protein phosphatase any enzyme that hydrolyses phosphate

groups from proteins. Together with protein kinases, these enzymes control the state of phosphorylation of cell proteins and thereby provide an important mechanism for regulating cellular activity. Protein phosphatases are classified into several groups. Class I enzymes are mainly specific for seryl- or threonyl-phosphate. Within this class, phosphatase I is  $\text{ATP}, \text{Mg}^{2+}$ -dependent (AMD phosphatase); it consists of a catalytic subunit of 38 kDa and a modulator subunit of 23 kDa, which is subject to phosphorylation, thus activating the phosphatase. Phosphatase 2A is polycation-stimulated (PCS), being directly stimulated by protamine, polylysine, or histone H1; it constitutes a subclass of several enzymes activated by different histones and polylysine. These have a very high affinity for the tumour promoter okadaic acid. Phosphatase 2B (or calcineurin) is a heterodimer; one of the subunits, of 61 kDa, contains the catalytic site, a high-affinity calmodulin-binding site, and a binding site for the other subunit, a 19 kDa,  $\text{Ca}^{2+}$ -binding protein. Phosphatase 2C is a  $\text{Mg}^{2+}$ -dependent monomeric 43 kDa protein; it has been purified as myosin light chain phosphatase, but is active against the phosphorylated forms of glycogen synthase, 6-phosphofructo-1-kinase, pyruvate kinase, fructose 1,6-bisphosphatase, and 6-phosphofructo-2-kinase. Class II enzymes hydrolyse tyrosylphosphates, and are generally designated 'phosphatase 3'. They are subdivided into those that are cytoplasmic, and others that are membrane-bound and may have receptor properties. Example of phosphatase 2A from human: database code P2AA\_HUMAN, catalytic subunit 309 amino acids (35.55 kDa); same in rabbit. This enzyme can modulate the activities of phosphorylase kinase  $b$ , casein kinase 2, mitogen-stimulated S6 kinase, and MAP-2 kinase. It is a cytoplasmic enzyme that exists in several oligomeric forms, all of which contain a catalytic (C) subunit (36-38 kDa) associated with one or both of two putatively regulatory subunits, the A subunit (61-65 kDa) and the B subunit (51-55 kDa). Example of protein tyrosine phosphatase, leukocyte antigen-related PTPase precursor from human: database code LAR\_HUMAN, 1897 amino acids (211.60 kDa).

protein-N'-phosphohistidine-sugar phosphotransferase EC 2.7.1.69; *systematic name: protein-N'-phosphohistidine:sugar N'-phosphotransferase; other name enzyme II*; any of a group of related membrane-bound bacterial enzymes, part of the phosphoenolpyruvate-dependent sugar phosphotransferase system for the transport of hexoses across the cell membrane. It involves phosphorylation of a protein substrate (9.5 kDa), a phosphocarrier known as HPr. Individual enzymes are specific for a range of sugars. They catalyse the reaction:

example from *Escherichia coli*: database code PT2G\_ECOLI, 477 amino acids (50.62 kDa).

protein S a single-chain glycoprotein occurring in blood,  $M_r$  69 000. It is a vitamin K-dependent protein (not a proteinase) that promotes the binding of protein C to platelets, and functions as a cofactor for the anticoagulant activity of activated protein C. It is named after Seattle, where it was discovered. protein splicing *see* splicing.

protein synthesis 1 (*in cell biology*) *see* protein and peptide biosynthesis. 2 (*in chemistry*) *see* peptidesynthesis (def. 2).

protein thiotemplate mechanism *see* thiotemplate mechanism.

proteinuria the presence of protein in urine. Normal excretion of protein in human urine is less than 0.1 mg every 24 h, about half of which is Tamm-Horsfall glycoprotein, and about 20% is albumin. Protein may appear in urine due to extrarenal factors such as fever, strenuous exercise, or burns; direct involvement of the kidney occurs in the nephrotic syndrome, which may arise from several causes, such as diabetic nephropathy, cancer of the kidney, or various forms of glomerulonephritis of unknown etiology.

protein Z a major protein of barley endosperm albumin. It is

## proteoclastic

structurally similar to a serpin, but its main role is as a storage protein, being especially rich in lysine. Database code PRTZ\_HORVU, 399 amino acids (22 lysine), 43.23 kDa.

**proteoclastic** an obsolete term for proteolytic.

**proteoglycan** any glycoprotein in which the carbohydrate units are glycosaminoglycans.

**proteolipid** a term variously applied to describe certain hydrophobic membrane proteins, or any other protein, that has a lipid moiety covalently bound to one or more of its constituent amino acids. Many such proteins are soluble in chloroform-methanol, a property that was significant in their first identification.

**proteoliposome** a liposome into which a specific protein, or group of proteins, has been incorporated.

**proteolysis** degradation of a protein, usually by hydrolysis at one or more of its peptide bonds. -proteolytic adj.

**proteolytic enzyme** see peptidase.

**proteome** the complete expression profile of the proteins of an organism. See also proteomics.

**proteomics** the study of the proteome by the analysis of protein structure and composition.

**proteosome** a variant spelling of proteasome.

**prothrombin** an alternative name for factor II; see blood coagulation.

**protide** 1 symbol: 'H-; a hydride (def. 1) ion derived from an atom of protium. 2 any hydride (def. 2) formed from protium. 3 or protid a generic name embracing protein, peptide, or amino acid, suggested by analogy with glucide and lipid(e). Its use in English is largely restricted to translations or abstracts from French. -protidic adj.

**proto+** comb. form indicating that one or more atoms of hydrogen in a hydrogen-containing chemical compound consists exclusively of protium.

**Protista** a taxonomic grouping of eukaryotic organisms that are unicellular, coenocytic, or multicellular but that are not classified as fungi, animals, or embryophytes.

**protium** symbol: IH; hydrogen-I, the nuclide of hydrogen,  $\{\text{H}\}$ , of relative atomic mass 1.008. It is a stable isotope, having a relative abundance in natural hydrogen of 99.98 atom percent. The name is used especially when distinction from deuterium or tritium is required.

**protoalkaloid** an alkaloid that does not contain a heterocyclic ring, e.g. damascenine in *Nigella* spp.

**probiont** one of the postulated first precursors of cells, supposed to have arisen when a boundary or membrane formed around one or more macromolecules possessing catalytic properties. Compare coacervate droplet.

**protochlorophyllide** Mg<sup>2+</sup>-vinylpheophorphyrin As methyl ether; an intermediate in the synthesis of chlorophyll, it is formed from Mg<sup>2+</sup>-protoporphyrin, and converted to chloro-

## proton number

phyllide by NADPH:protochlorophyllide oxidoreductase (EC 1.3.1.33). Protochlorophyllides may be suffixed with the letter of the related chlorophyll, e.g. protochlorophyllide *a*.

**protochlorophyllide holochrome** a pigment protein complex that carries out a light-catalysed reduction of protochlorophyllide to chlorophyllide with an external hydrogen donor, which is probably strongly bound NADPH. The enzyme involved in regenerating NADPH is NADPH:photochlorophyllide oxidoreductase; it is a single polypeptide, M, 36 000, and is only one component of the complex protein entity of the holochrome.

**protocollagen** collagen chains in which proline and lysine residues have not been hydroxylated. Protocollagens may be produced by experimental inhibition of the relevant hydroxylases either by use of a chelating agent or by imposed anaerobiosis. Compare procollagen.

**protoheme** or (esp. Brit.) **protohaem** the iron-porphyrin prosthetic group of the cytochromes *b*.

**protohemin** see hemin.

**protokaryon** an obsolete term for prokaryon.

**protokaryote** an obsolete term for prokaryote.

**protolysosome** see primary lysosome.

**protomer** any of the subunits of an oligomeric protein that are identical. See also monomer, oligomer. -protomeric adj.

**proton** 1 symbol: IH<sup>+</sup>; the cation derived from an atom of protium; a hydrogen ion of nucleon number unity; used in this sense especially when distinction between 'H<sup>+</sup>, 2H<sup>+</sup> (i.e. deuteron), and 3H<sup>+</sup> (i.e. triton) is needed; any solvated species is included. 2 symbol: H<sup>+</sup>; commonly used term for the cation derived from any atom of natural hydrogen (of which a small proportion is deuterium) by loss of its orbital electron; any solvated species is included. See also hydrogen ion, hydron. 3 symbol: p; a nuclear particle of nucleon number unity, having a charge equal and opposite to that of an electron and having a mass of 1.007 276 470 (12) Da. -protonic adj.

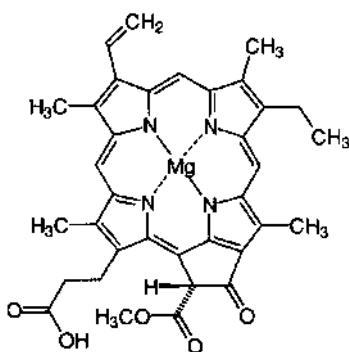

**proton magnetic resonance abbr.:** PMR or pmr; see nuclear magnetic resonance spectroscopy.

**proton magnetogyric ratio symbol:** yp; a fundamental physical constant, of value 2.675 221 28(81)  $\times 10^8 \text{ s}^{-1} \text{ T}^{-1}$ . See also gyromagnetic ratio.

**protonmotive** indicating, or related to an ability to transport protons (Le. hydrons).

**protonmotive Q cycle** a hypothetical mechanism put forward to explain the protonmotive and redox properties of certain components of the respiratory chain in the coupling membrane of bacteria, mitochondria, and chloroplasts. The Q cycle applies to the part of the respiratory chain involving passage of electrons through cytochrome *b*. Essentially, the cycle accepts two hydride ions from a reduced flavoprotein (e.g. of complex I or complex II of the respiratory chain; see complex I, II, III, IV) passes electrons singly to cytochrome *c1* and releases the two hydrons to the intermembrane space. Ubiquinone is the molecule that accepts the hydride ions, and releases the electrons and hydrons. Cytochromes *b666* and *b602* are involved in shuttling electrons between different oxidation states of ubiquinone during the cycle. The property of ubiquinone that it can exist as a semiquinone is important in the switch from two-electron to one-electron transfer.

**proton number** or **atomic number** symbol: Z; a dimensionless physical quantity, with a unique integral value for each chemical element, that is equal to the number of protons contained in the nucleus of each atom of the element irrespective of the mass of any particular atom. It also is equal to the number of unit positive charges on the nucleus of each atom of a given chemical element, to the number of orbital electrons surrounding the nucleus of an un-ionized atom of that element, and, for a specific nuclide of that element, to the arithmetical difference between the nuclide's nucleon number, A, and its neutron number, N; i.e. Z = N - A. The proton number of an element determines the position of the element in the periodic

protochlorophyllide a

## proton relaxation enhancement

table. It may be attached to the symbol for the element as a left subscript, e.g. 6C,  
proton pump another term (esp. in pharmacology) for hydrogen-ion pump.

**proton relaxation enhancement abbr.:** PRE; a technique that yields information concerning (macro)molecular motion. It depends on the enhancement of the solvent water-proton relaxation rates on addition of a macromolecule.

**protooncogene** a normal gene, usually concerned with the regulation of cell proliferation, that can be converted into a cancer-promoting oncogene by mutation. For example, in the case of the Rous sarcoma virus the viral oncogene is *v-src* (see *src*). This is closely related to a normal gene, *c-src*. The appearance of *v-src* is believed to have followed the acquisition of a copy of *c-src* by an ancestor of the Rous sarcoma virus. Through many generations this ancestral gene was mutated and became dominant. Protooncogenes encode proteins involved in all aspects of controlling cell proliferation, including growth factors, growth-factor receptors, nuclear factors regulating gene expression proteins that generate second messengers, and protein kinases.

**protoplasm** the living contents of a cell; i.e. the matter contained within (and including) the plasma membrane, usually taken to exclude large vacuoles and masses of secretory or ingested material. In eukaryotes it includes the nucleus and cytoplasm.

**protoplast** a spherical, osmotically sensitive plant cell without its cell wall but retaining an intact cell membrane. The cell wall is degraded by digestion with different hydrolytic enzymes, as a mixture or sequentially, e.g. cellulase, hemicellulase. Protoplasts are used to create hybrid cells via protoplast fusion. In some cases they are totipotent, and are thus capable of yielding plants. Such protoplasts can be used in plant transformation.

**protoporphyrin IX** the specific substrate for the enzyme ferrochelatase, which catalyses the insertion of iron to form protoporphyrin. It is also probably the substrate for the insertion of magnesium in the formation of chlorophylls in plants.

**prototroph** any strain of a microorganism (alga, bacterium, or fungus) that does not require any substances in its nutrition additional to those required by the wild type. Compare auxotroph. -prototrophic adj.

**Protozoa** a phylum or subkingdom comprising single-celled eukaryotic microscopic organisms, usually classified as animals. Compare Metazoa, Parazoa.

**provirus** a virus, e.g. a retrovirus, that is integrated into the chromosome of its host cell and can be transmitted through the generations without causing lysis of the host cell.

**provitamin** a compound which is converted to an active vitamin in the body. In practice the term is only applied to carotenes.

**Pro-X dipeptidase** EC 3.4.13.8; recommended name: proU-nase; other names: prolyl dipeptidase; iminodipeptidase; proU-nase; L-prolylglycine dipeptidase; an enzyme that catalyses the hydrolysis of Pro-I-Xaa dipeptides. It also acts on hydroxyprolyl analogues.

**proximal protein** any protein that binds early in the assembly of complex structures, such as ribosomes. Their presence in the partially assembled structure is required for the binding of distal proteins.

**proximate carcinogen** or proximate carcinogenic metabolite any metabolite of a chemical carcinogen that is itself carcinogenic; the term may embrace ultimate carcinogen.

**Prozac** see fluoxetine.

**PrP abbr.** for prion protein.

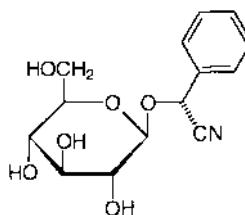

**PRP protein** abbr. for pre-mRNA processing protein.

**PRPP abbr.** (not recommended) for phosphoribosyl pyrophosphate (see (5-lphospho-(*a*-D)-ribosyl diphosphate).

**PRPP synthetase** another name for ribose-phosphate pyrophosphokinase.

**prunasin** (--)-(R)-mandelonitrile P-D-glucoside; a cyanogenic glycoside.

## pseudouridine

prunasin

**ps symbol** for picosecond.

**P-selectin** see selectin.

**pseudoalkaloid** any alkaloid in which the skeleton is partly derived from a terpene.

**pseudoallele** any of two (or more) mutations that are allelic functionally but not structurally. See allele.

**pseudoaxial (in chemistry) abbr.:** *a'*; see conformation.

**pseudocholesterol esterase** EC 3.1.1.8; recommended name: cholinesterase; other name: choline esterase II. An enzyme, found in blood and other tissues, that catalyses the hydrolysis of a variety of choline esters and a few other compounds. Compare acetylcholinesterase.

**pseudoequatorial (in chemistry) abbr.:** *e'*; see conformation.

**pseudoexon** a portion of an exon that is duplicated in an adjacent intron.

**pseudogene** symbol:  $\psi$ ; a sequence in DNA that is related to a functional gene but cannot be transcribed. This may be due to mutational changes that preclude it from being expressed in the form of functional products or the lack of some flanking control region in the promoter. Pseudogenes may not contain the introns of the functional gene. Examples include pseudogenes for  $\alpha$ ,  $\beta$ , and  $\zeta$  globulins in several species,  $V_{\kappa}$  chains of immunoglobulins, actin, and tubulin. Processed pseudogenes, or LINEs (see LINE), occur in a genome somewhere other than the normal position of the corresponding functional gene and so cannot be expressed because of alterations in regulatory DNA sequences, or coding sequences, or both.

**pseudoglobulin** a globulin that is soluble in solutions of low ionic strength or in pure water. Compare euglobulin.

**pseudointron** an intron that contains 5' and 3' splice sites that are appropriate but not utilized in the excision of the intron.

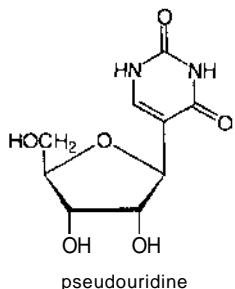

**pseudoisoenzyme** anyone of the epigenetically derived multiple forms of an enzyme.

**pseudo-operator** a functional operator element within a structural protein-coding region of DNA.

**pseudopepsin** see pepsinogen.

**pseudoplasmodium** (pl. pseudopodia) a temporary protrusion or retractile process of a cell, associated with flowing movements of the protoplasm and serving for locomotion and feeding. -pseudopodial adj.

**pseudouridine** symbol: *P*; 5-P-D-ribofuranosyluracil; a component of transfer RNA (tRNA) containing a C-C bond between the ribose (C-1) and uracil (C-5). Typical of the minor nucleosides present in tRNA, it is formed by modification of uridine in the original transcript; the chemistry of this process is unclear. When pseudouridine occurs in the anticodon of transfer RNA it base pairs with adenine. Compare uridine.

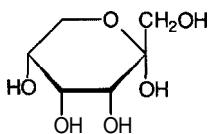

**psi** 1 symbol:  $\psi$  (lower case) or  $\Psi$  (upper case); the twenty-third letter of the Greek alphabet. For uses see Appendix A. 2 or p.s.i.  
abbr. for pounds per square inch (a unit of pressure in the Imperial and US systems of units).

**PSI** abbr. for photosystem I (see photosystem).

**psicofuranine** 6-amino-9-D-psicofuranosylpurine; an antibiotic produced by *Streptomyces hygroscopicus*, found to have antitumour activity. See also D-psicose.

