldehyde 3-phosphate and glycerone phosphate.

**Fischer conventions** conventions used in the construction of plane projection formulas and first formulated by E. H. Fischer (see Fischer def. 2). The first convention may be stated as 'All of the tetrahedral apices that connect asymmetric carbon atoms lie in a straight line in the plane of the paper. This line shall contain the lower edges of all these tetrahedra, their other apices being above the plane and on opposite sides of the line' (see Fischer projection). The second convention is the

assumption of one specified configuration for (+)saccharic acid and hence for glucose. At the time of Fischer's work, absolute configurations were not known. Fortunately, he guessed the correct configuration for (+)glucose (now designated D-glucose).

**Fischer ester former name for glyceraldehyde 3-phosphate (see *o*-glyceraldehyde 3-phosphate)**. [After H. O. 1. Fischer (see Fischer def. 5).]

**Fischer projection** a diagrammatic representation in two dimensions (as on paper) of the three-dimensional structure of an open-chain chiral molecule of the type RICHXR<sub>z</sub>, useful particularly for monosaccharides (X = OH) and their derivatives and for amino acids (X = NH<sub>2</sub>) and their derivatives. According to the first Fischer convention, the carbon chain is written vertically with the most highly oxidized carbon atom (number 1) at the top, the bonds between the carbon atoms being either in or below the plane of the paper; the hydrogen atoms and the X groups, written to the left and right of the carbon atoms to which they are attached, are considered as being in front of the plane of the paper. If X is on the right, the configuration at that carbon atom is designated by the prefix D- (from Latin *dexter*, turned to the right), whereas if X is on the left, the configuration is designated L- (from Latin *laevus*, turned to the left). See also OIL convention.

**FISH abbr. for fluorescence *in situ* hybridization**.

**fish-odour syndrome** a condition of humans characterized by an offensive odour of rotting fish, due to abnormal excretion of trimethylamine in the breath, urine, sweat, saliva, and vaginal secretions, especially after eating foods containing trimethylamine (e.g. sea fish) or choline. It results from a reduced ability to oxidize trimethylamine N-oxide, normally effected by liver microsomal monooxygenases.

**fish oil** oil obtained from the liver or flesh of fish; it is comparatively rich in fatty acids of the *n*-3 family (see fatty-acid nomenclature). Generally, the flesh of so-called oily fish, such as herring, mackerel, salmon, and trout, has a higher content of C<sub>20</sub> and C<sub>n</sub> *n*-3 acids than that of white fish such as cod or plaice. Recently, increasing the dietary content of long-chain *n*-3 fatty acids has been promoted as a prophylactic measure in the prevention of heart disease, though the mechanisms suggested are conjectural. See also cod-liver oil.

**Fiske and SubbaRow method** a colorimetric method for determination of inorganic phosphate, based on the production of a blue colour when the sample is treated with ammonium molybdate and 1-amino-2-naphthol-4-sulfonic acid. [After Cyrus Hartwell Fiske (1890-1978) and Yellapragrada SubbaRow (1896-1948).]

**FISP-12** another name for mouse connective tissue growth factor. fissile tending to undergo fission.

**fission** 1 or **nuclear fission** (in physics) a nuclear reaction in which a heavy atomic nucleus splits into two (or, rarely, three or four) approximately equally sized nuclides, with release of a considerable amount of energy. 2 (in biology) cleavage of cells or division of unicellular organisms into two (or more) parts.

**fission product** any of the stable or unstable nuclides resulting from fission (def. 1).

**FITC abbr. for** 1 fluorescein isothiocyanate. 2 the fluorescein isothiocarbamoyl group.

**fitness** (in biology) the survival value and the reproductive capability of a given genotype as compared with the average of the population or of other genotypes in the population.

**fix** 1 to render, or to become, stable, firm, or insoluble; to attach (to something). 2 (in chemistry) to convert a free element into one of its compounds; especially to convert atmospheric dinitrogen into nitrogen-containing substances (see nitrogen fixation); to convert a volatile or fluid substance into a non-volatile or solid form; to combine an inorganic substance with an organic substance. 3 (in biology) to preserve (and harden) cells, tissues, or organisms for subsequent (microscopic) study. 4 (in photography) to treat a film or plate with fixer so as to render permanent the developed image. -fixation *n.*

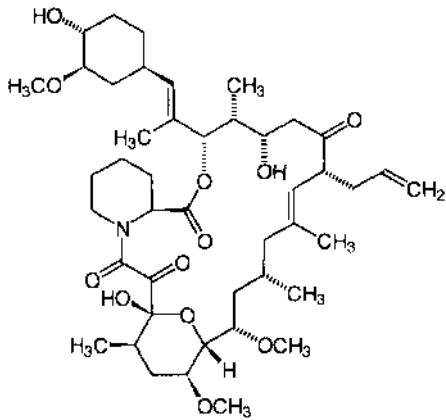

## fixative

fixative a protein-denaturing fluid, e.g. formaldehyde, that is used to fix (def. 3) biological material for (microscopic) study. fixed antibody see cell-bound antibody. Compare humoral antibody.

fixed nitrogen any product of nitrogen fixation.

fixer (*in photography*) a chemical solution used to remove unexposed, hence unreduced, silver halide granules from a photographic emulsion after the image has been developed.

**FK506** an immunosuppressant, isolated from *Streptomyces tsukubaensis*. It is a member of the macrolide antibiotic family, has an *Me* of 803, and binds to the FKBP-binding proteins. It is a potent inhibitor of T-cell activation and prevents allograft rejection. The *in vivo* function of this immunophilin is not clear but in a complex with FKBP it blocks the action of calcineurin in the liver. It is also a powerful neuroprotective agent in an *in vivo* model of focal cerebral ischemia and may have clinical potential for the treatment of stroke. FK506 also reduces nitric oxide production by inhibiting the calcineurin-mediated dephosphorylation of nitric-oxide synthase (EC 1.14.13.39). One proprietary name is Tacrolimus.

**FKBP** abbr. for FK506-binding protein; any of an extensive family of small proteins to which the immunosuppressant FK506 binds. They are found in many species from bacteria to humans. Like cyclophilin they possess peptidyl-prolyl isomerase activity (EC 5.2.1.8), but have no similarity in structure. Both types belong to the class of proteins termed immunophilins. Example from *Drosophila melanogaster*: database code FKBP\_DROME, 108 amino acids (11.6 kDa).

flagella the plural of flagellum.

**flagellate** 1 describing unicellular organisms that have a flagellum or flagella. 2 resembling a flagellum. 3 an organism that propels itself by means of a flagellum or flagella, especially any member of the protozoan superclass Mastigophora.

**flagellin** any member of a group of similar monomeric soluble globular proteins that constitute the subunits of bacterial flagella. They also comprise the major antigens of several bacteria, including *Salmonella* spp., which alternate between the production of two antigenic forms of flagella, termed phase I and phase 2. Example, phase-I flagellin from *S. typhimurium* SL877: database code STYFLGHII, 490 amino acids (51.28 kDa); there are three flagellin motifs.

**flagellum** (*pl.* flagella or flagellums) 1 the specialized locomotory appendage of bacteria of certain taxonomic groups, consisting of a noncontractile, filiform extension through the cell surface, borne singly, in groups, or as a covering layer. It is commonly 3–20 µm long and 12–25 nm in diameter, is built up of several (often three) longitudinally arranged chains of flagellin subunits (often in a spiral), and is anchored to the cell envelope by a basal body (def. 1), which imparts rotatory mo-

## flavan

tion to it. Bacterial flagella carry the H (or flagellar) antigens, which are useful in some instances, e.g. in *Salmonella* spp., for classification. 2 the specialized locomotory appendage of the motile cells of unicellular eukaryotes of certain taxonomic groups (e.g. some algae and protozoa) and also of the male gametes (spermatozoa) of most groups of animals. Usually borne singly or in small groups, it is a whiplike structure, similar to, but generally longer than a cilium, commonly about 40 µm long and 200–300 nm in diameter. It is built up of an outer membranous sheath, which is a continuation of the cell membrane, and an inner axoneme, which terminates within the cell at a basal body (def. 2). Eukaryotic flagella often exhibit undulatory motion, which in multiflagellate organisms can occur as coordinated beating. -flagellar *ad.*

**flame emission spectrophotometry** a type of atomic emission spectrophotometry in which excitation is produced by a flame.

**flame ionization detector** or flame ionisation detector a sensitive detector used in gas chromatography that depends on changes in the electrical conductivity of a flame (burning a mixture of dihydrogen and dinitrogen in air or dihydrogen and dioxygen), brought about by ionization of the vapours of organic substances emerging from the column.

**flame photometer** an instrument for flame photometry.

**flame photometry** an earlier and simpler, often direct-reading, version of atomic emission spectrophotometry in which isolation of the required emission line(s) is achieved by the use of an appropriate filter.

**flame spectrophotometry** any form of atomic absorption spectrophotometry or atomic emission spectrophotometry in which excitation is produced by a flame.

**flanking marker (DNA)** a DNA marker on either side of a locus; a DNA sequence on either side of a gene.

**flash evaporation** a technique for concentrating a solution at a relatively low temperature thus preventing denaturation of nonvolatile solutes. The solution is placed in a round-bottomed flask or other vessel, which is then rapidly rotated and evacuated; the vapour removed from the solution is liquefied in a condenser and retained in a cold trap. The rotation of the vessel causes the liquid to form a comparatively thin film, which increases its surface-to-volume ratio, thereby assisting evaporation.

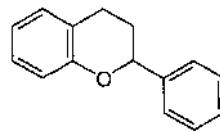

**flash evaporator** an apparatus for flash evaporation.

**flash photolysis** a technique for investigating short-lived primary or subsequent intermediates, e.g. radicals, in a photochemical reaction. The sample is subjected to a brief but powerful flash of light of appropriate wavelength and the photolysis products are identified by their absorption or fluorescence spectra, using an independent source of radiation. The kinetics of very fast reactions can be investigated by this technique.

**flash point** the lowest temperature at which the vapour above a volatile combustible substance will ignite to produce a momentary flash when a small flame is applied under specified conditions.

**flat-bed** indicating that a technique is carried out in a horizontal plane, e.g. flat-bed chromatography.

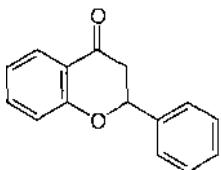

**flavan** 2-phenylchroman; 2,3-dihydro-2-phenylbenzopyran; the parent ring structure on which the structures of flavanols, flavanones, flavones, flavonols, and other classes of aglycons of flavonoids are based.

**flavanol**

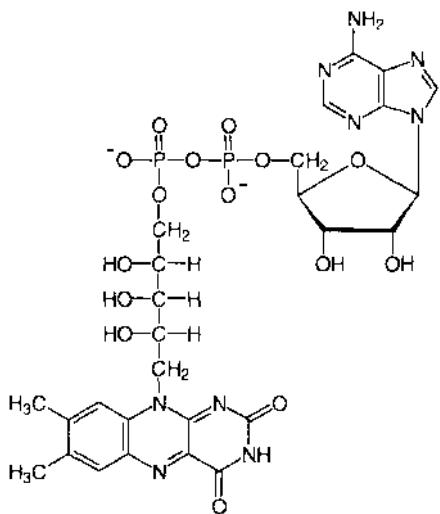

**flavanol** any hydroxylated derivative of **flavan**. Glycosides of flavan-3-ol and of flavan-3,4-diol respectively form two of the classes of **flavonoid** (def. I).

**flavanone** 1 2,3-dihydroflavone; 2-phenylchroman-4-one; 2,3-dihydro-2-phenylbenzopyran-4-one; it is the 4-oxo derivative of **flavan** and the 2,3-dihydro derivative of **flavone**. 2 any of a group of hydroxylated derivatives of flavanone. Flavanone glycosides are colourless; they are found in flowering plants and form one of the classes of **flavonoid** (def. I).

**flavin or (formerly) flavine** the stem name and trivial name for any member of a group of yellow-coloured, 10-substituted derivatives of 7,8-dimethylisoalloxazine, as in **riboflavin**, **flavin-adenine dinucleotide**, etc.

**flavin-adenine dinucleotide** abbr.: FAD; adenosine diphosphate riboflavin; adenosine(5')diphospho(5')riboflavin; riboflavin 5'-(adenosine 5'-diphosphate); 7,8-dimethyl-10-[5-(adenosine(5')diphospho)-D-ribityl]isoalloxazine; an atypical dinucleotide, not only in that it contains, as does **nicotinamide-adenine dinucleotide**, a phosphoric anhydride linkage between the component mononucleotide units, which in this instance are **adenosine 5'-phosphate** and **flavin mononucleotide**, but also because the latter is not strictly a nucleotide in any case, although considered as one (see **nucleotide** (def. 3)). It forms the coenzyme or the prosthetic group of various flavoprotein oxidoreductase enzymes, in which it functions as an electron acceptor by being reversibly converted to **flavin-adenine dinucleotide (reduced)**. See also **riboflavin**.

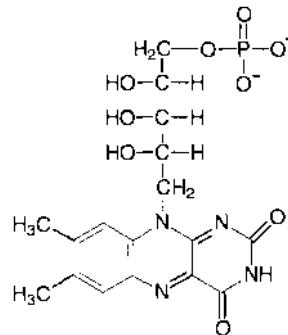

**flavin-adenine dinucleotide (reduced)** abbr.: FADH<sub>2</sub>; adenosine diphosphate dihydroriboflavin; 1,5-dihydro-7,8-dimethyl-10-[5-(adenosine(5')diphospho)-D-ribityl]isoalloxazine. The reduction occurs at the two unprotonated nitrogen atoms at positions I and 5 of FAD. See **flavin-adenine dinucleotide**.

**flavin coenzyme** a general name sometimes used for a **flavin nucleotide** when not covalently linked to an apoenzyme.

**flavin enzyme or flavoenzyme** any **flavoprotein** that is an enzyme.

**flavone**

**flavin mononucleotide** abbr.: FMN; riboflavin 5'-phosphate, 7,8-dimethyl-10-(5-phospho-D-ribityl)isoalloxazine. Although not strictly a mononucleotide, since it contains an alditol moiety rather than a glycone moiety, it nevertheless is considered as one (see **nucleotide** (def. 3)), and as such is a component of **flavin-adenine dinucleotide**. It forms the coenzyme (or occasionally the prosthetic group) of various flavoprotein oxidoreductase enzymes, where it functions as an electron acceptor by being reversibly converted to **flavin mononucleotide (reduced)**. See also **riboflavin**.

**flavin mononucleotide (reduced)** abbr. FMNH<sub>2</sub>; dihydroriboflavin 5'-phosphate, 1,5-dihydro-7,8-dimethyl-10-(5-phospho-D-ribityl)isoalloxazine. The reduction occurs at the two unprotonated nitrogen atoms at positions I and 5 of FMN. See **flavin mononucleotide**.

**flavin nucleotide** a general name sometimes used for **flavin-adenine dinucleotide** and **flavin mononucleotide**, and their reduced forms.

**flavin reductase** (in luminescent bacteria) the product of the *luxG* gene in several marine luminescent bacteria. It is presumed from sequence similarity to be an FAD/NAD(P) flavoprotein oxidoreductase. Example from *Vibrio fischeri*: database code LUXG\_VIBFI, 236 amino acids (26.47 kDa).

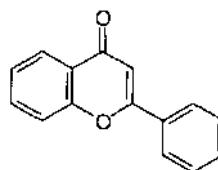

**flavo+** comb.form 1 yellow. 2 containing a **flavin nucleotide**.

**flavocytochrome** any protein that is both a **flavoprotein** and a **cytochrome**, e.g. yeast L-lactate dehydrogenase (cytochrome), (EC 1.1.2.3), also known as **cytochrome b<sub>2</sub>**.

**flavodoxin** any of a group of small protein electron carriers, widely distributed in anaerobic bacteria, photosynthetic bacteria, and cyanobacteria, that contain covalently linked flavin mononucleotide. They readily form stable blue semiquinones, and can substitute functionally for **ferredoxin**. Example from *Escherichia coli*: database code FLAV\_ECOLI, 175 amino acids (19.58 kDa).

**flavolans** see **tannin**.

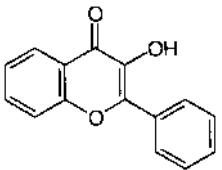

**flavone** 1 2-phenylchromen-4-one; 2-phenyl-4H-1-benzopyran-4-one; a potent inhibitor of **prostaglandin-endoperoxide synthase**. 2 any of a group of hydroxylated derivatives of flavone. Flavone glycosides occur as pigments, usually yellow, in flowering plants and form one of the classes of **flavonoid** (def. I). Distinguish from **flavanone**.

## flavonoid

**flavonoid** 1 any of a very large and widespread group of water-soluble phenolic derivatives, often brightly coloured and usually found in the vacuoles of plant cells. They are glycosides with the structures of their aglycon moieties based on the flavan skeleton, and are classified according to the oxidation state of its pyran ring. Some 10-12 classes are recognized. 2 any flavone, isoflavone, or neoflavone, or any of their derivatives, including bioflavonoids. *See also* apigenin, myricetin, quercetin. 3 of, relating to, or resembling flavone, isoflavone, or neoflavone.

**flavonol** 1 3-hydroxyflavone. 2 any of a group of hydroxylated derivatives of flavonol. Flavonol glycosides occur as pigments, usually yellow, in flowering plants, and form one of the classes of flavonoid (deL I). *Distinguish from* flavano!

**flavoprotein abbr.: FP**; any enzyme or other protein of which a flavin nucleotide is a coenzyme or prosthetic group. They occur in virtually all cells, where they act as oxidoreductases or as electron carriers in the terminal electron transport chains.

**Fleming, (Sir) Alexander** (1881-1955), British bacteriologist famous for his discovery of the bacteriolytic agents lysozyme and penicillin; Nobel Laureate in Physiology or Medicine (1945) jointly with E. B. Chain and H. W. Florey 'for the discovery of penicillin and its curative effect in various infectious diseases'.

**Fletcher factor** *see* plasma kallikrein.

**fig** *see* fibroblast growth factor receptor.

**flickering cluster model** a model for the structure of liquid water in which small, tetrahedrally coordinated, icelike regions, held together by hydrogen bonds, are thought to exist for short periods, continually breaking up and re-forming.

**flightin** the enzyme glycerol 3-phosphate dehydrogenase ( $\text{NAO}^+$ ) obtained from certain insects. It is so called because this and mitochondrial glycerol 3-phosphate oxidase play a major role in the transfer of energy needed for flight in insects.

**flip-flop** 1 (*in electronics*) a circuit or device having two stable states and two inputs corresponding to these states. The device remains in either state until caused to change to the other state by application of an appropriate signal to the inputs. 2 (*in enzymology*) a mechanism in which a functional interrelationship between distinct active sites on identical monomers, which are parts of an oligomeric enzyme showing Michaelian kinetics, is mediated by a structural modification, the flip-flop transition. *Compare* half-of-the-sites reactivity. 3 (*in genetics*) the informal name for a reversible, reciprocal exchange between recombinating segments of DNA in site-specific recombination systems in prokaryotes or eukaryotes. *See also* transposable element.

**flipping** a jargon term used in nuclear magnetic resonance spectroscopy for the change in orientation of an atomic nucleus from an angle  $\phi_0$  to  $(180 - \phi_0)$ , with respect to the direction of the magnetic field, caused by absorption of radiation energy of a specific radiofrequency.

**flocculate** to aggregate or cause to aggregate into 'woolly' clusters or masses.

**flocculation** 1 the act or process of flocculating (*see* flocculate). 2 the product of such an act or process.

**flocculation reaction or flocculation test** a precipitin test in which the precipitate appears as floccules.

**floccule** a small aggregated mass of flocculent material.

**flocculent** 1 having the appearance of wool or down. 2 (*in*

## fludrocortisone

*chemistry*) consisting of or occurring as small woolly or downy aggregates. 3 (*in biology*) covered with waxy flakes or tufts resembling wool.

**flora** 1 collective term for all the plants, or plant life, characteristic of a given place or period. 2 microbial flora; the microbial population of part of the body, e.g. of the gut, skin, etc. 3 a comprehensive treatise or list of all the plants or plant life of a particular region or period.

**Florey, (Sir) Howard Walter**, Lord Florey (1898-1968), Australian physiologist and experimental pathologist distinguished particularly for his role in the development of penicillin (with E. B. Chain) and cephalosporin C as clinically useful antibacterial agents; Nobel Laureate in Physiology or Medicine (1945) jointly with E. B. Chain and A. Fleming 'for the discovery of penicillin and its curative effect in various infectious diseases'.

**Florisil** the proprietary name for a type of activated magnesium silicate. It is an adsorbent and is useful for column chromatographic separation of lipids.

**flotation coefficient** a name sometimes given to a negative sedimentation coefficient.

**flow birefringence or double refraction** flow the birefringence induced in a fluid by shear, which causes orientation of any asymmetric molecules in the fluid.

**flow cabinet** another name for safety cabinet.

**flow cell** any cell (def. 2) so constructed that appropriate measurements (as of absorbance) may be made on a flowing fluid.

**flow cytofluorimeter** a flow cytometer in which fluorescence of the objects being counted is monitored.

**flow cytometer** an apparatus for flow cytometry in which cells, or subcellular components (e.g. isolated chromosomes), in aqueous suspension are made to flow at high speed, in single file, through a sensing region where optical or electric signals indicative of some important physical or chemical properties of the cells, or components, are generated. These signals are analysed and accumulated in a computer for quantitative evaluation. Typical flow rates that can be achieved are in the region of 1000 cells per second. *See also* flow sorter, fluorescence-activated cell sorter.

**flow cytometry** the technique for counting or measuring some property of cells, or subcellular components, using a flow cytometer, often after labelling with a fluorescent marker.

**flow dichroism** dichroism (deL I) induced in a fluid by shear, which causes orientation of any asymmetric molecules in the fluid.

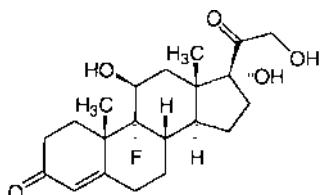

**flower** the reproductive structure of angiosperm plants. It consists generally of sepals, petals, and stamens and/or carpels. It is basically a highly modified leafy shoot.

**flow-signal** an earlier term for rheosome.

**flow sorter** (for cells) a flow cytometer to which has been added a device for physically separating cells, or subcellular components, of desired characteristics in order to provide subpopulations of high homogeneity. Typically the cell suspension is forced out of an orifice, 50-100  $\mu\text{m}$  in diameter, forming a high-speed liquid jet in air. Optical sensing of the jet takes place near the orifice and the jet is then broken up into uniform droplets by applied ultrasonic vibration. The droplets then traverse a region of high-intensity constant electric field where the decision-making and charging circuits, activated by the sensors, cause only droplets containing the wanted cells to be charged and deflected by the electric field into a separate collector.

**fluctuation test** a method of statistical analysis used to determine whether selected variants, e.g. phage- or drug-resistant bacterial mutants, arose spontaneously prior to exposure to the selective agent or were caused by the agent.

**fludrocortisone** 9a-fluorohydrocortisone (IIP)-9-fluoro-11,17,21-trihydroxypregn-4-ene-3,20-dione; a corticosteroid with about 10 times the glucocorticoid action of cortisol, but with 300-600 times greater mineralocorticoid action. It is used topically in ointments.

fludrocortisone

**fluence symbol:** For  $H$ ; (in photochemistry) the energy delivered in a given time interval,  $dt$ ;  $F = JIdt$  where  $I$  is the radiant intensity and  $t$  is time. It is expressed in  $J\text{ m}^{-2}$ .

**fluence rate** fluence per unit time; it is commonly referred to (strictly incorrectly) as flux.

**fluid** 1 any substance that can flow; any portion of matter in which the components (molecules or particles) continuously change their relative positions. In physics, the term comprehends any liquid or gas; in biology (and in common usage) it generally denotes only a liquid, especially one present in, or secreted by, a living organism. 2 able to flow or to change shape easily; not solid or rigid; liquid. 3 of, concerned with, or using fluid, a fluid, or fluids.

**fluidity (in physics)** the reciprocal of the viscosity of a fluid.

**fluid mosaic model** a model of cell-membrane structure in which the proteins that are integral to the membrane are considered as a heterologous set of globular molecules, each arranged in an amphipathic structure, i.e. with their ionic and highly polar groups protruding from the membrane into the aqueous phase and their nonpolar groups largely buried in the hydrophobic interior of the membrane. These globular molecules are partially embedded in a matrix of phospholipid, the bulk of which is organized as a discontinuous, fluid bilayer, although a small fraction of the lipid may interact specifically with the membrane proteins. Thus the fluid mosaic structure is formally analogous to a two-dimensional oriented solution of integral proteins (or lipoproteins) in a viscous phospholipid bilayer solvent.

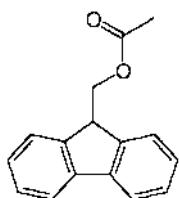

**Fluon** a proprietary name for polytetrafluorethylene.

**fluor** or **lumiphor** or **scintillator** any substance that displays fluorescence when excited by electromagnetic or particulate radiation. Fluors are useful especially in scintillation counters.

**fluor+** a variantform offluoro+(sometimes before a vowel).

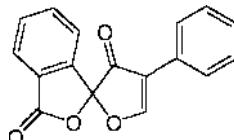

**fluoracetate** see fluoroacetate.

**fluorenylmethoxycarbonyl symbol:** Fmoc; **abbr.:** FMOC; fluoren-9-ylmethoxycarbonyl; a group used for linkage to amino groups for the purpose either of forming fluorescent amino-acid derivatives that can readily be detected after column chromatography, or to protect the amino groups of amino acids or nucleotides while other functional groups are undergoing reaction. Reagents useful for introducing the group are 9-fluorenylmethyl chloroformate and 9-fluorenylmethyl succinimidyl carbonate.

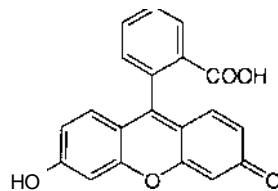

**fluonscamine** 4-phenylspiro[furan-2(3H),1'-(3'H)-isobenzofuran]-3,3'-dione; a nonfluorescent compound forming fluor-

escent structures on reaction with primary amines. *Proprietary name:* Flaram.

**fluorescein** 9-(2-carboxyphenyl)-6-hydroxy-3H-xanthen-3-one; Acid Yellow 73; CI 45350; an orange-red dye, the sodium salt of which is freely soluble in water to give a solution with yellowish-green fluorescence (to a dilution of 0.02 ppm) under UV light. Certain derivatives, e.g. fluorescein isothiocyanate, are useful for fluorescein labelling and others, e.g. the nonfluorescent fluorescein diacetate, are useful as substrates for the detection and assay of esterases.

**fluorescein labelling** the introduction of fluoresceinyl groups (see fluorescein) into biopolymers for fluorescence polarization studies and fluorescence immunoassay techniques.

**fluorescence** 1 a type of luminescence that consists of the emission by a substance of electromagnetic radiation, especially visible light, as a result of and immediately (10–100 ns) after the absorption of energy derived from exciting radiation of another, usually shorter, wavelength or from incident subatomic particles (especially electrons or alpha particles); the property of emitting such radiation. 2 the radiation emitted during fluorescence (def. 1). *Compare* phosphorescence. -fluorescent, fluorescing *adj.*; fluoresce *vb.*

**fluorescence-activated cell sorter or fluorescence-assisted cell sorter abbr.:** FACS; a type of flow sorter in which cells are characterized and sorted by the intensity of the fluorescence they emit when passing through an exciting laser beam.

**fluorescence depolarization or depolarization of fluorescence** the phenomenon occurring when fluorescence is excited by plane polarized radiation; the emitted radiation is always partially depolarized (see fluorescence polarization). The extent of such depolarization is due, *inter alia*, to the motion of the absorber (i.e. Brownian motion) and to energy transfer between like chromophores. Fluorescence depolarization can be used to follow the changes in the motion (rotation) of an entire macromolecule, or of a part of the molecule, to which fluorescent chromophores are attached; it can also be used to indicate the environment of a fluorescent probe in, e.g., a membrane – an environment that results from less tightly packed structures permits greater movement of the probe molecule, thus leading to greater depolarization. *See also* photon counter, time-resolved fluorescence polarization.

**fluorescence energy transfer** a process of energy transfer between two fluorophors, which can occur when the emission spectrum of the first fluorophor overlaps the absorption spectrum of the second fluorophor. Quenching of the emission from the first compound occurs but the excitation energy is absorbed by the second compound, which then emits its own characteristic fluorescence. If the two fluorophors are attached at different positions to a macromolecule, observations

## fluorescence enhancement

of fluorescence energy transfer between them may be used to determine the distance between the two attachment positions. fluorescence enhancement or enhancement of fluorescence a phenomenon occurring with a number of fluorophors whose fluorescence is markedly dependent on the polarity of the medium, in which fluorescence is greatly enhanced in a non-polar or rigid environment, but strongly quenched in an aqueous environment. Examples are 8-anilinonaphthalene sulfonate (ANS) when bound to an antibody or trapped in the hydrophobic environment within a protein; and ethidium when intercalated into double-helical regions of a nucleic acid.

fluorescence immunoassay or fluorescent immunoassay or fluoroimmunoassay abbr.: FIA; a method of assaying very small amounts of material that is similar in principle to radioimmunoassay but uses a fluorescent rather than a radioactive label for the antigen. Various techniques can be used for determination of the ratio of bound to free labelled antigen that do not necessitate a separation of the two; these may depend instead on fluorescence energy transfer, fluorescence enhancement, fluorescence depolarization, fluorescence quenching, or other phenomena.

fluorescence in Bitulhybridization abbr.: FISH; a procedure that involves the use of DNA probes to locate in a tissue section specific regions of DNA in the chromosomes. The probes are tagged with a selection of fluorescent molecules that are both excited by and emit light of different wavelengths and hence different colours. The structure and behaviour of individual chromosomes at all stages of the cell cycle can thereby be studied.

fluorescence microscopy a type of light microscopy by means of which fluorescent substances in a specimen may be detected and examined. Exciting light, commonly UV and of appropriate wavelengths, is isolated by means of a suitable filter placed between the light source and the condenser, and emitted radiation is selected by a different filter placed between the objective lens and the eye-piece. The technique is useful for visualizing certain components that are difficult to see by direct light, for localizing fluorescent substances bound to specific components of the specimen, and for determining the orientation of a specimen using the fluorescence depolarization technique.

fluorescence photobleaching recovery an alternative name for fluorescence redistribution after photobleaching.

fluorescence polarization or polarization of fluorescence the phenomenon that the light emitted from a fluorescent molecules is always partially polarized. This is true whether or not the exciting radiation is plane polarized. In consequence, when plane polarized radiation is used to excite fluorescence, fluorescence depolarization occurs.

fluorescence probe or fluorescent probe any small molecule that undergoes changes in one or more of its fluorescence properties as a result of noncovalent interaction with a protein or other macromolecular structure. Such probes are useful for studying the properties and behaviour of macromolecules. See probe (def. I).

fluorescence quantum yield in any fluorescent system, the ratio of the number of photons emitted to the number of photons absorbed; the fraction of excited singlets that become de-excited by fluorescence. See also quantum yield (def. I).

fluorescence quenching the reduction in the fluorescence quantum yield of a system due to de-excitation of the fluorescent molecules by environmental factors such as collision or complex formation with quenchers in the system, or by fluorescence energy transfer to them. The phenomenon is useful in studies of the binding of small molecules to proteins and other macromolecules.

fluorescence redistribution after photobleaching abbr.: FRAP; a technique, also termed fluorescence photobleaching recovery, for measuring two-dimensional lateral mobility of fluorescent particles in small ( $\approx 10 \mu\text{m}^2$ ) regions of a cell surface. A small spot on the surface is photobleached by a brief

## fluorography

exposure to an intense, focused laser beam, and the subsequent recovery of fluorescence, due to replenishment of intact fluorophor in the bleached spot by lateral transport from the surrounding surface, is followed.

fluorescence spectrophotometry the measurement, by means of a spectrofluorometer, of the wavelengths and the intensities of the light emitted from a fluorescent sample that is excited by more or less monochromatic exciting radiation.

fluorescence spectrum the emission spectrum of a fluorescent system that is excited by radiation of a given wavelength. Compare excitation spectrum.

fluorescent antibody technique an immunofluorescence technique in which antibody conjugated with a fluorophor is used to locate corresponding antigen in tissue sections or smears.

fluorescent immunoassay a variant spelling of fluorescence immunoassay.

fluorescent probe a variant spelling of fluorescence probe.

fluorescent screen a screen coated with a substance, e.g. zinc sulfide or calcium tungstate, that fluoresces when irradiated with electromagnetic radiation of certain wavelengths or with particulate radiation.

fluori+ a variant form of (sometimes before a vowel) fluor+.

fluoridation the addition of up to approximately 1 ppm of fluoride ion to a drinking water supply with the object of reducing tooth decay in consumers of the water. -fluoridate vb.

fluorimeter a variant spelling of fluorometer.

fluorinate 1 to treat or react (a substance) with difluorine. 2 to introduce (one or more) fluorine atoms into (a molecule of an organic compound), whether by addition or by substitution. -fluorinated adj.; fluorination n.

fluoro+ or (sometimes before a vowel) fluor+ comb. form 1 denoting a fluorine in organic linkage. 2 or fluori+ indicating fluorescence.

fluoroacetate the anion of fluoroacetic acid (= fluoroethanoic acid); a toxic substance found in the leaves of *Dichapetalum cymosum* and other plants that in animals is converted enzymically into fluorocitrate. Fluoroacetate and fluoroacetamide have been used as rodenticides.

fluorochrome any substance exhibiting fluorescence, especially one used to impart fluorescence to another molecule or to a specific structure in a biological specimen.

fluorocitrate the trianion of 1-fluoro-2-hydroxy-1,2,3-propanetricarboxylic acid; an extremely toxic substance formed in animal tissues from fluoroacetate. Fluorocitrate is a potent inhibitor of aconitase; it is believed that the fluorine atom interacts strongly with the  $\text{Fe}^{2+}$  ion at the active centre of the enzyme thereby inhibiting its activity. See also lethal synthesis.

fluorodeoxyuridine see fluorouracil.

fluorodeoxyuridylate see fluorouracil.

fluorodinitrobenzene see Sanger's reagent.

fluorogen the nonfluorescent precursor of a fluorophor. fluorogenic 1 producing fluorescence. 2 of or pertaining to a fluorogen; e.g. a fluorogenic substrate is a nonfluorescent material that can be acted on by an enzyme to produce a fluorescent substance.

fluorogram 1 or (sometimes) autofluorogram an autographic image derived by fluorography (def. 1). 2 or fluorograph a photographic image produced by fluorography (def. 2).

fluorography 1 or autofluorography or scintillation autoradiography or scintillation autoradiography an elaboration of autoradiography that shows a considerable increase in the efficiency of detection of low-energy-beta-particle-emitting nuclides, e.g. carbon-14, sulfur-35, and (especially) tritium, in preparations such as thin-layer chromatograms, gel electrophoretograms, tissue or whole-body sections, etc. The otherwise poor response of autoradiography in these situations results from internal absorption of most of the emitted radiation by the specimen in question. In fluorography this effect is diminished by impregnating the specimen (which preferably should be translucent and colourless) with fluor(s) prior to placing it in

**fluoroimmunoassay**

contact with an appropriately sensitive photographic emulsion or film, which then responds both to direct emission of beta particles from the specimen and to emission of photons of UV light (scintillations) generated by beta particles, exciting the fluor within the specimen. 2 photography of a fluorescent body, especially of an image on a fluorescent screen. -fluorograph *n.*, *vb.*; fluorographic *adj.*

**fluoroimmunoassay** *abbr.*: FIA; a variant spelling of fluorescence immunoassay.

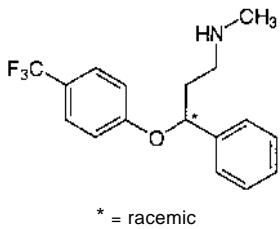

**fluorometer** or fluorimeter 1 a device for measuring the intensity and duration of fluorescence. 2 a device that may be attached to a fluoroscope to enable the position of a sought object to be determined with precision. -fluorometric or fluorimetric *adj.*; fluorometry or fluorimetry *n.*

**fluorophor** or fluorophore 1 a group of atoms in a molecule that renders the latter fluorescent. 2 a fluorescent substance.

**fluoroscope** 1 a screen coated with a substance that fluoresces when excited by X-rays; it is used to view the X-ray image of an object. 2 a device used to compare the fluorescence of a solution with that of a standard.

**fluorouracil** *symbol*: FUra (*not FU*); 5-fluorouracil; 5-fluoro-2,4(1H,3H)-pyrimidinedione; a synthetic analogue of uracil that is enzymically converted via its P-D-ribofuranoside, fluorouridine (*symbol*: FUDr), to fluorodeoxyuridine (*symbol*: FdUrd) and then to fluorodeoxyuridylate, which is a potent inhibitor of thymidylate synthase and, hence, of DNA synthesis. Thus fluorouracil is a suicide inactivator of thymidylate synthase. Fluorouracil and fluorodeoxyuridine are anticancer drugs, commonly used in combination therapy against fast-growing tumours.

**fluoxetine** ( $\pm$ )-N-methyl- $\gamma$ -[4-(trifluoromethyl)phenoxy]benzenepropanamine; a serotonin uptake inhibitor, used as an anti-depressant, particularly as the hydrochloride (*proprietary name*: Prozac).

**flush end** or blunt end an end of a duplex DNA fragment in which the two strands are coextensive, i. e. terminate at the same point. Such ends may be formed by scission of duplex DNA with some types of endonucleases. *Compare* cohesive end. -flush-ended *adj.*

**flux** 1 the rate of passage of energy or matter (usually in crossing a given area or passing through a given volume) under steady-state conditions. *See* diffusion coefficient, luminous flux, radiant power. 2 the number of particles passing through unit cross-sectional area of beam per unit time. 3 the rate of (chemical or physical) transformation of a substance within a living cell or tissue; the rate of translocation of a substance within a living cell or tissue, especially across a cell membrane. Such processes are usually measured in moles per second. *See also* metabolic flux. 4 the strength of a field of force orthogonal to unit area. *See* magnetic flux. 5 an alternative term for flux density (def. 2).

**flux control coefficient** *symbol*:  $C_E^J$ ; in a metabolic sequence at steady state, the response,  $\delta J$ , of the original system flux,  $J$ , to a small change,  $\delta E$ , in either the concentration or one of the kinetic parameters of a specified enzyme,  $E$ ; it is given by:

$$C_E^J = \left( \frac{\partial J/E}{\partial E/E} \right) p, q, r, \dots$$

and similarly for every other enzyme in the system. This is the

flux control coefficient of the enzyme  $E$  on the flux  $J$ . and is also called sensitivity coefficient or control strength. Similarly one can calculate a flux control coefficient for the substrate concentration,  $S$ , on the flux,  $J$  (this is also called sensitivity or net sensitivity) and a flux control coefficient of an effector concentration,  $I$ , on the flux,  $J$  (this is also called control strength).

**flux density** 1 (of energy or field strength) the flux per unit cross-sectional area; *see* luminous flux density, magnetic flux density. 2 or (sometimes) flux (of particulate radiation, including photons) the arithmetic product of the particle density and the mean velocity of the particles; neutron flux (density).

**flux-ratio method** a method for investigating the mechanisms of enzymic reactions in which simultaneous measurements are made of the rates of enzyme-catalysed isotopic transfers from one product to two substrates while the reaction system is in a steady state. It provides relatively unambiguous information about the order of binding of substrates.

**Fm** *symbol* for fermium.

**fMet** *symbol* for a residue of the  $\alpha$ -acylamino acid N-formyl-L-methionine.

**FMN** *abbr.* for flavin mononucleotide.

**FMN adenyllyltransferase** EC 2.7.7.2; *other name*: FAD pyrophosphorylase; an enzyme of the pathway for biosynthesis of FAD. It catalyses the reaction of ATP with FMN to form FAD with release of pyrophosphate.

**FMNH<sub>2</sub>** *symbol* for flavin mononucleotide (reduced).

**Fmoc** *symbol* for the fluorenlylmethyloxycarbonyl group.

**FMO<sub>C</sub>** *abbr.* for the fluorenlylmethyloxycarbonyl group.

**fmol** *symbol* for femtomole ( $10^{-15}$  mole).

**FMS** *symbol* for either the retroviral oncogene, *v-fms*, which is carried by the McDonough strain of feline sarcoma virus, or its related protooncogene, *c-fms*, which encodes the M-CSF-I receptor precursor (*see* colony stimulating factor). The latter is a type I transmembrane protein of the immunoglobulin superfamily; database code KFMS\_HUMAN, 972 amino acids (107.83 kDa). It possesses intrinsic protein tyrosine kinase activity within its cytoplasmic domain, which is activated by the binding of CSF-I (*see* colony stimulating factor) to the extracellular domain. Its transforming counterpart, *v-fms*, encodes a constitutively active receptor kinase that can transform both fibroblasts and hematopoietic cells in a CSF-I-independent manner. Mutations in the *c-fms* gene as well as a critical alteration of the 3' coding sequences appear to be responsible for fully activating its latent transforming potential. In the *v-fms* protein product, 40 C-terminal amino acids of the normal CSF-I receptor are replaced by 111 unrelated residues, suggesting that residues near the C terminus normally negatively regulate kinase activity in the absence of CSF-I.

**f-number** the numerical value of the relative aperture of a lens; it is the ratio of the focal length of a lens to its diameter.

**foam** 1 a dispersion in which a large proportion of gas by volume, in the form of gas bubbles usually  $>1$   $\mu\text{m}$  in diameter, is dispersed in a liquid, solid, or gel. 2 to produce or cause to produce such a foam.

**foam fractionation** a method of separation in which a component of the bulk liquid is preferentially adsorbed at the liquid/vapour interface and is removed by foaming.

**foaming agent** a surfactant that when present in small amounts facilitates the formation of a foam and/or stabilizes it.

**focal contact** any of the areas on the surface of fibroblasts where actin-containing microfilaments terminate. The filaments are involved both in the attachment of the cells to the substrate and in cell movement.

**fodrin** or brain spectrin or calspectin a protein from bovine brain, immunologically related to spectrin, that is involved in secretion, interacts with calmodulin in a calcium-dependent manner, and thus is a candidate for the calcium-dependent movement of the cytoskeleton at the membrane. It contains 20 repeats of 106 amino-acid residues; example from mouse (partial sequence): database code FODA\_MOUSE, 381 amino

acids (43.26 kDa).

*foetal* a variant spelling *offetal* (see *fetus*).

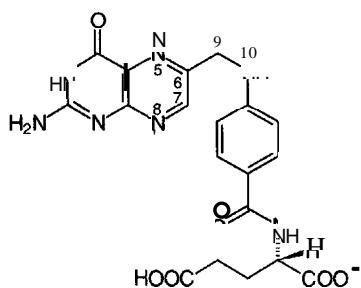

*foeto-* a variant spelling *offeto-*.

*foetus* an etymologically misconceived variant spelling *offetus*.

*folacin* a common name for folic acid.

*folate* 1 the recommended trivial name for pteroylglutamate;

N-[4-[(2-amino-3,4-dihydro-4-oxopteridin-6-yl)methyl]amino]benzoyl-L-glutamate; the anion of folic acid (def. 1). 2 any member of the family of pteroylglutamates, irrespective of the level of reduction of the pteridine ring, of the nature of anyone-carbon substituent, and of the number of glutamate residues. See also folic acid (def. 2).

*folate coenzyme* any of various interconvertible tetrahydrofolates that bear a one-carbon substituent and function as coenzymes in metabolic reactions involving the transfer of one-carbon units. The substituent may be 5-formimino, 5-formyl, 10-formyl, 5,10-methenyl, 5-methyl, or 5,10-methylene.

*Folch-Lees protein* the most abundant type of protein that is extractable from central-nervous-system myelin by chloroform:methanol (2:1 v/v); it is of at least 150 kDa and contains a high proportion of aliphatic amino acids. Compare *Wolfgang proteolipid protein*.

*Folch method* a method for the fractionation and isolation of lipids from either tissues or fluids. It involves extraction with various chloroform-methanol-water mixtures.

*fold* a description of protein conformations; there is no universally agreed criterion for proteins to be regarded as having the same fold but folds appear in the SCOP and CATH hierarchies (see Appendix E, Table 3).

*foldback DNA* an alternative term for hairpin DNA. See *hairpin*.  
*folding (in molecular biology)* 1 the process whereby an unorganized polypeptide acquires a specific three-dimensional structure. 2 the detailed pattern of three-dimensional structure of a native protein molecule.

*folding unit* a locally ordered region within the hydrophobic core of a globular protein molecule, formed by three-dimensional interaction between two or three segments of secondary structure (a helix and/or  $\beta$  strand) that are near one another along the polypeptide chain. The most important types are: (aa), ( $\alpha\beta$ ), ( $\beta\beta\beta$ ), ( $\beta\alpha\beta$ ). See also *domain*.

*folic acid* abbr.: (not recommended) FA or F; 1 the recommended trivial name for pteroylglutamic acid, the corresponding acid of folate (def. 1). 2 or folacin the name under which any folate (def. 2) is generally known in medicine, nutrition, etc. Folic acids are widely distributed members of the vitamin B complex, particularly plentiful in green leafy vegetables, liver, and yeast. Folates are essential for the synthesis of purines and pyrimidines, functioning as carriers of one-carbon units. A deficiency in humans results in megaloblastic anemia and in birth defects in children born to deficient mothers. Folic acids are also growth factors for certain microorganisms. See also *folinic acid*.

*folic acid conjugate* the corresponding acid of any folate (def. 2) containing two or more glutamyl residues.

*folic acid reductase* an alternative name for dihydrofolate reductase.

*Folin-eicolteau reagent* a phosphomolybdate tungstic acid reagent that gives a blue colour with phenols. The reagent has been used in the determination of tryptophan and tyrosine in proteins and peptides. See also *Lowry method*.

*folinic acid* 1 or (formerly) citrovorum factor (abbr.: CF) or (formerly) leucovorin or 5-formyltetrahydrofolic acid 5-formyl-5,6,7,8-tetrahydropteroyl-L-glutamic acid; the common name for the corresponding acid of folinate (5-formyltetrahydrofolate), a folate coenzyme discovered to be a growth factor for the bacterium *Leuconostoc citrovorum* (hence its former synonyms). Folinate is an intermediate in the metabolic conversion of formiminoglutamate to glutamate, ammonium, and active one-carbon. The calcium salt, calcium folinate (or formerly calcium leucovorin), is useful therapeutically, e.g. as an antidote to doses of methotrexate or other folate antagonists. 2 name sometimes used for certain other folates, e.g. tetrahydrofolate, especially as growth factors for microorganisms.

*Folin-Lowry method* a sensitive method of protein assay in which protein reacts both with an alkaline copper tartrate solution and with the Folin-Ciocalteu reagent to give a blue colour, the absorbance of which is measured at 750 nm. Compare *Lowry method*.

*Folin reaction* a colorimetric reaction used for the determination of ammonia and amino-acid nitrogen in which a red colour is produced when an alkaline solution of amino acids is treated with 1,2-naphthoquinone-4-sulfonate. [After Otto Knute Olof Folin (1867-1934).]

*Folin-Wu reagent* a phosphomolybdic acid solution, containing a little tungstate, used in the determination of glucose. It gives a blue colour with the copper (I) oxide produced when the sample containing glucose is heated with an alkaline copper (II) solution. [After Otto Knute Olof Folin (1867-1934) and Hsien Wu (1893-1959).]

*folliberin* the recommended name for follicle-stimulating hormone releasing hormone (abbr.: FSH-RH or FRH). Luteinizing hormone releasing hormone (abbr.: LHRH) stimulates not only release of luteinizing hormone from the anterior pituitary but also release of follicle-stimulating hormone. This activity is commonly named gonadotropin-releasing hormone. There is, however, evidence that a specific FSH-RH may exist in addition.

*follicle* 1 any small cavity or recess. 2 a cavity that has a secretory or excretory function, e.g. the Graafian follicle.

*follicle-stimulating hormone* abbr.: FSH; recommended name: follitropin; one of two gonadotropic glycoprotein hormones secreted by the anterior pituitary; of 34 kDa (human), 33 kDa (ovine), or 29 kDa (porcine), it consists of  $\alpha$  and  $\beta$  subunits, the  $\alpha$  subunit being almost identical within a given species to that of other glycoprotein hormones and the  $\beta$  subunit conferring hormonal specificity; the carbohydrate content is 16% (human), 8-9% (ovine), or 7-8% (porcine). In the female it stimulates the growth of Graafian follicles in the ovaries, whereas in the male it stimulates the epithelium of the seminiferous tubules to increased spermatogenesis. Example,  $\beta$  subunit from *Bos taurus*: database code FSHB\_BOVIN, 129 amino acids (14.71 kDa).

*follicle-stimulating hormone releasing factor* (abbr.: FRF or FSH-RF) or follicle-stimulating hormone releasing hormone (abbr.: FRH or FSH-RH) see *gonadotropin-releasing hormone*.

*follicular* 1 like, pertaining to, consisting of, or provided with a follicle or follicles. 2 affecting or involving follicles.

*follicular phase* see *estrous cycle*.

*folliculate* Cdl having or consisting of follicles.

*follipsin* a serine proteinase from pig ovarian fluid. It is a heterodimer, and cleaves Arg-I-Xaa bonds.

*follistatin* an activin-binding glycoprotein that regulates biosynthesis and secretion of follicle-stimulating hormone. Alternative isoforms are formed by alternative splicing. Example

**follitropin**

(precursor) from human; database code FSA\_RUMAN, 338 amino acids (37.33 kDa).

**follitropin** the recommended name for follicle-stimulating hormone.

**folyl** the trivial name for pteroylglutamyl, the acyl group derived from folic acid (def. I). Use of the name is no longer recommended.

**fomecin** any of several antibiotic substances produced by certain strains of the basidiomycetous fungus *Fomes juniperinus*, especially fomecin A, 2,3,4-trihydroxy-6-(hydroxymethyl) benzaldehyde.

**food** any material that can be ingested by an organism and metabolized to provide energy and precursors for biosynthetic reactions.

**footprinting** a technique for identifying sites where there is protein bound to DNA. Protein-DNA complexes are resistant to the action of nucleases, so that undegraded DNA (the 'footprint') remains after treatment with a nuclease.

**For symbol** for the formyl group, R-CO- (alternative to RCO).

**Forbes' disease** an alternative name for type III glycogen disease. [After Gilbert Burnett Forbes (1915-), US physician.]

**forbidden clone** a hypothetical clone of immunologically competent cells with specificity for some autoantigen that, in accord with the clonal selection theory, has become suppressed in the fetus but may be reactivated in adult life and cause an autoimmune disease.

**forbidden transition** any transition between energy states in an atom or molecule that is forbidden by the selection rules of quantum mechanics (but can occur nevertheless!).

**force symbol:** *F* (in physics) a vector quantity, the external influence that changes or tends to change the state of rest or uniform motion of a body, or the shape of a fixed body. The SI derived unit of force is the newton.

**formaldehyde** **dismutase** EC 1.2.99.4; systematic name: formaldehyde:formaldehyde oxidoreductase. An enzyme that catalyses a dismutation of two molecules of formaldehyde to formate and methanol. The enzyme functions to detoxify formaldehyde thus rendering the organism resistant to formaldehyde. Its synthesis is induced by addition of formaldehyde to the medium. Example from *Pseudomonas putida* (strain F61) DNA: database code PSEFDM, 399 amino acids (42.93 kDa).

**formaldehyde** **transketolase** EC 2.2.1.3; systematic name: D-xylulose-5-phosphate:formaldehyde glycolaldehydetransferase; other names: dihydroxyacetone synthase; DHAS; glycerone synthase. An enzyme that catalyses a reaction between D-xylulose 5-phosphate and formaldehyde to form glyceraldehyde 3-phosphate and glycerone; thiamine diphosphate is a coenzyme. The enzyme is important in organisms (some fungi and many prokaryotes) that can utilize methanol as a carbon source in converting formaldehyde, produced by methanol oxidation, into carbohydrate, xylulose 5-phosphate acting as C<sub>2</sub> donor. Example from *Hansenula polymorpha* (a species of yeast): database code DAS\_HANPO, 710 amino acids (78.75 kDa).

**formalin** or formol a 40% w/v aqueous solution of formaldehyde stabilized with approximately 12% v/v methanol. It is useful as a general disinfectant and for fixation and preservation of biological specimens.

**formate** 1 trivial and preferred name for metbanoate, the anion, H-COO<sup>-</sup>, derived from formic acid (methanoic acid). 2 any mixture of formic acid and its anion. It is useful as a buffer over the pH range 2.6-4.8; pK<sub>a</sub> (25°C) = 3.75. 3 any salt or ester of formic acid.

**formate-dihydrofolate ligase** EC 6.3.4.17; systematic name: formate dihydrofolate ligase (ADP-forming); an enzyme that catalyses the formation of 10-formyldihydrofolate from ATP, formate, and dihydrofolate with release of ADP and orthophosphate.

**formate-tetrahydrofolate ligase** EC 6.3.4.3; systematic name: formate:tetrahydrofolate ligase (ADP forming); other name: formyltetrahydrofolate synthetase; an enzyme involved

**formin**

in one of the transformations between folate coenzymes. It catalyses the formation of 10-formyltetrahydrofolate from ATP, formate, and tetrahydrofolate with release of ADP and orthophosphate. It is one of three enzymes (see also methenyltetrahydrofolate dehydrogenase (NADP<sup>+</sup>) and methenyltetrahydrofolate cyclohydrolase) necessary for the biosynthesis of purines, thymidylate, methionine, histidine, pantothenate, and formyl tRNA-Met. It is one activity of the trifunctional enzyme Cl-tetrahydrofolate synthase. See methenyltetrahydrofolate dehydrogenase (NADP<sup>+</sup>) for an example.

**formation constant** an alternative name for stability constant.

**formation function** see Sjerrum formation function.

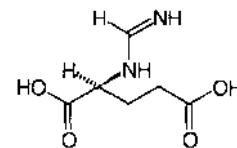

**formazan** 1 the compound NH<sub>2</sub>-N=CH-N=NH. 2 any substitution derivative of this compound. Many are brightly coloured and may be reversibly oxidized into the corresponding colourless tetrazolium compounds (see also Blue Tetrazolium). Formazans prepared by coupling the phenylhydrazones of acyclic aldoses with diazonium compounds are useful in characterizing such sugars.

**formed elements of the blood** a general term for the erythrocytes, leukocytes, and platelets.

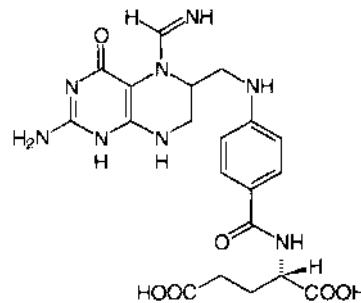

**formimidoyl** the acyl group, CH(=NH)-, derived from (the hypothetical) formimidic acid; the latter may also be regarded as the imino tautomer, CH(=NH)-OH, of formamide; hence also known as formimino.

**formimino** see formimidoyl.

**formiminoglutamate** abbr.: FIGLU; N-formimidoyl-L-glutamate; formamidino-L-glutarate; an intermediate in the catabolism of histidine. Its formimino (= formimidoyl) group is transferred to tetrahydrofolate to produce 5-formiminotetrahydrofolate. In folate (or vitamin B<sub>12</sub>) deficiency FIGLU accumulates in the tissues and its excretion in the urine increases. Estimation of the level of FIGLU in the urine is useful in assessing the extent of folate (or vitamin B<sub>12</sub>) deficiency.

**5-formiminotetrahydrofolate** a derivative of tetrahydrofolate that is an intermediate in the metabolism of one-carbon units. It is formed from tetrahydrofolate and formiminoglutamate, and with cyclodeaminase yields 5,10-methenyltetrahydrofolate.

**formin** one of several developmental nuclear phosphoproteins found in several tissue types. They are formed by alternative splicing of the mouse *Id* (limb deformity) gene. Mutations in this locus result in defects of growth and patterning of the limb and kidney during embryonic development. Example

formal

from *Mus musculus*: database code FORM\_MOUSE, 1468 amino acids (163.62 kDa).

**formol** (*formerly*) a proprietary name for formalin.

**formolize** or **formolise** to react the amino groups of amino acids, peptides, or proteins with formaldehyde.

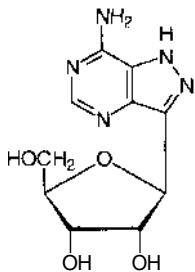

**formal titration** the pH titration, with alkali, of amino acids, peptides, or proteins in the presence of formaldehyde. The formaldehyde reacts with the amino groups and lowers their apparent *pK* values, allowing identification of the region in the titration curve where they are being titrated.

**formula** (*pl. formulas or formulae*) 1 (*in chemistry*) a collection of symbols of atoms and numbers giving information about the composition and structure of a molecular chemical entity.

2 (*in mathematics*) a general relationship, principle, or rule expressed in symbols, frequently as an equation. 3 a recipe, or prescription, for the preparation of a medicine, food, etc. giving the constituents, their amounts, and the method to be used.

**formula weight** a former name for relative formula mass.

**formycin** either of two related nucleoside antibiotics synthesized by the actinomycete *Nocardia interforma* that display antitumour activity. Formycin A; 8-aza-9-deazaadenosine; 7-amino-3-(*p*-D-ribofuranosyl)-1H-pyrazolo[4,3-d]pyrimidine; an analogue of adenosine that inhibits *de novo* purine biosynthesis in tumour cells and is incorporated into RNA. It is deaminated in erythrocytes to formycin B, a competitive inhibitor of NAD<sup>+</sup> in the action of NAD<sup>+</sup> ADP-ribosyltransferase and an inhibitor of purine nucleoside phosphorylase.

formycin A

**formyl symbol:** For or HCO; the acyl group, H-CO-, derived from formic acid.

**formylate** to introduce (one or more) formyl groups into an organic compound. -formylation *n*.

**N-formylmethionine symbol:** fMet; **codon:** AUG (when used as start codon for initiation) or GUG (when present as the first codon; within genes GUG encodes valine); a modified amino-acid residue which is found at the N terminus of nascent polypeptide chains in prokaryotes and bacteriophages. It is also present in the mitochondria and chloroplasts of eukaryotes, supporting the hypothesis that they are derived from prokaryotes.

**formylmethionine deformylase** EC 3.5.1.31; **systematic name:** N-formyl-L-methionine amidohydrolase; **other name:** polypeptide deformylase; an enzyme, found in prokaryotes, that removes the formyl group from the N-terminal *N*-formyl-methionine of many polypeptides produced by translation of mRNA; example from *Escherichia coli*: DEF\_ECOLI, 169 amino acids (19.33 kDa). See also post-translational modification.

**5-formyltetrahydrofolate** see folinic acid.

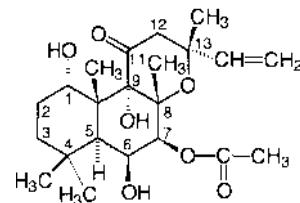

**5-formyltetrahydrofolate cyclo-ligase** EC 6.3.3.2; **other name:** 5,10-methenyltetrahydrofolate synthetase; an enzyme that catalyses the reaction between ATP and 5-formyltetrahydrofolate to form 5,10-methylenetetrahydrofolate with release of ADP and orthophosphate.

Forster theory

**formyltetrahydrofolate synthetase** see formate-tetrahydrofolate ligase.

**5-formyltetrahydrofolic acid** an alternative name for folinic acid.

**forskolin** colforsin; 7p-acetoxy-8,13-epoxy-1a,6p,9a-trihydroxyl-abd-14-en-II-one; a diterpene isolated from the roots of the Indian labiate plant *Coleus Jorskohlii*. It stimulates adenylate cyclase, has positive inotropic activity, and relaxes smooth muscle; at higher doses it is hypotensive and vasodilatory. The water-solubility of the active 7-0-hemisuccinyl-7-deacetyl- or (less potent) 7-deacetyl-6-(N-acetylglucyl)- derivatives is useful; the 1,9-dideoxy-derivative is inactive and can be used as a control.

**Forssman antibody** an antibody against Forssman antigen; it causes agglutination of sheep erythrocytes.

**Forssman antigen** or **Forssman hapten abbr.:** F antigen; a heterophil antigen, present on the tissue cells of many species, including horse, sheep, and mouse, but absent in human and rabbit. The glycolipid hapten (from horse) is a ceramide pentasaccharide, GaINAc(al-3)GaINAc(pl-3)Gal(α1-4)Gal(β1-4)Glc(β1-I)Cer; when incorporated in liposomes the nonpolar ceramide end anchors the hapten in the bilayer leaving the polar pentasaccharide region accessible to Forssman antibodies.

**Forster theory of fluorescence energy transfer** a theory giving the rate of dipole-dipole energy transfer in fluorescence as:

$$k_T = 8.71 \times 10^{23} (r^{-6} K^2 J n^{-4} k_F)$$

and the efficiency of transfer as:

$$E = r^{-6} / (r^6 + R_O^6),$$

where  $R_O$  the distance at which transfer efficiency is 50%, is given by:

$$R_O = 9.71 \times 10^3 (JK2Qo n^{-4})^{1/6} \text{ Å},$$

in which  $r$  is the distance between the centres of donor and acceptor chromophore,  $K^2$  is the orientation factor for a dipole-dipole interaction,  $J$  is the spectral overlap integral,  $n$  is the refractive index of the medium between the donor and acceptor,  $k_F$  is the rate constant for fluorescence emission by the energy donor, and  $Q_o$  is the quantum yield of fluorescence of the energy donor in the absence of the acceptor. For energy transfer to be efficient the fluorescence emission spectrum of the donor must overlap the absorption spectrum of the acceptor, i.e. the donor and acceptor must be in resonance, as measured by the spectral overlap integral  $J$ , which, in  $\text{cm}^3 \text{ M}^{-1}$ , is:

$$J = (F(\lambda) \epsilon(\lambda) \lambda^4 d\lambda) / (\int F(\lambda) d\lambda),$$

where  $F(\lambda)$  is the fluorescence intensity in arbitrary units of the energy donor at wavelength  $\lambda$  in nm, and  $\epsilon(\lambda)$  is the extinction coefficient of the energy acceptor in  $\text{cm}^{-1} \text{ M}^{-1}$ . The orientation factor,  $K^2$ , is given by:

$$K^2 = (\cos a - 3 \cos \beta \cos \gamma)^2,$$

where  $a$  is the angle between the donor and acceptor transition moments and  $\beta$  and  $\gamma$  are the angles between the donor moment and the acceptor moment and the line joining the cen-

## Forster transfer

tres of the donor and acceptor, respectively. [After T. Forster.]

Forster transfer the nonradiative, resonant energy transfer that occurs when electronic excitation of one chromophore in a molecule, or other structure, elicits fluorescence from a different chromophore located up to 5-7 nm distant. For example, excitation of a tyrosine residue in a protein molecule can lead to fluorescence from a tryptophan residue in the same protein, and excitation of a tryptophan residue can cause fluorescence of dyes attached to the protein surface or to an embedded coenzyme. Resonant energy transfer is important in photosynthesis; many of the chlorophyll molecules in a chloroplast transfer the energy they have absorbed to other chlorophyll molecules at reaction centres.

fortimycin any of several aminoglycoside antibiotics from the actinomycete *Micromonospora olivoasterospora*.

**FORTRAN** abbr. for formula translator; a high-level computer language much used in numerical applications and engineering and the development of structure refinement software in structural molecular biology.

forward mutation any gene mutation from wild-type to the mutant phenotype, as opposed to a back mutation.

forward scattering scattering of radiation in the direction of the beam of radiation, i.e. away from the radiation source.

**FOS** a gene family encoding nuclear transcription factors; *v-fos* is the oncogene of the FBJ and FBR murine osteosarcoma viruses and Fujinami (avian) sarcoma virus. *FOS* is rapidly (within 5 minutes) but transiently expressed following stimulation of cells by mitogens and also during the onset of differentiation and by wounding. The gene product, FOS, and JUN (from the related gene family *JUN*) form homo- and heterodimers that bind to DNA; the heterodimers bind to the AP-I consensus site (see *JUN*); FOS homodimers bind to the TPA response element (TRE) if GIU<sup>168</sup> is substituted by Lys. The proteins are members of the leucine zipper and helix-turn-helix superfamilies; five motifs; database code FOS\_HUMAN, 380 amino acids (40.65 kDa).

fosfomycin another name for phosphonomycin.

Fouchet's test a colour test for the presence of bilirubin in the urine. A green colour is produced when the sample is treated with iron (III) chloride solution and trichloroacetic acid.

Fourier analysis the fitting of the terms of a Fourier series to a set of periodic data.