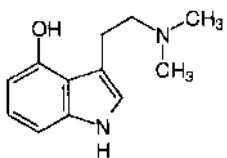

**D-psicose** a nonsystematic name for the keto-hexose D-ribo-2-hexulose. The hydroxyl at C-3 has the opposite configuration to that of D-fructose. It is a component of psicofuranine.

$\alpha$ -D-pyranose form

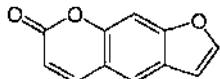

**PSI!** abbr. for photosystem II (see photosystem).

**psilocin** 3-[2-(dimethylamino)ethyl]-IH-indol-4-01; a hallucinogenic alkaloid extracted from the mushroom *Psilocybe mexicana*.

**P-site** abbr. for a peptidyl-tRNA binding site of ribosome; in bacteria this involves the ribosomal proteins L2, L14, L18, L24, L27, and L33, and a region close to the 3' end of 16S rRNA.

**psoralen** 6-hydroxy-5-benzofuranacrylic acid  $\alpha$ -lactone; a furocoumarin present as a phytoalexin in many plants. It has photosensitizing and phototoxic effects in humans and animals, and is used in photochemistry, intercalating into DNA and forming cross-links on irradiation. See also methoxysoralen.

**PSP** abbr. for pancreatic stone protein (see pancreatic thread protein).

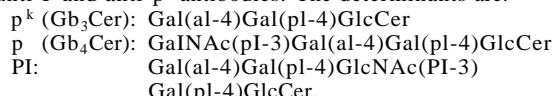

**psychosine** 1-O-P-D-galactosylsphingosine; it is formed from

UDPGalactose and sphingosine by sphingosine p-galactosyltransferase, EC 2.4.1.23. It is acylated to a cerebroside by reaction with a long-chain acyl-CoA.

**psychrometer** or wet-and-dry bulb hygrometer a type of hygrometer consisting of two thermometers, one with a wet bulb and one with a dry bulb. The cooling effect of evaporation from the wet bulb creates a temperature difference between the two thermometers, from which the relative humidity can be calculated.

**psychrophile** an organism that grows best at low temperatures (below about 20 °C). -psychophilic adj.

**P** system a system of blood groups in which the antigenic determinants are oligosaccharides. The antigens are detected on erythrocytes, erythroblasts, platelets, megakaryocytes, fibroblasts, and endothelial cells; they are designated pk, P, and PI'. The common phenotypes are PI (antigens PI and P positive) and  $P_Z$  (P antigen positive);  $p^k$  phenotypes are rare. Individuals with the p phenotype lack all of the above determinants, having only the core structure lactosylceramide, and have anti-P and anti- $p^k$  antibodies. The determinants are:

**Pt** symbol for platinum.

**PTA** abbr. for plasma thromboplastin antecedent (i.e. factor XI); see blood coagulation.

**PTC** abbr. for 1 plasma thromboplastin component (i.e. factor IX); see blood coagulation. 2 phenylthiocarbamoyL

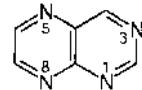

**Ptd** symbol for the phosphatidylgroup.

**PtdIns** symbol for phosphatidylinositol

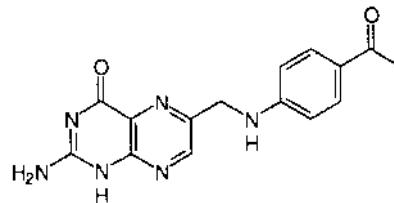

**PtdIns4P** or **PtdIns-4-P** symbol for phosphatidylinositol 4-phosphate.

**PtdIns(4,5)P<sub>2</sub>** or **PtdIns-4,5-P<sub>2</sub>** symbol for phosphatidylinositol 4,5-bisphosphate.

**pteridine** pyrazino[2,3-d]pyrimidine; the parent structure of pterins and the pteroyl group. See also xanthopterin.

**pteroyl** 4-[(2-amino-1,4-dihydro-4-oxo-6-pteridinyl)methyl]amino]benzoyl; the acyl group of pteroic acid, and the structural basis of folate and its derivatives.

**PTFE** abbr. for polytetrafluoroethylene.

**PTH** abbr. for 1 parathyroid hormone (Le. parathyrin). 2 phenylthiohydantoin; as in PTH-amino acid (i.e. the phenylhydantoin derivative of an amino acid).

**PTI** abbr. for pancreatic trypsin inhibitor.

**PTM** abbr. for post-translational modification.

**PTS** abbr. for phosphoenolpyruvate-dependent sugar phosphotransferase system.

**ptyalin** a substance in saliva, identified as a-amylase.

**Pu** symbol for plutonium.

**pUC vector** any of a series of plasmid cloning vectors having an

ampicillin resistance gene and part of the *lacZ* gene containing multiple cloning sites (MCSs). Different members of the series (e.g. pUC18, pUC19) vary in the restriction enzyme recognition sites included in the MCS. They are high copy number plasmids and so can be purified by rapid, small-scale methods of isolation. A related series of bacteriophage M13 vectors, the M13mp vectors, contain the same MCS and are useful for DNA sequencing. *See also* Messing vector.

**PUFA** *abbr.* for polyunsaturated fatty acid.

**puff** any discrete, localized expansion occurring at specific sites in polytene chromosomes, e.g. the giant salivary gland chromosomes in Diptera. Typically a few micrometres long, they are believed to be a gene or group of genes that are actively synthesizing RNA, which accounts for a considerable part of the mass of the puff. *See also* Balbiani ring.

**'pull'** model a *nickname for* the Monod-Wyman-Changeux model (for ligand-induced changes in protein conformation) because, in this model, ligands influence the equilibrium between enzyme states by sequestering the enzyme in ligand-bound forms. *Compare* 'push' model.

**pullulan** an extracellular glucan elaborated by *Aureobasidium pullulans* (yeast form) and formed by other fungi. It is a linear structure with both (1→4)- $\alpha$ -D- and (1→6)- $\alpha$ -D-linkages. Pullulan is used as a non-caloric material, a water-retention agent, and as a film and fibre former.

**pullulanase** 1 isopullulanase EC 3.2.1.57; an enzyme that catalyses the hydrolysis of pullulan to isopanose (i.e. 6-a-maltosylglucose). 2 neopullulanase EC 3.2.1.135; an enzyme that catalyses the hydrolysis of pullulan to panose (i.e. 6-a-o-glucosylmaltose). 3 *see* a-dextrin endo-1,6-a-D-glucosidase.

**pulsed field gel electrophoresis** *abbr.*: PFGE; a type of gel **electrophoresis** in which large fragments of DNA can be separated by continuously altering the angle at which the electric current is applied.

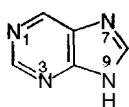

**pulse** radiolysis a technique whereby reactive chemical species are generated by pulses of high-energy radiation and the subsequent reactions of these species are followed spectrophotometrically as a function of time.

**pump** (*in cell biology*) any transmembrane protein that drives the active transport of ions and small molecules across the lipid bilayer. *See also* hydrogen-ion pump, sodium pump.

**PUMP-1** *see* matrilysin.

**pump-1 protease** *see* matrilysin.  
Purcell, Edward Mills (1912-97), US electrical engineer, physicist, and radioastronomer notable for his discovery (independently of F. Bloch) of the phenomenon of nuclear magnetic resonance of certain atomic nuclei and for being the first to report detection of the emission of 1420-Hz microwave radiation by interstellar dihydrogen; Nobel Laureate in Physics (1952) jointly with F. Bloch 'for their development of new methods for nuclear magnetic precision measurements and discoveries in connection therewith'.

**purine** 1 IH-purine; 7H-imidazo[4,5-d]pyrimidine; an organic nitrogenous base, sparingly soluble in water. 2 any of a class of derivatives of IH-purine; these form one of the two classes of nitrogen-containing ring compounds found in DNA and RNA, which include adenine and guanine. *See also* purine biosynthesis.

**purine biosynthesis** the biosynthesis of purine ribonucleotides. The pathway for the synthesis of purine ribonucleotides begins with the formation of 5-phospho-a-D-ribosyl diphosphate (5-phosphoribosyl-a-D-pyrophosphate, *common abbr.*: PRPP) by ribose-phosphate pyrophosphokinase, EC

2.7.6.1. This is converted to P-5-phosphoribosylamine (I) by reaction with glutamine, catalysed by amidophosphoribosyltransferase, EC 2.4.2.14; reaction of I with glycine, with hydrolysis of ATP to ADP and Pi, catalysed by phosphoribosylamine-glycine ligase, EC 6.3.4.13 (glycinamide ribonucleotide synthetase, *common abbr.*: GAR synthetase), brings about the formation of N1-(5-phospho-o-ribosyl)glycinamide (II, glycinamide ribotide, *common abbr.*: GAR); II reacts with 10-formyltetrahydrofolate to form 5'-phosphoribosyl-N-formylglycinate (III, *common abbr.*: FGAR), the enzyme being phosphoribosylglycinate formyltransferase, EC 2.1.2.2 (GAR transformylase); III is converted to 5'-phosphoribosyl-formylglycaminidine (IV, formylglycaminidine ribotide, *common abbr.*: FGAM) by phosphoribosylformylglycaminidine synthase, EC 6.3.5.3 (*common abbr.*: FGAM synthetase) by reaction with glutamine with ATP hydrolysis to ADP and Pi; IV is converted to 1-(5-phosphoribosyl)-5-aminoimidazole (V, 5-aminoimidazole ribotide, *common abbr.*: AIR), with hydrolysis of ATP to ADP and Pi, by phosphoribosylformylglycaminidine cyclo-ligase, EC 6.3.3.1 (*common abbr.*: AIR synthetase); V is carboxylated to 1-(5-phosphoribosyl)-5-amino-4-imidazole-carboxylate (VI, carboxyaminoimidazole carboxamide, *common abbr.*: CAIR), by phosphoribosylaminoimidazole carboxylase, EC 4.1.1.21 (*common abbr.*: AIR carboxylase); VI reacts with L-aspartate, with hydrolysis of ATP to ADP and Pi, to form 1-(5-phosphoribosyl)-5-amino-4-(N-succinocarboxamide)-imidazole (VII, 4-(N-succinylcarboxamide)-aminoimidazole ribotide, *common abbr.*: SACAIR) catalysed by phosphoribosylaminoimidazolesuccinocarboxamide synthase, EC 6.3.2.6 (*common abbr.*: SACAIR synthetase); VII is converted, with loss of fumarate, to 1-(5-phosphoribosyl)-4-carboxamide-5-aminoimidazole (VIII, aminoimidazolecarboxamide ribotide, *common abbr.*: AI CAR) by adenylosuccinate lyase, EC 4.3.2.2 (VII is an alternative substrate for this enzyme); VIII reacts with 10-formyltetrahydrofolate to form 5'-phosphoribosyl-5-formamido-4-imidazolecarboxamide (IX, formaminoimidazolecarboxamide ribotide, *common abbr.*: FAICAR), catalysed by phosphoribosylaminoimidazolecarboxamide formyltransferase, EC 2.1.2.3 (*common abbr.*: AI CAR transformylase); IX undergoes ring closure catalysed by IMP cyclohydrolase, EC 3.5.4.10, to form inosine monophosphate (IMP), from which other purine nucleoside monophosphates are formed. Thus it is converted to AMP via adenylosuccinate, in steps catalysed by adenylosuccinate synthase, EC 6.3.4.4, and adenylosuccinate lyase, EC 4.3.2.2. It is converted to GMP via xanthosine monophosphate, in steps catalysed by IMPdehydrogenase, EC 1.1.1.205, and GMP synthase, EC 6.3.4.1. A salvage pathway also exists, that reconverts purine bases released during nucleic-acid degradation to nucleoside monophosphates. The enzymes adenosine phosphoribosyltransferase and hypoxanthine-guanine phosphoribosyltransferase are responsible for these reactions.

**purine-nucleoside phosphorylase** *abbr.*: PNP; EC 2.4.2.1; *systematic name*: purine-nucleoside:orthophosphate ribosyl-transferase; *other name*: inosine phosphorylase. An enzyme that catalyses the phosphorylation of a purine nucleoside to a purine and a-o-ribose 1-phosphate. It functions in the degradation of purines; decreased activity leads to accumulation of dGTP, which affects DNA replication. Enzyme deficiency is associated with moderate immunodeficiency. Example from *Escherichia coli*, homohexamer: database code DEOD\_ECOLI, 238 amino acids (25.79 kDa).

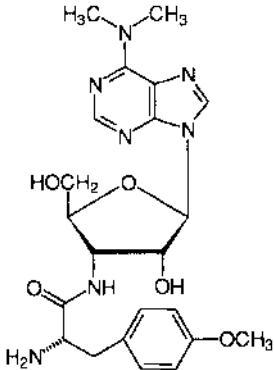

**purinergic** describing a type of nerve in which synaptic transmission is brought about by purine-like transmitter substances. *See* purinoceptor. *Compare* adrenergic, cholinergic.

**purinoceptor** or **purinergic receptor** a family of receptors (P<sub>1</sub>, P<sub>2X</sub>, P<sub>2Y</sub>, P<sub>2Z</sub>, P<sub>2T</sub>, and P<sub>2U</sub>) classified according to the relative potency of purine nucleotides - ATP, ADP, AMP, and UTP - in stimulating them and by their response to either adenosine (P<sub>1</sub>) or ATP (P<sub>2</sub>). P<sub>2Y</sub> and P<sub>m</sub> have seven transmembrane domains and regulate turnover of sphingomyelin; example of

## puromycin

$P_{2U}$  from *Rattus norvegicus*: database code P2UR\_RAT, 374 amino acids (42.26 kDa).  $P_{2X}$ ,  $P_{2Z}$ , and  $P_{2T}$  modulate the opening of an intrinsic cation channel but  $P_{2T}$  also stimulates release of intracellular  $\text{Ca}^{2+}$  and reduces synthesis of cyclic AMP. Example of  $P_{2X}$  from *R. norvegicus*: database code P2XLRAT, 472 amino acids (52.62 kDa).

puromycin a nucleoside antibiotic produced by the soil actinomycete *Streptomyces alboniger*. It interrupts protein synthesis by virtue of its structural similarity to the 3' end of aminoacyl-tRNA: it enters the A-site (see aminoacyl site) on the ribosome, and is incorporated into the growing polypeptide chain, thereby causing premature release of the puromycinyl polypeptide from the ribosome.

purothionin any of a group of basic peptides, isolated from grain and of  $M_r \approx 5000$ , that contain a large number of cysteine residues and are toxic to bacteria and fungi by inhibiting DNA transcription and RNA translation. Example purothionin  $\gamma$ -l from *Triticum aestivum*: database code THGI\_WHEAT, 47 amino acids (5.24 kDa).

**purple** membrane part of the cell membrane of *Halobacterium halobium* containing bacteriorhodopsin.

'push' model a nickname for the Koshland model (for ligand-induced changes in protein conformation) because, in this model, binding of the ligands results in a conformational change and does not simply select a pre-existing state. Compare 'pull' model.

putidaredoxin a ferredoxin, isolated from *Pseudomonas putida*, that is an electron carrier in a hydroxylase system acting on camphor and closely related monoterpenes. Compare adrenodoxin.

putrescine 1,4-diaminobutane; the polyamine formed by decarboxylation of ornithine and the metabolic precursor of spermidine and spermine.

PVA abbr. for 1 polyvinyl alcohol. 2 polyvinyl acetate.

PVC abbr. for polyvinyl chloride.

PVP abbr. for polyvinyl pyrrolidone.

PWM abbr. for pokeweed mitogen.

pycnometer an apparatus for measuring the density of liquids, and also sometimes of solids. It consists of a container whose volume can be accurately measured, and that can be filled with great precision, so that when filled with the liquid in question it can be weighed to determine the density. -pycnometric adj. Pyd symbol for a residue of an unspecified pyrimidine nucleoside (alternative to Y).

pyr-1 the symbol for the pyrimidine I gene, which encodes CAD protein in several eukaryotes.

pyran the trivial name for either of the hypothetical isomers  $\alpha$ -pyran, 2H-pyran, oxacyclohexa-3,5-diene, or  $\gamma$ -pyran, 4H-pyran, oxacyclohexa-2,5-diene,  $C_8H_6O$ . These pyrans are not known as such, but are the parent structures of various known pyranoid compounds such as dihydropyran,  $\alpha$ - and  $\gamma$ -pyrones, and pyranoses.