Fourier series the expression of any ordinary, single-valued (univalent) periodic function:

$$y=f(x) \quad (I)$$

as the sum of an infinite number of sine waves of successively higher orders. Substituting  $n\theta$  for  $x$ , to be appropriate to circular functions,

$$y = a_0 + a_1 \cos \theta + a_2 \cos 2\theta + a_3 \cos 3\theta + \dots + b_0 + b_1 \sin \theta + b_2 \sin 2\theta + b_3 \sin 3\theta + \dots \quad (2)$$

The coefficients  $a_n$  and  $b_n$  can be uniquely determined by equating equations (I) and (2) point by point for successive values of  $x$  and solving the simultaneous equations so found. [After Jean Baptiste Joseph Fourier (1768-1830), French mathematician.]

Fourier synthesis the process of computing the form of a function from the values of the coefficients of its Fourier series.

FP abbr. for flavoprotein.

F6P abbr. for fructose 6-phosphate.

F-pilus a type of sex pilus, one or two of which may be present in each cell of 'male' strains of *Escherichia coli*. Each pilus is approximately 8 nm in diameter and up to 20  $\mu\text{m}$  long. F-pili are consistently associated with the presence in the bacterium of the **F'** plasmid, which directs their synthesis; they are believed to serve as conductors of nucleic acids in various circumstances, e.g. during bacterial conjugation.

F plasmid or F factor the prototype 'fertility factor' responsible for conjugation in the K-12 strains of *Escherichia coli* used in

## fragmentation

the early studies of bacterial mating. The letter F refers specifically to this plasmid and thus should not be used to refer to other naturally occurring conjugative plasmids.

**F'** plasmid or F' factor an F plasmid derivative incorporating a segment of the bacterial chromosome. An organism in which an F' plasmid has arisen and that carries a chromosomal deletion corresponding to the segment incorporated by the plasmid is termed a primary F'-containing strain, and an organism into which an F' plasmid has been transferred is termed a secondary F'-containing strain.

FPS see FES/FPS.

Fr symbol for francium.

fraction 1 (in chemistry) anyone of several portions of a mixture that can be separated by a fractional process, e.g. by fractional distillation or chromatography, and consisting either of a mixture or of a pure compound. 2 to separate or divide into portions; to fractionate.

fraction I-VI (of blood plasma) see Cohn fractionation.

fractional 1 of, relating to, or being a fraction. 2 of or denoting any process by which parts of a mixture are separated by exploiting differences in their physical properties, e.g. their boiling points, solubility, or chromatographic characteristics. fractional centrifugation an alternative name for differential centrifugation.

fractional crystallization the separation of substances with nearly the same solubilities. It involves a series of recrystallizations at each stage of which the crystals will be enriched in one component and the mother liquor will be enriched in the other component.

fractional distillation the process of separating the components of a mixture by heating it and separately condensing portions of vapour at different temperatures, corresponding to the boiling points of the components of the mixture.

fractional precipitation the stepwise separation of substances, especially macromolecules, from a solution by exploiting differences in their solubilities in various conditions of pH, ionic strength, dielectric constant, etc. Changes in these conditions are effected by the addition of acid, alkali, salt (e.g. ammonium sulfate), ethanol, or other substances.

fractional sterilization an alternative name for tyndallization.

fractionate 1 to separate (a mixture) or cause (a mixture) to separate into portions or fractions, e.g. by distillation or crystallization. 2 to obtain (a part of a mixture) by a fractional process. -fractionation *n*.

fractionating column a vertical tube or hollow column frequently forming part of an apparatus for fractional distillation and usually filled with packing or intersected with perforated plates. An internal reflux takes place during distillation resulting in a gradual separation between the high-boiling-point fractions and the low-boiling-point fractions, the lowest-boiling-point fraction distilling over first.

fraction collector or (sometimes) fraction cutter an apparatus for the automatic collection of consecutive, commonly equal-sized, fractions of a flowing liquid, e.g. of the eluate from a chromatographic column. The size of the fractions may be predetermined by volume, mass, time, or number of drops.

fraction cutter 1 the device in a fraction collector that separates the flow of eluate into fractions of predetermined size, which then may be individually collected. 2 (sometimes) an alternative name for fraction collector.

fraction I protein a former name for RuBP carboxylase; see ribulose bisphosphate carboxylase.

fragile X syndrome an X-linked inherited disorder, with mental retardation and connective tissue abnormalities, arising from a trinucleotide repeat of CGG.

fragment-antigen binding see Fab fragment.

fragmentation 1 (in cell biology) a the separation of a small piece (i.e. a fragment) of a chromosome from the rest. b the division of a cell nucleus by simple splitting. 2 (in chemistry) the breakdown of a radical into a diamagnetic molecule and a smaller radical; the breakdown of a radical ion in a mass

## fragment-crystallizable

spectrometer to form an ion of lower molecular mass and a radical.

fragment-crystallizable *see* Fc fragment.

fragment ion (*in mass spectrometry*) any ion produced by the loss of one or more pieces from a parent molecular ion (or larger fragment ion).

fragmentography *see* molecular fragmentography.

fragmin a  $\text{Ca}^{2+}$ -sensitive protein, of  $M_r$  43 000 and isolated from *Physarum polycephalum*, that regulates the length of actin filaments *in vitro*.

frame *short name for* reading frame.

frameshifting (*in ribosomal function*) *see* programmed ribosomal frameshifting.

frameshift mutagen any mutagen that is capable of causing frameshift mutations.

frameshift mutation or phaseshift mutation any mutation involving the addition or deletion of nucleotide residues in a DNA molecule that results in out-of-phase translation, at positions beyond the site of mutation, of the messenger RNA formed from it. Since the genetic code is read as unpunctuated base triplets, additions or deletions in the message that are not multiples of three bases result in a shift in the reading frame.

frameshift suppressor any of a class of external suppressor mutations that specifically suppress a frameshift mutation by changing (correcting) the phase of translation. Frameshift suppressors are genetic alterations outside the mutated cistron. Some give rise to altered tRNA molecules, frameshift suppressor tRNAs, that recognize a base quadruplet instead of a base triplet.

Franck, James (1882-1964) German-born US physicist notable for his work on quantum theory (with G. Hertz), on photochemistry (e.g. the Franck-Condon principle), and on the development of atomic energy (but in opposing the use of nuclear weapons); Nobel Laureate in Physics (1925) jointly with G. Hertz 'for their discovery of the laws governing the impact of an electron upon an atom'.

Franck-Condon principle the principle that the time taken for electronic transitions in molecules is very short in comparison with the period of vibration of the atomic nuclei, with the consequence that the nuclei do not appreciably alter their positions during the emission or absorption of a photon. [After J. Franck and Edward Uhler Condon (1902-74), US physicists.]

Frank, Il'ja Mikhailovich (1908-1990), Russian-born Soviet physicist noted for establishing the theoretical basis of the Cherenkov effect; Nobel Laureate in Physics (1958) jointly with P. A. Cherenkov and I. Y. Tamm 'for the discovery and interpretation of the Cherenkov effect'.

Franklin, Rosalind Elsie (1920-58) British biophysicist, who obtained X-ray data for DNA that were consistent with and provided insight that contributed to the proposal of a helical structure published by J. D. Watson and F. H. C. Crick.

**FRAT** abbr. and proprietary name for free radical assay technique (*see* spin immunoassay).

frataxin a 210-residue protein identified from a mutation found in Friedreich's ataxia (abbr.: FRDA). Some FRDA patients have point mutations in the gene encoding frataxin, but the majority are homozygous for an unstable GAA trinucleotide expansion in the first intron. The function of the protein is unknown.

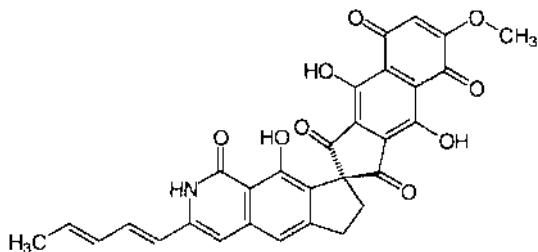

**fraudulent DNA** a DNA molecule containing fraudulent nucleotides.

**fraudulent nucleotide** any (artificial) nucleotide that contains a non-naturally occurring base that is an analogue of a purine or pyrimidine found in natural DNA.

**frayed end** (of DNA) an end region of a double-stranded polynucleotide in which there is imperfect complementarity of the base pairs.

**fredericamycin A** an antibiotic produced by *Streptomyces griseus* that contains a spiro ring system and is active against Gram-positive bacteria and fungi. It is cytotoxic against some transplantable tumours.

## freeze-etching

fredericamycin A

**free** (*in chemistry*) not chemically combined (with another substance); not physically bound (to another substance).

**free diffusion** diffusion in a gas phase or across a boundary between two solutions (or between a solution and pure solvent), as distinct from diffusion across a membrane or some other porous barrier.

**free-draining coil** a model for polymer molecules in solution that are not well approximated by a solid particle. In this model the polymer is considered as a string of beads through which the solvent streams during viscous flow.

**free electrophoresis** *an alternative name for* moving boundary electrophoresis (def. I).

**free energy** *an alternative name for* Gibbs energy.

**free energy change** *an alternative name for* Gibbs free energy change.

**free fatty acid** abbr.: FFA; a nonesterified fatty acid; the term is often used of such acids in the blood.

**free-flow electrophoresis** *an alternative name for* moving boundary electrophoresis (def. 1).

**free radical** *see* radical (def. I).

**free-radical scavenger** *the former term for* radical scavenger.

**free rotation** sterically unhindered rotation of atoms or groups about a single covalent bond.

**freeze-clamp** to halt abruptly the metabolic processes in a piece of tissue, or other specimen, by clamping it into a thin, frozen wafer between two aluminium (or other metal) plates, previously cooled in liquid nitrogen. The frozen specimen then may be pulverized and treated with a protein precipitant, e.g. acetone at -70°C. The technique is useful in the determination of the concentrations of various metabolites that otherwise are rapidly consumed by enzymic action continuing during an investigation.

**freeze-cleaving** *an alternative term for* freeze-fracturing; *see also* freeze-etching.

**freeze-dry** to dry in a frozen state at very low pressure (i.e. in a high vacuum) so that ice, or other frozen solvent, sublimes rapidly, leaving a porous solid; to lyophilize. Used, e.g. in histochemistry, as frozen biological material can be preserved by removal of water under vacuum without damage to cell structures.

**freeze-dryer** any apparatus used for freeze-drying.

**freeze-etching** or frozen replica method a technique of preparing, for electron-microscopic examination, a surface that has been exposed by fracturing or cutting a deep-frozen specimen. The sample is rapidly frozen to about -150°C and placed in a vacuum, where it is cleaved or sliced with a cold knife - the process known as freeze-fracturing. Etching is then achieved by evaporation of some of the solvent from the surface in a vacuum at about -100 °C to produce a textured field, in which nonvolatile macromolecules protrude from a frozen aqueous layer. A replica of the surface is then prepared by shadowing with carbon and/or a heavy metal while the sample is still in the vacuum. This replica is then lifted off, rinsed, and placed

## freeze-fracturing

on an electron microscope grid for examination. *See also* replica formation.

**freeze-fracturing** (in *electron microscopy*) a method of visualizing the interior of cell membranes in which cells are frozen at the temperature of liquid nitrogen in the presence of antifreeze and then the frozen block is cracked with a knife blade. The fracture plane often passes through the hydrophobic middle of lipid bilayers, thereby exposing the interior of cell membranes. The resulting fracture faces are shadowed with platinum, the organic material is dissolved away and the replicas floated off for electron microscopy.

**freeze-stop** to stop a reaction rapidly by freezing the reaction mixture; to freeze-clamp.

**freeze-thaw** to disrupt cells in a suspension, or to disperse emulsions, by repeated freezing and thawing.

**freezing** 1 the change of a liquid into a solid by a lowering of temperature. 2 the stopping of a reaction or other process at a particular point, often by a lowering of temperature. 3 or cryopreservation the use of temperatures below 0 °C in order to preserve biochemicals and foodstuffs, or to maintain viable populations of (micro)organisms.

**freezing-microtome** a microtome in which the tissue sample is frozen and maintained in a frozen state with liquid carbon dioxide. It is useful for (rapidly) obtaining sections of unfixed soft tissue. *Compare* cryomicrotome.

**freezing point** the temperature at which freezing (def. I) occurs.

**French chalk** *see* talc.

**French pressure cell** a device to disrupt chloroplasts and bacteria, yeasts, or other cells. A cell or chloroplast suspension is placed in a cylinder fitted with a piston and a narrow outlet controlled by a needle valve. After removal of air, the piston is forced into the cylinder with a hydraulic press to the desired operating pressure <>20 000 pound-force per square inch, 140 MPa). The valve is then opened. Extrusion through the narrow orifice together with the sudden release of pressure creates shear forces that break the suspended particles. *See also* Hughes press. [After Charles Stacy French (1907- ), US plant physiologist.]

**Freon** the proprietary name for any of a group of fluorocarbon or chlorofluorocarbon compounds that are clear, colourless liquids, chemically inert, and of low toxicity. They are useful as refrigerants, aerosol propellants, cleaning fluids, and solvents. These substances have been shown to be important in the chemical removal of ozone by chlorine-catalysed cycles in the polar region during winter and spring. Nitric oxide and ice-clouds are formed in the polar stratosphere during winter. Heterogeneous chemical reactions take place on the surface of these particles, dramatically shifting the balance between inactive and active forms of chlorine and increasing the efficiency of chlorine in catalytic ozone removal. The use of Freon is being phased out in many countries; it is being replaced by substances such as tetrafluoroethane (ICI Trademark KLEA) which are claimed not to cause depletion of ozone.

**frequency symbol:**  $\nu$  or  $f$ ; the number of complete cycles of any periodic process occurring in unit time. The SI derived unit of frequency is the hertz. The frequency of a wave is equal to its velocity divided by its wavelength.

**frequency distribution** a table, graph, or histogram constructed from a series of measurements to show the classes into which the measurements are divided and the numbers in each of these classes.

**fresnel** a non-SI unit of frequency of electromagnetic radiation, equal to  $10^{12}$  Hz.

**Fresnel diffraction** the diffraction occurring when electromagnetic radiation encounters abrupt discontinuities in refractive index, as in a Fresnel lens or in the examination of some specimens in (electron) microscopy. [After Augustin Jean Fresnel (1788-1827), French physicist.]

**Fresnel lens** a lens whose surface consists of a concentric series of lens sections (or one convex surface and one stepped sur-

## frontal analysis

face). This arrangement allows a thin lens of short focal length and large diameter to be easily made, and finds application in searchlights, viewing devices, and overhead projectors.

**fret** a broad membrane-bound channel interconnecting the grana of chloroplasts.

**Freund's adjuvant** a widely used immunological adjuvant (def. I), used to produce water-in-oil emulsions with aqueous antigens or antigen preparations. It consists of a mixture of mineral oil and emulsifier (incomplete Freund's adjuvant) in which killed mycobacteria have been dispersed (complete Freund's adjuvant). Omission of mycobacteria may modify the duration, intensity, and nature of the responses. [After Jules Freund (1891-1960).]

**Frey-Wyssling particle** a double-membrane particle (4-6  $\mu\text{m}$  in diameter) representing a minor component of rubber latex. [After Albert Frey-Wyssling (1900- ).]

**FRF abbr.** for follicle-stimulating-hormone-releasing factor; *see* gonadotropin-releasing hormone.

**FRH abbr.** for follicle-stimulating hormone releasing hormone; *see* gonadotropin-releasing hormone.

**friable** easily crumbled or pulverized.

**friction** the resistance to the relative motion of one body sliding, rolling, or flowing over another body with which it is in contact. -frictional *ad.*

**frictional coefficient or frictional constant symbol:**  $f$ ; the frictional force opposing the motion of a body in a fluid medium divided by the velocity of movement. It may be expressed in different ways. The translational frictional coefficient,  $f$ , for a rigid sphere of radius  $r$  moving at low velocity through a medium of viscosity  $\eta$ , is given by:  $f = 6\pi\eta r$  (Stokes' law of viscosity). For particles of other shapes additional terms must be included. The rotational frictional coefficient,  $f_{rot}$ , is a parameter relating the velocity of rotation of a rigid sphere of volume  $V$  in a fluid medium of viscosity  $\eta$ . It is given by:  $f_{rot} = 6\eta V$ . *See also* frictional ratio.

**frictional force** the force exerted on a particle moving through a fluid medium as a result of friction. It is the product of the velocity, relative to the medium, of the particle and its frictional coefficient.

**frictional ratio** the ratio of the experimentally determined translational frictional coefficient,  $f$ , of a hydrated, anisotropic macromolecule to the calculated frictional coefficient,  $f_0$ , of a nonhydrated spherical macromolecule of the same molecular mass. The ratio  $f/f_0$  gives some indication of the asymmetry of the macromolecule.

**Friedreich's ataxia** an autosomal recessive inherited disease that involves the central and peripheral nervous systems and the heart. It is the most common hereditary ataxia, and is associated with defects in the gene encoding frataxin.

**Friend cell** a cell of a cultured cell line of leukemic mouse erythroblasts obtained by transformation with Friend leukemia virus. In such cells development is arrested before any globin synthesis occurs, but treatment with certain chemicals, e.g. dimethylsulfoxide, causes a resumption of development and hemoglobin synthesis.

**Friend leukemia virus** a strain of mouse type C oncovirus that specifically affects immature erythroid cells in mice to cause an erythroleukemia. [After Charlotte Friend (1921- ).]

**frit filter or fritted filter or fritted glass filter** an alternative name for sintered glass filter.

**Fromm's method** a kinetic approach for studying the mechanism of action of enzyme systems that utilize three substrates. Such systems may be divided into two groups on the basis of their initial rate expressions: the first group is made up of sequential pathways of enzyme and substrate interaction alone, the second is the ping-pong type. The mechanisms in each category may further be separated either by initial rate measurements or from studies with competitive inhibitors. [After Herbert Jerome Fromm (1929- ), US biochemist.]

**frontal analysis** any analytical technique by which the progress of the separation of components of a mixture, as by

## frontal chromatography

frontal chromatography, moving boundary electrophoresis, or analytical ultracentrifugation, is followed, and the relative proportions of the components determined, by examination of the individual boundaries, or fronts, formed by each component with the solvent.

**frontal chromatography** a technique for chromatographic separation in which the sample (liquid or gas) is fed continuously into the chromatographic bed and only the component that emerges first is obtained in pure form.

**fronting (in chromatography)** the asymmetry of a peak such that, relative to the baseline, the front is less steep than the rear. In paper chromatography and thin-layer chromatography it refers to the distortion of a zone showing a diffuse region preceding the zone in the direction of flow.

**frontside attack** the mechanism of a chemical displacement reaction in which the configuration is retained.

**frozen replica method** *an alternative name for freeze-etching.*

**FRS abbr.** for Fellow of the Royal Society (of London).

**FRSE abbr.** for Fellow of the Royal Society of Edinburgh.

**Fru symbol** for a residue (or sometimes a molecule) of the ketohexose fructose. In the condensed system of symbolism of sugar residues, Fru signifies specifically a fructose residue with the common configuration and ring size, i.e. D-fructofuranose.

**fructan** any glycan composed only of D-fructose residues. Fructans occur commonly as food reserves in the roots, stems, leaves, and seeds of many plants, e.g. in tubers of dahlias and Jerusalem artichokes. There are two main types: (1) inulin-type, in which the fructofuranose residues are linked by  $\beta 2 \rightarrow 1$  glycosidic linkages; and (2) levan-type, in which the linkages are  $\beta 2 \rightarrow 6$ , which were formerly referred to as fruetosans.

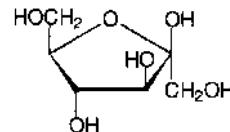

**$\beta$ -fructofuranosidase** EC 3.2.1.26; *other names:* invertase; saccharase; an enzyme that catalyses the hydrolysis of terminal nonreducing {J-D-fructofuranoside residues in {J-D-fructofuranosides, e.g. sucrose. Examples: precursors of invertases types 1,2 and 4 from yeast: database code INV1\_YEAST, 532 amino acids (60.50 kDa); INV2\_YEAST, 532 amino acids (60.57 kDa); INV4\_YEAST, 532 amino acids (60.51 kDa).

**fructokinase I** *the recommended name for the enzyme ATP:D-fructose 6-phosphotransferase; EC 2.7.1.4;* this catalyses the phosphorylation of D-fructose by ATP to form D-fructose 6-phosphate and ADP. The enzyme occurs in plants and in schistosomes, and is highly specific for D-fructose. In bacteria it is important in fructose utilization. Structurally it is similar to other carbohydrate kinases. Example from *Zymomonas mobilis*: database code SCRK\_ZYMMO, 301 amino acids (32.57 kDa). **2** *an alternative name for ketohexokinase (EC 2.7.1.3).* This usage is misleading since ketohexokinase yields D-fructose 1-phosphate.

**fructosaccharase** *a trivial name for any saccharase that attacks the fructose-containing end of appropriate oligosaccharides, liberating fructose.*

**fructosan I** *(formerly) a trivial name for 2,6-anhydrofructofuranose. 2 an (older) incorrect name for fructan.*

**fructose symbol:** Fru; *the trivial name for the ketohexose arabino-2-hexulose; there are two enantiomers. D-( $\text{--}$ )fructose (symbol: D-Fru), commonly known as fructose, and formerly known as fruit sugar, is levorotatory, hence formerly known also as levulose or (esp. UK) laevulose; it is the sweetest of the sugars. Aqueous solutions of D-fructose at room temperature contain an equilibrium mixture of {J-D-fructopyranose, {J-D-fructofuranose, a-D-fructofuranose, and the open-chain form, whereas in crystals the sugar is present entirely as {J-D-fructopyranose. Combined D-fructose is almost invariably in the furanose form, however. D-fructose is found free in a large number of fruits, in honey, and (as the sole sugar) in bull and human semen. In combined form it occurs at one residue per molecule of the disaccharide sucrose and the trisaccharides gentianose, melezitose, and raffinose, and as the sole component of the polysaccharide fructans.*

{J-D-fructofuranose

**fructose-bisphosphatase** EC 3.1.3.11; *systematic name:* D-fructose-1,6-bisphosphate 1-phosphohydrolase; *other names:* hexosediphosphatase; *(formerly)* fructose-1,6-diphosphatase. A phosphoric monoester hydrolase that hydrolyses D-fructose 1,6-bisphosphate to D-fructose 6-phosphate and orthophosphate. It is important in gluconeogenesis and in regulation of the reductive pentose phosphate cycle in chloroplasts. Example from rat: database code FI6P\_RAT, 362 amino acids (39.43 kDa); six motifs.

**fructose-2,6-bisphosphatase** an enzyme that hydrolyses fructose 2,6-bisphosphate to fructose 6-phosphate; it is the same protein as phosphofructokinase-2. *See* phosphofructokinase (def. 2).

**fructos-1,6-bisphosphatase deficiency** *see hereditary fructose-1,6-bisphosphatase deficiency.*

**fructose 1,6-bisphosphate or (formerly) fructose 1,6-diphosphate abbr.:** FBP; the Denantiomer is a metabolic intermediate in glycolysis and gluconeogenesis.

**fructose 2,6-bisphosphate** The Denantiomer is an important regulator of the glycolytic and gluconeogenic pathways. It inhibits fructose 1,6-bisphosphatase and activates phosphofructokinase, and its concentration is controlled by the phosphofructokinase (def. 2) and fructose 2,6-bisphosphatase activities of a 49 kDa protein.

**fructose-bisphosphate aldolase** EC 4.1.2.13; *systematic name:* D-fructose-1,6-bisphosphate D-glyceraldehyde-3-phosphate lyase; *other names:* aldolase; fructose-1,6-bisphosphate triosephosphate-Iyase. An enzyme that catalyses the reaction:

It is a universally distributed enzyme that functions in the pathways for both the catabolism and biosynthesis of glucose. Example from *Drosophila melanogaster*: database code NRL\_IFBAA, 360 amino acids (38.87 kDa); 3-D structure known.

**fructose-2,6-bisphosphate 2-phosphatase** EC 3.1.3.46; *other name:* fructose-2,6-bisphosphatase; an enzyme that catalyses the hydrolysis of D-fructose 2,6-bisphosphate to D-fructose 6-phosphate and orthophosphate, being part of the system for regulating the concelltration of fructose 2,6-bisphosphate. This enzyme is the phosphorylated form of the protein. If dephosphorylated, it functions as a 2-kinase for fructose 6-phosphate. Example, human liver isoform: database code F26L\_HUMAN, 471 amino acids (54.64 kDa). *See also* phosphofructokinase (def. 2).

**fructose-1,6-diphosphatase** *a former name for fructose-bisphosphatase.*

**fructose 1,6-diphosphate** *a former name for fructose 1,6-bisphosphate.*

**fructose disease** *see* essential fructosuria, hereditary fructose intolerance, hereditary fructose-bisphosphatase deficiency.

**fructose intolerance** *an alternative name for essential fructosuria.*

**fructose 6-phosphate abbr.:** F6P; the Denantiomer is an important intermediate in glycolysis, gluconeogenesis, and fructose metabolism.

**fructosuria** the presence of abnormal amounts of fructose in the urine. *See also* eSential fructosuria.

**Fru symbol** for a fructofuranose residue.

**fruit** the structure that develops from the fertilized ovary of a

**fruit fly**

flowering plant and contains the ripening seed or seeds. It may be fleshy or dry; the term is often extended to include other associated parts such as a fleshy receptacle.

**fruit fly** a common name for species of flies belonging to the genus *Drosophila*.

**fruit-ripening hormone** see **ethylene**.

**fruit sugar** a former name for the  $\alpha$  enantiomer of **fructose**.

**FSF** abbr. for fibrin-stabilizing factor (i.e. factor XIIIa); see **blood coagulation**.

**FSH** abbr. for follicle-stimulating hormone.

**FSH-RF** abbr. for follicle-stimulating hormone releasing factor; see **gonadotropin-releasing hormone**.

**FSH-RH** abbr. for follicle-stimulating hormone releasing hormone; see **gonadotropin-releasing hormone**.

**F, sphere** a submitochondrial structure containing the catalytic site for ATP synthesis.

**F'-strain** a bacterial strain containing an **F'** plasmid.

**F-type pentose phosphate pathway** see **pentose phosphate pathway**.

**ftz** the gene for Fushi Tazaru protein, a nuclear DNA-binding homeobox segmentation protein from *Drosophila melanogaster*. Database code HMFT\_DROME, 413 amino acids (46.82 kDa).

**FU** abbr. for fluorouracil (use proscribed; the symbol FUra is recommended).

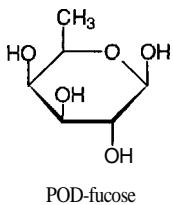

**Fuc** symbol for a residue (or sometimes a molecule) of the deoxyaldehyde **fucose**. In the condensed system of symbolism of sugar residues, Fuc signifies specifically a fucose residue with the common configuration and ring size, i.e. L-fucopyranose.

**fucan** a **glycan** composed only of fucose residues.

**fucoidan** or **fueoidin** any of a group of complex branched, sulfated heteropolysaccharides that are composed of residues of L-fucose (usually sulfated) together with small numbers of residues of various other monosaccharides. Fucoidans occur in the cell walls, intercellular matrix, and exuded mucilage of many (especially intertidal) species of marine algae, in which they appear to assist in water retention during periodic exposure.

**fucosamine** 2-amino-2,6-dideoxygalactose; an aminodeoxy-sugar, both enantiomers of which occur in lipopolysaccharides of *Salmonella* and other bacterial genera.

**fucose** symbol: Fuc; the trivial name for 6-deoxygalactose; there are two enantiomers. D-Fucose (symbol:  $\alpha$ -Fuc), 6-deoxy- $\alpha$ -galactose, occurs in glycosides in various plants belonging to the Convolvulaceae. L-Fucose (symbol: L-Fuc), 6-deoxy-L-galactose, occurs in polysaccharides (fucans) in seaweeds, especially *Fucus* spp., and in the cell wall matrix of higher plants. In animals fucosyl residues occur in a number of glycoproteins and glycolipids; the presence of  $\alpha$ -1,4-linked L-fucosyl residues at specific positions in the highly branched oligosaccharides of human erythrocyte surface antigens is controlled by the *Hand Le* blood-group genes.

**fucose-1-phosphate guanylyltransferase** EC 2.7.7.30; other name: GDPfucoselypyrophosphorylase; an enzyme that catalyses the formation of GDP-L-fucose from GTP and L-fucose 1-phosphate with release of pyrophosphate.

**$\alpha$ -fucosidase** any of several enzymes that hydrolyse  $\alpha$ -fucosides. 1  $\alpha$ -fucosidase, EC 3.2.1.51; systematic name:  $\alpha$ -L-fucoside fucohydrolase; it catalyses the hydrolysis of an

$\alpha$ -L-fucoside to an alcohol and L-fucose. Example from human: database code FUCO\_HUMAN, 461 amino acids (53.10 kDa). 2 1,3- $\alpha$ -L-fucosidase, EC 3.2.1.111; other names: almond emulsin; fucosidase I; an enzyme that catalyses the hydrolysis of 1,3-linkages between  $\alpha$ -L-fucose and N-acetylglucosamine residues in glycoproteins. 3 1,6- $\alpha$ -L-fucosidase, EC 3.2.1.127; an enzyme that catalyses the hydrolysis of 1,6-linkages between  $\alpha$ -L-fucose and N-acetyl- $\alpha$ -glucosamine in glycopeptides such as immunoglobulin G glycopeptide and fucosyl-asialo-agalacto-fetuin.

**fucosidosis** an inherited human metabolic disorder in which there is an inability to remove  $\alpha$ -L-fucosyl residues from various glycoproteins and glycolipids. It is subject to autosomal recessive inheritance.

**FUDR** or **FUDR** abbr. for fluorodeoxyuridine (use deprecated; the symbol FdUrd is recommended).

**fugu toxin** see **tetrodotoxin**.

**full agonist** an **agonist** that is able to elicit the maximal response of a tissue even when the tissue has spare receptors. In such a situation, several different agonists may be able to elicit the same maximal response, albeit at different receptor occupancies. Moreover, a full agonist in one tissue may be a **partial agonist** in another.

**fuller's earth** a naturally occurring, porous, absorptive aluminium-magnesium silicate clay. It is useful for decolorizing oils and other liquids and as a filtering medium. It is so-called because it was originally used to full (i.e. cleanse and thicken) wool and woollen cloth.

**fully overlapping code** see **overlapping code**.

**fumarase** EC 4.2.1.2; recommended name: fumarate hydratase. An enzyme of the **tricarboxylic-acid cycle** that catalyses the reaction:

There are two different enzymes in facultative bacteria (e.g. *Escherichia coli*). Example human mitochondrial enzyme, homotetramer: database code FUMH\_HUMAN, 467 amino acids (50.20 kDa).

**fumarate** 1 the trivial name for trans-1,2-ethylenedicarboxylate, (E)-butenedioate, the dianion of fumaric acid; the diastereoisomer of **maleate** and a key intermediate in metabolism. In the tricarboxylic-acid cycle it is formed from succinate by **succinate dehydrogenase**, and is converted to malate by **fumarase**. 2 any mixture of fumaric acid and its mono- and dianions. 3 any salt or ester of fumaric acid.

**fumarate hydratase** see **fumarase**.

**fumaryl** the bivalent *trans*-acyl group,  $-\text{CO}-\text{CH}=\text{CH}-\text{CO}-$ , derived from fumaric acid.

**fumaryl** the univalent *trans*-acyl group,  $\text{HOOC}-\text{CH}=\text{CH}-\text{CO}-$ , derived from fumaric acid.

**fumed silica** a preparation of pure silicon dioxide as an extremely fine, white powder with an external surface area of up to  $400 \text{ m}^2 \text{ g}^{-1}$ . It is useful for thickening and forming thixotropic gels. Fumed silica is used as a suspending and gelling agent in liquid-scintillation counting; a 3-5% concentration in dioxan, toluene, or xylene-based liquid scintillators will form an almost transparent, rigid gel, capable of holding an insoluble solid sample in suspension. Proprietary name: Cab-O-Sil.

**fume hood** a work space contained under a hood from which air is extracted to remove harmful vapours.

**function 1** (in chemistry) a **functional group**. 2 (in mathematics) a either of two variables so related to each other that for any value of one variable there is a corresponding value of the other. b a variable or expression that can take a set of values

**functional antagonism**

each of which is associated with the magnitude of an independent variable or variables. 3 (*in physiology*) the normal vital activity of a cell, organ, or tissue within an organism. -functional *adj.*

**functional antagonism** 1 antagonism arising by the antagonist's producing an opposite effect to the substance being antagonized through the antagonist's action at a different receptor. 2 antagonism arising when the antagonist interferes with events that follow receptor activation by the substance being antagonized.

**functional cloning** a cloning strategy in which knowledge of a gene's product (function) is used to clone the gene. An example is the gene for the  $\beta$  chain of hemoglobin responsible for sickle-cell anemia. This is in contrast to structural cloning where the function of the gene is not known. A common procedure would be to construct a DNA oligonucleotide based on the amino-acid sequence of the peptide and use this as a probe to isolate the gene from a DNA library. In cases where one protein is dominant in a cell, such as hemoglobin in the reticulocyte, the preparation of a cDNA from the mRNA also provides a useful probe for gene isolation.

**functional group or function** (*in chemistry*) any group (def. I) in a molecule of an organic compound that confers characteristic chemical and physical properties on the molecule and that may be considered to have replaced a hydrogen atom in a molecule of the corresponding hydrocarbon, e.g. the hydroxyl group in an alcohol.

**fungicide** any biological, chemical, or physical agent able to destroy fungi. -fungal *adj.*

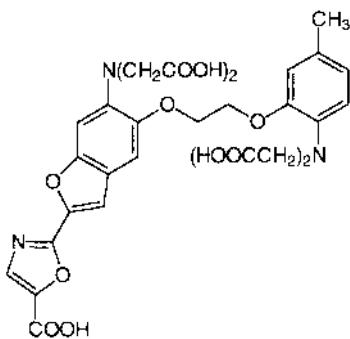

**fungistat** any drug, antibiotic, or other agent that inhibits the growth and multiplication of fungi. -fungistatic *adj.*

**fungus** (*pl. fungi*) any member of the taxonomic kingdom Fungi, a group of diverse and widespread unicellular, multicellular, or cenocytic eukaryotic organisms that do not contain chlorophyll. Fungi may be parasitic, saprophytic, or symbiotic. They reproduce through spores. See also microfungus. -fungal *adj.*

**FUR** abbr. for fluorouridine (use proscribed; the symbol FUrd is recommended).

**FURA** symbol for (a residue of) the synthetic pyrimidine base fluorouracil.

**Fura 2** 1-[2-(5-carboxyoxazol-2-yl)-6-aminobenzofuran-5-oxy]-2-(2'-amino-5'-methylphenoxy)-ethane-N,N,N',N'-tetraacetic acid; a highly sensitive calcium ion chelator that exhibits a spectral shift on binding  $\text{Ca}^{2+}$ . Calcium ion concentration can be measured directly, independent of dye concentration, by measuring the ratio of fluorescence at 510 nm after excitation at 340 nm and then at 380 nm. It is frequently used as the acetoxymethyl ester (Fura 2/AM, Fura 2-pentakis(acetoxymethyl)ester), which is a membrane-permeable derivative that can enter cells, after which it is rapidly hydrolysed by cytoplasmic esterases to Fura 2, which remains trapped within the cell and can thus report the intracellular  $\text{Ca}^{2+}$  concentration. See also Quin-2.

**furan** the trivial name for oxa-2,4-cyclopentadiene,  $\text{C}_4\text{H}_4\text{O}$ . See also furanose.

**furanoid** furan-like, i.e. describing a molecular structure that consists of or contains a ring of four carbon atoms and one oxygen atom (as in furan).

**furanose** symbol: *f*; any monosaccharide or monosaccharide derivative whose molecule contains a furanoid ring. Compare pyranose, septanose.

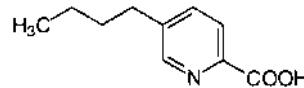

**furanoside** any glycoside in which the sugar moiety is in the furanose form.

**FUrd** symbol for (a residue of) the ribonucleoside fluorouridine (see fluorouracil).

**furin** the mammalian counterpart of kexin. Example from human: database code FURI\_HUMAN, 794 amino acids (86.58 kDa).

**furyl** either 2-furyl or 3-furyl, the two oxa-2,4-cyclopentadienyl groups derived from a molecule of furan by loss of a hydrogen atom from C-2 and C-3 respectively.

**fusaric acid** 5-butylpyridine-2-carboxylic acid; an antibiotic originally isolated from the fungus *Fusarium heterosporium* and obtained also from *Gibberella fujikuroi*. It inhibits dopamine  $\beta$ -hydroxylase and has hypotensive activity.

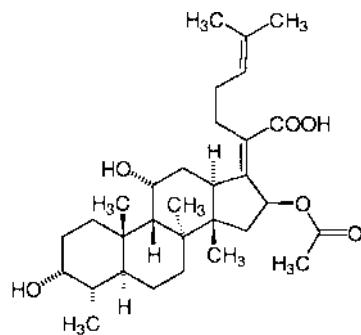

**fused ring** (*in chemistry*) any ring of atoms in a molecule that is joined to another ring of atoms in such a way that two atoms are common to both rings.

**fused rocket immunoelectrophoresis** a modification of rocket immunoelectrophoresis designed to follow the distribution of proteins among the fractions obtained in a separation experiment. Small volumes of fractions obtained in the separation experiment are placed in a row of sample wells in an antibody-free agarose gel and the samples are allowed to diffuse into the gel for 30-60 min. The proteins are then forced at right angles into an antibody-containing gel by electrophoresis; the resulting precipitation lines (rockets) show the elution profiles for each individual protein in the separation experiment and the distance between the precipitation line and the corresponding well is proportional to the amount of antigen precipitated.

**fusel oil** a colourless, oily liquid of variable composition obtained as a by-product in the distillation of alcoholic fermentation liquors. It contains chiefly isopentanol, 2-methyl-1-butanol, isobutanol, and propanol. It is considerably more toxic than ethanol. [From German *fuseln*, to bungle.]

**fusidic acid** 3 $\alpha$ , 11 $\alpha$ , 16 $\beta$ -trihydroxy-4 $\alpha$ , 8, 14-trimethyl-18-nor-5 $\alpha$ , 8 $\alpha$ , 9 $\beta$ , 13 $\alpha$ , 14 $\beta$ -cholest-17(20), 24-dien-21-oic acid 16-acetate; a steroid antibiotic, structurally related to cephalosporin P (see cephalosporin) and isolated from the fermentation broth of

**fusiform**

*Fusidium coccineum*. Fusidic acid is active particularly against Gram-positive organisms, especially *Staphylococcus* spp. It prevents translocation during protein synthesis and inhibits the accumulation of ppOpp.

fusiform spindle-shaped; elongated and tapering at both ends.  
 fusion 1 the act or process of melting. 2 the act or process of melting together or uniting. 3 the process whereby two membranes are joined together, as in cell fusion. 4 the process whereby nuclei of light elements are united to form nuclei of heavier elements with the release of energy: nuclear fusion. S the state of being fused. 6 something produced by fusion. 7 (in molecular biology) the act, process, or result of artificially linking genes that code for two different proteins, with the aim of generating a fusion protein.

fusion protein an expression product resulting from the fusion of two genes. Such a protein may be produced, e.g., in recombinant DNA expression studies or, naturally, in certain viral oncogenes in which the oncogene is fused to *gllg*. Their production sometimes results from the need to place a cloned eukaryotic gene under the control of a bacterial promoter for expression in a bacterial system; sequences of the bacterial system are then frequently expressed linked to the eukaryotic protein. Fusion proteins are used for the analysis of structure, purification, function, and expression of heterologous gene products.

fusogen any agent, or set of conditions, that gives rise to fusion of membranes, including cell membranes (and hence of cells). Killed Sendai virus was formerly much used for this purpose but now polyethylene glycol is commonly used as a

**FYN**

fusogen particularly in the preparation of hybridomas for the production of monoclonal antibodies. -fusogenic adj.  
 futile cycle any metabolic cycle that, if not controlled, acts as an ATPase and hence converts chemical energy (stored as ATP) to heat. For example, a coupling of phosphofructokinase, which converts fructose 6-phosphate to fructose 1,6-bisphosphate at the expense of ATP, with fructose-bisphosphatase, which hydrolyses fructose 1,6-bisphosphate to fructose 6-phosphate and (inorganic) phosphate, can form a cyclic process whose net effect is merely the hydrolysis of ATP to ADP and phosphate. A futile cycle may be an important control mechanism in some physiological conditions.

fuzzy coat or fuzzy layer the indistinct layer seen on electron microscopy outside the cell coat of various eukaryotic cells, e.g. cells of mammalian intestinal epithelium and a number of single-celled amoebae. It is composed principally of glycoproteins.

Fv fragment the N-terminal part of the Fab fragment of an immunoglobulin molecule, consisting of the variable portions of one light chain and one heavy chain.

**FYN** a gene family encoding nonreceptor tyrosine kinases of the Src family (see *src*) that are implicated in the control of cell growth. The gene product, p59<sup>Fyn</sup>, associates with the p85 subunit of 1-phosphatidylinositol 3-kinase. The proteins undergo myristylation and phosphorylation on serine and tyrosine residues; overexpression transforms fibroblasts. Example, database code KFYN\_HUMAN, 536 amino acids (60.56 kDa). The alternative gene symbols are *SYN* (from *src/yes*-related novel gene) and *SLK*.

# Gg

**9** symbol for 1 gram. 2 gaseous state. 3 gluon.

**g** 1 symbol for acceleration of free fall (formerly known as acceleration due to gravity). 2 abbr. for gauche.

**gn** symbol for standard acceleration of free fall, a fundamental physical constant equal by definition to 9.806 65 m s<sup>-2</sup>.

**G** symbol for 1 giga+ (SI prefix denoting 10<sup>9</sup> times). 2 gauss (alternative to Gs). 3 a residue of the α-amino acid glycine (alternative to Gly). 4 a residue of the base guanine in a nucleic-acid sequence. 5 a residue of the ribonucleoside guanosine (alternative to Guo). 6 a residue of the monosaccharide glucose (alternative to Glc). 7 ganglioside.

**G** symbol for 1 Gibbs energy. 2 gravitational constant. 3 weight (alternative to W or P). 4 electric conductance.

**Ga** symbol for gallium.

**Gaz** symbol for galabiose (alternative to GaOsez).

**Ga3** symbol for galatriose (alternative to GaOse3)'

**GA** abbr. (sometimes) for 1 glyceric acid. 2 glutamic acid. 3 glucuronic acid.

**GAA** a codon in mRNA for L-glutamic acid.

**GABA** abbr. for γ-aminobutyric acid or γ-aminobutyrate.

**GABAergic** 1 describing a nerve or other cell that is acted upon by γ-aminobutyrate. 2 describing nerves that act by releasing γ-aminobutyrate.

**GABA-gated channel** see **GABA receptor**.

**GABA-modulin** a brain protein that down-regulates the high-affinity binding site for γ-aminobutyric acid (GABA) on synaptic membranes.

**GABA receptor** any of several membrane proteins that bind γ-aminobutyrate (GABA) and mediate its effects as an inhibitory neurotransmitter. Two main types have been distinguished: GABA<sub>A</sub> receptors, known also as GABA-gated channels, which function as a Cl<sup>-</sup> channel; and GABA<sub>B</sub> receptors, which are G-protein-coupled receptors. **Baclofen** is a potent GABA mimetic that is selective for the GABA<sub>B</sub> receptor; **muscimol** is its counterpart for the GABA<sub>A</sub> receptor. The GABA<sub>A</sub> receptor is multimeric, with α (types α1–α6), β (types β1–β4), γ (types γ1–γ3), δ, and ρ subunits. Examples (all precursors, human): α<sub>1</sub>, database code GAALHUMAN, 456 amino acids (51.71 kDa); β<sub>1</sub>, database code GABI\_HUMAN, 474 amino acids (54.18 kDa); γ<sub>2</sub>, database code GAC2\_HUMAN, 467 amino acids (54.12 kDa); ρ<sub>1</sub>, database code GARLHUMAN, 473 amino acids (55.19 kDa). Subunits α and β have four putative transmembrane segments, with a domain distribution closely similar to that seen in the nicotinic acetylcholine receptor (nAChR) (see **cholinceptor**), with some homology between specific regions of the two receptor types: for the α subunit with the M1 region of nAChR, and for the β subunit with regions MI–M3. Increased Cl<sup>-</sup> ion flux brings about hyperpolarization of an excitatory neuron, which inhibits it from firing on receipt of a normal impulse. **Benzodiazepine** drugs interact with GABA<sub>A</sub> receptors; co-expression studies with cloned subunit variants have indicated that the γ subunit confers benzodiazepine sensitivity. The mode of action of GABA<sub>B</sub> receptors remains unknown. Indications variously suggest they may be coupled through G-proteins to stimulation of outward K<sup>+</sup> current, inhibition of inward Ca<sup>2+</sup> channels, inhibition of adenylate cyclase, and stimulation of the phosphatidylinositol-Ca<sup>2+</sup> system. See also **chloride channel**.

**gabase** an informal name for aminobutyrate aminotransferase (EC 2.6.1.19).

**GABA shunt** abbr. for γ-aminobutyrate shunt.

**GABA transaminase** see **4-aminobutyrate transaminase**.

**GAC** a codon in mRNA for L-aspartic acid.

**G-actin** the monomeric form of **actin**.

**Gaddum equation** a relationship, suggested to replace the Hill-Langmuir equation, that describes the situation when two

ligands, A and B, are in equilibrium with a common binding site. It is:

$$\text{PAR} = \frac{[A]IKA}{[A]IKA + [B]IK_B}$$

where PAR is the proportion of the binding sites occupied by ligand A; the square brackets indicate concentrations. Compare **Schild equation**. [After (Sir) John Henry Gaddum (1900–67), British pharmacologist.]

**gadelaiaidate** the trivial name for (E)-eicos-9-enoate, CH<sub>3</sub>–[CH<sub>2</sub>]<sub>9</sub>–CH=CH–[CH<sub>2</sub>]<sub>7</sub>–COO<sup>-</sup> (*trans* isomer), the anion derived from gadelaic acid, (E)-eicos-9-enoic acid. Compare **gadoleate**.

**gadoleate** the trivial name for (Z)-eicos-9-enoate, CH<sub>3</sub>–[CH<sub>2</sub>]<sub>9</sub>–CH=CH–[CH<sub>2</sub>]<sub>7</sub>–COO<sup>-</sup> (*cis* isomer), the anion derived from gadoleic acid, (Z)-eicos-9-enoic acid. Compare **gadelaiaidate**.

**gag** a gene that encodes the glucosaminoglycan core protein for a **retrovirus**. It is named from group-specific antigen gene, or glucosamino glycan gene. Example from avian erythroblastosis virus: database code AEVGAG, 962 amino acids (108.19 kDa). See also **erbA**, **erbB**.

**GAG** 1 a codon in mRNA for L-glutamic acid. 2 abbr. for glucosaminoglycan.

**Gaia** a theory of the role of biota in the maintenance of a climatic homeostasis, proposed by James Lovelock [(1919– ), British biochemist] in 1979. The original concept, and still the heart of the philosophy, is that all of the living organisms that inhabit the Earth can be regarded as a single vast organism capable of manipulating the atmosphere, geosphere, and hydrosphere to suit its needs. Lovelock named this organism Gaia, after the Greek goddess of the earth.

**Gal** symbol for a residue (or sometimes a molecule) of the aldohexose galactose. In the condensed system of symbolism of sugar residues, it signifies specifically a galactose residue with the common configuration and ring size, Le. D-galactopyranose.

**GAL4** a gene involved in the regulation of galactose utilization in yeast. The GAL4 protein (database code GAL4\_YEAST, 881 amino acids (99.39 kDa)) has a zinc-finger motif for binding to its upstream activator sequence (UAS), which it then activates, and a site for binding the complex of the GAL80 protein – encoded by the **GAL80** gene – and galactose. When this is bound, activation by GAL4 protein is prevented.

**GalA** symbol for a residue (or sometimes a molecule) of the uronic acid galacturonic acid.

**galabiose** symbol: Gaz or GaOsez; the trivial name for the disaccharide Gal(1-4)Gal.

**galactan** any glycan composed solely of galactose residues. The galactans thus form a subgroup of plant hemicelluloses.

**galactitol** or meso-galactitol or (formerly) **dulcitol** the trivial name for the hexitol formally derived by reduction of the aldehyde group of either D- or L-galactose. It is optically compensated internally and therefore does not require D or L as a configurational descriptor; the prefix *meso-* may however be added for clarity. It occurs widely especially in seaweeds and higher plants.

**galacto-** prefix (in chemical nomenclature) indicating a particular configuration of a set of (usually) four contiguous CHO groups, as in the acyclic form of D- or L-galactose. See **monosaccharide**.

**galactoceramide** see **galactosylceramide**.

**galactocerebroside** see **galactosylceramide**.

**galactokinase** EC 2.7.1.6; systematic name: ATP:o-galactose 1-phosphotransferase. An enzyme that catalyses the phosphorylation by ATP of o-galactose to o-galactose I-phosphate, with release of ADP; this is the first step in the metabolism of

## galactolipid

galactose. Example from *Escherichia coli*: database code GALLECOLI, 381 amino acids (41.26 kDa). galactolipid any glycolipid containing one or more residues of galactose and/or N-acetylgalactosamine. The term includes galactosylceramide and galactosyldiacylglycerol.

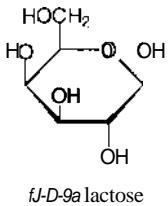

galactomannan any heteroglycan containing D-galactose and D-mannose residues; the structures have not been fully elucidated. They occur in seeds of various plants and trees, probably as storage polysaccharide. *See also* guaran.

galactoprotein A abbr.: Gap A; an alternative name for fibronectin.

galactosaemia a variant spelling (esp. Brit) of galactosemia.

galactosamine symbol: GalpN; the trivial name for the amino-deoxysugar 2-amino-2-deoxygalactopyranose; there are two enantiomers, D- and L-galactosamine. D-Galactosamine (symbol: D-GalpN), formerly known as chondrosamine, is a constituent (commonly as its N-acetyl derivative) of some glycolipids and of chondroitin sulfate, dermatan sulfate, and many bacterial glycosaminoglycans.

galactose symbol: Gal; the trivial name for the aldohexose galacto-hexose; there are two enantiomers, D- and L-galactose. D-Galactose (symbol: D-Gal), commonly known as galactose, and formerly known as brain sugar or cerebrose, rarely occurs free but is widely distributed in combined form in plants, animals, and microorganisms as a constituent of many oligo- and polysaccharides; it occurs also in galactolipids and as its glucoside in lactose and melibiose. Residues of both D-galactose and 3,6-anhydro-L-galactose (symbol: 3,6An-L-Gal) occur in the disaccharide agarobiose and in polysaccharides such as agarpectin and agarose.

galactose/glucose binding protein a signal transducing protein for bacterial chemotaxis. Example from *Escherichia coli*: database code NRL\_2GBP, 309 amino acids (33.33 kDa); 3-D structure known.

galactosemia or (esp. Brit.) galactosaemia comparatively rare condition in humans in which there is a supranormal concentration of D-galactose in the blood and a specific inability to metabolize galactose. It is caused either by (1) a hereditary autosomal recessive trait in which there is a virtual absence of UDPglucose-hexose-'phosphate uridylyltransferase activity; or less frequently (2) an inherited autosomal recessive trait in which there is a deficiency in galactokinase activity.

galactose oxidase EC 1.1.3.9; a copper-containing enzyme that catalyses the oxidation by dioxygen of D-galactose to D-galacto-hexodialdose and H<sub>2</sub>O<sub>2</sub>. Example from the fungus *Cladobotryum dendroides*: database code NRL\_IGOG, 639 amino acids (68.44 kDa); 3-D structure known.

galactose-1-phosphate uridylyltransferase see UDPglucose-hexose-'phosphate uridylyltransferase.

galactose-6-sulfatase sulfatase see N-acetylgalactosamine-6-sulfatase.

galactosidase either of two types of enzyme: a-galactosidase EC 3.2.1.22; systematic name: a-D-galactoside galactohydrolase; other name: melibiase. An enzyme that hydrolytically removes terminal nonreducing a-D-galactose residues in a-galactosides, including galactose oligosaccharides, galactomannans, and galactolipids. Example from *Escherichia coli*: database code AGAL\_ECOLI, 451 amino acids (50.60 kDa). p-galactosidase EC 3.2.1.23; systematic name: p-D-galactoside

## galactosyldiacylglycerol

galactohydrolase; other name: lactase. An enzyme that removes terminal p-D-galactose residues in p-galactosides by hydrolysis. Example, lacZ gene product of *E. coli*: homotetramer, similar to other glycosyl hydrolases, database code BGAL\_ECOLI, 1023 amino acids (116.22 kDa).

galactoside any glycoside in which the sugar moiety is galactose.

galactoside acetyltransferase EC 2.3.1.18; recommended name: galactoside O-acetyltransferase; systematic name: acetyl-CoA:/J'-D-galactoside 6-acetyltransferase; other name: thiogalactoside transacetylase. An enzyme that catalyses the acetylation by acetyl-CoA of p-D-galactoside to 6-acetyl- $\beta$ -D-galactoside with release of GDP. Such an enzyme is the lacA gene product in *Escherichia coli* (see lac operon). Its function remains unclear. Example from *E. coli*: database code THGA\_ECOLI, 203 amino acids (22.80 kDa).

galactoside 3(4)-L-fucosyltransferase EC 2.4.1.65; systematic name: GDP-L-fucose:p-D-galactosyl-N-acetyl-D-glucosaminyl-R 4-L-fucosyltransferase; other name: Lewis transferase. An enzyme that catalyses the transfer by GDP-L-fucose of fucose to 1,3-p-D-galactosyl-N-acetyl-D-glucosaminyl-R to form 1,3-p-D-galactosyl-(a-1,4-L-fucosyl)-N-acetyl-D-glucosaminyl-R with release of GDP; this forms the blood group determinant Lea of Lewis antigen. The enzyme also acts on the corresponding 1,4-galactosyl derivative, forming 1,3-L-fucosyllinks. It is a type II membrane glycoprotein, and a product of the Lewis blood group locus: database code GFT\_HUMAN, 361 amino acids (42.07 kDa).

p-galactoside permease any of several transport proteins in bacteria that facilitate the uptake of p-galactosides. An example is melibiose carrier protein from *Klebsiella pneumoniae*: database code MELB\_KLEPN, 471 amino acids (52.27 kDa). This is responsible for melibiose transport; it is capable of using hydrogen and lithium cations as coupling cations for co-transport, depending on the particular sugar transported (e.g. H<sup>+</sup>-melibiose, Li<sup>+</sup>-lactose), but cannot recognize Na<sup>+</sup> ions although it is an integral membrane protein of the sodium:galactoside symporter family. *See also* lactose permease.

galactosylceramidase EC 3.2.1.46; an enzyme that catalyses the hydrolysis of D-galactosyl-N-acylsphingosine to D-galactose and N-acylsphingosine. Example from human: database code JC2397, 669 amino acids (75.06 kDa).

galactosylceramide the recommended term for any D-galactosyl-N-acylsphingosine, i.e. any cerebroside in which the sugar moiety is D-galactose (less correctly termed galactoceramide or galactocerebroside).

galactosylceramide lipidosis or Krabbe's disease or globoid cell leukodystrophy one of a number of sphingolipidoses or sphingolipid lysosomal storage diseases. A rapidly progressive, invariably fatal, hereditary (autosomal recessive) disease of human infants caused by deficient activity of galactocerebroside p-galactosidase (galactosylceramidase; EC 3.2.1.46). Clinical symptoms usually start between the ages of 3 and 6 months and the condition is characterized by severe mental and motor deterioration and the presence of numerous globoid cells containing galactosylceramide in the white matter of the brain.

galactosylceramide sulfotransferase EC 2.8.2.11; an enzyme involved in sulfatide biosynthesis that catalyses the reaction between a galactosylceramide and 3'-phosphoadenylyl-sulfate to form galactosylceramide sulfate and adenosine 3',5'-bisphosphate.

galactosyldiacylglycerol any of a class of lipids in which one or two galactose residues are in glycosidic linkage with a 1,2-diacylglycerol (loosely termed mono- and digalactosyldiacylglycerols), more specifically as, e.g., 1,2-diacyl-sn-glycerol 3-p-D-galactoside or (preferred, as glycosphingolipids are named this way) 1,2-diacyl-3-p-D-galactosyl-sn-glycerol. They are widely distributed in plants and are the main constituent lipids of chloroplasts, where they occur in the thylakoid membrane. They are also present in mitochondria.

## /3-1,3-galactosyl-D-glycosyl-glycoprotein

gamone

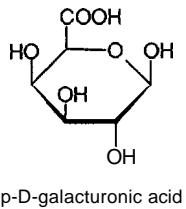

/3-1,3-galactosyl-D-glycosyl-glycoprotein  **$\beta$ -1,6-N-acetylglucosaminyltransferase** EC 2.4.1.102; other names: *O*-glycosyl-oligosaccharide-glycoprotein; N-acetylglucosaminyltransferase I; p6-N-acetylglucosaminyltransferase; core debranching enzyme; an enzyme that catalyses the reaction between UDP-*N*-acetyl-D-glucosamine and  $\beta$ -D-galactosyl-1,3-N-acetyl-D-glucosaminyl-R to form p-*D*-galactosyl-1,3-(N-acetyl-p-D-glucosaminyl-I,6)-N-acetyl-D-galactosaminyl-R with release of UDP. It introduces branches into a-linked glycoprotein oligosaccharides. Example from human: database code G6NT\_HUMAN, 428 amino acids (49.73 kDa).

galactosyl transferase any enzyme belonging to the sub-sub-class hexosyltransferases, EC 2.4.1, for which the glycosyl group is galactosyl; the acceptor is typically another carbohydrate molecule or lipid. See also B-transferase, lactose synthase, Lewis transferase.

galactowaldenase *a former name for* UDPglucose 4-epimerase. galacturonan or (formerly) polygalacturonide any glycan composed solely of galacturonic-acid residues; a specific kind of glycuronan.

galacturonate 1 the anion of galacturonic acid. 2 any salt or ester of galacturonic acid.

galacturonic acid symbol: GaiA or (formerly) GalU or GalVA; the uronic acid formally derived from galactose by oxidation of the hydroxymethylene group at C-6 to a carboxyl group. There are two enantiomers, D- and L-galacturonic acid; *D*-galacturonic acid is a component of plant gums and bacterial cell walls.

p-D-galacturonic acid

galanin a biologically active neuropeptide with a wide distribution in the central neurons of several mammalian species. Human galanin is the 30-residue sequence

GWTLNSAGYLLGPHAVGNHRSFSDKNGLTS;

porcine galanin had only 29 residues and differs at residues 16, 17 (I,D), 23 (H), 26 (Y), and 29 (*A-NH<sub>2</sub>*). Galanin effects contraction of smooth muscle of the gastrointestinal and genitourinary tracts, and regulates somatotropin release; it may be involved in the control of adrenal secretion, and is also produced in the islets of Langerhans from stimulated intra-islet nerve terminals. It inhibits insulin release *in vivo* and *in vitro*, and inhibits formation of cyclic AMP in cells stimulated by glucagon-related peptide. A fragment, GWTLNSAGYLLGPHAI, is an agonist at the hippocampal galanin receptor. Example from pig (precursor): database code GALA\_PIG, 123 amino acids (13.07 kDa); the hormone is derived from amino acids 33–61, with C-terminal amidation; a galanin message associated peptide (GMAP) is derived from amino acids 65–123.

galaptin any of various proteinaceous, p-galactoside-specific, animal lectins of relatively low molecular mass, that are isolated from a number of developing and adult tissues and are believed to mediate intercellular adhesion in some developmental systems.

galatriaose symbol: Ga3 or GaOse3; the trivial name for the trisaccharide Gal( $\alpha$ 1-4)Gal( $\alpha$ 1-4)Gal.

gall 1 an abnormal swelling or growth produced by a plant in response to the activities of various fungi, mites, and insects, especially members of the Cynipidae and Cecidomyiidae. Insect eggs and larvae are often found in galls. 2 a former name for bile.

gallate 1 the anion of gallic acid, 3,4,5-trihydroxybenzoic acid, a phenolic acid. 2 any salt or ester of gallic acid. The esters and polyesters are very widely distributed in angiosperms, usually as gallotannins.

gall bladder a hollow, muscular organ, found in many vertebrates, that receives dilute bile from the liver, concentrates and stores it, and discharges it into the duodenum.

gallotannic acid see tannic acid.

gallotannin or hydrolysable tannin any tannin consisting of a molecule of a polyhydric alcohol (usually glucose) esterified with several gallic-acid molecules, each of which may itself be esterified with a further gallic acid molecule, and so on.

Galp symbol for a galactopyranose residue.

GaipA symbol for a residue (or sometimes a molecule) of galactopyranuronic acid.

GaipN symbol for a residue (or sometimes a molecule) of the aminodeoxysugar galactosamine.

GaipNAc symbol for a residue (or sometimes a molecule) of the acetamido-deoxysugar N-acetylgalactosamine.

GalU or GalVA former symbol for galacturonic acid (GaiA now recommended).

galvanic cell an alternative name for cell (def. 3).

gamete a mature reproductive cell whose nucleus (and often cytoplasm) fuses with that of another gamete of similar origin but of opposite sex to form a zygote, which develops into a new individual. Gametes are haploid and are differentiated into male (+) and female (-).

gamma symbol:  $\gamma$  (lower case) or  $\Gamma$  (upper case); the third letter of the Greek alphabet. For uses see Appendix A.

gamma chain or  $\gamma$  chain 1 the heavy chain of an IgG immunoglobulin molecule. 2 one of the two types of polypeptide chain in a human fetal hemoglobin (Hb F) molecule.

gamma globulin or  $\gamma$ -globulin any of a band of serum proteins that migrate most slowly on electrophoresis. In humans this normally constitutes quantitatively the largest fraction of the total globulins. Since the  $\gamma$ -globulins are predominantly antibodies, and are not synthesized in the liver as are virtually all the other serum proteins, the albumin/globulin ratio has traditionally been a useful indicator of liver function. The  $\gamma$ -globulins may be separated from the other serum globulins in pooled adult serum and may then be used for administration by intramuscular injection to provide passive immunity in premature infants or for those in contact with cases of infectious hepatitis. Such  $\gamma$ -globulin preparations tend to form aggregates spontaneously and these can lead to severe anaphylactic reactions when administered intravenously on account of their ability to aggregate platelets and to activate complement and generate C3a and C5a anaphylatoxins. In certain diseases such as Bruton's congenital agammaglobulinemia the production of immunoglobulin in affected males is grossly depressed. In patients with myeloma the  $\gamma$ -globulin band on electrophoresis of serum proteins is markedly more prominent, indicating the presence of a raised antibody against an unknown antigen. See also globulin.

gamma helix or  $\gamma$  helix a configuration of a polypeptide chain in which each amide group forms hydrogen bonds with the groups five residues away in each direction along the chain. It has 5.1 amino-acid residues per turn; the translation along the helical axis is 0.99 Å per residue and 5.03 Å per turn.

gamma-peptidase see X-Pro dipeptidase.

gamma radiation or  $\gamma$ -radiation electromagnetic radiation with wavelengths in the range 0.1–100 pm (frequencies 3–3000 EH<sub>z</sub>) emitted by some atomic nuclei during transformation (def. 3). Gamma rays have shorter wavelengths than X-rays and higher photon energies.

gammopathy any pathological disturbance of gamma-globulin metabolism. Gammopathies may be monoclonal or polyclonal and are associated with increased immunoglobulin synthesis.

gamone any of a group of biological agents secreted by gametes that act on gametes of the opposite sex to initiate the processes leading to fertilization. They may be subdivided into

**ganciclovir**

gynogamones, liberated from female gametes, and androgamones, liberated from male gametes.

**ganciclovir** 9-[1,3-dihydroxy-2-propoxy]methylguanine; a nucleoside analogue of acyclovir that is more potent against cytomegalovirus. It is converted through ganciclovir mono- and diphosphate to ganciclovir triphosphate, which inhibits viral DNA synthesis by inhibition of viral DNA polymerase.

**ganglion** (*pl.* *ganglia*) a cluster of nerve cells and associated glial cells located outside the central nervous system.