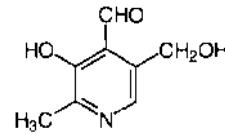

## pyrimidine dimer

pyranoid pyran-like, i.e. describing a molecular structure that consists of or contains a ring of five carbon atoms and one oxygen atom (as in pyran).

pyranose symbol:  $p$ ; any monosaccharide or monosaccharide derivative whose molecule contains a pyranoid ring. Compare furanose, septanose.

pyridine-nucleotide coenzyme any of a group of coenzymes containing a nicotinamide nucleotide residue, e.g. nicotinamide-adenine dinucleotide ( $NAD^+$ ); now known as nicotinamide-nucleotide coenzymes.

pyridoxal abbr.: PL; 3-hydroxy-5-(hydroxymethyl)-2-methyl-4-pyridine carboxaldehyde; a compound with vitamin  $B_6$  activity.

pyridoxal kinase EC 2.7.1.35; an enzyme that catalyses the formation of pyridoxal 5'-phosphate from ATP and pyridoxal with release of ADP. Example (fragment) from sheep: database code A61483, 11 amino acids (1.24 kDa).

pyrimidine 1,3-diazine; an organic nitrogenous base, sparingly soluble in water. 2 any of a class of derivatives of pyrimidine (def. 1); these form one of the two categories of nitrogen-containing ring compounds found in DNA and RNA, which include cytosine, thymine, and uracil. See also pyrimidine biosynthesis.

pyrimidine biosynthesis or pyrimidine ribonucleotide biosynthesis pyrimidines are formed from carbamoyl phosphate (see carbamoyl-phosphate synthase) after conversion to carbamoyl aspartate in a reaction with L-aspartate catalysed by aspartate transcarbamylase, EC 2.1.3.2. Carbamoyl aspartate is converted to orotate via dihydroorotate, in steps catalysed by dihydroorotate, EC 3.5.2.3, and dihydroorotate dehydrogenase, EC 1.3.99.11. Orotate is phosphorylated to orotidine monophosphate (OMP) in a reaction with 5-phospho-a-D-ribosyl diphosphate catalysed by orotate phosphoribosyltransferase, EC 2.4.2.10. OMP is converted to uridine monophosphate by orotidine 5'-phosphate decarboxylase, EC 4.1.1.23.

pyrimidine dimer any structure formed within a strand of DNA from two neighbouring pyrimidine residues through covalent cross-linking induced by ultraviolet irradiation. Two types are known. (1) Addition of one pyrimidine ring to the other at each end of their respective 5,6-double bonds generates a cyclobutadipyrimidine, a fully substituted cyclobutane. Such a dimer is formed most readily from two thymine residues (see thymine dimer), but may be formed also from two cytosine residues, or from one cytosine and one thymine residue. For each of these varieties there are four possible configurational isomers: if the pyrimidine rings have become linked in a parallel manner, i.e. by 5-5' and 6-6' bonds, the configuration is designated by the prefix *syn*-, but if they are linked in an antiparallel manner, i.e. by 5-6' and 6-5' bonds, it is designated by *anti*-; further, if the pyrimidine rings are both on the same side of the plane of the cyclobutane ring, the dimer is described as being in the 'doghouse configuration', designated by the prefix *cis*-, but if the rings are on opposite sides of the cyclobutane plane, the dimer is said to be in the 'chair configuration', designated by *trans*-. The presence of a

**pyrimidine-nucleoside phosphorylase**

cyclobutadipyrimidine in a DNA strand causes a local distortion of the DNA duplex and blocks the action of DNA polymerase, thus preventing replication; cell death may ensue unless repair is effected by photoreactivation. (2) Alternatively, addition may take place between position 6 of one pyrimidine residue and position 4 of an adjacent one, with creation of a single covalent link and generation of a (6-4)photoproduct. Such a dimer is usually formed between position 6 of a cytosine or thymine residue on the 5' side of a dinucleotide segment and position 4 of a cytosine residue on its 3' side. The (6-4)photoproduct is thought to be the main type of lesion in DNA responsible for mutations; it is not susceptible to photoreactivation, but can be eliminated by other DNA-repair mechanisms, e.g. excision repair.

**pyrimidine-nucleoside phosphorylase** any of several enzymes that function in the catabolism of pyrimidines; examples are: (1) Uridine phosphorylase, EC 2.4.2.3; it catalyses the phosphorylation of uridine to uracil and α-D-ribose 1-phosphate. Example from *Escherichia coli*, homohexamer showing 4-, 6-, and 8-fold symmetry; database code UDP\_ECOLI, 252 amino acids (27.00 kDa). (2) Thymidine phosphorylase, EC 2.4.2.4; it catalyses the phosphorylation of thymidine to thymine and 2-deoxy-D-ribose 1-phosphate. Example from *E. coli*, homodimer; database code DEOA\_ECOLI, 441 amino acids (47.28 kDa).

**pyro-** or (*before a vowel*) **pyr+** *comb. form* 1 of, relating to, caused, or produced by fire. 2 (*in chemistry*) indicating material derived by the action of heat; it often indicates an acid formed by loss of a molecule of water in a heating process, and hence also some anhydrides, e.g. pyrophosphate.

**pyrocatechol** or **pyrocatechin** or (*formerly*) catechol 1,2-benzenediol; o-dihydroxybenzene. Compare catecholamine, o-benzoquinone, hydroquinone.

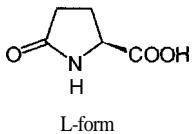

**pyrolysis** the decomposition or dissociation of a chemical compound by the application of heat. See also thermolysis. -**pyrolytic** *ad.*; **pyrolyse** or (*sometimes, US*) **pyrolyze** *vb.*

**pyrophosphatase** 1 *an imprecise name for* inorganic pyrophosphatase. 2 *the generic name for* any of a number of the enzymes within sub-subclass EC 3.6.1 (enzymes acting on diphosphate bonds); e.g. ATP pyrophosphatase (EC 3.6.1.8).

**pyrophosphate** *an older name for* diphosphate (def. 1-5) (use no longer recommended although it is still used as an alternative in such terms as inorganic pyrophosphate, pyrophosphatase, etc.). See also inorganic diphosphate.

**pyrophosphokinase** *the general name for* any enzyme belonging to the sub-subclass EC 2.7.6, diphosphotransferases, which transfer a diphosphate group from ATP to a named substrate; e.g. GTP pyrophosphokinase (EC 2.7.6.5), which converts guanosine 5'-triphosphate, GTP to guanosine 3'-phosphate 5'-triphosphate, pppGpp.

**pyrrolidonecarboxylic acid symbol:** <Glp; pyroglutamic acid; 5-oxoproline; pyrrolid-2-one-5-carboxylic acid.

**1-pyrroline-5-carboxylate dehydrogenase** EC 1.5.1.12; an enzyme that catalyses a reaction between 1-pyrroline-5-carboxylate (*abbr.*: P5C), NAD+, and H<sub>2</sub>O to form L-glutamate and NADH. P5C is an intermediate in the conversion of glutamate, proline, and ornithine. Example from *Escherichia coli*, a bifunctional protein that also has proline dehydrogenase activity; database code PUTA\_ECOLI, 1320 amino acids (143.66 kDa).

**pyrroloquinoline-quinone abbr.:** PQQ; *an alternative name for* methoxatin.

[**pyruvate kinase]-phosphatas8**

**pyruvate** *trivial name for* 2-oxopropanoate, CH<sub>3</sub>COCOO-; it is found in virtually every type of cell and species, being an important intermediate in many pathways including the catabolism of glucose, and the biosynthesis of amino acids and carbohydrates.

**pyruvate carboxylase abbr.:** PCB; EC 6.4.1.1; *systematic name:* pyruvate:carbon dioxide ligase (ADP-forming); *other name:* pyruvic carboxylase; an enzyme that catalyses a reaction between ATP, pyruvate, and HCO<sub>3</sub><sup>-</sup> to form oxaloacetate, ADP, and orthophosphate; biotin and manganese or zinc are cofactors. Example from yeast (PCB1) homotetramer: database code PYCL\_YEAST, 1178 amino acids (129.95 kDa). **pyruvate decarboxylase** EC 4.1.1.1; *systematic name:* 2-oxoacid carboxy-lyase; *other names:* a-carboxylase, pyruvic decarboxylase; a-ketoacid carboxylase. An enzyme that catalyses the decarboxylation of a 2-oxo acid to an aldehyde and CO<sub>2</sub>; thiamine diphosphate is a coenzyme. Example from yeast (there are three related isozymes), homotetramers, isozyme I: database code DCPLYEAST, 563 amino acids (61.44 kDa).

**pyruvate decarboxylase kinase** or **pyruvate dehydrogenase kinase** a subunit of the mammalian pyruvate dehydrogenase complex. It phosphorylates three serine residues on pyruvate dehydrogenase (lipoamide) resulting in loss of activity, and is stimulated by elevated levels of acetyl-CoA and NADH.

**pyruvate dehydrogenase complex** an enzyme complex that catalyses the overall reaction between pyruvate, NAD+, and coenzyme A to form acetyl-CoA, NADH, and CO<sub>2</sub>. The complex consists of three activities: (1) pyruvate dehydrogenase (lipoamidell, designated E<sub>1</sub>), catalysing a reaction between pyruvate and lipoamide to form S-acetyldihydrolipoamide and CO<sub>2</sub>; (2) dihydrolipoamide S-acetyltransferase, designated E<sub>2</sub>, catalysing a reaction between S-acetyldihydrolipoamide and coenzyme A to form acetyl-CoA and dihydrolipoamide; and (3) dihydrolipoamide dehydrogenase, designated E<sub>3</sub>, which oxidizes dihydrolipoamide to lipoamide. The complex is regulated by the phosphorylation and dephosphorylation of the pyruvate dehydrogenase (lipoamide) component, phosphorylation being catalysed by pyruvate decarboxylase kinase and removal of phosphate being catalysed by [pyruvate dehydrogenase (lipoamidell phosphatase) (or pyruvate decarboxylase phosphatase), EC 3.1.3.43]. Elevated levels of NADH and acetyl-CoA inhibit the complex by stimulating the kinase.

**pyruvate dehydrogenase** (lipoamidell EC 1.2.4.1; *systematic name:* pyruvate:lipoamide 2-oxidoreductase (decarboxylating and acceptor-acetylating); *other names:* pyruvate decarboxylase; pyruvate dehydrogenase; pyruvic dehydrogenase. A component enzyme of the pyruvate dehydrogenase complex. It catalyses a reaction between pyruvate and lipoamide to form S-acetyldihydrolipoamide and CO<sub>2</sub>; thiamine diphosphate is a coenzyme. Example, pyruvate dehydrogenase E<sub>1</sub> component from *Escherichia coli*, homodimer, flavoprotein: database code ODPLECOLI, 886 amino acids (99.50 kDa).

**pyruvate dehydrogenase** (lipoamidell-phosphatase EC 3.1.3.43; an enzyme that catalyses the hydrolysis of phosphate from [pyruvate dehydrogenase (lipoamide)] phosphate. This hydrolysis activates the enzyme activity. Example (precursor) from *Bos taurus*, catalytic subunit: database code PDP\_BOVIN, 538 amino acids (61.12 kDa).

**pyruvate kinase** EC 2.7.1.40; *systematic name:* ATP:pyruvate 2-O-phosphotransferase; *other names:* phosphoenolpyruvate kinase; phosphoenol transphosphorylase. An enzyme that catalyses the formation of pyruvate and ATP from phosphoenolpyruvate and ADP; it requires Mg<sup>2+</sup> and K<sup>+</sup>. In the glycolytic pathway, it effects the phosphorylation of ADP to ATP. In many cases the enzyme is a homotetramer. Example from yeast: database code KPYK\_YEAST, 500 amino acids (54.48 kDa).

**pyruvate kinasel-phosphatase** EC 3.1.3.49; an enzyme that

**pyruvate-malate cycle**

catalyses the hydrolysis of phosphate from [pyruvate kinase] phosphate in order to activate pyruvate kinase.

**pyruvate-malate cycle** a metabolic cycle involving malate dehydrogenase (oxaloacetate-decarboxylating) (the **malic enzyme**) that occurs during fatty-acid biosynthesis. In this situation, acetyl-CoA is transported into the cytoplasm as citrate, formed by mitochondrial citrate synthase; the citrate is cleaved in the cytoplasmic compartment to acetyl-CoA, which participates in fatty-acid synthesis, and oxaloacetate. No transport system exists for taking this oxaloacetate back into the mitochondrion; however, it can be reduced to malate by

cytoplasmic NAD<sup>+</sup>-linked malate dehydrogenase, and the malate so formed can be converted to pyruvate by malic enzyme, EC 1.1.1.38; the pyruvate can then be transported into the mitochondrion, to be carboxylated to oxaloacetate by **pyruvate carboxylese**.

**pyruvate-malic carboxylase** an alternative name for **malic enzyme**.

**PYV** abbr. for peptide YY.

**PZ** abbr. for pancreozymin.

**PZP** abbr. for pregnancy zone protein.

# Qq

**q** symbol for quartet (in nuclear magnetic resonance spectroscopy).

**q** symbol for 1 heat (alternative to *Q*). 2 partition function (individual entity). 3 specific humidity.

**Q** symbol for 1 a residue of the α-amino acid L-glutamine (alternative to *Gin*). 2 a residue of the ribonucleoside pseudouridine (replacing *Ψ* for computer work). 3 coenzyme Q (i.e. ubiquinone); not recommended. The number of prenyl residues may be indicated by a suffixed arabic number, e.g. Q-IO. 4 queuosine.

**a** symbol for 1 heat (alternative to *q*). 2 electric charge. 3 radiant energy (alternative to *W*). 4 or *Qv* quantity of light. 5 partition function (whole system).

**O'** symbol for temperature coefficient of a reaction.

**Q<sub>CO<sub>2</sub></sub>** symbol for metabolic quotient in respect of discharge of carbon dioxide; it is expressed in terms of microlitres CO<sub>2</sub> evolved per milligram dry mass of material per hour.

**Q<sub>O<sub>2</sub></sub>** symbol for metabolic quotient in respect of uptake of dioxygen; it is expressed in terms of microlitres O<sub>2</sub> absorbed per milligram dry mass of material per hour.

**qS** symbol for a measure of the activity of an enzyme, especially a respiratory enzyme, defined as the number of microlitres (at stp) of gaseous substrate S used up per hour per milligram enzyme. It could be extended to nongaseous substrates by taking 1 μmol as equivalent to 22.4 μL.

**QAE** abbr. for the quaternized aminoethyl; denoting the group diethyl-(2-hydroxypropyl)aminoethyl; (C<sub>2</sub>H<sub>5</sub>)<sub>2</sub>(CH<sub>3</sub>-CHOH-CH<sub>2</sub>)N<sup>+</sup>-CH<sub>2</sub>-CH<sub>2</sub>-; a strongly basic substituent sometimes used in hydroxylated chromatographic support matrices, as in QAE-Sephadex, to form anion exchangers. Compare DEAE.

**Q cycle** an alternative name for protonmotive Q cycle.

**Q enzyme** an alternative name for amylopectin branching enzyme; see branching enzyme.

**Q gas** a mixture of 98.7% helium and 1.3% Butane, used as filling for gas-flow Geiger counters.

**QH<sup>+</sup>** symbol for ubisemiquinone.

**QH<sub>2</sub>** symbol for ubiquinol.

**quad** denoting four kinetically important substrates or products in an enzyme mechanism. See reactancy of enzymes.

**quad'l'i+** or (sometimes) **quadrū+** Or (before a vowel) **quad'r+** comb.form four; fourth or one-fourth; square.

**quadruplex DNA** another name for tetraplex DNA.

**quality factor** or (formerly) relative biological effectiveness an index of the ability of a given type of ionizing radiation to cause biological damage, depending on the density of the ionization produced relative to that produced by gamma radiation. For all X- (and gamma) radiation and beta particles (+ or -) likely to be encountered in the use of radioisotopes it is assigned a value of unity, for thermal neutrons usually a value of 3, and for all alpha particles a value of 10. See also dose equivalent.

**quanta** the plural of quantum.

**quantal** 1 of, pertaining to, or being a quantum or something that is quantized; or of pertaining to the quantum theory. 2 of a biological effect or response in which there are only two categories, conditions, or states (e.g. all or none, alive or dead). -quantally *adv.*

**quantitative electrophoresis** (sometimes) an alternative name for crossed immunoelectrophoresis.

**quantity** or physical quantity (*in systems of measurement*) any property whose value can be expressed as the product of a numerical value and a unit. In the International System of Units (*see 51*) there are seven base quantities, physical quantities regarded as being dimensionally independent; these are: length, mass, time, electric current, thermodynamic temperature, amount of substance, and luminous intensity; all are arbitrari-

ily defined. Derived units are expressed algebraically in terms of the base units. Symbols for physical quantities are printed in italic type; they are generally single Roman or Greek letters, and may be lower case or capital.

**quantity of electricity** an alternative name for electric charge. **quantize** or quantise to restrict (a physical quantity) to a set of discrete values, characterized by quantum numbers. A quantized physical quantity cannot vary continuously but must change in steps. -quantization or quantisation *n.*

**quantum** (*pl. quanta*) 1 a (specific) quantity or amount of something. 2 a unit amount of a physical quantity, especially of electromagnetic energy, such that all other amounts are integral multiples of it. According to the quantum theory, a quantum of energy released during radiation emission or taken up during radiation absorption is equal to *hν*, where *h* is the Planck constant and *ν* the frequency of the radiation in hertz. A quantum of light (or other electromagnetic energy) is termed a photon.

**quantum efficiency** 1 (*in a luminescent system*) the fraction of the molecules in a particular excited state that emit luminescence. 2 (*in biochemistry*) an alternative term for quantum yield (def. 1).

**quantum mechanics** a mathematical theory developed from the quantum theory (*see quantum*) as a replacement for classical mechanics in order to explain satisfactorily the behaviour of atoms, molecules, and elementary particles in terms of observable quantities such as the intensities and frequencies of spectral lines.

**quantum number** any of a set of small integral or half-integral numbers that give the various possible values of a quantized property of a system. Quantum numbers are used especially in describing the properties of elementary particles, such as their charge (values of 0, +1, or -1) or spin (values of +½, or -½), and in specifying the energy states of electrons in atomic orbitals (each of which is characterized by a unique set of four quantum numbers).

**quantum requirement** (*in photosynthesis*) the inverse of quantum yield (def. 2); i.e. the number of quanta of light energy required to bring about the release of one molecule of oxygen. The theoretical value is eight, but the value observed in an experimental system is generally somewhat higher, depending on conditions.