**ganglioside** any ceramide oligosaccharide carrying, in addition to other sugar residues, one or more sialic residues. Gangliosides are so named because they were first isolated from ganglion cells (neurons) of the grey matter of the brain but are in fact widely distributed in vertebrate tissues. They are *N*-acetyl- (or *N*-glycoloyl-) neuraminosyl-(X)osylceramides, where (X) stands for the root name of the neutral oligosaccharide to which the sialosyl residue is attached; the acyl groups in the ceramide moiety are commonly stearoyl or lignoceroyl. Gangliosides are soluble in water and do not pass through semipermeable membranes, so may be purified by dialysis. In the Svennerholm system of abbreviations gangliosides are designated G for ganglioside, plus subscript M, D, or T for mono-, di-, or trisialo, respectively, the subscript letter being followed by a subscript arabic numeral to indicate the sequence of migration in thin-layer chromatograms. The principal gangliosides of human brain are:

(1) monosialo gangliosides: GM<sub>1</sub>, Gal(pl-3)GaINAc(jJ1-4)(NeuAc(a2-3)Gal(jJ1-4)GlcplCer (GAL denotes the asialo derivative of GM<sub>1</sub>); GM<sub>2</sub>, GaINAc(pl-4)(NeuAc(a2-3)Gal(jJ1-4)GlcplCer (GA<sub>2</sub> denotes the asialo derivative of GM<sub>2</sub>); GM<sub>3</sub>, NeuAc(a2-3)Gal(pl-4)GlcplCer;

(2) disialo gangliosides: G<sub>D1a</sub>, NeuAc(a2-3)Gal(jJ1-3)GaINAc(jJ1-4)(NeuAc(a2-3)Gal(jJ1-4)GlcplCer; G<sub>D1b</sub>, Gal(β1-3)GaINAc(jJ1-4)(NeuAc(a2-8)NeuAc(a2-3)Gal(jJ1-4)GlcplCer; G<sub>D3</sub>, NeuAc(a2-8)NeuAc(a2-3)Gal(jJ1-4)GlcplCer;

(3) trisialogangliosides: GT<sub>Ta</sub>, NeuAc(a2-8)NeuAc(a2-3)Gal(jJ1-3)GalNAc(β1-4)(NeuAc(a2-3))Gal(β1-4)GlcplCer; GT<sub>Tb</sub>, NeuAc(a2-3)Gal(pl-3)GaINAc(Pl-4)(NeuAc(a2-8)NeuAc(a2-3)Gal(pl-4)GlcplCer.

**ganglioside galactosyltransferase** EC 2.4.1.62; *other name*: UDPgalactose-ceramide galactosyltransferase; an enzyme that catalyses the reaction between UDPgalactose and *N*-acetyl-*o*-galactosaminyl-(N-acetylneuraminy)-*o*-galactosyl-*o*-glucosyl-N-acylsphingosine to form the ganglioside GM<sub>1</sub>, with release of UDP.

**gangliosidosis** any of a group of inherited human diseases involving defects in ganglioside breakdown. They are characterized by: progressive mental and motor deterioration with fatal outcome; autosomal recessive inheritance; neuronal lipidoses secondary to storage of gangliosides and structurally related glycolipids, polysaccharides, or glycoproteins; and absence or severe deficiency of specific lysosomal glycohydrolases. The principal gangliosidoses are GM<sub>1</sub> and GM<sub>2</sub> gangliosidoses (the names indicating which ganglioside accumulates). GM<sub>1</sub> gangliosidoses are due to a striking deficiency of p-galactosidase activity when tested using GM<sub>1</sub> or galactose-containing glycoproteins as substrates. Type 1 or infantile GM<sub>1</sub> gangliosidosis is a generalized gangliosidosis with bony involvement and onset of signs from birth or shortly after. Type 2 or juvenile GM<sub>1</sub> gangliosidosis is of slower onset than type 1 and with milder bony abnormalities. There are three types of GM<sub>2</sub> gangliosidosis. Type 1 GM<sub>2</sub> gangliosidosis (*or* Tay-Sachs disease) is the commonest gangliosidosis, occurring especially in Ashkenazi Jews. It is caused by a severe deficiency of hexosaminidase A. Type 2 GM<sub>2</sub> gangliosidosis (*or* Sandhoff's disease) occurs much less frequently than Tay-Sachs disease and is caused by severe deficiency of both hexosaminidases A and B; globoside accumulates in addition to GM<sub>2</sub> in this disease. Type 3 or juvenile GM<sub>2</sub> gangliosidosis is caused by either severe or partial deficiency of hexosaminidase A.

**gas flow counter**

**gangliotetraose symbol**: Gg<sub>4</sub> or GgOse<sub>4</sub>; a trivial name for the tetrasaccharide Gal(jJ1-3)GaINAc(pl-4)Gal(pl-4)Glc.

**gangliotriaose symbol**: Gg<sub>3</sub> or GgOse<sub>3</sub>; a trivial name for the trisaccharide GaINAc(jJ1-4)Gal(pl-4)Glc.

**GaOsez symbol** for galabiose (alternative to Ga<sub>2</sub>')

**GaOse3 symbol** for galatriose (alternative to Ga<sub>3</sub>')

**gap** 1 a space introduced into the written form of a sequence of residues in a biopolymer to demonstrate homology with the sequence of a similar polymer from the same or another source. 2 a discontinuity in one of the two strands of duplex DNA resulting from enzymic elimination of one or more nucleotide residues. *Compare nick*.

**GAP abbr.** for 1 GnRH-associated peptide (*see* gonadotropin-releasing hormone). 2 *abbr.* for GTP-binding GTPase activating protein; a protein that activates the hydrolysis of GTP bound to certain monomeric proteins, especially p21<sub>ras</sub> (*Ras*, *see HAS*), but also for other Ras-related proteins, e.g. Rho (*see Rho protein*) and Ran (*see RAN*). Since GTP-bound Ras is the active form, binding to GAP inactivates it. The protein has SH2 and SH3 domains (*see SH domains*) and pleckstrin homology domains. The v-ras product is not stimulated by GAP. Example from *Bos taurus*: database code GTPA\_BOVIN, 1044 amino acids (115.76 kDa).

**Gap A abbr.** for galactoprotein A (i.e. plasma fibronectin).

**GAPDH abbr.** for glyceraldehyde-3-phosphate dehydrogenase.

**gap gene** a type of gene in *Drosophila*. There are at least six gap genes, which act early in embryogenesis to make out the coarsest subdivisions of the embryo. Mutations in these genes result in gaps in the segmentation pattern; the Krüppel and hunchback proteins are products of gap genes.

**gap junction** *or* **nexus** any specialized area of the plasma membranes of apposed vertebrate cells where the membranes are 2-4 nm apart and penetrated by a connexon that bridges the extracellular space and provides open means of communication between the cytoplasm of one cell and that of the other cell. *Compare tight junction*.

**gap phase** either of the two phases, designated G<sub>1</sub> and G<sub>2</sub>, in the cell-division cycle during interphase in growing eukaryotic cells during which there is no DNA synthesis.

**gap repair** the process of repair of a gap (def. 2) in one strand of a duplex DNA molecule.

**garosamine** 3-deoxy-4-C-methyl-3-(methylamino)-L-arabinose; a component of gentamicins.

**gas** a substance whose physical state is such that it always occupies the whole of the space in which it is contained, irrespective of the amount present. *See also gas laws; ideal gas*.

**gas chromatography abbr.**: GC; any form of chromatography in which the mobile phase is a gas. The term commonly refers to gas-liquid (partition) chromatography in which the stationary phase is a liquid, normally deposited on a solid support in a coiled column of glass or stainless steel, or the wall of a capillary column, but it also includes gas-solid chromatography, in which the stationary phase is a solid. The column is normally heated in an oven.

**gas chromatography/mass spectrometry abbr.**: GC/MS; an analytical technique that combines the separation process of gas chromatography with the highly selective detection technique of mass spectrometry.

**gas constant symbol**: R; a fundamental physicochemical constant; R = 8.314 510 (70) J K<sup>-1</sup> mol<sup>-1</sup>.

**gas exchange** (*in physiology*) the exchange of gases between an organism and its environment. It includes oxygen uptake and carbon dioxide elimination in the respiration of all aerobic organisms, including plants, and carbon dioxide uptake and oxygen release in photosynthetic processes.

**gas flow counter** any gas-filled radiation detector in which the gas filling is renewed continuously. It may be operated in either the Geiger or the proportional regions of the voltage-current curve. Such devices are especially useful for detection and counting of alpha and soft-beta emitters, as no window is present to absorb the radiation.

**gas laws**

gas laws either of two laws describing the effects of changes in pressure,  $p$ , and thermodynamic temperature,  $T$ , on the volume,  $V$ , of an ideal gas. Boyle's law (or Mariotte's law) states that at constant temperature the volume of a given mass of gas is inversely proportional to the pressure; i.e.  $pV = \text{constant}$ . Charles's law states that at constant pressure the volume of a given mass of gas is directly proportional to its thermodynamic temperature; i.e.  $V/T = \text{constant}$ . These two laws may be combined in the expression:  $pV \propto T$ , or, for one mole of gas:  $pV = RT$ , where  $R$  is the gas **constant**.

**gas-liquid (partition) chromatography** an analytical method based on the partition chromatographic separation of the components of a mixture through the use of a stationary liquid phase held in place on a solid support and a mobile gas phase flowing over the liquid phase in a controlled manner. Typically, the column is heated to temperatures in the range 50–300 °C and the technique is applicable to compounds that partition appreciably into the vapour phase in that range. Detection of the eluents is commonly by a flame ionization detector.

**gas-solid chromatography** see gas chromatography.

**gastr+** a variant form of **gastro+** (before a vowel).

**gastric** of, pertaining to, or derived from the stomach.

**gastric acid** the hydrochloric acid that is secreted from parietal (or oxytic) cells of the wall of the stomach and forms part of the gastric juice.

**gastric inhibitory peptide abbr.:** GIP; or glucose-dependent insulinotropic peptide or glucose-dependent insulin-releasing peptide a 5 kDa polypeptide hormone produced by the K cells of the proximal small intestine and released into the bloodstream in response to the presence of glucose in the intestine. It is structurally related to glucagon, secretin, and vasoactive intestinal polypeptide having the sequence (human) YAEQT-FISDYSIAMDQHQQDFVNWLAAQKGKNDWKHNITQ, porcine being similar but with Arg<sup>18</sup> and Ser<sup>34</sup>. The porcine hormone appears to be heterogeneous, the major component having 42 amino-acid residues and the main secondary component being two residues shorter at the N-terminus. Its two main physiological functions are the inhibition of gastric secretion and motility (enterogastrone effect), and the stimulation of insulin release when administered during hyperglycemia (insulinotropic effect); in the latter action GIP may be synonymous with incretin.

**gastric juice** the thin, clear, acidic fluid secreted by glands of the stomach mucosa in response to the ingestion of food. It contains mucus, intrinsic factor, hydrochloric acid (about 155 mM in humans) from the parietal cells, and pepsinogen, the precursor of pepsin proteolytic enzymes.

**gastricsin** EC 3.4.23.3; other names: pepsin C, pig parapepsin II; an enzyme of the pepsin family that appears to be present in the gastric juice of most vertebrates. It effects preferential cleavage at Tyr-I-Xaa bonds. It is a single-chain phosphoprotein formed by limited proteolysis of pepsinogen C with a more restricted specificity than pepsin A but high activity towards hemoglobin. Example, (precursor) from human: database code PEPC\_HUMAN, 388 amino acids (42.38 kDa).

**gastrin** any of various members of a group of interrelated peptide hormones from the G cells of the pyloric antral mucosa of the stomach, and of the proximal duodenum, that strongly stimulate acid secretion by the stomach mucosa. There are three principal, biologically active forms: big gastrin (or G-34); little gastrin, (or G-17 or gastrin I); and mini gastrin (or G-14); these have 34, 17, and 14 amino-acid residues, respectively. The sequence of human big gastrin (gastrin I in parentheses, but with pE for the terminal Q) is pELGPQGPP-HLVADPSKK(QGPWLEEEEAAYGMDF-NH<sub>2</sub>), where pE indicates pyroglutamyl. Each has a counterpart, e.g. G-17S (or gastrin II), in which the tyrosyl residue is sulfated. There are other, larger immunoreactive forms, known as big-big gastrins, that elute from a gel column before G-34. The entire physiological activity is possessed by the C-terminal tetrapeptide amide sequence that ends in a phenylalaninamide residue.

The C-terminal pentapeptide sequence of gastrin is the same as that of cholecystokinin and cerulein. Example, gastrin precursor, a member of the gastrin/cholecystokinin family, a precursor for gastrin (17 amino acids) and big gastrin (34 amino acids) from human: database code GAST\_HUMAN, 101 amino acids (11.38 kDa). See also gastrinoma, pentagastrin, Zollinger-Ellison syndrome.

**gastrinoma** a tumour of the gastrin-producing G cells of the pancreas, stomach, or duodenum. Gastrinomas are associated with high gastrin levels in the circulating blood, gastric hypersecretion, and fulminant gastroduodenal ulcerations (Zollinger-Ellison syndrome).

**gastrin receptor** see cholecystokinin receptor.

**gastrin-releasing protein** a growth factor secreted by some small-cell lung cancers.

**gastro+** or (often before a vowel) **gastr+** comb. form meaning stomach. [From Greek *gaster*, belly.]

**gastroenteric** an alternative term for gastrointestinal.

**gastrointestinal** or **gastroenteric** of, or pertaining to, the stomach and intestines.

**gastrointestinal hormone** any member of a diverse group of peptides with hormone or hormone-like actions that occur in specific cells of the gastrointestinal tract, the pancreatic islets, and other locations. The best characterized include cholecystokinin, gastric inhibitory polypeptide, gastrin, glucagon, insulin, motilin, neuropeptides, pancreatic polypeptide, secretin, substance P, and vasoactive intestinal polypeptide. See also gut hormone.

**gastrula** an early stage of development of an animal embryo, following the blastula, in which the cells are invaginating to form the rudiment of a gut cavity.

**gas vacuole** any membrane-bound, gas-containing, intracellular organelle. Gas vacuoles provide aquatic prokaryotes with buoyancy. See also gas vesicle.

**gas vesicle** the submicroscopic component of the gas vacuole in certain aquatic prokaryotes, especially cyanobacteria. It is constructed of molecules of a single protein ( $\approx 15$  kDa), which form a monolayer enclosing a hollow space into which gases diffuse. Typically it is cylindrical with conical ends, 3–300 nm in diameter and 300–1000 nm in length.

**GATA-1** or **ERYFI** or **GF-1** or **NF-E1** a transcriptional activator protein that serves as a general switch factor for erythroid development. It binds to DNA sites with the consensus sequence [A/T]GATA[A/G] within regulatory regions of globin genes and other genes expressed in erythroid cells. Other transcription factors with similar sequences are termed GATA-type. Example from human: database code GATLHUMAN, 413 amino acids (42.70 kDa).

**GATase** see glutamine amidotransferase.

**gate** (in electronics) 1 a logic circuit that gives an output signal only in response to a combination of two or more input signals. 2 a signal that allows or controls the passage of another signal.

**gated channel** a channel in the membrane of a cell (especially an excitable cell) that allows entry of ions into the cell only under specific conditions. See also ligand-gated, voltage-gated ion channel.

**gating** the opening and closing of a gated channel.

**gating current** an electric current arising from the movement of charged groups in the protein of the sodium-ion channels of excitable nerve membranes, during the passage of an action potential, prior to the opening of the channel.

**g-atom** abbr. for gram-atom or gram-atomic weight.

**GAU** a codon in mRNA for L-aspartic acid.

**gauche** abbr.: g; (in chemical nomenclature) a conformational descriptor indicating a synclinal conformation. See conformation.

**Gaucher's disease** an autosomal recessive inherited lysosomal storage disease showing several types, all of which involve some degree of glucosylceramide accumulation, especially in macrophages which are found in large numbers in spleen, bone marrow, and liver. The disease is due to a deficiency of

glucosylceramidase (EC 3.2.1.45). There is a juvenile form which is associated with mental retardation, and a milder form that is not manifested until adult life. *See also saposin.* [After Philippe Charles Ernest Gaucher (1854-1918), French physician.]

**gauss symbol:** G or Gs; the cgs unit of magnetic flux; it is equal to a magnetic flux density of one maxwell per cm<sup>2</sup>, one line of magnetic induction per cm<sup>2</sup>, or 10.4 tesla.

**Gaussian distribution** *an alternative name for* normal distribution.

**gavage** the administration of food or other material in liquid form through a tube directly into the stomach; forced feeding in this manner.

**Gb3 symbol** for globotriaose (alternative to GbOse3)

**Gb4 symbol** for globotetraose (alternative to GbOse4)

**G-banding** or Giemsa banding; a commonly used procedure in which Giemsa's stain is used to identify chromosomal bands in a karyotype.

**GbOse3 symbol** for globotriaose (alternative to Gb3).

**GbOse4 symbol** for globotetraose (alternative to Gb4).

**GBP** abbr. for glucose bisphosphate (*formerly called* glucose diphosphate).

**G-1,6-BP** abbr. for glucose 1,6-bisphosphate (*formerly called* glucose 1,6-diphosphate).

**Gc symbol** for the glycoloyl group.

**GC abbr.** for gas chromatography.

**GCA** a codon in mRNA for L-alanine.

**GC box** a nucleotide sequence element common in eukaryotic promoters: consensus GGGCGC.

**GCC** a codon in mRNA for L-alanine.

**G cell** a gastrin-producing cell found in the antrum of the stomach and to a lesser extent in the mucosa of the duodenum, though the distribution varies in different species. In humans, G cells are small and pyriform while in dogs they are larger and triangular in shape. They can be identified by immunofluorescence using a gastrin-specific antibody.

**GCG** 1 a codon in mRNA for L-alanine. 2 a suite of computer programs widely used for nucleic acid and protein sequence analysis, structure prediction, and sequence alignment. It is available for UNIX, VMS, and XWindows, and is produced by UWGCG.

**GC/MS abbr.** for gas chromatography/mass spectrometry.

**GCN4** a gene for a yeast transcription factor that binds, as a dimer, to the sequence TGA[C/G]TCA. The protein has a leucine zipper, and resembles *FOS* and *JUN*. Database code: GCN4\_YEAST, 281 amino acids (31.28 kDa).

**G-CSF** abbr. for granulocyte colony stimulating factor.

**GCU** a codon in mRNA for L-alanine.

**Gd symbol** for gadolinium.

**GDC** abbr. for Graves' disease carrier protein; it is similar in structure and some other properties to ADP,ATP carrier protein.

**G4 DNA** abbr. for DNA containing a G-quartet.

**GDNF** abbr. for glial cell line-derived neurotropic factor; a glycosylated disulfide-bonded homodimer that promotes survival and morphological differentiation of dopaminergic neurons. Human and rat GDNFs have 93% homology. The precursor, database code GDNF\_HUMAN, 211 amino acids (23.72 kDa), yields a mature protein of 134 amino acids. *Compare* brain-derived neurotropic factor.

**GOP** abbr. for 1 guanosine diphosphate. 2 glucose diphosphate (now called glucose bisphosphate).

**G-1,6-DP** abbr. for glucose 1,6-diphosphate (now called glucose 1,6-bisphosphate).

**GDP-fucosepyrophosphorylase** *see* fucose-1-phosphate guanyltransferase.

**GDPM** or **GDPmannose** abbr. for guanosinediphosphomannose.

**GDPmannose 6-dehydrogenase** EC 1.1.1.132; an enzyme that catalyses the reaction between GDP-D-mannose, 2 NAD<sup>+</sup> and H<sub>2</sub>O to form GDP-D-mannuronate and 2 NADH. Example from *Pseudomonas aeruginosa*: ALGD\_PSEAE, 436 amino acids (47.58 kDa).

**GDPmannose 3,5-epimerase** EC 5.1.3.18; an enzyme that catalyses the interconversion of GDP-D-mannose and GDP-L-galactose.

**GDS** (*in clinical chemistry*) abbr. for guanine deaminase.

**Ge symbol** for germanium.

**Geiger counter** or Geiger-Müller counter a device for detecting and measuring ionizing radiation (alpha or beta particles or gamma-ray photons). It consists of a glass envelope containing low-pressure gas and an anode and a cathode, between which a large electric-potential difference is maintained. The ions produced in the gas by the incoming ionizing radiation are accelerated towards their appropriate electrodes, causing a momentary drop in the potential between the latter. The voltage pulses so produced may be counted with a suitable electronic circuit. [After Hans Wilhelm Geiger (1882-1945), German physicist, and Erwin Wilhelm Müller (1911-77), German-born US physicist.]

**Geiger region** or Geiger-Müller region the part of the curve of applied voltage against number of ions collected for a given incoming radiation by a Geiger counter, where all possible ion-pairs, both primary and secondary, are collected; i.e. the signal is relatively independent of the applied voltage. *Compare* proportional region.

**gel** 1 a colloidal system, with the semblance of a solid, in which a solid is dispersed in a liquid. A gel has a finite, usually rather small, yield stress. 2 to become, or cause to become, a gel.

**gelatin** a heterogeneous mixture of water-soluble proteins of high average *M<sub>r</sub>*, derived from collagen by partial hydrolysis in either acid (type A) or alkali (type B). Collagen obtained by boiling skins, ligaments, tendons, etc. with water is also termed gelatin as also is collagen denatured by heating for 15 minutes at 45°C, used as a substrate for gelatinase. It is colourless, or slightly yellow, and transparent, and occurs as brittle sheets, flakes, or coarse powder; these swell in water to form gels below 35-40°C, containing 5-10 times as much water as gelatin by weight. Nutritionally gelatin is an incomplete protein containing only small amounts of certain essential amino acids, especially tryptophan. It is widely used in foods and in the manufacture of adhesives, photographic films and plates, and light filters.

**gelatinase** EC 3.4.24.24; *recommended name:* gelatinase A; *other names:* 72 kDa gelatinase; matrix metalloproteinase 2; type IV collagenase. An enzyme that catalyses the cleavage of gelatin and collagen types IV, V, VII, and X; it cleaves the collagen-like substrate sequence Pro-Gln-Gly- $\beta$ -Ile-Ala-Gly-Gln; zinc and calcium are cofactors. It is a metallo (zinc) endopeptidase with fibronectin domains, and is produced by fibroblasts. Example from human (precursor): database code COG2\_HUMAN, 660 amino acids (73.80 kDa); there is a large pro region; the enzyme starts at amino acid 110.

**gelation** 1 the (usually reversible) act or process of forming a gel (def. 1) from a sol. *Compare* solation. 2 the solidification of a liquid by cold. -gelate vb.

**gel chromatography** *see* liquid-gel chromatography.

**gel diffusion** (*in immunology*) a technique in which antibodies and antigens are allowed to diffuse independently through a gel, often of agar, and form a precipitate within the gel where homologous antigens and antibodies meet in optimal proportions.

**gel electrophoresis** a type of zone electrophoresis in which the supporting medium is a gel of uniform concentration, commonly of polyacrylamide, agarose, or starch. *See* polyacrylamide (gel) electrophoresis. *Compare* gradient (acrylamide) gel electrophoresis.

**gel filtration** or gel-filtration chromatography *see* gel-permeation chromatography.

**gel-filtration chromatography** *see* gel-permeation chromatography.

**gel-filtration high-performance liquid chromatography** a technique of gel-permeation chromatography that uses a support material of high mechanical strength and chemical inertness

## gel fluorography

gene

thereby enabling separations to be effected under the conditions, and with the advantages of high-pressure liquid chromatography.

**gel fluorography** the application of fluorography (def. 2) to the detection of substances separated in gels, as by gel electrophoresis.

**gellify** to cause to become a gel (def. I); to become gel-like; to gel (def. 2).

**gelonin** or **ribosome-inactivating protein** or **rRNA N-glycosidase EC 3.2.2.22; recommended name: rRNA N-glycosidase**; an extremely stable, potent toxin extracted from seeds of *Gelonium multiflorum* (a plant of the spurge family). It is a single-chain glycoprotein of 28-30 kDa containing terminal mannose residues. It acts as a powerful inhibitor of protein synthesis in cell-free systems but not in intact cells; it inactivates the 60S ribosomal subunit but has no effect on the 40S subunit. Its action is to hydrolyse one specific N-glycosidic bond of an adenosine on the 28S rRNA. In cell-free protein-synthesizing systems gelonin acts like the A chains of abrin, ricin, and modeccin, suggesting that it lacks the ability to bind to cell surfaces and enter cells. Example from *G. multiflorum*: RIPG\_GELMU, 316 amino acids (35.42 kDa).

**gel-permeation chromatography** a method for the separation of substances in solution, commonly known as gel filtration or gel-filtration chromatography. The separation is based mainly on exclusion effects, such as differences in molecular size and/or shape or in charge, when the stationary phase is a swollen gel. The gel used is commonly a water-swollen insoluble carbohydrate polymer from which macromolecules are excluded and migrate without retention in the interstitial fluid. Substances of low or intermediate relative molecular mass penetrate into the gel particles to an extent that is, in most instances, determined by their molecular dimensions and the degree of cross-linking of the gel. The larger molecules therefore pass through the bed more rapidly than smaller molecules. The technique can be used to determine the relative molecular mass ( $M_r$ ) of unknown materials, since, for a particular column, elution occurs at a volume determined by the equation

$$VRIV_O = 1 - p \log(M_r/M_{r0})$$

where  $V_r$  is the elution volume of the unknown,  $V_O$  is the volume of the mobile phase in the column,  $M_r$  is the  $M_r$  of the unknown,  $M_{r0}$  is the  $M_r$  of the largest totally permeating molecule, and  $p$  is a factor that is a property of the column. Thus each column must be calibrated using standard proteins, and a plot made of the elution volumes against  $10^6 M_r$  of the standards, from which the unknown  $M_r$  can be determined.

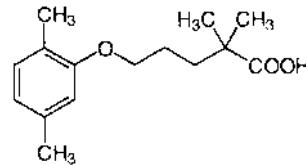

**gelsolin** a heat-labile, monomeric protein of apparent  $M_r$  90 000 isolated from macrophages, platelets, and plasma. It appears to promote the gel-sol transformation of actin and may thereby be important in the control of locomotion, secretion, and endocytosis in these and other cells;  $\beta$ -actin has a similar action. There are two forms of gelsolin, plasma and cytoplasmic, generated by alternative splicing. The cytoplasmic, calcium-regulated, actin-modulating form binds to the barbed ends of actin monomers or filaments, preventing monomer exchange; it also promotes nucleation and binds with high affinity to fibronectin. Example (cytoplasmic form) from mouse: database code GELS\_MOUSE, 731 amino acids (80.79 kDa).

**gem- prefix (in chemical nomenclature)** denoting the presence of geminal substituents.

**gemeprost** 16,16-dimethyl-trans-Az-prostaglandin E<sub>1</sub> methyl

ester; II, 15-dihydroxy-16,16-dimethyl-9-oxoprosta-2,13-dien-I-oic acid methyl ester; an analogue of prostaglandin E<sub>1</sub> with uterine stimulant activity.

**gemfibrozil** 2,2-dimethyl-5-(2,5-xylyloxy)valeric acid; an anti-hyperlipoproteinemic agent with actions similar to clofibrate.

**geminal (in chemistry)** describing two like groups or atoms attached to the same atom in a molecule, i.e. the geminal groups or atoms are separated by two bonds attached to the same atom. The presence of geminal substituents is denoted by the prefix *gem-* attached to the name of the compound. Compare vicinal (def. 2).

**geminate** occurring in pairs; doubled, twin.

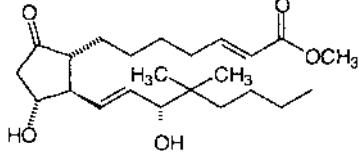

**+gen or (after a consonant) +ogen comb. form** signifying producing or capable of producing (either directly or indirectly). In biological sciences it is used especially (1) with word-stems relating to physiological or pathological processes, states, conditions, etc., to denote a causative agent (e.g. antigen, lactogen, mutagen, estrogen); (2) with names of certain proteinases or blood components, to denote their inactive precursors or substances from which they can be derived by enzymic action (e.g. angiotensinogen, caseinogen, fibrinogen, trypsinogen) (see also *pro+* (def. 3), *zymogen*); (3) with names or name-roots of certain metabolites, to denote either a storage substance (e.g. glycogen, phosphagen) or a biosynthetic precursor (e.g. porphobilinogen); (4) with word-stems relating to physical properties (e.g. chromogen, luminogen). **-+genic or +genous adj. suffix**.

**Genaminox KC** the proprietary name for detergents similar to lauryldimethylamine oxide, but with different alkyl chain lengths (9-13).

**Genapol** the proprietary name for a series of nonionic polyoxyethylene detergents of the general formula  $CH_3(CH_2)_x-O(CH_2CH_2O)_y-H$ ; Genapol X-080 has  $x = 12$ ,  $y = 8$ , CMC 0.06-0.15 mM; Genapol X-100 has  $x = 12$ ,  $y = 10$ , aggregation number 88, CMC 0.15 mM. Compare *exE*<sup>W</sup> Lubrol, Triton, Tween.

**GenBank** a large database of protein and nucleic-acid sequences. See Appendix E.

**gene** in classical genetics, a statistical entity that correlates with a particular phenotypic characteristic; the functional unit of heredity. Before their biochemical nature was understood, genes were defined in terms of units of mutation and/or recombination. Discovery of the role of DNA in genetic processes, followed by elaboration of the central dogma of protein synthesis, led to enunciation of the 'one gene-one enzyme' hypothesis, i.e. that a gene consisted of DNA that coded for a protein that performed the functions associated with the phenotypic expression of the gene. In current molecular genetics, the concept requires modification in a number of ways. First, the genomic DNA that codes for a polypeptide is associated with regulatory sequences such as promoters. Second, the polypeptide resulting from translation of mRNA may be subsequently split to give several polypeptides with different functions (see polyprotein). Third, the RNA transcribed may give rise to several different proteins as a result of alternative splicing. Three types of genes are now distinguished: those that are both transcribed into mRNA and translated into polypeptides (structural genes); those that are only transcribed into RNA (e.g. rRNA, tRNA); and those that function as regulators of the expression of the other two types (regulator genes). In diploid organisms a gene may occur in alternative forms

(8118les). The term gene is sometimes used interchangeably with cistron.

**gene amplification** the selective, repeated replication of a certain gene or genes without a proportional increase in other genes in the genome. It occurs, e.g., in the DNA puffs of *Rhynchosciara* and some other flies and in the amplification of the genes coding for ribosomal RNA (so-called ribosomal DNA) in amphibian oocytes.

**gene bank** *an alternative name for* gene library.

**gene cloning** *see* molecular cloning.

**gene cluster** or **gene complex** any group of two or more functionally related genes that are closely linked on a chromosome. The genes of a gene cluster are often structural genes coding for the enzymes that catalyse the various steps of a metabolic pathway.

**gene oomplex** *an alternative name for* gene cluster.

**gene dosage** the number of times a particular gene is present in the genome.

**gene duplication** the phenomenon, occurring in some higher organisms, in which there is duplication of the DNA sequences representing particular genes. This process is thought to have played a decisive part in the evolution of these organisms, through the occurrence of different mutations in the two duplicated genes.

**gene expression** the process by which the information carried by a gene or genes becomes manifest as the phenotype. It involves transcription of the gene into complementary RNA sequences and, for structural genes, subsequent translation of mRNA into polypeptide chains and their assembly into the ultimate protein products. Gene expression is tightly regulated by promoters, enhancers, and transcription factors.

**gene frequency** a measure of the proportion of an allele in a given population, equal to the number of loci at which a given allele occurs, divided by the total number of loci at which it could occur.

**gene library** or **cloned library** or **gene bank** or **shotgun collection** a random collection of DNA fragments cloned in a vector (def. 3), and which may include all the genetic information of a particular species. It may be prepared from a variety of sources, including an extract of mRNA, in contrast to a genomic library which is prepared from genomic DNA.

**gene mutation** any mutation (def. 1) occurring within a single gene.

**gene pool** the sum of the genetic information in the reproductive members of a population of sexually reproducing organisms.

**gene product** any of the types of RNA (transcription products) or any of the proteins or protein subunits (translation products) synthesized biochemically on the basis of the information encoded in a genome.

**general acid-catalysis** homogeneous catalysis in which the catalysts are various hydron donors (acids). *Compare* specific acid-catalysis.

**general base-catalysis** homogeneous catalysis in which the catalysts are various hydron acceptors (bases). *Compare* specific base-catalysis.

**generally labelled** describing the labelling of a molecule in such a way that a radionuclide may be present at any or all (but not necessarily all) possible positions. *Compare* uniformly labelled.

**general transcription factor** any of the proteins whose assembly around the TATA box is required for the initiation of transcription of most eukaryotic genes.