**quantum theory** *see quantum.*

**quantum yield** 1 abbr.: *Q*; (*in a luminescent system*) the probability of luminescence occurring in given conditions, expressed by the ratio of the number of photons, i.e. quanta of light, emitted by the luminescing species to the number absorbed. Compare quantum efficiency. The measurement of *Q* requires the counting of photons, because

$$Q = \text{photons emitted}/\text{photons absorbed}.$$

**It** requires highly specialized instrumentation, but a less rigorous method may be employed in which the fluorescence of a fluor is compared with that of a fluor of known *Q*. Then

$$Q_x = [I_x Q_s A_s J] / [I_s A_x J]$$

where *Q<sub>s</sub>* is the quantum yield of the standard, *I<sub>x</sub>* and *I<sub>s</sub>* are the fluorescence intensities of the sample and standard and *A<sub>s</sub>* and *A<sub>x</sub>* are the percentage of absorption of each solution at the exciting wavelength. 2 (*in photosynthesis*) the inverse of quantum requirement; i.e. the fractional number of molecules of carbon dioxide reduced per photon absorbed.

**quartz** a colourless, often transparent, glassy form of silica, SiO<sub>2</sub>, used in optical devices and cuvettes because of its transparency to near-ultraviolet radiation. It is enantiomorphous,

## quaternary

the right- and left-handed forms rotating the plane of polarized light in opposite directions.

**quaternary** 1 consisting of four (items, parts, etc.); by or in fours. 2 (*in chemistry*) consisting of or containing an atom bound to four atoms or groups. 3 of the fourth order; fourth in a series or hierarchy.

**quaternary ammonium compound** any compound that can be regarded as derived from ammonium hydroxide or an ammonium salt by replacement of all four hydrogen atoms of the  $\text{NH}_4^+$  ion by organic groups. Certain compounds of this class – ones in which one of the organic groups is a long-chain ( $\text{C}_{12}\text{-C}_{18}$ ) alkyl group and the other three are shorter-chain alkyl or other groups – have the properties of cationic detergents and are powerful antimicrobial agents. They are bacteriostatic at low concentrations and bactericidal at higher concentrations, being generally more active against Gram-positive than Gram-negative organisms. They display relatively low toxicity to higher animals and humans, and hence are widely used as antiseptics and disinfectants.

**quaternary structure** the fourth order of complexity of structural organization exhibited by protein, nucleic acid, and nucleoprotein molecules. It refers to the arrangement in space of the subunits of a multimeric macromolecule and the ensemble of its intersubunit contacts and interactions without regard to the internal geometry of the subunits. Hence it is possessed only when the molecule in question is made up of at least two (identical or nonidentical) subunits that are (at least potentially) separable, i.e. are not linked by covalent bonds.

**Quellung reaction** or Neufeld Quellung reaction or pneumococcus capsule swelling reaction the swelling of the capsule observed when specific antibody is mixed with suitable bacterial cells (e.g. pneumococci). It is probably due to deposition of antibody on the outside of the capsule, making the latter clearly visible. [From the German, *Quellung*, swelling; described by Ferdinand Neufeld (1869-1945), German bacteriologist, in 1902.]

**quench correction** (*in liquid-scintillation counting*) a correction to be applied to an observed count rate to allow for losses resulting from quenching (def. 2).

**quenched flow** see rapid-reaction kinetics.

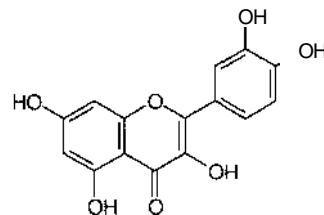

**quencher** a substance capable of reducing or destroying luminescence through deactivation of an excited chemical species. In biological systems this usually occurs by chemical reaction (e.g. complex formation), by exchange of energy on collision, or by resonance energy transfer.

**quenching** 1 the reduction or destruction of luminescence, especially fluorescence, of a sample by addition or inclusion of a quencher. Fluorescence quenching is the basis of a useful technique for studying the binding of small molecules to proteins or other macromolecules. 2 the reduction by whatever means of the efficiency of energy transfer from beta particles to the photomultiplier(s) in a liquid-scintillation counter. Such means include: (1) dilution quenching – reduction of the probability of scintillation occurring through dilution of the scintillator by the sample; (2) chemical (or impurity) quenching – absorption by a component of the sample of some of the energy of the beta particles without emitting photons, or (without fluorescing and in competition with the primary fluor) of some of the photons emitted by excited solvent molecules; and (3) colour quenching – absorption by a coloured component of the sample of some of the photons emitted by the secondary fluor. 3 the termination of a chemical or enzymic reaction by addition of another reagent or sudden change of the conditions.

**quercetin** 3,3',4',5,7-pentahydroxyflavone; a member of the flavonoids, or flavones, widely distributed in plants, often as glycosides; it is the aglycon of quercitrin, rutin, and other materials. Known in folk medicine for its anti-inflammatory properties, it inhibits the lipoxygenase pathway, has some antiplatelet and antithrombotic activity *in vivo*, inhibits mast-cell degranulation, and possesses anti-asthmatic activity. It inhibits many

## quinacrine mustard

enzymes, including protein kinases, and also inhibits DNA, RNA, and protein synthesis. A number of its actions may reflect its property as a nucleoside antagonist.

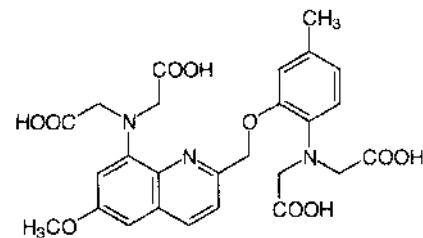

**quercitrin** quercetin-3-L-rhamnoside. See also quercetin.

**query language** very high level computer language used in interrogating databases.

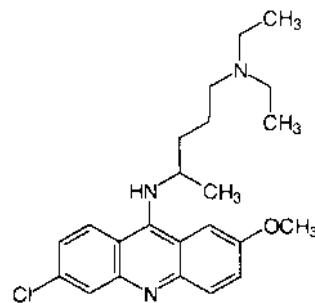

**queuosine symbol:** Q; anyone of a series of nucleosides found in tRNA and having an additional pentenyl ring added via an NH group to the methyl group of 7-methylguanosine. The pentenyl ring may carry other substituents.

**Qui** symbol for a residue (or sometimes a molecule) of the deoxyaldohexose quinovose.

**Quin-2** abbr. for 2-[(2-amino-5-methylphenoxy)methyl]-6-methoxy-8-aminoquinoline-N,N,N',N'-tetraacetic acid; a molecule functionally related to the  $\text{Ca}^{2+}$ -chelating agent EGTA, but containing fluorescent groups. The quantum yield of fluorescence is greatly enhanced on binding  $\text{Ca}^{2+}$ , leading to its use as a quantitative indicator of  $\text{Ca}^{2+}$  concentration. It is normally used as its tetraacetox ester, which readily crosses the plasma membrane and is then hydrolysed within the cell by esterases to Quin-2, the polar nature of which causes it to be retained as an intracellular indicator. See also Fura-2, INDO-1.

**quinacrine** or mepacrine or atebrine 6-chloro-9-(4-diethylamino-1-methylbutylamino)-2-methoxyacridine; a derivative of acridine, formerly used as an antimalarial and anthelmintic. It fluoresces powerfully in UV light and can be used as a fluorochrome to label DNA in chromosomes.

**quinacrine mustard** a compound derived by chloro-substitution of the terminal methyls of quinacrine ethylamino groups, and possessing properties of an alkylating agent; this enhances its value as a DNA-labelling agent.

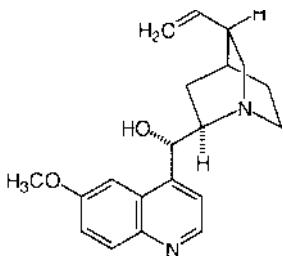

**quinhydrone**

**quinhydrone** an addition compound of one mole each of hydroquinone and p-benzoquinone. It is a reddish-brown crystalline substance with a dark-green lustre, useful as an antioxidant, in photography, and as a redox system in the **quinhydrone electrode**.

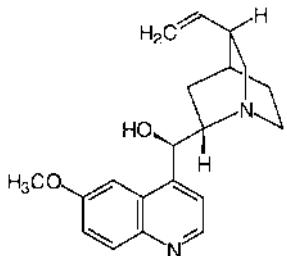

**quinhydrone electrode** a half-cell consisting of a bright platinum (or sometimes gold) electrode immersed in a test solution to which has been added a little **quinhydrone**. It has an electric potential related to the pH value of the solution and thus is useful as a secondary hydrogen electrode for the electrometric measurement of pH.

**quinic acid** the D enantiomer (*1a,3a,4a,5p*)-*1,3,4,5-tetrahydroxycyclohexanecarboxylic acid* occurs commonly in plants, either free or as esters (e.g. **chlorogenic acid**), and may make up as much as 2–10% of the dry weight of leaves. It may be formed by the **shikimate pathway**. Its catabolism to protocatechuic acid has been extensively studied in *Aspergillus nidulans* and *Neurospora crassa*.

**quinidine** p-quinine; 6'-methoxycinchonan-9-01; a stereoisomer of **quinine** noted for its cardiac anti-arrhythmic effects.

**quinine** 6'-methoxycinchonan-9-01; a bitter-tasting alkaloid obtained especially from the bark of cinchona, any of a number of trees or shrubs of the tropical genus *Cinchona* (especially the Javan species *C. ledgeriana* and various South

American species). It was formerly much used (and sometimes is still needed) for the prevention and treatment of malaria; it

**quisqualate receptor**

binds to the DNA of the malarial parasite, *Plasmodium* spp., and is thought thereby to inhibit biosynthesis of the parasite's nucleic acids. Quinine and drinks containing it (e.g. tonic water) help to prevent cramp. Compare **quinidine**.

**quinoid or quinonoid** of, derived from, or resembling a **quinone** (deL 2).

**quinol** an alternative name for **hydroquinone**.

**4-quino lone antibiotic** a generic term for any of a wide range of synthetic antibacterial compounds whose molecular structures contain a 4-oxo-1,4-dihydroquinoline or a 4-oxo-1,4-dihydrocinnoline nucleus; e.g. **cinoxacin**, **ciprofloxacin**, **nalidixic acid**, **oxolinic acid**. Their antibiotic activity derives from interaction with the A subunit of bacterial DNA gyrase (see type II **DNA topoisomerase**); this results in trapping of bacterial DNA in the complex it forms with the A subunit. Rejoining of the DNA strands broken by the enzyme is thereby arrested.

**quinone** 1 a common name for **p-benzoquinone**. 2 any member of a class of diketones derivable from aromatic compounds by conversion of two CH groups into CO groups with any necessary rearrangement of double bonds. Simple quinones are usually p-quinones, i.e. derivatives of *p*-benzoquinone (compare **hydroquinone** (deL 2)), but they may also be o-quinones, i.e. derivatives of **a-benzoquinone** (compare **catechol** (deL 2)). Naturally occurring quinones form a large, varied, and widespread group of compounds; they include numerous pigments, various electron carriers (e.g. **plastoquinone**, **ubiquinone**), and vitamins K. See also **semiquinone**.

**+quinone** comb. form denoting a **quinone** (def. 2); e.g. benzoquinone, anthroquinone, naphthoquinone.

**quinonoid** an alternative term for **quinoid**.

**quinoprotein** a proposed name for any of a number of bacterial oxidoreductase enzymes within the sub-subclass EC 1.1.99 that have pyrroloquinoline-quinone (see **methoxatin**) as co-enzyme or prosthetic group. The category includes alcohol dehydrogenase (acceptor) (EC 1.1.99.8) of methylotrophic bacteria, glucose dehydrogenase (pyrroloquinoline-quinone) (EC 1.1.99.17), and a number of dehydrogenases acting on other specified (types of) alcohols or polyols.

**quinovosamine** 2-amino-2,6-dideoxy-D-glucose; an amino derivative of **quinovose** present in bacterial polysaccharides.

**quinovose** symbol: Qui; a trivial name for 6-deoxy-D-glucose. α-Quinovose occurs, e.g., as its 6-sulfo derivative (6-deoxy-α-D-glucopyranosyl 6-C-sulfate) in the sulfoquinovosyl diacylglycerols, which form one of the two major groups of the glycerolipids of chloroplasts. The sulfoquinovosyl derivative also occurs in some **cardiac glycosides**.

**quisqualate receptor** see **a-amino-3-hydroxy-5-methyl-isoxazole-propionic acid receptor**.

# R

r 1 symbol for ribo+ (def. I); it is used as a prefix in (one- or three-letter) symbols for ribonucleosides for emphasis or clarity, especially to distinguish from 2'-deoxyribonucleosides. 2 symbol for reaction. 3 abbr. for rat (as a prefix to an abbreviation for the name of a peptide hormone); denoting derived (or as if derived) from a rat or rats; e.g. rGH.

r symbol for 1 concentration ratio. 2 rate of concentration change. 3 radius. 4 interatomic distance.

R symbol for 1 a residue of the α-amino acid L-arginine (alternative to Arg). 2 a residue of an incompletely specified base in a nucleic-acid sequence that may be either adenine or guanine. 3 a residue of an unspecified purine nucleoside (alternative to PuO). 4 an unspecified univalent group in a formula of an organic compound. The group must be attached by means of carbon and derived from an aliphatic, carbocyclic, or heterocyclic compound. Up to three such groups, when different, may be designated R, R', and R'', or R<sub>1</sub>, R<sub>2</sub>, and R<sub>3</sub>; for more than three such groups, superscript numerals only should be used. 5 rontgen (a non-SI unit of radiation exposure). 6 resonance effect (in electron displacement).

R symbol for 1 electric resistance. 2 thermal resistance. 3 gas constant. 4 molar refraction.

R stereochemical descriptor denoting rectus; i.e. the absolute configuration of a chiral compound in which the priority (obtained using the Cahn-Ingold-Prelog sequence rules) of the substituent groups on the chiral centre decreases in a clockwise (right-handed) direction. For use as a prefix in chemical nomenclature, the descriptor is placed in parentheses and connected with a hyphen, e.g. (R)-alanine. For chiral compounds in which the relative but not the absolute configuration is known, rectus configuration is denoted by the prefix (R\*). See sequence rule. Compare S.

R<sub>B</sub> symbol for R<sub>B</sub> value.

R, or R<sub>F</sub> symbol for R<sub>f</sub> value.

R<sub>p</sub> symbol for phosphorylation state ratio.

R. symbol for saturation ratio.

RAB a gene encoding a Rab protein - any of a family of GTP-binding proteins similar to Ras proteins (see RAS) and probably involved in membrane traffic, etc. Example, Rab-2 from human and dog (identical sequences): database code RAB2\_HUMAN, 212 amino acids (23.52 kDa).

rabbit aorta-contracting substance abbr.: RCS; a name given (in 1969) to an unstable factor released from guinea-pig lung that caused contraction of isolated strips of rabbit aorta. The activity was probably due to the presence of thromboxane A<sub>2</sub> (see thromboxane).

rabbit reticulocyte system a cell-free system, from lysed rabbit reticulocytes, that translates added eukaryote mRNAs from a wide variety of heterologous sources. Endogenous mRNA is destroyed using a Ca<sup>2+</sup>-dependent ribonuclease, micrococcal endonuclease; this enzyme is inactivated by adding EGTA. Heterologous mRNA is then added and is translated by the system.

rac- abbr. for racemo-.

RACE abbr. for rapid amplification of cDNA ends; a variation on the polymerase chain reaction designed for amplification of cDNA corresponding to low-abundance mRNA.

racemase any enzyme that interconverts the two enantiomers of a chiral compound; such enzymes are categorized in subclass EC 5.1 (which also includes epimerases). If more than one chiral centre is present, a racemase must invert configuration of all the chiral centres. Thus, the name methylmalonyl-CoA racemase, sometimes used for methylmalonyl-CoA epimerase (EC 5.1.99.1), is incorrect - the enzyme does not change configurations of the chiral centres of the CoA moiety.

racemate any homogeneous phase containing equimolar amounts of enantiomeric molecules.

**racemic symbol:** (f)- or (formerly) dl-; denoting the presence of equimolar amounts of the dextrorotatory and levorotatory enantiomers of a compound, regardless of whether the (optically inactive) product formed is crystalline, liquid, or gaseous. A homogeneous solid phase composed of equimolar amounts of enantiomeric molecules is termed a racemic compound, and a mixture of equimolar amounts of enantiomeric molecules present as separate solid phases is termed a racemic mixture; see also racemate. A (f)-product may be resolved into its (+)- and (-)-components. The term is derived from racemic acid [from Latin *racemus*, bunch of grapes], the optically inactive mixture of (+)- and (-)-tartaric acids sometimes found during the manufacture of wine. By extension, the term is applied to DL- and (RS)-mixtures. See OIL convention, optical isomerism, sequence rule. See also racemo-.

**racemize** or racemise to induce the formation of a mixture of the two possible enantiomers from one of the pure isomers of a chiral compound. -racemization or racemisation n.

**racemo-** abbr.: rac-; prefix (in chemical nomenclature) designating a racemate. It may be used as an alternative to the symbol (f)- or (for certain classes of racemic compounds) the symbol DL-. Compare meso-.

rachitic of, pertaining to, or afflicted with rickets.

rachitis an alternative name for rickets.

rachitogenic tending to cause rickets.

**rad** 1 symbol for radian. 2 symbol: rad or (to avoid possible confusion with rad (def. I)) rd; the cgs unit of absorbed dose of ionizing radiation, equivalent to an absorption of 0.01 joule of energy per kilogram (= 100 ergs per gram) of irradiated material. Whereas the rad represents, in practice, about the same amount of energy as the rontgen (the exact equivalence depending on the material irradiated), it applies to any type of ionizing radiation in any medium. 1 rad = 0.01 Gy. 3 abbr. for radiation.