**generate** (*in mathematics*) to conceive a point, line, or surface to be moving in a specified way so as to form a line, surface, or solid, respectively.

**generation** 1 the act or process of producing or reproducing, naturally or artificially. 2 the phase in a life cycle that extends from one to the immediately successive reproduction. 3 any group comprising all those members of a population who are equally removed from a common ancestor or from coeval ancestors.

**generation of diversity** (*in immunology*) the process by which a large number of variable regions are generated in the immunoglobulins. The stem cell genome contains multiple variants of L-chain V (variable) and J genes and of the H-chain V, J, and D (diversity) genes. As the stem cells differentiate, the maturing lymphocyte constructs particular L and H genes of virtually unique structure by a recombination process that randomly selects one out of each set of gene segments and assembles them, together with a C (for the constant region) gene into a mature H or L gene. This, combined with recombinational inaccuracies, somatic point mutations, and the varied combinations of L and H chains found in immunoglobulins results in a repertoire of millions of lymphocytes each with H and L genes encoding unique molecules. *See also* immunoglobulin.

**generation time** the time between division of a cell and that of its daughter cells, averaged over a whole cell population.

**gene redundancy** the presence in a cell of many copies of a single gene. The multiple copies may be inherited or result from selective gene duplication during development.

**gene-regulatory protein** any protein that binds to a specific DNA sequence to alter the expression of a gene.

**+genesis comb. form** denoting beginning or origin; development; generation. *See also* +gen. -+genetic or +genic adj. comb. form.

**gene splicing** biochemical and/or chemical manipulations with the object of attaching one DNA molecule to another. The neatest method is to cleave the DNA to be inserted (foreign DNA) with a restriction endonuclease that yields single-stranded ends that are complementary to each other. The cloning vector into which the foreign DNA is to be inserted is treated with the same endonuclease so that the complementary ends of the two DNAs specifically associate under annealing conditions and are subsequently covalently joined (spliced) through the action of DNA ligase. If the endonuclease produces fragments with 'blunt' or flush ends then a similar procedure is adopted. If the foreign DNA and the cloning vector have no common restriction sites then terminal deoxynucleotidyl transferase may be used which adds nucleotides to the 3'-terminal OH group of a DNA chain. For this purpose tails of poly(dT) and poly(dA) may be used. The transformed cells are then grown and those containing the spliced DNA are selected (cloning). The preferred method of splicing is one that allows the foreign DNA to be removed easily by means of a restriction endonuclease, preferably the same one that was initially used in splicing. By this means large amounts of the foreign DNA can be synthesized and used for many different purposes. Alternatively the cloned cells containing the foreign DNA can be used to permit the expression of a foreign protein which is then recovered.

**genetic** or **genetical** of or pertaining to genetics, genes, or the origin of something. -genetically adv.

**genetically engineered** describing a cell, strain, or organism whose phenotype has been altered by manipulation of its genetic material. *See* genetic engineering.

**genetic block** a reduction in the activity of a particular enzyme in a metabolic pathway as a result of gene mutation. A genetic block is termed complete when the particular enzyme activity is absent, or incomplete (*or leaky*) when the enzyme formed is defective and of limited activity.

**genetic carrier** *see* carrier (def. 9).

**genetic code** all the regularities in nucleotide sequence according to which genetic information for the sequences of all the polypeptides synthesized by transcription and translation is encoded in DNA (or RNA in some viruses). A sequence of three nucleotide residues (a codon) is required to code for one amino-acid residue, and since there are four different kinds of base in nucleic acids (apart from minor constituents), i.e. 64 different nucleotide triplets can exist. But only 20 different amino-acid residues in polypeptides can be coded for; therefore the code is degenerate in that most amino acids can be

specified by more than one codon. In terms of the sequence of nucleotides in mRNA, i.e. the nucleotides complementary to those in the genetic material, the genetic code, reading from the 5' end to the 3' end of each codon, is given in the table. (The letter A symbolizes a nucleotide residue containing adenine; G, guanine; C, cytosine; and V, uracil; each amino-acid residue is represented by its usual three-letter symbol.)

VVV: Phe	VCV: Ser	VAV: Tyr	VGV: Cys
VVC: Phe	VCC: Ser	VAC: Tyr	VGC: Cys
VVA: Leu	VCA: Ser	VAA: Tert	VGA: Tert
VVG: Leu	VCG: Ser	VAG: Tert	VGG: Trp
CVV: Leu	CCV: Pro	CAU: His	CGV: Arg
CVC: Leu	CCC: Pro	CAC: His	CGC: Arg
CVA: Leu	CCA: Pro	CAA: Gin	CGA: Arg
CVG: Leu	CCG: Pro	CAG: Gin	CGG: Arg
AVV: Ile	ACV: Thr	AAV: Asn	AGV: Ser
AVC: Ile	ACC: Thr	AAC: Asn	AGC: Ser
AVA: Ile	ACA: Thr	AAA: Lys	AGA: Arg
AVG: Met‡	ACG: Thr	AAG: Lys	AGG: Arg
GVV: Val	GCV: Ala	GAV: Asp	GGV: Gly
GVC: Val	GCC: Ala	GAC: Asp	GGC: Gly
GVA: Val	GCA: Ala	GAA: Glu	GGA: Gly
GVG: Val	GCG: Ala	GAG: Glu	GGG: Gly

t termination codon. UAA was once called ochre codon; UAG, amber codon; UGA, opal codon.

‡ initiation codon. The methionine codon AUG is the most common starting point of translation of a genetic message but GUG sometimes serves.

The genetic code is almost universal but differences have been found in the DNA of mitochondria from a number of organisms. For example, in human mitochondria VGA codes for Trp and not for termination; AVA codes for Met and not for Ile; AGA and AGG are termination codons and do not code for Arg; AVA and possibly AVV act as initiation codons as well as AVG.

genetic colonization the introduction by a parasite of genetic information into a host such as to cause the host to synthesize products that only the parasite can use. This occurs in some plants, e.g., in cases of parasitism by *Agrobacterium* spp.

genetic complementation the phenomenon whereby the introduction of two chromosomes, each from different heterozygote cells and carrying different mutations in the same genetic region, results in the restoration of normal biochemical function, when this is deficient in either heterozygote.

genetic cross 1 any mating of two organisms that results in a genetic recombinant. 2 the offspring of two (or more) parent organisms produced by mating or other means.

genetic defect any alteration in the genetic information carried in an individual organism, the effect of which is to produce a phenotype that is at a disadvantage in competing with a normal organism of the same species or in meeting the challenges of its environment. See also inborn error of metabolism, molecular disease.

genetic disease any disease ultimately caused by a genetically determined biochemical defect. In the strict sense a genetic disease is only slightly influenced by environmental factors.

genetic drift 1 any change with time in gene frequency in a population. It may be either directed, steady drift, or undirected, random drift. 2 irregular, random fluctuations in gene frequency in a (relatively) small population caused by statistical effects.

genetic engineering the genetic manipulations used to produce individuals having a new combination of inherited properties. Such manipulation may be of two kinds: (I) cellular manipulation, involving the culturing of (haploid) cells and

the hybridization of somatic cells (see cell fusion); and (2) molecular manipulation, involving the construction of artificial recombinant DNA molecules, their insertion into a vector (def. 3), and their establishment in a host cell or organism. The latter approach has been called recombinant DNA technology. genetic information the information carried in a sequence of nucleotides in a molecule of DNA or RNA.

genetic locus see locus.

genetic map any diagram showing the linear order of, and the relative distances between, mutable sites on a chromosome as deduced from genetic recombination experiments.

genetic mapping any method that may be used to determine the positions of, and the relative distances between, genes of a linkage group or of sites within a gene (fine-scale mapping). In classical genetics, mapping relied on a study of recombination frequency and was measured in morgans. In molecular biology, mapping relies on the sequencing of DNA in a chromosome. Current work is aimed at mapping entire genomes. See also genetic map, map unit.

genetic marker 1 any genetically controlled phenotypic difference that can be used in analysing the genetic make-up of an organism. 2 any gene difference in either one or both alleles used in the detection of genetic recombination events.

genetic material the molecular carrier of primary genetic information that serves as a template for its own replication and provides the structural and regulatory information for the processes of protein synthesis and cell development. It consists of double-stranded DNA in higher organisms, bacteria, and most bacteriophages, single-stranded DNA in some bacteriophages, and RNA in the RNA viruses.

genetic polymorphism the regular and simultaneous existence in the same population of two or more discontinuous variants or genotypes, in frequencies that cannot be due to recurrent mutations, e.g. the different human blood groups.

genetic profiling or DNA fingerprinting, a technique for providing profiles of DNA fragments (resulting from digestion with restriction enzymes) that characterize a genome. The human genome is scattered with minisatellites, regions of DNA consisting of tandem repeats of short base sequence which can show extensive variation in the number of repeats, leading to multi-allelic variation and high degrees of heterozygosity. This extreme level of variation renders minisatellite or VNTR (variable number tandem repeats) loci invaluable as genetic markers. The DNA is digested with a suitable restriction endonuclease and the fragments are electrophoresed through agarose gel and transferred by blotting to a nylon filter. Hybridization is with a minisatellite probe labelled with  $^{32}\text{P}$ . The use of the polymerase chain reaction (PCR) to amplify hyper-variable loci, including very short tandem-repetitive microsatellites, has greatly increased the sensitivity of DNA typing systems and the ability to type degraded human DNA. The method can be used to identify an individual's DNA and also to trace the parentage of an individual. The method is not confined to humans but has been applied to a wide range of species.

genetic recombinant any organism produced by genetic recombination.

genetic recombination the processes by which a new genotype is formed by reassortment of genes resulting in gene combinations different from those that were present in the parents. In eukaryotes genetic recombination can occur by chromosome assortment, intrachromosomal recombination, or nonreciprocal interchromosomal recombination. Intrachromosomal recombination occurs by crossing over. In bacteria it may occur by genetic transformation, conjugation, transduction, or F-duction. See also Holliday junction.

genetics 1 the branch of biology concerned with heredity and variation in organisms. It embraces the phenomenology and physiology of heredity; the nature of genetic information; the storage of genetic material; the replication, mutation, transmission, and recombination of genetic material; and the way it

## genetic screening

## geotaxis

is translated into systems that control development and metabolism, and determine the reappearance of parental characters among progeny. 2 the genetic features and constitution of any single organism, species, or group of organisms. See also reverse genetics.

**genetic screening** the testing of individuals or groups of individuals for some specific gene product or resulting metabolite for the purpose of identifying genetic defects or diseases.

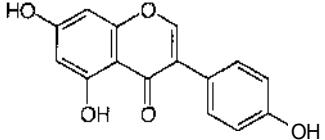

**genetic transformation** see transfection (def. 1).

**genetic variance** that part of the phenotypic variance caused by the varying genotypes of the individuals within a population.

**genic** of, or relating to, a gene or genes.

**genin** 1 *the class name for* the noncarbohydrate residue of steroid glycosides. It is used as a suffix in forming trivial names of the naturally occurring glycoside precursors; e.g. digitogenin (from digitonin), saponin (from saponin). 2 *a former name for* spirostan, 16,22:22,26-diepoxycholestane.

**genistein** 4,5,7-trihydroxyisoflavone; 5,7-dihydroxy-3-(4-hydroxyphenyl)-4H-1-benzopyran-4-one; an inhibitor of tyrosine-specific protein kinases and other protein kinases. It is a competitive inhibitor at the ATP binding site, which is a conserved structural feature in protein kinases.

**genome** the whole of the genetic information of an organism. It is contained as DNA in eukaryotes and prokaryotes, and as either DNA or RNA in viruses. A given organism has only one genome regardless of whether the organism is haploid, diploid, or polyploid. The term was originally used to denote one haploid set of chromosomes in a eukaryote organism. - genomic ad).

**genome mutation** any mutation (def. 1) occurring by alteration of the number of chromosomes in the genome.

**genome-regulatory protein** any site-specific protein involved in the regulation of transcription, such as a polymerase, repressor, or activator.

**genomic blotting** *an alternative name for* Southern blotting.

**genomic DNA** all of the DNA comprising one genome.

**genomic library** a set of clones containing DNA fragments that *in toto* embrace an entire genome. It is prepared by firstly randomly cutting the genomic DNA to give fragments of varying length. The average fragment length is controllable by discrimination in the choice of restriction enzymes used for cutting, and is selected to optimize the length such that fragments will contain entire open reading frames without excessive lengths of additional DNA at either end. Secondly the DNA fragments thus obtained are ligated into a suitable vector (def. 3), which is cloned in a host of choice.

**genophore** the structural equivalent of a genetic linkage group in any organism. The term comprehends the linear chromosome of the (enveloped) eukaryon of all animal and plant cells, the circular chromosome of the (nonenveloped) prokaryon of cells of bacteria, the duplex DNA of mitochondria, chloroplasts, kinetoplasts, plasmids, and episomes, and the nucleic acid, whether DNA or RNA, single-stranded or double-stranded, of viruses.

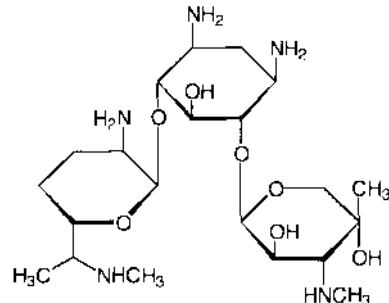

**genotheque** a term proposed as an alternative to gene library. [From gene (ultimately from Greek *genos*, descent + *thēkē*, case, box.)]

**genotoxic** exerting an effect by damaging or otherwise interfering with the action of a gene.

**genotype** 1 the total genetic constitution of an organism. It comprises the genetic information carried both in the chromo-

somes and extrachromosomally. Compare phenotype. - genotypic ad).

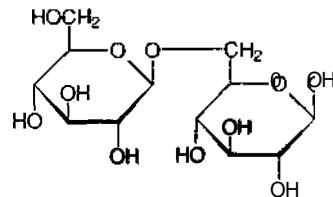

**gentamicin** or gentamycin any of a group of aminoglycoside antibiotics produced by fermentation of some *Micromonospora* spp. They are inhibitors of protein synthesis, and are particularly effective in the treatment of *Pseudomonas aeruginosa* infections.

gentamicin C,

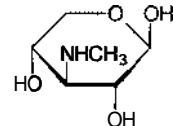

**gentianose** the trisaccharide, *O*- $\beta$ -D-glucopyranosyl-(1 $\rightarrow$ 6)-*O*- $\alpha$ -D-glucopyranosyl-(1 $\rightarrow$ 42)-*O*- $\alpha$ -fructofuranoside. It is found in the rhizomes of many species of *Gentiana*.

**gentiobiose** or (formerly) amygdalose the disaccharide, *O*- $\beta$ -D-glucopyranosyl-(1 $\rightarrow$ 46)-*O*-glucose. It is a component of some glycosides, e.g. amygdalin.

(*i*-gentiobiose)

**gentosamine** 3-deoxy-3-methylamino-D-xylose; a component of gentamicin A, one of the structural variants of gentamicin.

**genus** (*pl. genera*) (*in taxonomy*) a category used in biological classification consisting of species with a common phylogenetic origin that appear to be clearly differentiated from other species.

+geny comform denoting origin or mode of development. - +genic ad).

**geometric isomer** or geometrical isomer *an alternative term for cis-trans isomer.*

**geometric; isomerism** or geometrical isomerism *an alternative term for cis-trans isomerism.*

**geometric mean** or geometric average for  $n$  positive numbers, the  $n$ th root of the product of the numbers. Thus for a set of positive numbers  $x_1, x_2, x_3, \dots, x_n$  the geometric mean is  $(x_1 \cdot x_2 \cdot x_3 \cdots x_n)^{1/n}$ . Compare mean.

**geotaxis** the movement of an organism or a cell under the influence of a gravitational field. In positive geotaxis the organ-

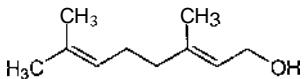

**geotropism**

ism moves in the same direction as the gravitational field, while in negative geotaxis the movement is in a direction opposite to the gravitational field. -geotactic *adj.*

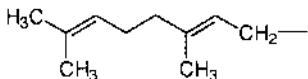

**gephryin** a cytoplasmic protein that associates with microtubules and is required for clustering of glycine receptors in spinal cord. It has a role in molybdoenzyme function in non-neuronal tissue. Example, GEPH\_RAT, 736 amino acids (79.83kDa).

**g-equiv** abbr. for gram-equivalent or gram-equivalent weight.

**geraniol** (2E)-3,7-dimethyl-2,6-octadien-1-ol, a monoterpene alcohol with a sweet rose odour, present in oil of rose and other essential oils.

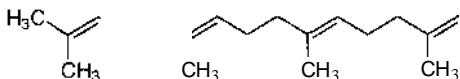

**geranyl** the (2E)-3,7-dimethyl-2,6-octadien-1-yl group. The 1-diphosphate derivative is an intermediate in the synthesis of cholesterol and in the formation of **geranylgeranyl** diphosphate.

**geranyl-diphosphate synthase** see **dimethylallyltransferase**.

**geranylgeranyl** the (2E,6E,10E)-3,7,11,15-tetramethyl-2,6,10,14-hexadecatetraen-1-yl group. The 1-diphosphate derivative is a substrate for enzymes introducing the geranylgeranyl group into proteins. See also **prenylation**.

**geranylgeranyl pyrophosphate synthetase** see **farnesyl transferase**.

**geranyltransferase** EC 2.5.1.10; systematic name: geranyl-diphosphate:isopentenyl-diphosphate geranyl transferase; other names: farnesyl-diphosphate synthase; farnesyl pyrophosphate synthetase (abbr.: FPP synthetase). An enzyme of the pathway synthesizing **prenyl** groups, **sesquiterpenes**, and **cholesterol**. It catalyses the reaction between geranyl diphosphate and isopentenyl diphosphate to form *trans,trans*-farnesyl diphosphate with release of pyrophosphate. Example from yeast: database code FPPS\_YEAST, 352 amino acids (40.48 kDa).

**Gerbich system** abbr.: Ge; a blood-group system whose antigenic determinants are located on the extracellular, glycosylated domain of **glycoporphins** C and D (GPC and GPD). The polypeptide sequences of these give rise to several Ge phenotypes: on GPD the antigenic site for Ge2 resides between residues I and 17, and that for Ge3 resides between residues 19 and 34; on GPC, the antigenic site for Ge4 is at the N terminus, and that for Ge3 between residues 40 and 55.

**GERL** abbr. for Golgi, endoplasmic reticulum, Lysosomes; a term formerly used to describe a specialized region of smooth **endoplasmic reticulum** with high levels of acid phosphatase and other acid hydrolase activities. It is thought to be a region where acid hydrolases are concentrated and packaged into Lysosomes. It may also be concerned in packaging other materials, including epinephrine granules in the adrenal medulla, tyrosinase and other materials in premelanosomes in mouse melanomas, peroxidase, etc. in secretory granules in

**gibberellin**

cells of parotid and submaxillary glands, and un-iodinated thyroglobulin in thyroid epithelial cells.

**germ cell** any cell of the **germ line**, including **gametes**.

**germ-free** describing any group of animals or plants that is bred and maintained in such conditions that they contain no microorganisms, either normal symbionts or abnormal, infective ones. Compare **gnotobiotic**.

**germin** a pepsin-resistant water-soluble glycoprotein of the walls of germinated plant embryos that may alter the properties of cell walls during germinative growth. Its synthesis coincides with the onset of growth in germination. The protein has oxalate oxidase activity. Example from *Triticum aestivum*: germin GF-2.8 precursor, homopentamer; database code GER2\_WHEAT, 224 amino acids (23.58 kDa).

**germ line** any line of cells that gives rise to gametes and is continuous through the generations.

**Gerstmann-Straussler syndrome** a transmissible **spongiform encephalopathy** of humans, usually familial, characterized by widespread degeneration of the nervous system. See also **prion**. [After Joseph Gerstmann (1887-1969), Austrian neurologist.]

**GF-1** see **GATA-1**.

**GFR** abbr. for (renal) glomerular filtration rate.

**Gg<sub>3</sub>** symbol for gangliotriose (alternative to GgOse3)

**Gg<sub>4</sub>** symbol for gangliotetraose (alternative to GgOse4)

**GGA** a codon in mRNA for a glycine residue.

**GGC** a codon in mRNA for a glycine residue.

**GGG** a codon in mRNA for a glycine residue.

**GgOse3** symbol for gangliotriose (alternative to Gg<sub>3</sub>)

**GgOse4** symbol for gangliotetraose (alternative to Gg<sub>4</sub>)

**GGU** a codon in mRNA for a glycine residue.

**GH** abbr. for growth hormone (i.e. **somatotropin**).

**ghilanten** see **antistasin**.

**ghost** an empty red-blood-cell membrane, usually obtained by lysis of red cells by the controlled reduction in the osmotic pressure of the suspending medium followed by restoration of normal osmotic conditions causing the membranes to reseal. Ghosts are extensively used in studies of the properties of membranes.

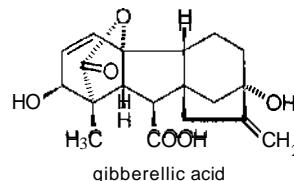

**GHRF** abbr. for growth hormone releasing factor (see **GHRH**).

**GHRH** abbr. for growth hormone releasing hormone; other names: growth hormone releasing factor (abbr.: GHRF) or somatotropin; any of a family of peptide hormones that act on the anterior pituitary to stimulate the secretion of growth hormone and exert a trophic effect on the gland. Example from *Bos taurus*: database code SUB\_BOVIN, 44 amino acids (5.109 kDa). It is synthesized as a precursor; example from *Oncorhynchus nerka*: database code PACA\_ONCNE, 173 amino acids (19.7 kDa). See also **GHRH receptor**.

**GHRH receptor** abbr. for growth hormone releasing hormone receptor; other name: growth hormone releasing factor receptor (abbr.: GRFR); any of a family of integral membrane proteins that bind GHRH and mediate its intracellular effects. These receptors are seven-transmembrane-helix receptors coupled to a G-protein that stimulates adenylate cyclase. A defect in this receptor (Asp<sup>60</sup> → Gly<sup>60</sup>) is associated with hypoplasia of the anterior pituitary in mice. Example (precursor) from *Mus musculus*: database code GRFR\_MOUSE, 423 amino acids (47.04 kDa).

**GH-RIH** abbr. for growth hormone release inhibiting factor (i.e. **somatostatin**).

**gibberellin** any of a widely distributed, multimembered group

## Gibbs-Duhem equation

of highly modified C<sub>20</sub> (and C<sub>19</sub>) terpene plant hormones, the first of which was isolated from plants infected with the fungus *Gibberella fujikuroi*. The most important is gibberellin A<sub>3</sub>, also known as gibberellic acid. Gibberellins accelerate shoot growth, and can actively stimulate RNA synthesis in dwarf mutant plants, making them grow like normal plants. Other physiological effects, e.g. overcoming the need for vernalization in long-day plants, have also been recorded.

**Gibbs-Duhem equation** an equation relating the chemical potential and concentration of a chemical species in a mixture at constant temperature and pressure. If  $n_i$  moles of species  $i$ , having chemical potential  $\mu_i$ , are present in a mixture, then

$$\sum_i n_i d\mu_i = \sum_i x_i d\mu_i = 0$$

where  $x_i = n_i / \sum n_i$  is the mole fraction and  $d\mu_i$  is the change in chemical potential for  $d\mu_i$  a small change in the amount of species  $i$  present, in moles. [After Josiah Willard Gibbs (1839-1903), US physical chemist, and Pierre Duhem (1861-1916), French physical chemist.]

**Gibbs energy** or Gibbs free energy or Gibbs function symbol: G; a thermodynamic property of a system; it is defined as  $H - TS$ , where  $H$  is the enthalpy,  $S$  the entropy, and  $T$  the temperature. For a molecule in solution, Gibbs energy is concentration-dependent. The Gibbs free energy ( $G_i^{\circ}$ ) of the  $i$ th component is equal to the standard free energy of the component ( $G_0^{\circ}$ , the free energy at unit activity) plus a term to adjust for concentration. Thus

$$G_i = G_0^{\circ} + RT \ln a_i$$

where  $R$  is the gas constant, and  $a_i$  the activity of the  $i$ th component. The molar free energy is referred to as the chemical potential. See also Gibbs free energy change.

**Gibbs energy diagram** or Gibbs energy profile for a chemical reaction, a diagram showing the relative standard Gibbs energies of reactants, transition states, reaction intermediates, and products in the same sequence as they occur in the reaction.

**Gibbs energy of activation** or Gibbs free energy of activation symbol:  $\Delta_f^{\circ}G^{\circ}$ ; the standard Gibbs energy difference between the transition state of a chemical reaction (either elementary or stepwise) and reactants.

**Gibbs free energy change** the difference in Gibbs free energy ( $G$ ) at any instant in time between the reactants and products of any reaction. Thus for a reaction  $A + B \rightleftharpoons C + D$ , at any particular concentration of reactants and products, the free energy change,  $\Delta G$ , for that state is calculated as

$$G_C + G_D - G_A - G_B$$

Since, for each substance,

$$G_x = G_0^{\circ} + RT \ln a$$

(see Gibbs energy), this leads to

$$\Delta G = \Delta G^{\circ} + RT \ln \{a_C a_D / a_A a_B\};$$

$$\Delta G^{\circ} = \Delta G_0^{\circ} + \Delta G_0^{\circ} - \Delta G_0^{\circ} - \Delta G_0^{\circ},$$

and is the standard free energy change. All chemical reactions proceed in the direction of negative free energy change until equilibrium is reached, at which point  $\Delta G$  is zero. Since at equilibrium  $a_C a_D / a_A a_B = K$ , it follows that the standard free energy change  $\Delta G^{\circ} = -RT \ln K_0$  where  $K_0$  is the standard equilibrium constant.

**Gibbs-Helmholtz equation** an equation that may be expressed as

$$\Delta G - \Delta H = T[\delta \Delta G / \delta T]_P$$

where  $\Delta G$  is the change in Gibbs energy during a reaction,  $\Delta H$  the increase in enthalpy,  $P$  the pressure, and  $T$  the temperature. Giemsa's stain a stain used for staining chromosomes, in which it reveals bands known as G-bands (from the name). These are rich in A-T nucleotide pairs. Other compounds, e.g. the antibiotic olivomycin, stain G-C-rich bands known as R-bands (because they give the 'reverse' of the G-bands). [After Gustav Giemsa (1867-1948), German parasitologist]

## gliadin

**GIF** abbr. for growth hormone-inhibitory factor (i.e. somatostatin).

**giga+** symbol: G; 1 the SI prefix denoting  $10^9$  times. 2 (*in computing*) prefix used to indicate a multiple of  $2^{30}$ , e.g. gigabyte. **gigantism** a condition arising from the excessive release of somatotropin leading to an individual of excessive size. Compare acromegaly.

**Gilbert**, Walter (1932- ), US theoretical physicist and molecular biologist; Nobel Laureate in Chemistry (1980) jointly with F. Sanger 'for their contributions concerning the determination of base sequences in nucleic acids' [prize shared with P. Berg].

**Gilman**, Alfred Goodman (1941- ), US pharmacologist; Nobel Laureate in Physiology or Medicine (1994) jointly with M. Rodbell 'for their discovery of G-proteins and the role of these proteins in signal transduction in cells'.

**GIP** abbr. for gastric inhibitory peptide.

**GIPL** abbr. for glycoinositolphospholipid (see GPI anchor).

**GIP receptor** any of the integral membrane proteins that bind gastric inhibitory peptide (GIP) and mediate its intracellular effects. They are G-protein-coupled, seven-transmembrane-helix receptors that activate adenylyl cyclase. Example (precursor) from *Rattus norvegicus*: database code GIPR\_RAT, 455 amino acids (52.26 kDa); residues 1-18 are the signal peptide, 19-455 the receptor.

**Gla** symbol for a residue of the a-amino acid L-4-carboxyglutamic acid.

**Glanzmann thrombasthenia** see von Willebrand factor.

**glass electrode** an electrode made of glass whose potential, when immersed in a solution, is a function of the hydrogen-ion activity, i.e. pH, of the solution. A common form of glass electrode consists of a thin glass bulb inside which is mounted a reference electrode, often a silver/silver chloride electrode, immersed in a solution of constant pH and containing the ion to which the inner reference electrode is reversible. A number of special glasses have been made in an effort to extend the range of pH over which the electrode responds linearly, to reduce errors caused by other ions in solution, to extend its useful temperature range, etc.

**Glc** symbol for a residue (or sometimes a molecule) of the aldohexose glucose. In the condensed system of symbolism of sugar residues, Glc signifies specifically a glucose residue with the common configuration and ring size, i.e. D-glucopyranose. (Note: Glu is the symbol for a glutamic residue.)

**GLe or gle** abbr. for gas-liquid chromatography.

**GlcA** 1 symbol for a residue (or sometimes a molecule) of the uronic acid glucuronic acid. 2 former symbol for a residue (or sometimes a molecule) of the aldononic acid gluconic acid (no symbol now recommended).

**Glcf** symbol for a glucofuranose residue.

**GleN** symbol for a residue (or sometimes a molecule) of the aminodeoxysugar glucosamine.

**GlcNAc** symbol for a residue (or sometimes a molecule) of the N-acetylated aminodeoxysugar N-acetylglucosamine.

**GlcP** symbol for a glucopyranose residue.

**GlcU or GleVA** former symbol for glucuronic acid (GlcA now recommended).

**GLI** abbr. for glucagon-like immunoreactant (or glucagon-like immunoreactivity).

**glia** or neuroglia the special connective tissue of the central nervous system constituting some 40% of the total volume of the brain and spinal cord. It has supportive and nutritive functions and is made up of glial cells - oligodendrocytes, astrocytes, ependymal cells, and microglial cells.

**gliadin** or (formerly) gliadine any of a group of proline-rich proteins (prolamins) found in the seeds of the cereals wheat and rye. All gliadins are mixtures of simple proteins of similar composition and properties. They are differentiated from glutenin, with which they are associated in gluten, by their solubility in 70% aqueous ethanol. With water, gliadins form a sticky mass, which binds flour into a dough. They constitute

## glial cells

the major seed storage proteins in wheat. Gladiins fall into two groups:  $\alpha/\beta$  gliadins (*also* prolamin or gliadin AI-V) are in five homology classes; there are more than 100 copies of the gene per haploid genome;  $\gamma$ -gliadins are in three homology classes (classes BI-III). For both groups, sequence divergence between the respective classes is due to single base substitutions and to duplications or deletions within or near direct repeats. These proteins have nine motifs. Examples (precursors):  $\alpha/\beta$ , database code GDA1\_WHEAT, 262 amino acids (30.37 kDa);  $\gamma$ , database code GDB1\_WHEAT, 304 amino acids (34.21 kDa). [French *gliadine*; from Greek *glia*, glue.]

glial cells *see* glia.

glial derived nexin a glycoprotein serine protease inhibitor, similar to serpin, that promotes neurite extension. Example (precursor) from human: database code GDN\_HUMAN, 398 amino acids (43.95 kDa). *See also* nexin.

glial fibrillary acidic protein *abbr.*: GFAP; a class III intermediate filament and a cell-specific marker that, during the development of the central nervous system, distinguishes astrocytes from other glial cells. It is similar to other intermediate filament proteins. Example from human astrocyte: database code GFAP\_HUMAN, 432 amino acids (49.82 kDa).

glibenclamide *see* gliburide.

glicentin a peptide of originally obtained as a component of porcine enteroglucagon and known at first as porcine gut GLI-I. It reacts fully with antisera to the N-terminal moiety of glucagon from pancreas. The known amino-acid sequence includes the entire sequences of glicentin-related pancreatic peptide (at residues 1-30) and pancreatic glucagon (at residues 33-61), and is identical with the N-terminal moiety of the sequence of proglucagon. It was initially thought to be composed of 100 amino-acid residues, hence the name.

glicentin-related pancreatic peptide *or* glicentin-related pancreatic polypeptide *abbr.*: GRPP; originally, any polypeptide material present in extracts of porcine pancreas and in the secretory granules of the pancreatic A cell that reacted with certain antisera to glicentin but not with any antisera to glucagon. The term is now usually applied to a specific component of such material that is a 30-residue peptide identical in sequence to the N-terminal 30-residue sequence of proglucagon, is secreted by the pancreas concomitantly with glucagon, and thus is probably a cleavage product of proglucagon.

GLI-I *see* glicentin.

gliostatin *see* platelet-derived endothelial cell growth factor.