**radial** 1 of, resembling, or relating to a radius or ray; in rays. 2 emanating from the centre of a circle or a common central point. 3 spreading out uniformly in all directions on a surface. -radially adv.

**radian symbol:** rad; the SI supplementary unit of plane angle. One radian is equal to the angle subtended at the centre of a circle by an arc whose length is equal to the radius. It is dimensionless. There are  $2\pi$  radians in a circle; 1 rad = 57.29578°.

**radiant energy symbol:** Q or W; the energy of any form of electromagnetic radiation. The SI derived unit is the joule.

**radiant intensity symbol:** I; the radiant power of radiation from a point source per unit of solid angle; i.e.  $I = d\Phi/d\Omega$ , where  $\Phi$  is the radiant power and  $\Omega$  is the solid angle measured in steradians. The SI unit is the watt per steradian (W sr<sup>-1</sup>).

**radiant power or radiant flux symbol:** P or  $\Phi$ ; the rate of flow of energy of radiation; i.e.  $\Phi = dQ/dt$ , where Q is the radiant energy. The SI derived unit is the watt.

**radiation** 1 the emission of energy from a source and its transmission as particles, rays, or waves, especially as electromagnetic rays or waves, sound waves, or streams of subatomic particles. 2 energy so transmitted, especially the corpuscular and electromagnetic rays emitted in the decay of radionuclides. 3 ionizing radiation. 4 divergence from a common point, especially radially from a central point or source.

**radiation absorbed dose** see absorbed dose, rad (def. 2).

**radiation biology** an alternative name for radiobiology.

**radiation-chemical reaction** any chemical reaction that is initiated by the absorption of radiation but is distinguishable from a photochemical reaction by its lack of specificity (i.e. by

giving rise to a variety of reaction products) and by occurring at higher radiation energies (i.e. by absorption either of electromagnetic radiation from the mid-ultraviolet region onwards or of high-energy particulate radiation) and thus by resulting always in the formation of detectable ions.

**radiation chemistry** the branch of chemistry concerned with radiation-chemical reactions. *Compare* radiochemistry.

**radiation damage** the totality of the harmful changes induced in a cell or tissue by radiation. The harmful effects may include formation of thymine dimers in DNA or of radicals from polyunsaturated acyl groups in lipids.

**radiation dose equivalent** *see* dose equivalent.

**radiation inactivation method** a technique, based on target theory, that enables the size of the functional unit of a biologically active macromolecule (or of its complexes with other molecules) to be estimated; it can be used on unpurified (e.g. membrane-bound) material. Determinations are made of the biological activity remaining in a sample after exposure to various large doses of ionizing radiation (electrons or X- or gamma radiation of at least 1 MeV), and the value,  $D_{37}$ , of the radiation dose, expressed in Mrad, required to reduce the activity to 37% of (i.e.  $e^{-1}$  times) its original value is obtained; the relative molecular mass,  $M_r$ , of such a macromolecule may then be found from the empirical relationship

$$M_r = 6.4 \times 10^5 / D_{37}, \text{ where } D_{37} \text{ is determined at } 30^\circ\text{C.}$$

**radiation source** a quantity of radioactive material used as a source of ionizing radiation.

**radical** (*in chemistry*) 1 any molecular entity, charged or uncharged, that possesses an unpaired electron (but normally excluding any paramagnetic metal ion); often formed by homolysis of a covalent bond. Radical character is indicated in a formula by a centred dot symbolizing the unpaired electron and placed (if possible) beside the symbol for the atom of highest spin density; e.g.  $\text{HOO}'$ ,  $\cdot\text{CH}_3$ . The term free radical is now preferably restricted to any radical that does not form part of a radical pair. 2 *a former name for group* (def. 2).

**radical anion** *see* radical ion.

**radical cation** *see* radical ion.

**radical centre** the atom in any polyatomic radical (def. 1) on which the unpaired electron is largely localized.

**radical ion** any radical (def. 1) that carries an electric charge.

One carrying a negative charge is termed a radical anion (e.g. the benzene radical anion,  $\text{C}_6\text{H}_5'$ ); one carrying a positive charge is termed a radical cation (e.g. the benzene radical cation,  $\text{C}_6\text{H}_5^+$ ).

**radical pair** any two radicals (def. 1) in close proximity in liquid solution, with a solvent cage. They may have been formed simultaneously, e.g. by homolysis, or have come together by diffusion. Whilst together, correlation of their unpaired electron spins occurs and manifests itself as a distortion of nuclear magnetic resonance spectra.

**radical scavenger** any substance that can react readily with, and thereby eliminate, radicals. In biological systems or materials, radical scavengers may function as antioxidants or may protect from damage by ionizing radiation. Among the important radical scavengers that function in animal tissues at physiological concentrations are the water-soluble substances ascorbate, glutathione, and the purine bases, and the fat-soluble substances tocopherols, the retinols, the carotenes, and the ubiquinones.

**radioactivate** to convert a stable nucleus into one undergoing radioactive decay by bombardment with high speed particles, including protons, alpha particles, neutrons, and deuterons. These are formed in a cyclotron or synchrotron from a radioactive source, and accelerated through a potential difference of a few thousand volts by a magnetic field before being focused on the substance to be converted.

**radioactivation analysis** or activation analysis a method for the qualitative and/or quantitative estimation of the chemical elements in a sample. It depends on the identification and de-

termination of the radionuclides formed when the sample is bombarded with neutrons or other particles.

**radioactive** having the properties associated with a radioactive isotope.

**radioactive concentration** the activity (def. 2) per unit quantity of any material in which a radionuclide occurs. *See also* specific activity.

**radioactive decay** *see* decay (def. 1b).

**radioactive isotope** or radioisotope any isotope of a chemical element whose nucleus is unstable and emits alpha, beta, or gamma rays. The product is another element, which may be stable or unstable; if the latter, it decays further. Thus, the principal isotope of uranium,  $^{238}\text{U}$ , emits an alpha particle and decays to  $^{234}\text{Th}$ , which emits a beta particle forming  $^{234}\text{Pa}$ ; this chain continues to the formation of  $^{206}\text{Pb}$ , which is stable.

**radioactive label** or radiolabel a radioactive isotope incorporated into a molecule to confer on it the property of radioactivity.

**radioactive tracer** or radiotracer a radioactive substance that is added to a metabolic system in quantities (mass) too small to perturb the system, in order to follow, by isolating the radioactive intermediates formed, the sequence of transformations undergone normally by the same (nonradioactive) molecule under similar conditions.

**radioactivity** 1 the emission of radiation from certain nuclides by the spontaneous transformation of their nuclei. 2 (*loosely*) the radioactive material itself or its emitted radiation. *See* activity (def. 2).

**radioallergosorbent test** abbr.: RAST; a test used primarily for quantifying the levels of antigen-specific immunoglobulin E (IgE) in serum. A specific allergen, which has been covalently coupled to an insoluble Sephadex carrier, is incubated with serum containing the unknown amount of IgE. The carriers are then washed and further incubated with radiolabelled antibodies to IgE, the amount of radioactivity bound being a measure of the amount of IgE. The advantage of this method over the radioimmunosorbent test is that IgE specific to a particular antigen can be selectively quantified.

**radioassay** any type of assay in which a radioactive isotope is used in the measurement. The term embraces, e.g., immuno-radiometric assay, radioimmunoassay, and competitive protein-binding assay.

**radioautogram** or radioautograph or autoradiogram the pattern formed after development of an X-ray film that has been exposed to a paper, gel, or thin-layer chromatogram containing radioactive compounds.

**radioautograph** 1 *an alternative term for radioautogram*. 2 to prepare a radioautogram. -radioautography *n.*

**radiobiology** or radiation biology the study of the interaction between radiation and biological material.

**radiocarbon** any radioactive isotope of carbon, usually carbon-II or carbon-14.

**radiochemical purity** abbr.: Rep; the proportion of the total activity (def. 2) that is present in the stated chemical form in a radioactive material.

**radiochemistry** the branch of chemistry concerned with the compounds of radioactive nuclides. *Compare* radiation chemistry.

**radiochromatogram** a chromatogram of substances some or all of which contain a radioactive isotope.

**radiofrequency radiation** electromagnetic radiation encompassing wavelengths in the region 1 mm (300 GHz) to 30 km (10 kHz) (frequencies in parentheses). This range includes microwave radiation and lies above that of infrared radiation.

**radiography** the use of X-rays to examine the internal structures of a body. An X-ray film is placed behind the body, through which X-rays are passed. After exposure, there are areas of the film in which development has not occurred due to absorption of the X-rays by structures of the body, thus yielding a pattern of these structures. -radiographer *n.*; radiographic *adj.*; radiographically *adv.*

## radioimmunoassay

**radioimmunoassay** abbr.: RIA; a highly sensitive method of assay of nonradioactive material. A known amount of antibody (Ab) directed against the substance (antigen, Ag) to be assayed is saturated with a mixture of Ag and radioactive Ag ( $\text{Ag}^*$ ), so that total Ag ( $\text{Ag} + \text{Ag}^*$ ) is in excess. When non-radioactive Ag is added to Ab along with  $\text{Ag}^*$ , Ag and  $\text{Ag}^*$  compete for binding to Ab, so that less  $\text{Ag}^*$  will be found in the antibody-antigen complex as the ratio Ag: $\text{Ag}^*$  increases. If the antibody-antigen complex is then separated from free antigen, the total amount of antigen (the substance being assayed) can be calculated from the ratio Ab- $\text{Ag}^*$ : $\text{Ag}^*$  and the known titre of antibody. It is often convenient to attach the antigen to plates so that the amount of ligand bound to the plate is proportional to the amount of test antibody.

**radioimmunosorbent test** abbr.: RIST; a test used primarily for quantifying total serum immunoglobulin E (IgE) levels. Antibodies specific for 19B, covalently linked to an insoluble dextran, are incubated first with a known amount of radio-labelled IgE and then with the serum containing the unknown amount of IgE. From the decrease in the amount of radiolabel bound to the immobilized antibodies, due to competition by the unlabelled IgE in the serum, the total amount of IgE in the serum can be estimated.

**radioiodinate** to incorporate one or more atoms of radioiodine (usually iodine-125 or iodine-131) into a molecule.

**radioiodine** any radioactive isotope of iodine, notably iodine-125 (half-life 60 days) and iodine-131 (half-life 8 days).

**radioisotope** a radioactive isotope.

**radiolabel** 1 a radioactive label. 2 to incorporate a radiolabel.

**radioligand** any ligand containing a radioactive isotope; *see also* Scatchard plot.

**radiology** the study and use of radiation and radioactive substances, especially in the diagnosis and treatment of disease. It includes the use of diagnostic X-rays in radiography, the therapeutic use of ionizing radiation to treat disease (radiotherapy), and the experimental and diagnostic use of radioisotopes introduced into the body. -radiological *adj.*; radiologically *adv.*; radiologist *n.*

**radiolysis** the cleavage of chemical bonds by high-energy radiation. -radiolytic *adj.*; radiolyse *vb.*

**radiometer** 1 any instrument used to measure radiant energy.

2 Crookes radiometer a specific type of radiometer in which the different behaviour of a polished surface, which reflects energy, and a blackened surface, which absorbs it, is utilized to cause a rotor to turn at a rate related to the intensity of radiation. [After William Crookes (1832-1919), British chemist and physicist.] -radiometric *adj.*; radiometry *n.*

**radiomimetic** 1 describing any drug or other chemical substance, typically an alkylating agent, whose effects in living systems (e.g. carcinogenic, immunosuppressive, mutagenic) resemble those produced by ionizing radiation; more loosely, describing any such agent able to cause gene and chromosome mutations. 2 a radiomimetic (def. 1) substance or agent.

**radionuclide** a radioactive nuclide. -radionuclidic *adj.*

**radionuclidic impurity** any radionuclide, other than the nuclide that should be present, in a radioactive material.

**radionuclidic purity** or radiopurity (of a radioactive material) the proportion of the total activity (def. 2) that is in the form of the stated radionuclide.

**radiotherapy** *see* radiology.

**radiotracer** an alternative name for radioactive tracer.

**radixin** a protein of the erythrocyte band 4.1 family present in a variety of eukaryotic cells; it shares about 75% homology with human ezrin. It is an actin barbed-end capping protein, highly concentrated in the undercoat of the cell-to-cell adherens junction and the cleavage furrow in the interphase and mitotic phase. Example from human: database code RAD1\_HUMAN, 583 amino acids (68.49 kDa).

**radyl** (in chemical nomenclature) a term used to indicate any acyl, alkyl, or alkenyl group where this cannot be specified in detail.

Ramsay

**RAF** any of a family of genes encoding Raf proteins; there are at least three Raf proteins, Raf-I, A-Raf, and B-Raf. These are protooncogene cytoplasmic serine/threonine protein kinases (EC 2.7.1.-) of the Ras/Mos family; they show similarity to members of the protein kinase C family in both their conserved C-terminal catalytic and regulatory N-terminal domains. Example, Raf-1 (human), which has binding domains for ATP, phorbol ester, and diacyl glycerol: database code KRAF\_HUMAN, 648 amino acids (72.97 kDa). This protein is involved in transduction of mitogenic signals from the cell membrane to the nucleus. In the mouse, *raf1*, v-Raf having a truncated regulatory domain that causes constitutive activation of kinase activity. The c-Raf-I protein kinase, a 74 kDa protein, has been found in all mammalian cells tested. Raf-I is an important mediator of signals involving cell growth, transformation, and differentiation and is activated by a wide variety of extracellular stimuli. It has MAP kinase kinase kinase activity. In many cell types, Raf functions immediately downstream of the G-protein Ras (see HAS) in the activation pathway; although Ras does not directly activate Raf, it mediates translocation of Raf-I from cytoplasm to plasma membrane where it is activated. In some cells Raf may be phosphorylated and activated by members of the protein kinase C family. The first physiological substrate to be discovered for Raf kinase was a protein kinase (MEK) of yeast that is required for meiotic recombination and which on phosphorylation can activate MAP kinase.

**raffinose** or gossypose or melitrose or melitroside the trisaccharide O-a-D-galactopyranosyl-(1 $\rightarrow$ 6)-O- $\alpha$ -D-glucopyranosyl-(1 $\rightarrow$ 2)-p-D-fructofuranoside; it occurs in plants almost as commonly as sucrose, being present, e.g., in cereal grains, cotton seeds, and many legumes. It is the first member of a series in which galactosyl residues are attached to sucrose, others being the tetrasaccharide stachyose and the pentasaccharide verbascose; these are all synthesized from sucrose by transfer reactions in which an a-D-galactopyranoside of myo-inositol (i.e. galactinol) is the donor of the galactosyl residues.

**r.a.m.** abbr. for relative atomic mass.

**Ramachandran plot** or conformational map a plot that shows the ranges of bond angles that are permissible and the main types of structure of an L-polypeptide chain (e.g. a helix,  $\beta$ -pleated sheet). As the peptide bond, -C'O-NH-, is planar, a polypeptide chain has only two degrees of freedom per residue, the twist about the  $\text{C}\alpha$ -N bond axis,  $\phi$ , and that about the  $\text{C}\alpha$ -C' axis,  $\psi$ . Some foldings will be easily achieved; others will be impossible because they would bring neighbouring unbonded atoms or groups within van der Waals contact distances. The Ramachandran plot shows the permitted range within a plot of  $\phi$  against  $\psi$ . [After G. N. Ramachandran (1922- ).]

**Raman**, (Sir) Chandrasekhara Venkata (1888-1970), Indian physicist; Nobel Laureate in Physics (1930) 'for his work on the scattering of light and for the discovery of the effect named after him'.

**Raman scattering** the inelastic scattering of a photon by a molecule, producing in the scattered light weak radiation of frequencies not present in the incident light. The sample does not have an absorption band at the wavelength of the incident light (compare fluorescence) and the frequency differences between the weak Raman lines in the spectrum and the exciting line are characteristic of the scattering substance and independent of the frequency of the exciting line. [After C. V. Raman.]

**Raman spectrum** a plot of Raman scattering over a range of frequencies.

**Ramón y Cajal**, Santiago (1852-1934), Spanish anatomist and histologist; Nobel Laureate in Physiology or Medicine (1906) jointly with C. Golgi 'in recognition of their work on the structure of the nervous system'.

**Ramsay**, (Sir) William (1852-1916), British physical and inorganic chemist; Nobel Laureate in Chemistry (1904) 'in recog-

nition of his services in the discovery of the inert gaseous elements in air, and his determination of their place in the periodic system'.

**RAN** a gene encoding a small nuclear G-protein, first identified as a well-conserved gene distantly related to *H-RAS*. Its product, Ran, interacts with RCCt, and the complex is involved in regulating cell-cycle progression and messenger RNA transport. In the absence of RCCI, GDP-Ran predominates and this results in activation of M-phase-promoting factor and chromatin condensation. The presence of RCCI activates nucleotide exchange on Ran, increasing the amount of GTP-Ran and preventing premature chromatin condensation. Example from *Mus musculus*: database code RAN\_MOUSE, 216 amino acids (24.42 kDa). *See also* nuclear pore.

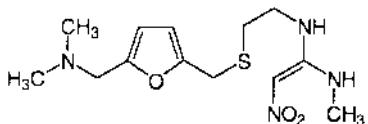

**random coil** the condition in solution of a linear polymer that exhibits little side group interaction, or resistance to rotation about the bonds in its chain. There are no preferred conformations. Quantitative expressions have been developed for the average radius of gyration. The term has formerly been incorrectly applied to various states of protein chains.

**random copolymer** a polymer of more than one species of monomer, in which the sequence of species within the polymer is not predetermined by controlled steps during synthesis, but depends only on random collisions between the reactant molecules. An example is the sequence of bases in RNA synthesized from nucleoside diphosphates by polynucleotide phosphorylase.

**random mechanism** or **random pathway** (for an enzymic reaction involving two substrates, A + B ⇌ C) a mechanism in which the enzyme, E, may first react with either substrate and the resulting enzyme-substrate complex then reacts with the second substrate, e.g. A + E ⇌ EA then EA + B ⇌ EAB, or, B + E ⇌ EB then EB + A ⇌ EAB, subsequently EAB ⇌ E + C. *Compare* ordered mechanism.

**random sample** a selection of part of a population made in such a way that no individual is favoured over any other individual. *See also* sample, statistical sample.

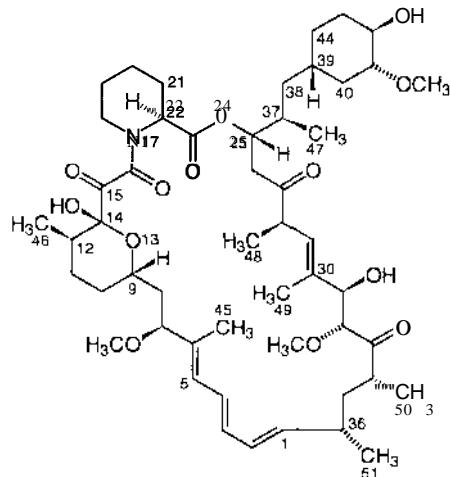

**ranitidine** a competitive antagonist at histamine *H*<sub>2</sub> receptors, being the major and pharmacologically more selective analogue of the imidazole derivative, cimetidine. It inhibits histamine- and pentagastrin-evoked gastric acid secretion and cardiac stimulation and also inhibits gastric secretion evoked by physiological stimuli, agonists at muscarinic cholinoreceptors, and gastrin. It is used in the treatment of gastric and duodenal ulcers. *One proprietary name:* Zantac (hydrochloride).

**RANTES** abbr. for regulated upon activation, normal T-cell expressed and secreted chemokine; *other names:* smaU inducible cytokine A5; a chemokine secreted by T cells and macrophages on stimulation by mitogens, that acts as a chemoattractant, and stimulates basophils and eosinophils. Example from human (precursor): database code SISD\_HUMAN, 91 amino acids (10.07 kDa); residues 1-23 are the signal, 24-91 RANTES.

**ranunculeic acid** another name for columbinic acid.

**rapamycin** an immunosuppressant (and antifungal agent) from *Streptomyces hygroscopicus*; it is used to reduce rejection of organ transplants. It is a lipid-soluble macrocyclic lactone, with the unusual feature of a cyclohexane ring with hydroxyl and methoxyl substituents. It competes with FK506 for a common binding site on FKBP. *See also* cyclosporin.

rapamycin

**RAPD peR** abbr. for random polymorphic DNA PCR; a variation of the polymerase chain reaction in which many short ( $\approx$ 10 nucleotide) primers are used. The products of the reaction from different sources can lead to recognition of polymorphisms and physical maps.

**rape** or **colza** a herbaceous plant, *Brassica napus*, of the mustard family, Cruciferae; it resembles a turnip, and the seeds yield valuable rapeseed oil.

**rapeseed oil** oil derived from the seed of rape; it is widely used as a lubricant and cooking fuel, and for the manufacture of animal foodstuffs, soap, and synthetic rubber. It contains erucic acid, which has cardiotoxic effects varying with species; rape varieties of low erucic acid content have recently been developed.

**rapid-reaction kinetics** the kinetic analysis of an enzyme reaction before the steady state is reached. The stopped-flow method is commonly used, in which two independent sources of substrate and enzyme are mixed immediately before flow through a spectrophotometer cell. An opposing syringe stops the flow immediately before activating the detection and recording system, such that reaction times of a few milliseconds can be achieved. Characteristically, reaction rates may be appreciably faster than during the steady state. In the quenched flow modification of the method, a further reagent is added to stop the reaction immediately before detection and recording. *See also* relaxation kinetics.

**Rapoport-Lübbing shunt** a unique feature of erythrocyte glycolysis in which the glycolytic intermediate 3-phosphoglycerol phosphate is converted by bisphosphoglycerate mutase to 2,3-bisphosphoglycerate, which is in turn converted to 3-phosphoglycerate and inorganic phosphate by bisphosphoglycerate phosphatase, both reactions being catalysed by a single enzyme molecule. The shunt bypasses the near equilibrium phosphoglycerate kinase reaction, one of the two ATP-generating reactions of glycolysis. Since 2,3-bisphosphoglycerate is an important intracellular modulator of hemoglobin function, regulation of the Rapoport-Lübbing shunt balances the energy needs and oxygen-transporting function of the red cell. [After Samuel Mitja Rapoport (1912- ) and J. Lübbing.]

**rare earth** (strictly) an oxide of a rare earth metal, or (more loosely), a rare earth metal itself.

**rare earth metal** or **rare earth element** scandium, yttrium, or a lanthanoid.

**RAS**

**RAS** an oncogene (*v-ras*) first discovered in the retroviruses Harvey and Kirsten rat sarcoma viruses; three closely related (85% homology) oncogenes are now known, *Ha-ras*, *Ki-ras*, and *N-ras*. Their cellular counterparts encode 21 kDa guanine nucleotide-binding proteins that play a pivotal role in regulating growth and differentiation in nearly every eukaryotic cell studied. There are two subfamilies, the Rho and Rac proteins (involved in relaying signals from the cell-surface receptors to the actin cytoskeleton) and the Rab family (involved in regulating the traffic of intracellular transport vesicles). Ras proteins undergo a number of modifications of the N and C termini that result in their localization to the plasma membrane. Ras binds both GTP and GDP with high affinity. It is considered active in the GTP-bound form and inactive in the GDP-bound form. The intrinsic rate of nucleotide exchange and GTPase activity is very slow. Ras·GDP predominates in resting cells, but when Ras is activated by occupied receptors, specific guanine nucleotide exchange factors (GEFs), e.g. Sos, enhance nucleotide exchange leading to Ras·GTP, GTP exceeding GDP in cytoplasm. Ras·GTP then activates downstream effector proteins such as Raf-1 (see *RAF*). Activated GTPase activating protein (GAP) causes the formation of inactive Ras·GDP. The retroviral oncogene, *v-ras*, encodes a protein that differs from the *c-ras* product as a result of a point mutation. If this affects amino acids 12, 13, 59, 61, or 63 the protein fails to hydrolyse its bound GTP and so persists abnormally in its active state, constitutively transmitting an intracellular signal for cell proliferation. Alternatively, some transforming mutations increase the rate at which Ras can exchange guanine nucleotides, e.g. when amino acids 116, 117, 119, or 146 are affected, again increasing the amount of Ras·GTP. Activated *ras* oncogenes have been found in up to 30% of all human tumours analysed, with the most common point mutations being at codons for amino acids 12 and 13. In some types of malignancy, the figure is nearly 100%. Two genes corresponding to *H-ras* occur in yeast; they encode G-proteins that inhibit adenylate cyclase. 3-D structure known (including GDP bound to guanine nucleotide-binding domain) for human protein H-Ras-I: database code NRL\_4Q21, 168 amino acids (19.07 kDa).

**RAST** abbr. for radioallergosorbent test.

**rate coefficient** see rate constant.

**rate constant** or **rate coefficient symbol:** *k*; a constant relating the concentration of a reactive species to the velocity of a reaction; thus for a first order reaction (see order of reaction) such as: EA → E + A, the rate of reaction, *v*, is proportional to the concentration of the reactant EA, so *v* = *k*[EA], where *k* is the first-order rate constant. For a second order reaction, e.g. E + A → EA, the rate is proportional to the product of the reactant concentrations, i.e. *v* = *k*[E][A], where *k* is the second-order rate constant.

**rate-determining step** see rate-limiting step.

**rate-limiting step** the slowest step in a reaction sequence; i.e. the step with the smallest rate constant.

**rate of consumption** see rate of reaction.

**rate of conversion symbol:**  $\xi$ ; for a specified chemical reaction, the rate of increase of the extent of reaction at any moment in time, regardless of the conditions under which the reaction is carried out:  $\dot{\xi} = d\xi/dt$ , where  $\xi$  is the extent of reaction and *t* is time. In the case of a reaction with one-to-one stoichiometry, such as a typical simple enzyme-catalysed reaction, the extent of reaction is equal to the amount of a reactant consumed or the amount of a product formed. Rate of conversion is an extensive quantity (see extensive property), its dimensions are (amount of substance) divided by time, and it is expressed in mol s<sup>-1</sup> (compare rate of reaction). It is therefore independent of the volume of the system. Where this volume remains constant, as during a typical enzyme-catalysed reaction, the rate of conversion is equal to the rate of reaction multiplied by the volume:  $\dot{\xi} = vV$ . The term was formerly known in physical chemistry as rate of reaction. See also catalytic activity.

rate of formation see rate of reaction.

**rate of reaction** or **velocity of reaction** or (sometimes) reaction rate 1 symbol: *v*; for a specified enzyme-catalysed reaction of a typical kind (i.e. one involving a single substrate, S, a single product, P, one-to-one stoichiometry between them, and constant-volume conditions), the rate of consumption of substrate or the rate of formation of product at any moment in time is given by:

$$v = -d[S]/dt = d[P]/dt,$$

where [S] and [P] are respectively the concentrations of substrate and product, and *t* is time. A similar set of relationships applies where there are several reactants in one-to-one stoichiometry, but if the overall stoichiometry is not one-to-one—a situation rarely arising in enzyme kinetics—the relationships are more complicated. Where intermediates are formed in amounts comparable to those of the reactants, there is time-dependent stoichiometry and a rate of reaction for the complete reaction cannot be specified. Rate of reaction is an intensive quantity (see intensive property), its dimensions are (amount-of-substance concentration) divided by time, and it is expressed in mol L<sup>-1</sup> s<sup>-1</sup> (compare rate of conversion). See also initial velocity, limiting rate. 2 (formerly, in physical chemistry) the extensive quantity now termed rate of conversion.

**rate theory of agonist action** a theory of agonist action stating that the response to an agonist is proportional to the number of receptor-agonist associations per unit time, i.e. to the rate of receptor occupation, the binding of agonist to receptor being reversible. The response is therefore maximal at time zero and falls exponentially to an equilibrium value.

**Rayleigh** see Strutt.

**Rayleigh ratio symbol:** *R*; the ratio of the intensity of light scattered by particles (molecules) in solution at an angle  $\theta$  from the incident beam, *I*, multiplied by the square of the distance, *r*, from the particle to the detector, divided by the intensity of the incident light, *I<sub>0</sub>*, i.e.  $R = ler^2/I_0$ . The reduced Rayleigh ratio,  $R_\theta = ler^2/I_0 + \cos^2\theta$ . Many literature references do not distinguish between these two. See also Rayleigh scattering. [After J. W. Strutt, Lord Rayleigh.]

**Rayleigh scattering** the elastic scattering of photons of light by molecules or atoms of the substance through which the light is passing. When light passes through a liquid or gas, atoms or molecules are polarized by the electric vector of the light, thus inducing a rapidly fluctuating dipole in the atoms or molecules in the light path. The fluctuating dipole leads to the emission of electromagnetic waves in various directions of the same frequency as the incident radiation, and this emission is seen as scattered light. See also Rayleigh ratio. [After J. W. Strutt, Lord Rayleigh.]

**Rb symbol** for rubidium.

**RB** a human tumour suppressor gene that encodes a nuclear phosphoprotein, retinoblastoma protein. Inactivation or loss of *RB* on both copies of the chromosome (13q14) leads to retinoblastoma.

**R band** see Giemsa's stain.

**RBC** or *rbc* or *r.b.c.* abbr. for red blood cell. See erythrocyte.

**Rbe** abbr. for relative biological effectiveness (i.e. quality factor).

**RBS** abbr. for Réné Borghgraef solution; the proprietary name for any of a range of general-purpose surfactants and decontaminating agents, especially for laboratory use, that have combined detergent and chelating properties. They are identified with a number or other designation, e.g. RBS 25, RBS 35, RBS solid.

**RCCI** a chromatin-bound guanine nucleotide release (or exchanging) factor. Its function is required for the normal coupling of the completion of DNA synthesis and the initiation of mitosis, and in its absence mitosis initiates before DNA replication is complete. RCCI therefore appears to be involved in the regulation of this process. It is also necessary for RNA export from the nucleus. It binds to and acts on the nuclear G-protein, Ran. Example from the yeast *Candida albicans*:

database code RCC\_CANAL, 464 amino acids (51.27 kDa). [From regulator of chromosome condensation.]

**RCF** abbr. for relative centrifugal force.

**R chromophore** a chromophore that gives rise to low-intensity absorption bands at long wavelengths. Compare Kchromophore. [From German *Radikal*.]

**RCP** abbr. for radiochemical purity.

**RCS** abbr. for rabbit aorta-contracting substance.

**rd symbol** for rad (def. 2) (alternative to rad).

**Rd** abbr. for rubredoxin.

**rDNA** 1 abbr. for ribosomal DNA. 2 (sometimes) abbr. for recombinant DNA; use not recommended because of possible confusion with ribosomal DNA.

**Re-prefix** (in chemical nomenclature) denoting *rectus* (i.e. right, or clockwise) configuration of a face of a trigonal atom. See *ReS*; convention.

**Re symbol** for rhenium.

**Re symbol** for Reynolds number.

**RE** abbr. for (eukaryotic) response element.

**reactancy of enzymes** the number of reactants involved in an enzyme-catalysed reaction in a given direction. The numbers of kinetically important substrates or products in an enzyme mechanism are designated by Uni (1), Bi (2), Ter (3), or Quad (4). Thus, e.g., Uni Uni indicates one substrate and one product, and Ter Bi indicates three substrates and two products.

**reactant** any material participating in a chemical reaction in a given direction.

**reaction** (in chemistry) any process in which molecules interact with one another, leading to chemical or physical change.

**reaction centre** see photosystem. Compare photosynthetic reaction centre.

**reaction intermediate** a transient chemical species, with a lifetime appreciably longer than a molecular vibration time, formed directly or indirectly from the reactants of a chemical (often enzymic) reaction, and that further reacts (directly or indirectly) to give the reaction products.

**reaction rate** (sometimes) an alternative term for rate of reaction.

**reaction time** an alternative name for latent period (def. 1).

**reactivate** to restore activity to any enzymic or cellular system.

**reactive** describing any molecular entity or centre that is capable of reacting readily. Thus, a reactive centre is the point in the molecule at which electron configurations favour a reaction.

**reactive oxygen** a highly active oxygen species, such as superoxide ion.

**reactivity** the degree to which a molecule or centre is reactive.

**reading** (in molecular biology) the process of one-way linear decoding of a nucleotide sequence during, e.g., transcription or translation.

**reading frame** any sequence of bases in DNA that codes for the synthesis of either a protein or a component polypeptide. The point of initiation of reading determines the frame, i.e. the way in which the bases will be grouped in triplets as required by the genetic code. For example, the sequence

-ATGGTCA-

could be grouped

-A,TGG,TCA-

or

-AT,GGT,CA-

or

-ATG,GTC,A-

depending on the point at which the reading frame begins. See also open reading frame.

**readthrough** the continuation of DNA transcription beyond a normal termination sequence, due to a failure of RNA polymerase to recognize the termination signal. Readthrough may also occur in translation, where a mutation has caused a ter-

mination codon to be converted to a codon for an amino acid (a sense codon); this is the underlying etiology of several hemoglobinopathies. See also readthrough protein.

**readthrough protein** a product formed by translation of a messenger RNA when one of its termination codons is misread or is recognized by a suppressor tRNA. Polypeptide-chain synthesis then continues until the next termination codon is reached, resulting in the production of a variant protein with a C-terminal extension.

**reagent** 1 any chemical substance that reacts or participates in or is necessary for a reaction. 2 a substance used for the detection or determination of another substance by chemical or microscopical means, usually in solution; e.g. the Folin-Ciocalteu reagent.

**reagent grade** a level of purity of a chemical; chemicals of this quality conform to the specifications established by the Committee on Analytical Reagents of the American Chemical Society and may often be sufficiently pure to use as primary standards in an analytical laboratory, with information concerning the actual percentage of impurities or at least the maximum limit of impurities being given on the label.

**reagin** 1 a term originally used to describe a heat-labile antibody-like substance in the serum of many people suffering from atopic allergies and that has now been identified as immunoglobulin E (IgE). The immediate hypersensitivity (type I) generated by the binding of IgE to its specific antigen on the surface of mast cells involves the release of cell mediators via the reaginic or anaphylactic mechanism. 2 a special kind of antibody response produced by syphilitics that has specificity for cardiolipin antigens.

**real-time** (in computing) indicating that a computer monitors a process continuously as it occurs, in distinction to the analysis of recorded data.

**rearrangase** or S-S rearrangase an alternative name for protein disulfide isomerase.

**rearrangement reaction** a reaction in which molecular bonds are rearranged without the loss of any atom from the molecule, e.g. as in the conversion of glucose 6-phosphate to fructose 6-phosphate.