GLIP *abbr.* for glucagon-like insulinotropic peptide; a gastrointestinal peptide that potentiates release of insulin. It is released during a meal and after oral glucose administration. It is GLP-1<sup>7-37</sup>. *See* glucagon.

Gin symbol for a residue of the  $\alpha$ -amino acid L-glutamine (alternative to Q or Z).

globin the colourless and basic protein moiety (and biosynthetic precursor) of hemoglobin and myoglobins. In normal human adult hemoglobin, the globin component comprises two nonidentical pairs of polypeptide chains, whereas in myoglobin there is only one polypeptide chain. Pharmaceutical globin is prepared by adding ox hemoglobin to acetone-HCl; this causes the heme groups to separate and remain in solution while the globin precipitates. It is used in the preparation of globin-insulin, which is absorbed more slowly than soluble insulin and has a prolonged action.

globo+ prefix for an oligosaccharide, signifying the core structure GaINAc(pl-3)Gal(al-4)Gal(pl-4)Glc (I), present in globo-side from which the term originated. Also, by derivation it signifies Gal(al-4)Gal(j11-4)Glc, residues 2-4 of I. Compare isoglobo+.

globoside *or* cytolipin K symbol: GbOse4Cer or Gb4Cer; globotetraosylceramide; ceramide globotetraoside; the major neutral glycosphingolipid in normal kidney and erythrocytes. The name originated from the discovery of this lipid on red cells, and led to the use of globo+ as a root signifying this core

## glucagon

carbohydrate structure. Compare globotriaosylceramide. *See also* globotetrasylceramide, P system.

globotetraose symbol: GbOse4 or Gb4; the tetrasaccharide GaINAc(j11-3)Gal(al-4)Gal(j11-4)Glc. *See also* P system, globo+.

globotetraoylceramide symbol: GbOse4Cer or Gb4Cer; a glycolipid having the structure

It is the P determinant in the P system of blood groups. *See also* globo+.

globotriaose symbol: GbOse3 or Gb3; the trisaccharide Gal(al-4)Gal(j11-4)Glc. *See also* globo+.

globotriaoylceramide symbol: GbOse3Cer or Gb3Cer; a glycolipid globoside having the structure Gal(al-4)Gal(pl-4)GlcCer. It is the major neutral glycosphingolipid in leukocytes, platelets, liver, spleen, and most other non-neurial tissues. It is the pk determinant in the P system of blood groups. *See also* globo+.

globular protein any protein whose polypeptide chain(s) are folded so as to give the whole molecule a rounded shape.

globulin any simple, globular protein that is insoluble or sparingly soluble in water but soluble in dilute salt solutions, and can be precipitated from solution by half-saturating the solution with neutral ammonium sulfate. Globulins may be distinguished by, e.g., electrophoresis into  $\alpha$ -,  $\beta$ -, and  $\gamma$ -globulins, or by ultracentrifugation into 7S globulins, 19S globulins, etc. *See also* gamma globulin, immunoglobulin.

glomerular filtrate the filtrate, free of cells and major plasma proteins, that passes from the blood through a renal glomerulus into the lumen of a nephron in the kidney.

glomerular filtration rate *abbr.*: GFR; the rate at which the glomerular filtrate is produced in the kidney(s). It is a measure of renal efficiency and is usually expressed in terms of the renal clearance of some substance, e.g. inulin, that is freely filterable by the glomerulus and is neither reabsorbed nor excreted by the renal tubules.

glomerula (pl. glomeruli) 1 a knot of blood capillaries projecting into the capsular end of a nephron and from which the glomerular filtrate is formed. *See also* Malpighian body. 2 any compact tuft or tangled mass of processes, nerve fibres, or blood vessels. -glomerular *adj.*

glp a regulon of *Escherichia coli* encoding proteins required for the utilization of glycerol 3-phosphate and its precursors. Operons for enzymes of these pathways are controlled negatively by glp repressor and positively by the cyclic AMP-cyclic AMP receptor protein complex.

GlP symbol for a residue of the  $\alpha$ -amino acid L-5-oxoproline (often known as pyroglutamic acid or pyrrolidinecarboxylic acid).

GLP *abbr.* for glucagon-like peptide (*see* glucagon-related polypeptide).

Glu symbol for a residue of the  $\alpha$ -amino acid L-glutamic acid (alternative to E). (*Note:* Glc is the symbol for a glucose residue.)

gluc+ a variant (sometimes, before a vowel) of Iuco+.

glueaeemie a variant spelling (*esp. UK*) of glucemia; *see* glycemia.

glucagon a 3.5 kDa, single-chain, 29 residue hormone synthesized in the A cells of pancreatic islets and mammalian (except human) gastric mucosa. Formerly sometimes known as hyperglycemic-glycogenolytic factor (*abbr.*: HGF), or hyperglycemic factor. The amino-acid sequence is highly conserved, being identical in human and all other mammalian glucagons studied so far (except guinea-pig):

there are two motifs, characteristic of the glucagon family. It is secreted in response to falling blood glucose levels and has an opposing action to that of insulin by increasing the glucose concentration in the blood. The effects of glucagon are mediated in responsive tissues by either (1) stimulation of adenyl-

ate cyclase or (2) activation of inositolphospholipid-specific phospholipase C with increase in intracellular  $\text{Ca}^{2+}$  concentration. Its effects include the stimulation of glycogenolysis and gluconeogenesis in liver, increased lipolysis in adipose tissue, and increased insulin secretion. Three peptides (glucagon itself and glucagon-like peptides I and 2 (GLP-I and -2)) derive from the precursor. These peptides have  $\approx 50\%$  similarity in their primary structure. The sequence for GLP-I is the same in all mammalian species studied but its biological role is unknown. While GLP-I is the major form in the pancreas, a smaller fragment, GLP-17-36-amide, predominates in the intestine. This is a potent stimulator of insulin secretion and is a potent inhibitor of gastric secretion. Receptors for this peptide have been shown to be present in rat insulinoma cell lines and in brain. Exendin<sup>9,39</sup> is a GLP-1 receptor antagonist. Intracerebroventricularly administered GLP-1 powerfully inhibits feeding in the starving rat. This effect is blocked by exendin<sup>9,39</sup>. Example, human (precursor): database code GLUC\_HUMAN, 180 amino acids (20.89 kDa). See also enteroglucagon, glicentin, glucagon receptor, proglucagon.

glucagon-37 see enteroglucagon.

glucagon-like immunoreactant abbr.: GLI; any member of a group of peptides found in extracts of mammalian gastrointestinal tract that react with N-terminal-specific anti-glucagon antibodies. A particular component of such material may be denoted by means of a suffixed roman numeral, e.g. GLI-I, and the relative molecular mass of the component in question may be indicated by a superscript, e.g. 8000GLI. The principal molecular species recorded include one of  $\approx 12$  kDa (12000GLI), a second of  $\approx 8$  kDa (8000GLI), and a third of  $\approx 4.5$  kDa (4500GLI), the first two being the predominant forms. All have glucagon-like biological activities; e.g. they bind to glucagon receptors of liver plasma membrane, activate hepatic adenylate cyclase, and cause the release of insulin. See also glicentin, proglucagon.

glucagon-like insulinotropic peptide see GIP.

glucagon-like peptide receptor any of the membrane proteins that bind glucagon-like peptides (abbr.: GLPs) and mediate their intracellular effects. A receptor for GLP-I has been characterized. It is a seven-transmembrane-segment protein that is coupled to a G-protein activating adenylate cyclase. Example from human: database code GLPR\_HUMAN, 463 amino acids (53.06 kDa).

glucagonoma a neoplasm (benign or malignant), originating usually from the A cells of pancreatic islets, that autonomously secretes glucagon or glucagon-like immunoreactant, frequently with associated diabetes mellitus.

glucagon receptor any of several membrane proteins that bind glucagon and mediate its intracellular effects. Activation of the liver glucagon receptor gives rise to both elevation of intracellular cyclic AMP and phosphoinositide hydrolysis with elevation of intracellular  $\text{Ca}^{2+}$ . A single clone has been isolated that, when expressed in transfected COS-7 cells, codes for a receptor that on activation can both increase cyclic AMP and intracellular  $\text{Ca}^{2+}$ , suggesting that two types of receptor may not be necessary for these two effects. This gene codes for a protein of the seven-transmembrane-segment type; database code GLR\_RAT, 485 amino acids (55.04 kDa). The gene product is related to the receptors for calcitonin, parathyroid hormone, secretin, vasoactive intestinal peptide, and glucagon-like peptide 1. The  $K_d$  of the expressed receptor has been found to be 20 nM (COS-7 cells) or 37 nM (BHK cells).

glucagon-related polypeptide or glucagon-like peptide any member of a diverse group of peptides found, e.g., in gastrointestinal tissue and blood that react with anti-glucagon antibodies and presumably contain part or all of the amino-acid sequence of glucagon. They include: enteroglucagon, glicentin, glucagon-like immunoreactant, and proglucagon.

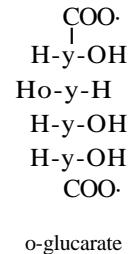

glucan any glycan composed solely of glucose residues. See also dextran.

glucan 1,4-a-glucosidase EC 3.2.1.3; other names: glu-

coamylase; amyloglucosidase; a-amylase; lysosomal a-glucosidase; acid maltase; exo-1,4-a-glucosidase. An enzyme that hydrolyses terminal 1,4-a-D-glucosidic bonds (at the non-reducing end) of polysaccharides, producing P-D-glucose with inversion of the configuration. It is less active towards oligosaccharides. Some of these enzymes (including the example) have a raw-starch binding domain. The enzyme from *Aspergillus niger* is used commercially in production of glucose. Example (precursor) from *Neurospora crassa*: database code S36364, 626 amino acids (66.50 kDa); this is a good example of a protein with a kex2 site. See also glucosidase.

$\alpha$ -glucan phosphorylase a phosphorylase with affinity for  $\alpha$ -glucans. Example (precursor) from potato chloroplasts: database code PHSL\_SOLTU, 966 amino acids (109.38 kDa); this is the L-isoform.

glucarate 1 the dianion of glucaric acid, the aldaric acid derived from either glucose or galactose. There are two enantiomers L- and D-glucarate; D-glucarate, formerly known as saccharate, is derived from either D-glucose or L-galactose (and vice versa for L-glucarate). 2 any salt or ester of glucaric acid.

glucemia or (esp. UK) glucaemia an alternative term for glycemia.

glucitol see sorbitol.

gluco+ or (sometimes before a vowel) gluc+ comb. form indicating glucose. See also glyco+ (def. 2).

glueo-prefix (in chemical nomenclature) indicating a particular configuration of a set of (usually) four contiguous CHO groups as in the acyclic forms of D- or L-glucose. See monosaccharide.

glucoamylase another name for glucan 1,4-a-glucosidase.

P-glucocerebrosidase see glucosylceramidase.

glucoconjugate a former term for glycoconjugate.

glucocorticoid or glucocorticosteroid any naturally occurring or synthetic hormonal corticosteroid that acts primarily on carbohydrate and protein metabolism, e.g. by promoting hepatic glycogen deposition, and that has an anti-inflammatory effect. Glucocorticoids are produced in the middle layer (zona fasciculata) of the adrenal cortex, and include cortisol, corticosterone, and cortisone. In the rat, corticosterone is the major product; in humans and most other mammalian species, cortisol is the major product - in humans it is secreted at a rate of  $\approx 8-25$  mg per day, compared with corticosterone at 1-4 mg per day. Glucocorticoid secretion is enhanced during stress, including hypoglycemia, hypotension, trauma (including surgery), and illness. The main physiological actions of glucocorticoids include stimulation of liver glucose output (by both glycogenolysis and gluconeogenesis), inhibition of glucose utilization by tissues, mobilization of amino acids by breakdown of muscle protein, and mobilization of fatty acids from adipose tissue. Anti-inflammatory actions include stabilization of lysosomal membranes, preventing the release of degradative enzymes, depression of phagocytosis and suppression of T-cell activity, suppressing the synthesis of interleukin-1, and stimulating the synthesis of lipocortin. The actions of glucocorticoids are mediated in large part through glucocorticoid receptor molecules, which regulate gene transcription. Compare mineralocorticoid.

glucocorticoid receptor a mammalian transcription factor in-

## glucocorticoid response element

volved in the regulation of eukaryotic gene expression and affecting cellular proliferation and differentiation in target tissues. It is a cytosolic, soluble glucocorticoid-binding protein of  $M_r \approx 90\,000$ , probably existing in a complex with heat-shock protein hsp90, the total complex mass being about 300 kDa. Binding of steroid induces DNA-binding function and translocation to the nucleus where the receptor-steroid complex interacts with DNA at a glucocorticoid response element to regulate gene transcription. Cloning and other studies have indicated the presence of a glucocorticoid-binding site in the C-terminal region (beyond residue 527 in the human protein), with a DNA-binding region in mid-molecule with two zinc fingers (residues 421–481). There is also a modulating N-terminal domain. There are two forms ( $\alpha$ ,  $\beta$ ), which differ only in their C-terminal sequences; they are probably generated by alternative splicing of a single gene. The human receptor cDNA sequence predicts a more abundant 777-residue  $\alpha$  form, and a 742-residue  $\beta$  form, which have identical sequences up to residue 727. The glucocorticoid receptor is similar to other steroid/thyroid/retinoic nuclear hormone receptors. Example, a form (human): database code GCRA\_HUMAN, 777 amino acids (85.56 kDa).

**glucocorticoid response element** abbr.: GRE; a specific regulatory DNA sequence involved in mediating the effects of glucocorticoids on gene transcription through interaction with the activated glucocorticoid receptor. As yet it is not well characterized, but it is likely that there are a number of GREs, probably trans-acting. A consensus sequence for one such GRE is the almost palindromic structure GGTACAnnnTGTTCT.

**glucocortin** a protein,  $M_r$  17 000, induced by glucocorticoids in adipocytes, liver, fibroblasts, and thymus, and common to all glucocorticoid target cells examined.

**glucogenesis** the production of glucose in an organism, especially from noncarbohydrate precursors.

**glucogenic** describing a substance, some or all the carbon atoms of which can be used to produce glucose in an organism. In particular, a glucogenic amino acid is any amino acid that gives rise to increased urinary glucose excretion when fed to a diabetic animal.

**glucokinase 1** the recommended name for the enzyme ATP: D-glucose 6-phosphotransferase (EC 2.7.1.2), which catalyses the phosphorylation by ATP of D-glucose to D-glucose 6-phosphate with release of ADP. The enzyme occurs in invertebrates and microorganisms. Unlike hexokinase, which will catalyse the same reaction, it is highly specific for D-glucose.

**2** a name frequently applied to an isoenzyme of hexokinase (EC 2.7.1.1) that is characteristic of mammalian liver.

**glucon** or (formerly) glucone any glycon in which the sugar involved is glucose.

**gluconate** 1 the anion of gluconic acid. 2 any salt or ester of gluconic acid.

**gluconeogenesis** the metabolic formation of carbohydrates from non-carbohydrate organic precursors in liver. Formerly the term was restricted to the metabolic formation of glucose from noncarbohydrate precursors. Physiologically, an important source of precursor molecules is amino acid released from muscle protein during fasting. This is under hormonal control, especially by glucocorticoids. Alanine is an important precursor, and there is extensive conversion in muscle of other amino acids to alanine, which is then transported to the liver, where it undergoes transamination to form pyruvate. See also glucogenic pathway.

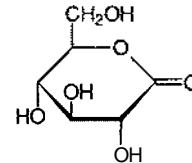

**gluconeogenic pathway** the pathway in liver by which non-carbohydrate precursors are converted to glucose 6-phosphate and thence to glucose or other carbohydrates. Precursor molecules must first be converted to pyruvate, thence successively to oxaloacetate, phosphoenolpyruvate, 2-phosphoglycerate, 3-phosphoglycerate, 1,3-bisphosphoglycerate, glyceraldehyde 3-phosphate plus glycerone phosphate, fructose 1,6-bisphosphate, fructose 6-phosphate, glucose 6-phosphate, and glucose (or other sugars). The enzymes involved are in many cases the same as those involved in the corresponding reverse step in the

## glucose

glycolytic pathway. The enzymes specific to the gluconeogenic pathway are pyruvate carboxylase, phosphoenolpyruvate carboxykinase, fructose 1,6-bisphosphatase and glucose 6-phosphatase (see individual entries for each enzyme). The pathway is hormonally regulated, especially by glucagon, which increases cyclic AMP levels, thereby stimulating protein kinase activity. Control is effected by phosphorylation of liver pyruvate kinase, which inactivates the enzyme and thus restricts glycolysis, and phosphorylation of phosphofructokinase-2, which converts its action to that of a phosphatase which hydrolyses the 2-phosphate of fructose 2,6-bisphosphate, thereby inactivating phosphofructokinase.

**gluconic acid** the aldonic acid derived from glucose.

**gluconolactone** the trivial name for the  $\gamma$ -lactone (D-glucono-1,4-lactone) or  $\delta$ -lactone (D-glucono-1,5-lactone) of D-glucconic acid.

D-glucono-1,5-lactone

**glucophore** the pharmacophore, or common structural feature, postulated to be present in molecules of all substances, whether chemically related or not, that possess a sweet taste, and thus to confer sweetness on them. The essential components of the glucophore are considered to be a polarized bond A-H (e.g. O-H in a sugar or N-H in a sweet amino acid), an electronegative atom B (typically =O), and a polarizable hydrophobic group X (such as H or Cl). The approximate distances between them are: A-B, 260 pm; A-X, 350 pm; B-X, 550 pm. The groups A-H and B are considered to bind respectively to similar B and A-H groups in the receptor, and the group X to bind to the receptor by charge-transfer or dispersion bonding.

**glucoprotein** a former name for glycoprotein.

**glucosaccharase** the trivial name for any saccharase that attacks the glucose end of appropriate oligosaccharides, liberating glucose.

**glucosamine symbol:** GlcpN; the trivial name for the amino-deoxysugar 2-amino-2-deoxyglucopyranose; there are two enantiomers. D-Glucosamine (symbol: D-Glc<sub>N</sub>), formerly known as chitosamine, occurs in combined form in chitin, in mucoproteins, and in mucopolysaccharides, and is one of the most abundant natural monosaccharides.

**glucosamine N-acetyltransferase** EC 2.3.1.3; other name: glucosamine acetylase; an enzyme forming N-acetyl-D-glucosamine from acetyl-CoA and D-glucosamine while releasing CoA. **glucosamine-6-phosphate isomerase** EC 5.3.1.10; systematic name: D-glucosamine-6-phosphate ketol-isomerase (deaminating). An enzyme that catalyses the hydrolysis of D-glucosamine 6-phosphate to D-fructose 6-phosphate and NH<sub>3</sub>. The amino-acid sequences of bacterial and fungal types are similar. Example from *Escherichia coli*: database code NAGB\_ECOLI, 266 amino acids (29.74 kDa); 3-D structure known.

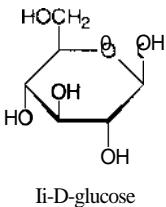

**glucosaminic acid** the common biochemical name for 2-amino-2-deoxygluconic acid.

**glucosan** 1 an obsolete name for glucan. 2 an old trivial name (established by usage but not recommended) for 1,6-anhydroglucopyranose.

**glucose symbol:** Glc; the trivial name for the aldohexose glucose; there are two enantiomers, D- and L-glucose. D-(+)-Glucose (symbol: D-Glu), commonly known as glucose, and formerly known as grape sugar or corn sugar, is dextrorotatory, hence also formerly (and sometimes still) known as dextrose; it is 0.74 times as sweet as sucrose. Aged aqueous

## glucose-alanine cycle

solutions of D-glucose contain an equilibrium mixture of  $\alpha$ -D-glucopyranose, P-D-glucopyranose, and the open-chain form (*see also* mutarotation), whereas in crystals  $\alpha$ -D-glucopyranose monohydrate is the stable form below 50°C. Combined D-glucose may have either the  $\alpha$  or the  $\beta$  configuration, but is invariably in the pyranose form. D-Glucose is an important source of energy for living organisms. It is found free in fruits and other parts of plants, in honey, and in animals, especially in the blood ( $\approx 5$  mM in human blood). In combined form it occurs in many homo- and hetero-oligosaccharides and polysaccharides, especially in the animal storage polysaccharide glycogen and in the plant storage polysaccharides cellulose and starch.

**glucose-alanine cycle** or alanine cycle a metabolic cycle in which alanine is formed peripherally, e.g. in muscle, by transamination of glucose-derived pyruvate, and is transported to the liver where its carbon skeleton is reconverted to glucose.

**glucose-assimilation coefficient symbol:**  $K$ ; *see* glucose-tolerance test.

**glucose-dependent insulinotropic peptide** or **glucose-dependent insulin-releasing peptide** *see* gastric inhibitory peptide. **glucose effect** the ability of glucose in the growth medium to inhibit the synthesis of certain enzymes in bacteria growing on the medium. *See also* catabolite repression.

**glucose fatty-acid cycle** a concept to explain how changes in plasma levels of glucose and fatty acids influence one another so as to provide a homeostatic control mechanism. Its essential features are: (1) the release, for oxidation, of fatty acids from muscle or adipose tissue acylglycerols restricts glucose metabolism in muscle; and (2) glucose uptake by muscle or adipose tissue restricts the release of fatty acids from acylglycerols in these tissues. The cycle thus provides a primitive, hormone-independent mechanism tending to maintain a constant plasma glucose level in animals that feed intermittently. Insulin modifies this mechanism by enhancing glucose uptake by muscle and adipose tissue, inhibiting fatty-acid release by adipose tissue, and increasing fatty-acid esterification in both muscle and adipose tissue.

**glucose isomerase** a bacterial enzyme preparation that catalyses the reaction:

It is used on a large scale in industry to convert glucose-containing materials to the much sweeter mixture of glucose plus fructose. The enzymes are usually immobilized on a variety of supports. The product is known as high-fructose corn syrup and is widely used as a sweetening agent. No enzyme for which this is the main function has been isolated. EC 5.3.1.18 (glucose isomerase) is now a deleted entry.

**glucose oxidase** EC 1.1.3.4; *other names:* glucose oxyhydrase; notatin; *systematic name:* P-D-glucose:oxygen I-oxidoreductase; a flavoprotein (FAD) enzyme that catalyses the oxidation by dioxygen of P-D-glucose to D-glucono-I,5-lactone and  $\text{H}_2\text{O}_2$ . It has application in the experimental determination of glucose concentration (e.g. in medicine) and has some industrial uses. Example from *Aspergillus niger*: database code NRL\_I GAL, 581 amino acids (63.00 kDa); 3-D structure known.

## glucose-tolerance test

**glucose-'-phosphatase** EC 3.1.3.10; *systematic name:* D-glucose-I-phosphate phosphohydrolase. An enzyme that catalyses the hydrolysis of D-glucose I-phosphate to D-glucose and orthophosphate. Example (precursor) from *Escherichia coli*: database code AGP\_ECOLI, 413 amino acids (45.63 kDa).

**glucose-6-phosphatase** EC 3.1.3.9; *systematic name:* D-glucose-6-phosphate phosphohydrolase. An enzyme that catalyses the hydrolysis of D-glucose 6-phosphate to D-glucose and orthophosphate. It has rather wide specificity. It is the final enzyme in the gluconeogenic pathway. Example from mouse: database code U00445, 357 amino acids (40.43 kDa).

**glucose-6-phosphatase deficiency** *see* glycogen storage disease.

**glucose-6-phosphate dehydrogenase abbr.: G6PDH or (in clinical chemistry) GPD; EC 1.1.1.49; recommended name: glucose-6-phosphate I-dehydrogenase; systematic name: D-glucose-6-phosphate:NADP+ I-oxidoreductase; other name (obsolete): Zwischenferment.** An enzyme that catalyses the conversion of D-glucose 6-phosphate and NADP+ to D-glucono-I,5-lactone 6-phosphate and NADPH. This is an early step in the pentose phosphate pathway and the Entner-Doudoroff pathway, and thus in heterolactic fermentation. The enzyme has the greatest known variability of all enzymes in humans. Molecular variants that result in deficient activity are associated with a drug-induced hemolytic anemia, favism. This arises because the enzyme is involved in maintaining reduced glutathione in red cells. Example from *Drosophila melanogaster*: database code G6PD\_DROME, 523 amino acids (60.05 kDa). *See also* glucose-6-phosphate dehydrogenase deficiency.

**glucose-6-phosphate dehydrogenase deficiency** a hereditary X-linked deficiency of glucose-6-phosphate dehydrogenase that affects mostly males. It is associated with a hemolytic anemia, but also confers some protection against malaria, since the parasite is unable successfully to pass through the schizont stage in red cells lacking this enzyme activity; hence there is a particularly high incidence in tropical Africa and the Middle and Far East. Lack of the enzyme in red cells results in failure to reduce NADP+ to NADPH in adequate amounts (the pentose phosphate pathway playing a major role in this in the red cell), as a result of which oxidized glutathione cannot be reduced by glutathione reductase. Consequently, there can be hemolysis, as hemoglobin is not maintained in the ferrous state and the peroxides produced as a result of drug action promote red-cell destruction. The antimalarial drug primaquine and related compounds generate oxidative stress, and during World War II their administration led to the discovery of the condition in many service personnel. The multi-allelic nature of the gene has led to many investigations of its distribution. *See also* favism.

**glucose-6-phosphate isomerase abbr. (in clinical chemistry): GPI; EC 5.3.1.9; systematic name: D-glucose-6-phosphate ketol-isomerase; other names: phosphoglucose isomerase; phosphohexose isomerase; phosphohexomutase; oxoisomerase; hexosephosphate isomerase; phosphosaccharomutase; phosphoglucosidomerase; phosphohexoisomerase. An enzyme of the glycolytic pathway that catalyses the interconversion of glucose 6-phosphate and fructose 6-phosphate. Example from *Escherichia coli*, homodimer: database code G6PI\_ECOLI, 549 amino acids (61.45 kDa).**

**glucose-tolerance curve** the curve relating blood glucose concentration to time that is obtained in a glucose-tolerance test, either oral or intravenous.

**glucose-tolerance factor abbr.: GTF**; a water-soluble, relatively stable organic chromium complex of  $M_r \approx 500$  that is believed to be required in the diet for normal glucose tolerance in animals, including humans. It is a coordination complex between chromium (III) ions, nicotinate, glycine, glutamate, and cysteine or glutathione.

**glucose-tolerance test** any procedure designed to assess the response of an individual to a loading dose of glucose, widely used in the diagnosis of diabetes mellitus. The standard oral

**glucose transporter**

glucose tolerance test is performed in the morning following at least 3 days' unrestricted diet, physical activity, and freedom from medication. The subject should have fasted for 12 hours before the test and remain seated and non-smoking during the test. After collection of the fasting blood sample, 75 g (or 1.75 g per kg of body weight for children) glucose is ingested in 5 minutes in 200-500 mL water (formerly loads of 50 g and 100 g glucose were used). Blood samples are then collected at 30-minute intervals for 2 hours, and urine samples are collected at 0, 1, and 2 hours. All samples are assayed for glucose. For capillary blood samples, a maximum glucose level below 10 mmol L<sup>-1</sup> (180 mg/100 mL) and a 2-hour value less than 7.5 mmol L<sup>-1</sup> (135 mg/100 mL) are the criteria for normality. If venous blood is used the corresponding values are 8.9 mmol L<sup>-1</sup> (160 mg/100 mL) and 6.1 mmol L<sup>-1</sup> (110 mg/100 mL). The urine samples should be glucose free. The intravenous glucose tolerance test may be used when abnormal carbohydrate absorption from the gut is suspected. A common procedure for this test is to take a fasting blood sample and further samples at 10-minute intervals for 1 hour following intravenous injection of 50 mL of 50% w/v glucose solution over a period of 2 minutes. Glucose is assayed in the blood samples and the logarithms of the values are plotted against time. The slope of the resulting straight line, multiplied by 100, is the glucose-assimilation coefficient, *K*, which represents the percentage fall in blood glucose per minute. Values of *K* in excess of 1.1 per cent per minute are taken as normal.

**glucose transporter** any sugar-transport protein for which glucose is a substrate. Apart from certain ABC types (e.g. in *Escherichia coli*) many glucose transporters belong to the 12-helix superfamily of integral transmembrane proteins. They resemble one another and also the typically sugar-H<sup>+</sup> symport proteins of bacteria even though the mammalian examples are usually facilitated diffusion proteins. Examples from human; type 1 (erythrocyte and brain): database code GTR1\_HUMAN, 492 residues (54.15 kDa); type 4 (insulin responsive, muscle and brown fat): database code GTR4\_HUMAN, 509 amino acids (54.72 kDa). The latter is a candidate for the factor responsible for certain post-receptor defects in non-insulin-dependent diabetes mellitus. See also sugar transporter.

**glucosidase** any glycosidase that hydrolyses O-glucosyl-, N-glucosyl-, or S-glucosyl-compounds.

$\alpha$ -Glucosidase EC 3.2.1.20; systematic name:  $\alpha$ -D-glucoside glucohydrolase; other names: maltase; glucoinvertase; glucosidase; maltase-glucoamylase. An enzyme that hydrolyses maltose and terminal (nonreducing end) 1,4- $\alpha$ -D-glucosidic bonds of oligosaccharides to yield  $\alpha$ -D-glucose with retention of configuration. Maltases from some sources (especially intestine) act also on polysaccharides and may slowly hydrolyse (1 $\rightarrow$ 6)- $\alpha$ -D-glucosidic linkages as well. Most active with oligosaccharides, the enzyme catalyses the final step in the degradation of starch and is widely distributed in plants. Example (precursor) from the yeast *Candida tsukubaensis*: database code AGLU\_CANTS, 1070 amino acids (118.50 kDa). See also glucan 1,4- $\alpha$ -glucosidase.

$\beta$ -Glucosidase EC 3.2.1.21; systematic name: P-D-glucoside glucohydrolase; other names: cellobiase; gentiobiase. An enzyme that hydrolyses terminal (nonreducing end) 1,4-P-D-glucosidic bonds to yield P-D-glucose with retention of configuration. Example (precursor) from the yeast *Kluyveromyces marxianus*: database code bglKLUMA, 845 amino acids (93.81 kDa).

**glucoside or (formerly) glycoside** any glycoside (def. 1) in which the sugar moiety is a glucose residue.

**glucosuria** the presence of glucose in the urine. It is sometimes loosely referred to by the older term glycosuria, which now strictly implies the presence of any type of sugar in urine. Glucosuria occurs in diabetes mellitus and is diagnostically important. It may also occur because of renal defects, as in Fanconi syndrome. See also fructosuria.

**glucosVI** any glycosyl group formed by detaching the anomeric

**glucuronoside**

hydroxyl group, on C-I, from a cyclic form (pyranose or furanose) of glucose or a glucose derivative.

**glucovlated hemoglobin** a misnomer for glycated hemoglobin.

**glucosylation** glycosylation with one or more glucosyl groups. -glucosylated adj.

**glucosylceramidase** EC 3.2.1.45; other names: p-glucocerebrosidase; acid p-glucosidase; systematic name: o-glucosyl-N-acylsphingosine glucohydrolase; a lysosomal enzyme that catalyses the hydrolysis of o-glucosyl-N-acylsphingosine to o-glucose and N-acylsphingosine. A deficiency of this enzyme is the cause of Gaucher's disease, in which there is an accumulation of glucocerebroside. Example (precursor) from human: database code GLCM\_HUMAN 536 amino acids (59.63 kDa).

**glucosylceramide** the recommended term for any o-glucosyl-N-acylsphingosine, i.e. any cerebroside in which the sugar moiety is o-glucose.

**glycosyloxy** any of the glycosyloxy groups formed by detaching the hydrogen atom from the anomeric hydroxyl group, on Col, from a cyclic form (pyranose or furanose) of glucose.

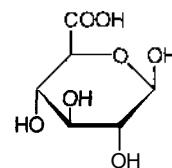

**gluco8yltransferase** any hexosyltransferase enzyme (EC 2.4.1) for which the glycosyl group transferred is glucosyl. The acceptor may be orthophosphate (as for e.g. phosphorylase), but more often is another carbohydrate molecule (as for e.g. glycogen synthase) and sometimes a lipid (as in the synthesis of 3-o-glucosyl-1,2-diacylglycerol). See also B-transferase, lactose synthase, Lewis transferase.