**rseA** a gene in *Escherichia coli* encoding a protein, RecA, involved in genetic recombination and in the SOS response for DNA repair (see SOS repair). The protein has two activities: (1) a DNA-dependent ATPase in the presence of single-stranded DNA that catalyses the ATP-dependent uptake of single-stranded DNA to form the heteroduplex required in recombination. (2) In the presence of DNA fragments it becomes a protease (RecA\*; EC 3.4.99.37) that cleaves a specific Ala-I-Gly bond in certain repressor molecules, including its own repressor (see *texA*). This allows all the SOS genes to be activated. Example from *E. coli* and *Shigella flexneri* (identical sequences): database code RECA\_ECOLI, 352 amino acids (37.80 kDa); 3-D structure known; eight motifs. See also exodeoxyribonuclease V, recombinational repair, recombinase.

**recalcitrance** or persistence the ability of a substance to remain in a particular environment in an unchanged form.

**recBC** a gene in *Escherichia coli* for exodeoxyribonuclease V, an ATP-dependent nuclease specific for double-stranded DNA; it mediates genetic recombination.

**recDNA** (sometimes) abbr. for recombinant DNA.

**receptor** any cellular macromolecule that undergoes combination with a hormone, neurotransmitter, drug, or intracellular messenger to initiate a change in cell function. Receptors are concerned directly and specifically in chemical signalling between and within cells. Cell-surface receptors, e.g. the acetylcholine receptor and the insulin receptor, are located in the plasma membrane, with their ligand-binding site exposed to the external medium. Intracellular receptors, e.g. steroid-hormone receptors, bind ligands that enter the cell across the plasma membrane.

**receptor assay** 1 the determination of receptor numbers and the dissociation constant of receptor-ligand binding. The

**receptor cross-talk**

binding at various concentrations of ligand is measured, often by use of a radioactive ligand, and is analysed by means of a **Scatchard plot**. 2 the determination of the concentration of a ligand by utilizing a purified receptor in a manner similar to that used in **radioimmunoassay**; in this case the receptor, rather than an antibody, performs the role of specific binding agent. **receptor cross-talk** interaction between two receptors such that one receptor, when activated, modulates the action of the other. This type of interaction often involves the production by the first receptor of a **second messenger**, which then modulates the action of the second receptor.

**receptor-destroying enzyme** an enzyme that brings about chemical change in a (usually membrane-bound) receptor, leading to inactivation of the receptor. Knowledge of the specificity of the enzyme provides information about the nature of the groups or linkages exposed to enzyme attack, and thus to receptor structure or orientation in the membrane. Examples are **sialidase** and **trypsin**.

**receptor-effector complex** the complex that results when an occupied receptor binds to another protein (the **effector**), the activation of which by the occupied receptor leads to signal transduction.

**receptor-mediated** describing a response that requires the intermediary action of a receptor, especially one located in a membrane.

**receptor-mediated endocytosis** a form of **endocytosis** involving the internalization (i.e. passage into the cell interior) of stretches of membrane into which receptors have clustered after binding of ligand. The cytoplasmic surfaces of these stretches of membrane are coated with **clathrin** and are termed **coated pits**. See also **endosome**.

**receptor transformation** see **transformation** (def. 3).

**recessive** describing an **allele** that lacks effect when accompanied in the same diploid by a **dominant** form of the same gene. Most (not all) defective mutant genes are recessive to their normal functional counterparts. -recessivity *n.*

**recipient bacterium** see **bacterial conjugation**.

**reciprocal** 1 expressed in the reverse direction, in response to an initial application of any force or stimulus. 2 (*in mathematics*) the inverse value, obtained when the values of numerator and denominator are reversed; the reciprocal of *x* is obtained by evaluating  $1/x$ .

**reciprocal plot** a plot in which the units of both the ordinate and the abscissa are reciprocals of the values that have been determined. Compare **Uneweaver-Burk plot**.

**recircularization or recircularisation** the restoration of circularity to a plasmid vector following the insertion of recombinant DNA. The plasmid used for gene cloning is a small circular molecule. This is cut with a **restriction endonuclease** to create linear DNA molecules. The foreign DNA fragment with the same cohesive ends is then annealed to the cut plasmid to form a recombinant DNA circle. The DNA molecule containing the foreign DNA insert is then covalently sealed with **DNA ligase**. Recircularization also occurs during the replication of some DNA phages by a **rolling circle** replication mechanism.

**recognition** any specific binding interaction between molecules. Such interaction between two molecules is based on the existence of **recognition sites**, one (or more) on each of the interacting molecules, that are tailored to fit in such a way that highly specific binding occurs; i.e. the two molecules uniquely 'recognize' each other. See also **chiral recognition**, **molecular recognition**.

**recognition sequence** the part of the sequence of a macromolecule that is able to recognize and bind to a particular sequence in another macromolecule.

**recognition site** 1 (*in proteins*) a site for **recognition** of another protein, involving a specific sequence of amino acids; the latter may be in a single chain (e.g. target sites for protein phosphorylation), or may involve amino acids in separate chains brought into juxtaposition by quaternary structure. 2 (*in nucleic acids*) a site for recognition of a protein, involv-

**recombinational repair**

ing a specific sequences of bases; see **restriction endonuclease**. 3 (*in pharmacology*) a region of a receptor macromolecule to which an endogenous agonist binds.

**recombinant clone** a population of bacteria or other host derived from a single cell into which a vector containing **recombinant DNA** has been introduced.

**recombinant DNA** a fragment of deoxyribonucleic acid (DNA) that has been inserted into a cloning vector, thereby leading to its use in the isolation of a clone of cells characterized by the presence of the fragment. The term is derived from the concept that insertion into the vector is a form of **genetic recombination**. [Note: The abbreviation rDNA has sometimes been applied to recombinant DNA, but this use is discouraged (rDNA having been pre-empted for ribosomal DNA); while alternatives such as recDNA or rtDNA have been suggested, IUBMB considers a standard abbreviation unnecessary.] See also **recombinant DNA technology**.

**recombinant DNA technology** an area of biotechnology concerned with the manipulation of **recombinant DNA**. It has many important applications, including (1) DNA sequencing, which may lead to the ability to predict the primary structure of a protein where this is the product of a cloned gene, (2) the synthesis of recombinant protein by a suitable expression system, and (3) the production of DNA **probes** (def. 3) for use in hybridization techniques. The technology has led, e.g., to the production of human insulin for the treatment of diabetes, human growth hormone for administration to children with growth defects, and a vaccine for hepatitis B. DNA probes are essential for the detection of aberrant genes which are the cause of numerous diseases and the technique has the potential for gene therapy. See also **genetic engineering**.

**recombinant protein** a protein coded for by a gene - **recombinant DNA** - that has been cloned in a system that supports expression of the gene and translation of messenger RNA (see **expression system**). Modification of the gene by recombinant DNA technology can lead to expression of a mutant protein. Proteins coexpressed in bacteria will not possess post-translational modification, e.g. phosphorylation or glycosylation. Eukaryotic expression systems are needed for this; see, e.g., **baculovirus**.

**recombinase** 1 an enzyme that recognizes specific sites involved in the joining of V-region gene segments in L- and H-chain gene segment pools in the generation of antibody. 2 RecA protein (see **recA**) is also a recombinase, the activity of which is increased in *Escherichia coli* following damage to DNA. RecA binds to a region of single-stranded DNA and catalyses the formation of duplex DNA; hydrolysis of ATP is involved. A recombinase recognizes and binds to each of two recombinant sites on different DNA molecules or within the same DNA. One DNA strand in each site is cleaved at a specific point within the site, and the recombinase becomes covalently linked to the DNA at the cleavage site through a phosphotyrosine (sometimes a phosphoserine) bond. The transient protein-DNA linkage preserves the phosphodiester bond lost in cleaving the DNA; cofactors such as ATP are unnecessary in subsequent steps. The cleaved DNA strands are rejoined to new partners, with new phosphodiester bonds created at the expense of the protein-DNA linkage. The result of the initial breakage and rejoining process is the **Holliday junction**. To complete the reaction, the process must be repeated at a second point within each of the two recombination sites. In summary the recombinase can be viewed as a site-specific endonuclease and ligase in one package.

**recombination** see **genetic recombination**, **recombinant DNA**, **immunoglobulin synthesis**.

**recombinational heteroduplex** see **heteroduplex**.

**recombinational repair** a mechanism to restore the integrity of DNA when replication of DNA stops at a **thymine dimer** but resumes after the dimer is passed, creating a gap. The undamaged parental strand recombinates into the gap, a process promoted by RecA protein (see **recA**). The new gap in the parental

strand is filled by the action of DNA polymerase and DNA ligase. The thymine dimer itself is not repaired in this process but time is allowed for the excision system to repair this damage later.

**recoverin** an EF-hand  $\text{Ca}^{2+}$ -binding protein, apparent molecular mass 26 kDa; *also known as* cancer-associated retinopathy protein. It selectively localizes to the retina and pineal gland and is implicated in the activation of retinal rod guanylate cyclase by rhodopsin, possibly being involved in the blocking of the phosphorylation of rhodopsin, by forming an inhibitory complex with rhodopsin kinase. It has been identified as an autoantigen in cancer-associated retinopathy, a putative autoimmune process. Example from human: database code RECO\_HUMAN, 199 amino acids (22.97 kDa).

**recovery** the portion of material or activity that remains after any extraction or purification, usually expressed as a percentage of the amount that was present as starting material.

**recruitment** the action by any cell, cell constituent, or molecule that brings about the cooperation of any other component in performance of any function.

**recrystallize** or **recrystallise** to dissolve a crystalline substance and subsequently crystallize it from the solution, usually to increase the purity of the substance. -recrystallization or recrystallisation *n.*

**rectangular hyperbola** a hyperbola whose asymptotes are at right angles. It is sometimes said that, for enzymes that follow so-called Michaelis kinetics, the plot of initial rate against substrate concentration has the shape of the curve of a rectangular hyperbola. It is true that the Michaelis-Menten equation does yield a curve that is part of a rectangular hyperbola, but the axes of the hyperbola must be rotated through  $45^\circ$ , and displaced, if they are to coincide with the axes of the Michaelis-Menten plot.

**rectification** 1 (*in physics*) the process of obtaining a direct current from an alternating electrical supply. 2 (*in physiology*) the regulation of membrane conductance by the voltage across the membrane; strong rectification implies that ionic channels carrying current are open at some membrane potentials and shut at others. Conductance is low at very negative membrane potentials, but increases as the potential becomes less negative. 3 (*in chemistry*) the process of purifying a liquid by distillation.

**rectus** Latin right; used to describe the right, or clockwise, configuration of one of the two faces of a compound containing a trigonal carbon atom. It is designated by the prefix *Re-*. Compare *sinister*. See also *Re/Si* convention.

**recycle** to pass again through a system one or more times after return to a starting condition or state.

**red drop** a phenomenon in photosynthesis, in which the quantum yield is relatively constant in light of wavelengths between 500 and 600 nm, but drops dramatically at longer wavelengths.

**redistil** or (*US*) **redistill** to distil again that which has already been distilled, usually as an aid to purification of liquids.

**red marrow** see bone marrow.

**red muscle** dark, skeletal, voluntary muscle that is relatively rich in myoglobin and cytochromes, and derives energy for contraction from a high oxidative capacity, in contrast to white muscle, which has a high glycolytic capacity. The distinction between muscle types should more strictly be based on muscle-fibre types. Type I fibres have a high oxidative capacity based on a high activity of tricarboxylic-acid cycle and respiratory chain enzymes. Type IIA fibres have high oxidative and high glycolytic capacity. Type IIB fibres have low oxidative and high glycolytic capacity. The proportions of these fibres vary in different muscle types; accordingly the muscle may have the ability to engage in very rapid but quickly exhausted 'fast twitch' contractions characteristic of white muscle, or less powerful but more sustained contractions typical of red muscle.

**reodox** abbr. for reduction-oxidation; see oxidation-reduction.

**redox balance** the ratio of the number of reductions to the number of oxidations in a given metabolic pathway. Compare redox state.

**redox couple** the oxidized (electron acceptor) and the reduced (electron donor) forms of the species of a given redox reaction; e.g.  $\text{NAD}^+$  and  $(\text{NADH} + \text{H}^+)$ . The potential of any redox couple in solution can be measured against a reference electrode, and a table of relative potentials constructed. See redox potential.

**redox hypothesis** a now discounted model for the Pasteur effect in glycolysing muscle extracts. Addition of redox indicators that changed the redox state in the direction of oxidation decreased the rate of lactate formation; it was therefore suggested that the effect of oxygen might be connected with a change of the redox state in the same direction.

**redox indicator** see indicator (def. 3).

**redox potential** or **oxidation-reduction potential symbol:**  $E_\text{o}$ ; for a particular redox couple at a given pH and temperature, the potential of an electrode (usually bright platinum) immersed in a solution containing 1 M oxidant and 1 M reductant, relative to a standard hydrogen electrode. The more 'reducing' the couple, the more negative is  $E_\text{o}$ ; the convention in biochemistry is that the more 'oxidizing', the more positive is  $E_\text{o}$ . Some standard potentials, measured against the hydrogen electrode, are:  $\text{NAD}^+/\text{NADH} + \text{H}^+$ ,  $-0.32$  V; fumarate/succinate,  $+0.032$  V; cytochrome b( $\text{Fe}^{3+}$ )/cytochrome b( $\text{Fe}^{2+}$ ),  $+0.22$  V; cytochrome c( $\text{Fe}^{3+}$ )/cytochrome c( $\text{Fe}^{2+}$ ),  $+0.25$  V;  $\text{O}_2 + 2\text{H}^+/\text{H}_2$   $+0.82$  V.

**redox reaction** a chemical reaction in which the oxidation of one reactant is coupled to the reduction of a second reactant, electrons being transferred from the reactant being oxidized to that being reduced.

**redox state** the ratio of the concentration of the oxidized member of a redox couple to the concentration of the reduced member; e.g.  $[\text{NAD}^+]/[\text{NADH}]$  or  $[\text{Fe}^{3+}]/[\text{Fe}^{2+}]$ . The term should only be applied to a particular redox system and not to a heterogeneous system.

**red shift** any shift of the peaks of a spectrum to longer wavelengths (i.e. towards the red end of the spectrum), including a shift from the red to infrared. Compare blue shift.

**red tide** a bloom of the dinoflagellate *Ptychodiscus brevis* (*Gymnodinium breve*), an organism that produces brevetoxins and causes epidemics of food poisoning.

**reduce** to cause or undergo reduction.

**reduced Rayleigh ratio** see Rayleigh ratio.

**reducing agent** any substance acting as a reductant. Compare oxidizing agent.

**reducing end** the end of an oligo- or polysaccharide molecule that carries a potential hemiacetal or hemiketal (reducing) group.

**reducing sugar** any sugar that will reduce heated alkaline solutions of cupric salts, such as Fehling's or Benedict's solutions, due to the presence of a hemiacetal or hemiketal group.

**reductant** the chemical species that donates an electron in an oxidation-reduction reaction; i.e. the species that undergoes oxidation in such a reaction. Compare oxidant.

**reductase** a donor:acceptor oxidoreductase enzyme (EC class I) when named after the more oxidized alternative substrate and when  $\text{O}_2$  is not a substrate. See oxidoreductase.

**reduction** the chemical process by which oxygen is withdrawn from, hydrogen is added to, or (more generally) an electron is added to (with or without addition of a proton) a molecular entity. Compare oxidation. -reductive *adj.*; reduce *vb.*

**reduction division** the first division of meiosis.

**reduction potential** the electrode potential that measures the tendency of one half of a redox reaction to proceed so as to gain electrons. See oxidation potential, redox potential.

**reductive alkylation** the reaction of amino groups with an alkyl carbonyl group, followed by reduction of the resulting Schiff base with a reducing agent such as sodium borohydride. See reductive amination.