**glucuronate** 1 the anion of glucuronic acid. 2 any salt or ester of glucuronic acid.

**glucuronate pathway** or glucuronate oxidation pathway the metabolic pathway by which o-glucuronate is converted, via L-gulonate, L-xylulose, xylitol, and o-xylulose, to o-xylulose 5-phosphate, an intermediate in the pentose phosphate pathway. In essential pentosuria there is defective conversion of L-xylulose to xylitol. In a side branch of the pathway L-ascorbate is formed, via L-gulonolactone, from L-gluconate. Primates and the guinea pig lack the ability to convert L-gulonolactone to L-ascorbate (see ascorbic acid).

**glucuronate reductaae** EC 1.1.1.19; systematic name: L-gulonate:NADP+ 6-oxidoreductase. An enzyme that reduces the aldehyde group at Col of o-glucuronate thus forming L-gulonate. See glucuronate pathway.

**glucuronic acid** abbr. (sometimes): GA; symbol: GleA (or formerly) GlcU or GleUA; the uronic acid formally derived from glucose by oxidation of the hydroxymethylene group at C-6 to a carboxyl group. There are two enantiomers; o-glucuronic acid is widely distributed in plants and animals, where it usually occurs as glucuronides.

P-D-glucuronic acid

**p-glucuronidae** abbr. (in clinical chemistry): GRS; EC 3.2.1.31, an enzyme that catalyses the hydrolysis of a p-o-glucuronoside to o-glucuronate and the corresponding hydroxy compound, which may be an alcohol, a phenol, or a saccharide. Deficiency of p-glucuronidase occurs in human type VII mucopolysaccharidosis. It is a homotetramer, and a lysosomal enzyme. Example (precursor) from human: database code BGLR\_HUMAN, 651 amino acids (74.63 kDa).

**glucuronide** former name for glucuronoside.

**glucuronoside** or (formerly) glucuronide any compound formed by combination in ( $\alpha$  or  $\beta$ ) glycosidic linkage of a hydroxy compound with the anomeric carbon atom of glu-

**glucuronosyl**

curonate. The hydroxy compound may be a saccharide, an alcohol, or a phenol. p-D-Glucuronosides are formed in so-called **detoxication** reactions.

**glucuronosyl** the glycosyl group formed by removal of the anomeric hydroxyl group from glucuronic acid or glucuronate.

**glucuronosyltransferase** another name for **UDPglucuronosyl-transferase**.

**glucuronoyl** the univalent acyl group derived from glucuronic acid.

**glued** see **dynactin**.

**Glu(NH<sub>2</sub>)** (formerly) symbol for a residue of the a-amino acid L-glutamine (Gln or Q now recommended).

**Glu-NH<sub>2</sub>** symbol for a residue of the a-amino acid L-isoglutamine.

**Glu(OEt)** symbol for a residue of y-ethyl glutamate; O5-ethyl hydrogen glutamate.

**Glu-OEt** symbol for a residue of a-ethyl glutamate; OJ-ethyl hydrogen glutamate.

**GluR receptor** see **glutamate receptor**.

**GLUT** an abbr. commonly used for **glucose transporter**.

**glutaconyl-CoA decarboxylase** EC 4.1.1.70; an enzyme that catalyses the decarboxylation of glutaconyl-CoA (pent-2-enoyl-CoA) to but-2-enoyl-CoA, releasing CO<sub>2</sub>. Biotin is a coenzyme. The enzyme is dependent on Na<sup>+</sup>, and functions as a sodium pump in the bacterial membrane.

**glutamate 1** (in biochemistry) glutamate(1-); glutamic-acid monoanion; hydrogen glutamate. In theory, the term denotes any ion or mixture of ions formed from **glutamic acid** and having a net charge of -1, although the species -OOC-[CH<sub>2</sub>]h-CH(NH<sub>3</sub><sup>+</sup>)-COO<sup>-</sup> generally predominates in practice. 2 (in chemistry) the systematic name for glutamate(2-); glutamic-acid dianion. 3 any salt containing an anion of glutamic acid. 4 any ester of glutamic acid.

**glutamate N-acetyltransferase** EC 2.3.1.35; other names: ornithine acetyltransferase; ornithine transacetylase; an enzyme of the pathway in bacteria for the formation of ornithine from glutamate. It catalyses a reaction between N<sup>2</sup>-acetyl-L-ornithine and L-glutamate to form L-ornithine and N-acetyl-L-glutamate (abbr.: AGA). In bacteria, AGA is then converted to N-acetylglutamate 5-semialdehyde, which undergoes transamination to N2-acetyloornithine. Example from *Bacillus stearothermophilus*: database code ARGJ\_BACST, 410 amino acids (43.33 kDa); this is a bifunctional enzyme (other name: AGS/OCTase) containing activities for this and also **amino-acid N-acetyl transferase**.

**glutamate-ammonia ligase** EC 6.3.1.2; systematic name: L-glutamate:ammonia ligase (ADP-forming); other name: glutamine synthetase. An enzyme that catalyses a reaction between ATP, L-glutamate, and NH<sub>3</sub> to form ADP, orthophosphate, and L-glutamine. This is the first step in the fixation of ammonia in plants, the ATP-dependent incorporation of NH<sub>4</sub><sup>+</sup> into the amide position of glutamine. The second step involves L-glutamate synthase (ferredoxin) and the combined effect of the two enzymes is to produce L-glutamate from 2-oxoglutarate and ammonium (NH<sub>4</sub><sup>+</sup>), a major NH<sub>4</sub><sup>+</sup> assimilatory route. Glutamate-ammonia ligase has a molecular mass of 33 kDa and its eight monomers are arranged in two parallel tetramers. Example from *Escherichia coli*: 12 subunits in two hexagons, database code GLNA\_ECOLI, 468 amino acids (51.71 kDa). The activity is controlled by adenylylation in the presence of ATP by [**glutamate-ammonia-ligase**] **adenylyl transferase** to adenylate a tyrosine residue; the fully substituted enzyme is inactive; transcription is regulated by **nitrogen regulatory protein**.

[**glutamate-ammonia-ligaseJ**] **adenylyl transferase** EC 2.7.7.42; other name: glutamine-synthetase adenylyltransferase; an enzyme that catalyses the adenylylation of [L-glutamate:ammonia ligase (ADP-forming)] by ATP to form adenylyl-[L-glutamate:ammonia ligase (ADP-forming)] with release of pyrophosphate. The adenylylation regulates enzyme activity (see **glutamate-ammonia ligase**). Example from *Escherichia coli*: database code GLNE\_ECOLI, 945 amino acids (108.15 kDa).

**glutamate receptor**

*ichia coli*: database code GLNE\_ECOLI, 945 amino acids (108.15 kDa).

**glutamate/aspartate transporter** any membrane protein that transports glutamate and aspartate. Two types are known. (1) An H<sup>+</sup>-symport protein of the bacterial (inner) membrane; it is probably a 12-helix integral membrane protein. Although Na<sup>+</sup> is not involved, there is a sequence resemblance to the second type (below). Example from *Escherichia coli*: database code GLTP\_ECOLI, 437 amino acids (47.10 kDa). (2) The sodium-dependent transporter of brain; it is similar to sodium-dicarboxylate symporters. Putatively it is a glycosylated integral membrane protein of brain (high levels in Purkinje cell layer). Example from rat: database code GLTI\_RAT, 573 amino acids (62.03 kDa).

**glutamate-cysteine ligase** EC 6.3.2.2; other name: y-glutamylcysteine synthetase; an enzyme of the pathway for the formation of glutathione. It catalyses the formation of y-L-glutamyl-L-cysteine from ATP, L-glutamate, and L-cysteine with release of ADP and orthophosphate. Example from *Escherichia coli*: database code GSGL\_ECOLI, 518 amino acids (58.18 kDa).

**glutamate dehydrogenase** EC 1.4.1.2; systematic name: L-glutamate:NAD<sup>+</sup> oxidoreductase (deaminating). An enzyme that catalyses the reaction:

This oxidative removal of the amino group from glutamate avoids the need for an oxo-acid acceptor, and in **ureotelic** animals is a major route for the removal of nitrogen as NH<sub>4</sub><sup>+</sup>, which is then converted to urea in the **ornithine-urea cycle**. Example from *Neurospora crassa*: database code DHE2\_NEUCR, 1026 amino acids (115.52 kDa). Example from yeast, homotetramer: database code DHE2\_YEAST, 1092 amino acids (124.19 kDa). See also **glutamate dehydrogenase (NADP<sup>+</sup>)**.

**glutamate dehydrogenase (NADP<sup>+</sup>)** EC 1.4.1.4; systematic name: L-glutamate:NADP<sup>+</sup> oxidoreductase (deaminating). An enzyme that catalyses the oxidation by NADP<sup>+</sup> of L-glutamate to form 2-oxoglutarate, NH<sub>3</sub>, and NADPH. Two forms exist. One is a homotetramer. Example from *Neurospora crassa*: database code DHE2\_NEUCR, 1026 amino acids (115.52 kDa). The other form, found in bacteria and plants, mainly proceeds in the direction of glutamate synthesis, as an NH<sub>3</sub>-assimilatory enzyme. It is the product of the *am* gene, and is a homohexamer. Isoforms of this enzyme provided the first demonstration of **interallelic complementation**. Example from *Neurospora crassa*: database code DHE4\_NEUCR, 453 amino acids (48.67 kDa).

**glutamate-oxaloacetate transaminase** see **aminotransferase**.

**glutamate-pyruvate transaminase** see **aminotransferase**.

**glutamate receptor** abbr.: GluR; any of a number of membrane proteins that bind glutamate and mediate its effects in neurotransmission. A major subdivision within glutamate receptors is between those (ionotropic) that act as ligand-gated ion channels and those (metabotropic) that are coupled to G-proteins. **Ionotropic GluR receptors** are further subdivided into three classes, named after dicarboxylic amino acids that act as agonists: (1) N-methyl-D-aspartate (NMDA) receptors; they play a key role in memory acquisition, learning, and neurological disorders and are the target for **conantokin-G**; (2) a-amino-3-hydroxy-5-methyl-4-isoxalone (AMPA) receptors, formerly designated quisqualate receptors; and (3) kainate receptors. Most of the fast excitatory synaptic transmission in the vertebrate central nervous system is mediated by GluR channels. There are many molecular subtypes of GluR in these categories; however, in all ionotropic receptors an ion channel is an intrinsic property of the receptor structure, generally with a broad ionic selectivity to monovalent ions; NMDA channels are also five to ten times more permeable to Ca<sup>2+</sup> ions than to Na<sup>+</sup> or K<sup>+</sup> ions. The sequences of the subunits of these recep-

## glutamate 1-semialdehyde

tors reveal four putative transmembrane segments; these subunits have been designated  $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ ,  $\varepsilon$ , and  $\zeta$ . The members of the  $\alpha$  subfamily constitute AMPA-selective GluR channels; the  $\beta$  and  $\gamma$  subfamilies include the subunits of the kainate-selective GluR channel; NMDA receptor channels are composed of  $\varepsilon\zeta$  heteromers. Example of an ionotropic receptor (precursor) from rat: database code JN0339, 885 amino acids (99.34 kDa). **Metabotropic GluR receptors** (mGluR) that have been cloned include mGluR<sub>1</sub>, of which two alternatively spliced versions exist (1199 and 906 amino acids), and mGluR<sub>2</sub> (872 amino acids); both of these types have seven transmembrane segments. The activity of this receptor is mediated by a G-protein that activates a phosphatidylinositol-Ca<sup>2+</sup> second messenger system. Example, receptor I (precursor) from rat, transmembrane glycoprotein, seven motifs: database code MGRLRAT, 1199 amino acids (133.08 kDa) of which amino acids 21–1199 comprise the receptor.

**glutamate 1-semialdehyde** glutamic  $\alpha$ -semialdehyde; the L enantiomer, L-glutamate 1-semialdehyde, (S)-4-amino-5-oxopentanoate, is the precursor of 5-aminolevulinic acid (*see glutamate-1-semialdehyde 2,1-aminomutase*). It is synthesized in plants from glutamate bound to a specific tRNA; after reduction of the I-carboxyl group, the tRNA is removed to yield glutamate 1-semialdehyde. *Compare glutamate 5-semialdehyde.*

**glutamate 5-semialdehyde** glutamic  $\gamma$ -semialdehyde; the L enantiomer, L-glutamate 5-semialdehyde, (S)-2-amino-5-oxopentanoate, is an intermediate in the synthesis of proline from ornithine. In plants and bacteria it is formed in a pathway in which L-glutamate is first converted to N-acetyl-L-glutamate, which is reduced to N-acetyl-L-glutamate 1-semialdehyde, from which the acetyl group is then removed. In animals it is formed from ornithine by transamination of the  $\alpha$ -amino group. *See proline. Compare glutamate 1-semialdehyde.*

**glutamate-1-semialdehyde 2,1-aminomutase** EC 5.4.3.8; *other name:* glutamate-1-semialdehyde aminotransferase. The enzyme synthesizing 5-aminolevulinic in plants; it catalyses the conversion of (S)-4-amino-5-oxopentanoate (*i.e. glutamate 1-semialdehyde*) to 5-aminolevulinic. Example from *Escherichia coli*: database code GSA\_ECOLI, 426 amino acids (45.42 kDa).

**glutamate synthase (ferredoxin)** EC 1.4.7.1; *systematic name:* L-glutamate:ferredoxin oxidoreductase (transaminating). An enzyme that catalyses the second step in the fixation of ammonia in plants, *i.e.* the transfer of the NH<sub>2</sub> group from the amide group of glutamine to 2-oxoglutarate to form L-glutamate. The reaction is between L-glutamine, 2-oxoglutarate, and two molecules of reduced ferredoxin; the products are two molecules of L-glutamate and two of oxidized ferredoxin. In plants the combination of the action of **glutamate-ammonia ligase** and this enzyme results in the production of one molecule of glutamate from one of 2-oxoglutarate and one of NH<sub>4</sub><sup>+</sup>. *See also glutamate synthase (NADH), glutamate synthase (NADPH).*

**glutamate synthase (NADH)** EC 1.4.1.14; *systematic name:* L-glutamate:NAD<sup>+</sup> oxidoreductase (transaminating). An enzyme that catalyses a reaction between L-glutamine, 2-oxoglutarate, and NADH to form two molecules of L-glutamate and NAD<sup>+</sup>. FMN is a cofactor. Example from alfalfa: database code GLSN\_MEDSA, 2194 amino acids (240.10 kDa).

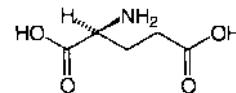

**glutamate synthase (NADPH)** EC 1.4.1.13; *systematic name:* L-glutamate:NADP<sup>+</sup> oxidoreductase (transaminating). An enzyme that catalyses the formation of two molecules of L-glutamate and one of NADP<sup>+</sup> from L-glutamine, 2-oxoglutarate, and NADPH. It is an iron-sulfur flavoprotein. It brings together nitrogen and carbohydrate metabolism in bacteria, since in association with **glutamate-ammonia ligase** it functions as the second step in a major NH<sub>3</sub>-assimilatory pathway. It exists as an aggregate of four heterodimers of large and small subunits; glutamine binds to the large subunit and transfers -NH<sub>2</sub> from its amido group to 2-oxoglutarate, which apparently binds to the small subunit. Example from *Escherichia coli*: small subunit, database code GLTD\_ECOLI, 470 amino

## glutamine synthetase

acids (52.09 kDa); large subunit, database code GLTB\_ECOLI, 1514 amino acids (166.04 kDa).

**glutamic** the general name for a residue of glutamic acid, whether or not the  $\gamma$ -carboxyl group is protonated.

**glutamic acid abbr. (sometimes): GA; the trivial name for  $\alpha$ -aminoglutamic acid; 2-aminopentanedioic acid; HOOC-[CH<sub>2</sub>]<sub>2</sub>-CH(NH<sub>2</sub>)-COOH; a chiral  $\alpha$ -amino acid. L-Glutamic acid (*symbol:* E or Glu), (S)-2-aminopentanedioic acid, is a coded  $\alpha$ -amino acid found in peptide linkage in proteins; codon: GAA or GAG. In mammals it is a nonessential dietary amino acid and is glucogenic. Residues of D-glutamic acid (*symbol:* D-Glu or DGlu), (R)-2-aminopentanedioic acid, are found in the cell-wall material of various bacterial species and (as poly-D-glutamic acid) in the capsular substances of *Bacillus anthracis*, *B. subtilis*, and other bacteria. One residue of D-glutamic acid per molecule occurs in the antibiotic bacitracin A (*see bacitracin*) and also in **glutathione**.**

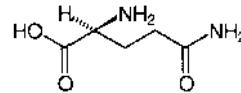

L-glutamic acid

**glutamic amide I** glutamic I-amide (*i.e. isoglutamine*). 2 glutamic 5-amide (*i.e. glutamine*).

**glutaminase** EC 3.5.1.2; *other and systematic name:* L-glutamine amidohydrolase; an enzyme that catalyses the hydrolysis of L-glutamine to L-glutamate and NH<sub>3</sub>. Example (kidney isoform) from *Rattus norvegicus*: database code GLSK\_RAT, 674 amino acids (73.94 kDa).

**glutamate I** the glutamine anion; the anion, HzN-CO-[CH<sub>2</sub>]<sub>2</sub>-CH(NH<sub>2</sub>)-COO<sup>-</sup>, derived from glutamine. 2 any salt containing glutamine anion. 3 any ester of glutamine.

**glutamine** the trivial name for the  $\gamma$ -amide of glutamic acid; glutamic 5-amide;  $\alpha$ -aminoglutaramic acid; 2-amino-4-carbamoylbutanoic acid; H<sub>2</sub>N-CO-[CH<sub>2</sub>]<sub>2</sub>-CH(NH<sub>2</sub>)-COOH; a chiral  $\alpha$ -amino acid. L-Glutamine (*symbol:* Q or Gln or (formerly) Glu(NH<sub>2</sub>)), (S)-2-amino-4-carbamoylbutanoic acid, is a coded  $\alpha$ -amino acid found in peptide linkage in proteins; codon: CAA or CAG. In mammals it is a nonessential  $\alpha$ -amino acid and is glucogenic. D-Glutamine (*symbol:* D-Gln or DGln), (R)-2-amino-4-carbamoylbutanoic acid, is not known to occur naturally. *Compare isoglutamine.*

L-glutamine

**glutamine amidotransferase** abbr.: GATase; a nonsystematic name for carbon-nitrogen ligases that employ glutamine as the amido-N-donor; *i.e.* members of the sub-subclass EC 6.3.5. These enzymes transfer the -NH<sub>2</sub> group from glutamine to another reactant, *e.g.* **GMP synthase**. The enzyme activity is also an activity associated with **CAD protein** in mammals. *See also glutamate synthase (ferredoxin), glutamate synthase (NADH), glutamate synthase (NADPH).*

**glutamine-pyruvate aminotransferase** EC 2.6.1.15; *other names:* glutaminase II; glutamine-oxo-acid transaminase; glutamine transaminase L; an enzyme that catalyses the reaction:

Pyridoxal-phosphate is a cofactor. *See also transamination.*

**glutamine synthetase** *see glutamate-ammonia ligase.*

## glutamine-synthetase adenylyltransferase

glutamine-synthetase adenylyltransferase *see* [glutamate-ammonia-ligase] adenylyltransferase.

glutamine transaminase L *see* glutamine-pyruvate aminotransferase.

glutamino 1 *N*<sup>2</sup>-glutamino the alkylamino group, HzN-CO-[CH<sub>2</sub>h-CH(COOH)-NH-, derived from glutamine by loss of a hydrogen atom from its a-amino group. 2 N5-glutamino the acylamino group, H2N-CH(COOH)-[CH<sub>2</sub>h-CO-NH-, derived from glutamine by loss of a hydrogen atom from its amide group.

glutaminyl the acyl group, H<sub>2</sub>N-CO-[CH<sub>2</sub>]<sub>2</sub>-CH(NH<sub>2</sub>)-CO-, derived from glutamine. *Compare* isoglutaminyl.

glutamo the alkylamino group, HOOC-[CH<sub>2</sub>]<sub>2</sub>-CH(COOH)-NH-, derived from glutamic acid.

glutamoyl the diacyl group, -CO-[CH<sub>2</sub>]<sub>2</sub>-CH(NH<sub>2</sub>)-CO-, derived from glutamic acid.

a-glutamyl glutamyl-l-yl; the a-monoacyl group, HOOC-[CH<sub>2</sub>l-CH(NH<sub>2</sub>)-CO-, derived from glutamic acid.

y-glutamyl or (formerly) isoglutamyl, glutam-5-yl; the y-monoacyl group, -CO-[CH<sub>2</sub>h-CH(NH<sub>2</sub>)-COOH, derived from glutamic acid.

glutamyl aminopeptidase EC 3.4.11.7; *other names*: aminopeptidase A; angiotensinase A; differentiation antigen gp160; an enzyme that removes an N-terminal glutamyl residue from a peptide. It can also hydrolyse N-terminal aminopeptidase, and can thus inactivate angiotensin II, being expressed in kidney, as well as on cells of the capillaries and intestine, and on lymphocytes. Example from human: database code AMPE\_HUMAN, 957 amino acids (109.24 kDa).

y-glutamyl cycle an integrated cycle of chemical events that uses the y-carboxyl group of glutamate to transport amino acids actively across (mammalian) cell membranes. Glutathione supplies the activated y-glutamyl group, which reacts by transpeptidation with the amino acid to be transported. The resulting y-glutamylamino acid enters the cell, where it is split into the free amino acid and 5-oxoproline. The latter is then converted to glutamate in an ATP-dependent reaction. The cysteinylglycine formed from glutathione in the initial transpeptidation step is hydrolysed by a peptidase. Glutathione is then regenerated in two ATP-dependent steps. *See also* glutamyltransferase.

y-glutamylcysteine synthetase *see* glutamate-cysteine ligase. glutamyl endopeptidase EC 3.4.21.19; *other names*: staphylococcal serine proteinase; V8 proteinase; protease V8; endopeptidase Glu-C. An enzyme that catalyses the preferential cleavage: Asp-I-Xaa, Glu-I-Xaa. Example (precursor) from *Staphylococcus aureus*: database code STSP\_STAAU, 336 amino acids (36.29 kDa).

glutamyltransferase abbr. (*in clinical chemistry*): GMT; EC 2.3.2.2; *recommended name*: y-glutamyltransferase; *systematic name*: (5-L-glutamyl)-peptide:amino acid 5-glutamyltransferase; *other name*: y-glutamyl transpeptidase. An enzyme that reversibly transfers a I'-L-glutamyl residue (linked to the substrate by an isopeptide bond) from the N terminus of a peptide, normally glutathione, to the amino group of an amino acid. It is present in high concentrations in liver, kidney, prostate, and pancreas, and is useful diagnostically in liver or biliary disease, levels being five times normal or more in cholestasis, hepatitis, and cirrhosis, and also in pancreatitis; it is also elevated in the plasma of alcoholics. The level in normal human (male) plasma is <60 IU L<sup>-1</sup>. *See also* y-glutamyl cycle.

glutaraldehyde pentanedral; a compound that is useful as a tissue fixative in electron microscopy, as a crosslinking agent for compounds containing amino groups, and as a sporicide.

glutaramic acid the trivial name for 4-carbamoylbutanoic acid; HzN-CO-[CH<sub>2</sub>h-COOH; the monoamide of glutaric acid (*see* glutarate).

glutarate 1 trivial name for propane-1,3-dicarboxylate; pentanedioate; -OOC-[CH<sub>2</sub>h-COO-; the dianion of glutaric acid (pentanedioic acid). 2 any mixture of free glutaric acid and its

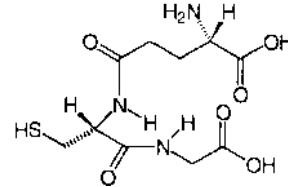

## glutathione transferase

mono- and dianions. 3 any (partial or full) salt or ester of glutaric acid.

glutaredoxin a monomeric polypeptide with a similar function to thioredoxin. It can replace thioredoxin, or may be the main reactant, in the pathway for nucleotide reduction. Example from *Escherichia coli*: database code GLRX\_ECOLI, 85 amino acids, (9.67 kDa).

glutaryl-CoA dehydrogenase EC 1.3.99.7; a flavoprotein decarboxylase that catalyses the reaction between glutaryl-CoA and acceptor to form crotonyl-CoA, CO<sub>2</sub>, and reduced acceptor. Example from *Pseudomonas* sp. (fragment): database code A48367, 20 amino acids (2.10 kDa).

glutathione abbr.: GSH; symbol: Glu(-Cys-Gly); y-glutamylcysteinylglycine, a tripeptide that is widely distributed in most if not all cells. It acts as a coenzyme for some enzymes and as an antioxidant in the protection of sulphydryl groups in enzymes and other proteins; it has a specific role in the reduction of hydrogen peroxide and oxidized ascorbate, and it participates in the y-glutamyl cycle. Glutathione may be oxidized with the formation of a disulfide bridge linking two molecules and generation of the compound known as oxidized glutathione (*or* the oxidized form of glutathione) (abbr.: GSSG). For clarity, glutathione is sometimes termed reduced glutathione (*or* the reduced form of glutathione).

glutathione dehydrogenase (ascorbate) EC 1.8.5.1; an enzyme that restores ascorbate to its reduced state after exercise of its function of reducing agent. It catalyses the reduction by two molecules of glutathione of dehydroascorbate to form oxidized glutathione and ascorbate.

glutathione peroxidase EC 1.11.1.9; *systematic name*: glutathione:hydrogen-peroxide oxidoreductase. An enzyme that catalyses the oxidation by hydrogen peroxide of two molecules of glutathione to form oxidized glutathione and two molecules of H<sub>2</sub>O. It has a UGA-encoded selenocysteine residue at its active site. The main role of the enzyme is to protect hemoglobin from oxidative breakdown: the oxidized glutathione is reduced by glutathione reductase, the system thus contributing to a reduction of peroxide levels in the cell. Example from human: database code GSCH\_HUMAN, 201 amino acids (21.87 kDa).

glutathione reductase abbr. (*in clinical chemistry*): GTD; EC 1.6.4.2; *recommended name*: glutathione reductase (NADPH); *systematic name*: NADPH:oxidized-glutathione oxidoreductase. An enzyme that catalyses the reaction:

It is a dimeric protein, has FAD as cofactor, and is important in maintaining glutathione in the reduced state. Example from *Escherichia coli*: database code GSHR\_ECOLI, 450 amino acids (48.72 kDa).

glutathione synthetase EC 6.3.2.3; *other name*: glutathione synthetase; an enzyme that catalyses the formation of glutathione from ATP, y-L-glutamyl-L-cysteine, and glycine with release of ADP and orthophosphate. Example from *Escherichia coli*: database code GSH2\_ECOLI, 316 amino acids (35.52 kDa); 3-D structure of parts is known.

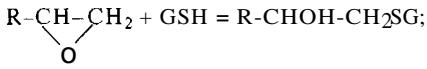

glutathione transferase EC 2.5.1.18; *systematic name*: RX:glutathione R-transferase; *other names*: glutathione S-alkyltransferase; glutathione S-aryltransferase; S-(hydroxalkyl)glutathione lyase; glutathione S-aralkyltransferase;

## glutelin

glutathione S-transferase. Glutathione transferases catalyse various glutathione-dependent reactions:  
(1) nucleophilic substitution, e.g.

where RX is an aryl- or alkyl-halide (EC 2.5.1.18); (2) addition of GSH across activated unsaturated carbon-carbon or carbon-nitrogen bonds (often  $\alpha,\beta$ -saturated ketones! thiones) or oxirane, e.g.

(3) organic hydroperoxide reduction (selenium-independent GSH peroxidase):

(4) organic nitrite reduction

(5) isomerizations in which GSH acts as cofactor, e.g. conversion of prostaglandin H to prostaglandin D. The proteins also bind a variety of hydrophobic anions, e.g. hematin, fatty acid and steroid metabolites, and various xenobiotics!metabolites including the GSH conjugates which may be their catalytic products. Such binding is responsible for their retention by S-linked GSH-Sepharose, hence the widely used simple purification of GST fusion proteins. GSH transferases were originally identified as binding proteins (*see ligandin*) and are widely distributed, abundant dimeric soluble enzymes or trimeric membrane-bound forms. They are generally considered an important part of phase II metabolism of xenobiotics. Five classes of soluble GSH transferase subunits have been distinguished ( $\alpha$ ,  $\mu$ ,  $\pi$ ,  $\epsilon$ , and  $\sigma$ ) and heterodimers occur at least within classes yielding, for example, about 20 different isoenzymes in the rat. Distinct soluble mitochondrial and bacterial forms also occur. Example, GST 5.7 from mouse: database code GTSA\_MOUSE, 222 amino acids (25.55 kDa). Example, GST I-I from *Drosophila melanogaster*: database code GT\_DROME, 209 amino acids (23.84 kDa).

**glutelin** any member of a group of simple proteins found especially in the seeds of cereal plants. They are insoluble in water, dilute salt solutions, and ethanol but are soluble in dilute acids or alkalis. The group includes the glutenins of wheat, the hordenins of barley, and the oryzemins of rice. They serve as storage proteins, and have Gin-rich domains. Example from rice, homohexamer of subunits (acidic and basic chain derived from one precursor) with Gin-rich domains; glutelin I precursor: database code GLULORYSA, 499 amino acids (56.15 kDa). *Compare prolamin.*

**gluten** a proteinaceous fraction obtained from certain cereal seeds, especially wheat, consisting of a considerable number of proteins that are all either glutenins or prolamins. It forms a sticky mass when wet, and gives dough its characteristic consistency. *See also celiac disease.*

**glutenin** any glutelin of the endosperm of wheat seeds. Glutenins form aggregates of high molecular mass in which they are linked together by disulfide bridges; they are thought to be responsible for the viscoelastic properties of wheat dough. The sequences contain repeats of two motifs,

and

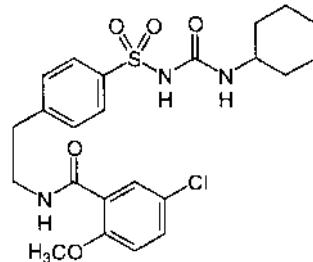

Example, high molecular mass DYIO precursor: database code GLTO\_WHEAT, 648 amino acids (69.55 kDa). *Compare gliadin.*

**Glx** general symbol for a residue of any  $\alpha$ -amino (or imino) acid that yields L-glutamic acid on acid hydrolysis. It was formerly used only for either of the  $\alpha$ -amino acids L-glutamic acid (*specific symbol: Glu*) or L-glutamine (*specific symbol: Gin*), but may now be used to represent any such residues, including

## glycated proteins

those of L-4-carboxyglutamic acid (*specific symbol: Gla*) and 5-oxoproline (= pyroglutamic acid) (*specific symbol: Glp*); (alternative to Z).

**Gly** symbol for a residue of the achiral ( $\alpha$ -)amino acid glycine (alternative to G).  
glyburide 1-[[P-[2-(chloro-o-anisamido)ethyl]phenyl]sulfonyl]-3-cyclohexylurea; glibenclamide; a sulfonylurea with oral hypoglycemic actions similar to tolbutamide.

**glyc+** a variant form of glyeo+ (before a vowel).

**glycaemia** a variant spelling (esp. UK) of glycemia.

**glycamine** any  $w$ -amino- $w$ -deoxyalditol, i.e. any compound formally derived from an alditol by replacement of a terminal hydroxyl group by an amino group.

**glycan** or polysaccharide any polymer consisting of more than about 10 monosaccharide (i.e. glycose) residues joined to each other by glycosidic linkages. A homoglycan (or homopolysaccharide) is composed of only one type of monosaccharide residue, whereas a heteroglycan (or heteropolysaccharide) is composed of two or more different kinds of monosaccharide residue. A homoglycan is named, generally, after the constituent monosaccharide, with the -ose ending replaced by -an; hence, cellulose, dextran, dextrin, and starch are all glucans, after glucose. Distinguish from glyeosan.

**glycaric acid** an obsolete name for aldaric acid.

**glycated hemoglobin** or **glycohemoglobin** any derivative of hemoglobin that is formed nonenzymically by reaction at the N terminus with glucose. In the normal adult human such derivatives constitute a few percent of the total erythrocyte hemoglobin, the most abundant being hemoglobin Ale, which increases severalfold in concentration in diabetes mellitus. Glycation of other proteins such as lens crystallins, collagen and low-density lipoproteins has been implicated in the pathogenesis of diabetic complications. The extent of glycation of hemoglobin is a useful measure of the degree to which the diabetes has been controlled by the administration of insulin. It is sometimes improperly termed glucosylated hemoglobin or glycosylated hemoglobin. *See also glycation.*