## reductive amination

reductive amination the process whereby ammonia or a primary or secondary amine reacts with ketones and aldehydes in the presence of reducing agents such as H<sub>2</sub> and a metal catalyst, or more conveniently, NaBH<sub>4</sub> or its derivative NaBH<sub>3</sub>CN, to produce primary, secondary, or tertiary amines. In a formal sense, the amine is alkylated in this reaction while the carbonyl group is reduced, hence the term reductive amination, or alternatively reductive alkylation. Amino acids have been made from oxo acids by this process. A variation of reductive amination, termed the Eschweiler-Clarke reaction, involves the methylation of an amine to the tertiary amine stage using formic acid as the reducing agent and formaldehyde as the methylating reagent.

reductive carboxylic-acid cycle or reductive tricarboxylic-acid cycle a metabolic cycle used by members of the Chlorobiaceae for CO<sub>2</sub> fixation. The usual operation of the tricarboxylic-acid cycle is reversed, with three enzyme replacements, and other supplementary reactions are used. Initially one CO<sub>2</sub> reacts with succinyl-CoA to form oxoglutarate; oxoglutarate synthase (EC 1.2.7.3) replaces the usual oxoglutarate dehydrogenase complex. A second CO<sub>2</sub> converts oxoglutarate to isocitrate with use of isocitrate dehydrogenase, and isocitrate proceeds to citrate. Citrate is then cleaved by ATP citrate (*pro-S*) lyase to acetyl-CoA and oxaloacetate; the latter recycles to succinyl-CoA with fumarate reductase (NADH) replacing succinate dehydrogenase. These operations reverse the usual tricarboxylic-acid cycle and convert two CO<sub>2</sub> to acetyl-CoA. A net gain of oxaloacetate is possible by conversion of acetyl CoA and one CO<sub>2</sub> to pyruvate (pyruvate synthase), pyruvate to phosphoenolpyruvate (phosphoenolpyruvate synthase) and phosphoenolpyruvate and one CO<sub>2</sub> to oxaloacetate (phosphoenolpyruvate carboxylase). The overall result is that four CO<sub>2</sub> yield a net gain of the four-carbon oxaloacetate.

reductive methylation a specific form of reductive alkylation, in which the alkyl group is methyl. Formaldehyde is often used as a reagent in this case.

reductive pentose-phosphate cycle or Calvin cycle *other names:* carbon reduction cycle; C<sub>3</sub> cycle/pathway; more appropriately, Calvin-Bassham cycle; the cyclic set of reactions, occurring in chloroplasts in the majority of higher plants (C<sub>3</sub> plants), that results in the fixation of CO<sub>2</sub> as glucose using the ATP and the NADPH formed in the light reactions of photosynthesis. Briefly, CO<sub>2</sub> reacts with ribulose 1,5-biphosphate under the action of ribulose-bisphosphate carboxylase (Rubisco), EC 4.1.1.39, to form two molecules of 3-phosphoglycerate; these are phosphorylated (by ATP) to 1,3-bisphosphoglycerate, which in turn is reduced (by NADPH) to glyceraldehyde 3-phosphate. This is then converted by aldolase, transketolase, and other enzymes to fructose 6-phosphate and ribulose 5-phosphate; the latter being phosphorylated (ATP) to ribulose 1,5-biphosphate, completing the cycle. See also Hatch-Slack pathway.

reductone any reducing substance with a chemical structure containing the stabilized enediol -C(OH)=C(OH)-. Reductones are generated when monosaccharides are heated for prolonged periods with strong alkali, whereby the enols originally produced are broken down to strongly reducing fragments. Another notable example is ascorbic acid, and in some contexts reductones are described as 'apparent ascorbate', i.e. the reductive acids that are present in certain processed foods and react similarly to ascorbate, interfering with its determination. Re-face (of an atom or molecule) see Rs/Siconvention.

reference something that acts as a standard in relation to quality, quantity, or type against which other values or characteristics can be compared; e.g. reference spectrum.

reference electrode any electrode, selected by convention, against which the electronegativity of compounds is measured. The standard biochemical reference is the hydrogen electrode, normally a platinum electrode in hydrochloric acid through which hydrogen gas is passed. A cell is constructed such that another electrode is immersed in a test solution and the poten-

## regeneration

tial difference between these two half-cells is measured. For convenience, however, the reference electrode is often a calomel electrode, and after measurements have been made against this, the electronegativity against the hydrogen electrode can be calculated from the known difference between this and the hydrogen electrode.

reflect to change the path of electromagnetic radiation, when it meets a surface, such that it returns partially or completely in a direction on the same side of the surface as the source.

reflectometer *see* densitometer (def. I).

reflex (*in physiology*) an automatic or involuntary response of the nervous system to a stimulus. A reflex may be a monosynaptic spinal reflex (e.g. a simple motor response to a sensory stimulus), involving transmission through the spinal cord only, or polysynaptic and involving synaptic transmission in the brain. A conditioned reflex is one that is learned through repeated association of a stimulus with either rewarding (e.g. food) or aversive (e.g. punishment) events.

refolding (for proteins) the restoration of three-dimensional structure in a manner that may not achieve a full return to the native state following denaturation.

refraction the change in direction undergone by a wave of electromagnetic radiation on passing through a boundary between two media in which its velocity differs. Snell's law states that  $n \sin\{\theta_1\} = n_2 \sin\{\theta_2\}$ , where  $n_1$  and  $n_2$  are the refractive indices of the two media, and  $\theta_1$  and  $\theta_2$  are the angles between the radiation and the normal to the boundary in the corresponding media. [After Willebrord Snell (1591-1696), Dutch astronomer and mathematician.]

refractive index *abbr.:* RI; *symbol:*  $n$ ; for a given medium, a measure of the degree of refraction induced by the medium when light or other electromagnetic radiation passes through it. The refractive index of a medium is the ratio of the speed of light in a vacuum,  $C_0$ , to the speed of light in the medium,  $c$ ; i.e.  $n = c_0/c$ . For many practical purposes the speed of light in air may be used instead of that in a vacuum.

refractivity a measure of the extent to which a medium will cause the deviation of a ray of light or other electromagnetic radiation entering its surface. If the refractive index of a medium is  $n$ , its refractivity is  $(n - 1)$ . The specific refractivity is given by  $(n - 1)/p$ , where  $p$  is the density of the medium. The molecular refractivity is the specific refractivity multiplied by the relative molecular mass.

refractometer an instrument for measuring refractive index.

refractory 1 (of a clinical condition) resistant to treatment. 2 (of a cell or tissue) resistant to stimulation, as by a drug, hormone, or nerve impulse, especially during a period following previous stimulation. See also tachyphylaxis. 3 (of a substance or material) resistant to heat, corrosion, mechanical deformation, or other aggressive agents causing alteration. 4 a substance or material having such resistance.

Refsum's disease a rare autosomal recessive inherited disease with neurological symptoms, including retinitis pigmentosa, peripheral neuropathy, cerebellar ataxia, and nerve deafness. It is caused by a defect in alpha oxidation of fatty acids, which is important for the oxidation of phytanic acid. The defect results in the accumulation of this acid in tissues and serum of patients. The symptoms are reduced by restriction of dietary dairy products and meat from ruminants, which contain phytanic acid.

regeneration 1 (*in chemistry*) the process of restoring to a state of preparedness for use, as in the case of an ion-exchange resin washed with acid or alkali to restore it to the H<sup>+</sup> or OH<sup>-</sup> form. 2 (*in biology*) the growth of new tissues or organs to replace ones lost or damaged, e.g. through injury or surgery. In some tissues, such as liver, epithelial tissue, or pancreas, regeneration occurs by simple duplication of cells, with the regeneration time varying from one week to a year. In other systems, such as epidermis, renewal is from specialized stem cells. Regenerating liver can be used as a model in which systems involved in proliferation are more highly activated than

## regeneration time

in normal liver. It is a unique property of liver that it is possible to remove two thirds of the organ yet it regenerates to form an organ of similar total weight to the original, albeit with somewhat different organization of the lobes. Many plants can regenerate a complete plant from a shoot segment or a single leaf or from tissue culture cells.

**regeneration time** the time taken for a tissue or organ to regain its former size or weight following damage or removal. For example, if two-thirds of the liver of a rat is removed surgically the liver regains its former weight in about two weeks. The proliferation of cells can be measured by the use of [<sup>3</sup>H]thymidine to label the cells synthesizing DNA.

*regio+ comb. form* denoting, or relating to, an area or site.

**regioselective** pertaining to a chemical change that occurs with greater frequency at one site than at a number of other possible sites of similar type, usually involving a structural or positional isomer.

**regiospecific** describing a chemical reaction that occurs specifically in only one of two possible ways, but not including stereospecificity (*see* stereospecific).

**registration peptide** one of the postulated extensions of the *a* chains of tropocollagen, when synthesis has just been completed; two *a1* extensions and one *a2* extension interact to form a stable assembly with the correct chains brought together into register.

**regression coefficient** *see* regression line.

**regression line** a line fitted to a series of two variable quantities, *x* and *y*, so as to minimize the sum of the squares of the distances parallel to the *y* axis of the observations from the line. The regression line of *y* on *x* has the equation (regression equation):  $y = a + bx$  where  $a = \sum y - b\sum x/n$  and  $b$ , the regression coefficient, is the slope of the line and is given by:

$$b = (\sum xy - \sum x \sum y) / (\sum x^2 - (\sum x)^2)$$

where *n* is the number of pairs of observations. In an analogous manner a regression equation, line, and coefficient may be obtained for *x* on *y*.

**regucalcin** a hepatic  $\text{Ca}^{2+}$ -binding protein, and also a GTP-binding protein, that modulates the hormonal regulation of plasma membrane  $\text{Ca}^{2+}/\text{Mg}^{2+}$ -ATPase.

**regulation (in metabolism)** control of the rate of a metabolic system, especially in intact organs and cells as a result of interaction from components of related systems. *-regulatory adj.*

**regulator gene** or **regulatory gene** any gene that does not contribute structural information to the proteins whose synthesis it controls, but that determines the production of a specific cytoplasmic substance, a repressor, that inhibits information transfer from a structural gene (or genes) to protein. It may control the synthesis of several different proteins, which are determined by a coordinated group of structural genes (*see* operon). Although, when it was put forward, the concept of the regulatory gene was helpful, it is now realized that the genome codes for many different proteins that control the transcription of the structural genes (*see*, e.g., attenuators, transcription factors), and that can be classed as gene-activator proteins; these will possess two domains, one to recognize a specific regulatory DNA sequence, the other to contact the transcription machinery.

**regulator-site hypothesis** a hypothesis to explain the control of insulin release from pancreatic islet B cells by glucose. It postulates that the glucoreceptor is an enzyme that is activated (or inhibited) by glucose and catalyses the production from a precursor of an activator, which controls the release process. *Compare* substrate-site hypothesis.

**regulatory enzyme** an enzyme that regulates the rate of a metabolic pathway; under regulating conditions, it is the enzyme of lowest activity in the pathway. Commonly, the rate is altered either by variation in the amount of regulatory enzyme (as a result of increased or decreased synthesis or degradation), or by variation in its activity by covalent modification (often by phosphorylation or dephosphorylation by kinases or

## relative centrifugal force

phosphatases) or by allosteric modifiers. Classic examples are phosphofructokinase and glycogen phosphorylase (*see* phosphorylase).

**regulatory gene** *see* regulator gene.

**regulatory sequence** a sequence in a DNA molecule concerned with regulating the expression of a gene; e.g. a promoter or operator.

**regulatory site** a specific site on an enzyme that is distinct from the substrate-binding site and that binds a feedback inhibitor or other regulatory molecule. *Compare* allosteric site.

**regulatory subunit** any of the subunits of a multimeric enzyme (composed of nonidentical subunits) that has a regulatory rather than a catalytic function.

**regulon** a group of genes, whether linked in clusters or unlinked, that respond to a common regulatory signal.

**rehydrate** to restore water to material that has been lyophilized (*see* freeze-dry) or otherwise dehydrated.

**Reichstein**, Tadeus (1897-1996), Polish-born Swiss chemical engineer, organic chemist, and botanist renowned for his isolation and study of 29 different steroids from the cortex of the adrenal gland and (in 1933) for devising a method of synthesizing ascorbic acid, vitamin C, from glucose that is still in use industrially; Nobel Laureate in Physiology or Medicine (1950) jointly with E. C. Kendall and P. S. Hench 'for their discoveries relating to the hormones of the adrenal cortex, their structure and biological effects'.

**reiterated** describing nucleotide sequences that occur many times within a genome. These occur especially in higher organisms. *See also* repetitive sequences.

**REL** a gene family encoding transcription factors of the  $\kappa B$  family; *v-rei* is the oncogene of avian reticuloendothelial virus strain T (REV-T), encoding p69<sup>v,rel</sup>. Rei and v-Rel form homo- or heteroditimers that bind to NF- $\kappa B$  motifs. v-Rel has lost two N-terminal amino acids and 118 C-terminal residues compared with Rel. Example of Rel product from mouse: database code REL\_MOUSE, 587 amino acids (64.96 kDa). Example of p69<sup>v,rel</sup>: database code TREL\_AVIRE, 503 amino acids (55.91 kDa).

**relA** a gene in *Escherichia coli*, mutations in which can lead to a 'relaxed' phenotype in which amino-acid starvation fails to switch off ribosomal RNA biosynthesis. The gene product is an enzyme active in the presence of ribosomes and uncharged tRNA, and called GTP pyrophosphokinase, EC 2.7.6.5; systematic name: ATP:GTP 3'-pyrophotransferase; other names: pppGpp synthetase I; stringent factor; guanosine 3',5'-polyphosphate synthase; it catalyses a reaction between ATP and GTP to form guanosine 3'-diphosphate 5'-triphosphate and AMP. The product is referred to as pppGpp and is converted to ppGpp (guanosine 3'-diphosphate 5'-diphosphate), which is the active nucleotide in evoking the stringent response. Database code RELA\_ECOLI, 744 amino acids (83.76 kDa).

**relative atomic mass** or (*formerly*) atomic weight abbr.: r.a.m.; symbol:  $A_r$ . 1 (of an atom) the ratio of the mass,  $m_a$ , of the atom in question, to the atomic mass constant,  $m_u$ , which is one-twelfth of the mass of the nuclide  $^{12}\text{C}$ ; i.e.  $A_r = m_a/m_u$ .  $A_r$  is a mass ratio, a pure number with no units. 2 (of an element) the ratio of the average mass,  $\bar{m}_a$ , of the atoms in a specified sample of the element in question,  $E$ , to the atomic mass constant,  $m_u$ ; i.e.  $A_r(E) = m_a(E)/m_u$ . Since, in general, elements are mixtures of isotopes of differing nucleon numbers (mass numbers), an average mass of the atoms is required in this definition. Furthermore, the isotopic composition of many elements can vary with the origin of the sample and its treatments. Hence there are limits to the precision with which the values of the relative atomic masses of many elements can be given.

**relative band rate** or **relative band speed** *see*  $R_B$  value.

**relative biological effectiveness** abbr.: RBE; an alternative term for quality factor.

**relative centrifugal force** symbol:  $G$ ; the force acting on a particle in a centrifugal field expressed in multiples of the ac-

## relative density

## renin

celeration due to gravity,  $g$ .  $G = w^2r$ , where  $w$  is the angular velocity in rad s<sup>-1</sup> and  $r$  the radial distance from the axis of rotation in m. ( $G = 1440 \times \pi^2 w^2 r$  where  $w$  is in revolutions per minute and  $r$  in cm.)

**relative density symbol:**  $d$ : the ratio of the mass density of a substance,  $\rho$ , at a given temperature, to the mass density of a reference substance (usually water),  $\rho_0$  at a reference temperature (usually 4°C); i.e.  $d = \rho/\rho_0$

**relative formula mass** the relative molecular mass as calculated from the formula of a compound.

**relative molecular mass or relative molar mass or molecular weight abbr.:** r.m.m.; **symbol:**  $M_r$ ; the ratio of the mass of a molecule,  $m_r$ , to the atomic mass constant,  $m_u$ , which is one-twelfth of the mass of the nuclide J2C; i.e.  $M_r = m_r/m_u$ .  $M_r$  is a mass ratio, a pure number with no units. The convention for indicating the size of a protein is thus ' $M_r$ ' followed by a number without units, e.g.  $M_r$  10000; the equivalent molecular mass, i.e. its mass in daltons, would be 10 kDa. *See also* dahon, relative atomic mass, unified atomic mass unit.

**relative permittivity symbol:**  $\epsilon_r$ ; formerly called dielectric constant, the ratio of the permittivity of a substance,  $\epsilon$ , to the permittivity of vacuum,  $\epsilon_0$ , i.e.  $\epsilon_r = \epsilon/\epsilon_0$ .

**relaxation (in chemistry)** the process of self-adjustment of a molecular system to a new state of minimum free energy following a disturbance.

**relaxation kinetics** a technique used to study rapid reactions in which a mixture at equilibrium is rapidly adjusted to a new set of conditions. The system is then observed as it approaches its new equilibrium, a process known as relaxation. The temperature-jump method is often used, whereby an electric discharge is used to increase the temperature by several degrees in a period of about 1  $\mu$ s. *See also* rapid-reaction kinetics.

**relaxation spectrometry** the use of spectrometry to follow the kinetics of a reaction undergoing relaxation from a perturbation. *See relaxation kinetics.*

**relaxed control** a mechanism of control of plasmid replication in which replication of plasmids greatly exceeds that of the chromosome. *Compare* stringent control.

**relaxed DNA** circular DNA that is not supercoiled (*see* supercoil), and instead has an unwound loop. The supercoiled form is energetically favoured over the relaxed form. Since the supercoiled DNA is more compact it moves faster when centrifuged or upon electrophoresis, and so the two forms of DNA can be separated.

**relaxed form abbr.:** R form; one of two alternative quaternary structures of a protein, the other being the tense form (or taut form, *abbr.:* T form). These forms derive from the concept of two conformational states of a protein, which differ in their affinities for a ligand. Factors affecting the conformational equilibrium also influence the affinity of ligand-binding and vice versa. Such factors may include the ligand itself, which could enhance or reduce the affinity of the protein, giving rise to positive cooperativity or negative cooperativity of binding respectively. The T form has a lower affinity for the substrate. For example, oxyhemoglobin is R, and deoxyhemoglobin is T; the binding of O<sub>2</sub> to the heme group causes the iron atom to move with respect to the heme plane, and this favours the move from T to R. *See also* allosteric constant, Monod-Wyman-Changeux model (for allosteric compounds).

**relaxed mutant** a bacterial mutant that lacks the *rel* (*relaxed*) gene, which exerts a critical control over the stringent response. The *rel-* mutant is unresponsive to amino-acid starvation, so that rates of RNA synthesis, for example, continue as before. *See also* *reiA*.

**relaxin** a protein hormone ( $M_r \approx 5600$ ) that is responsible in most mammals (including humans) for dilation of the symphysis pubis, softening of the cervix, and various other physiological changes prior to parturition. It is synthesized and stored in the corpus luteum. Like insulin, the hormone consists of two polypeptide chains linked by two disulfide bonds, with

an intrachain disulfide bridge also present. Although otherwise dissimilar in primary structure, the two proteins have very similar tertiary structures. As with insulin, synthesis is thought to occur via an inactive, single-chain precursor, in this case prorelaxin, and storage is as granules in vesicles. Example from human (precursor): database code RELI\_HUMAN, 185 amino acids (21.12 kDa). *See also* insulin-related growth factors.

**release factor abbr.:** RF or (formerly) R factor; proteins that participate in the release of a nascent polypeptide chain from a ribosome. There are two classes of release factors, one codon-specific and the other non-codon-specific. In bacteria two codon-specific factors have been identified, RF-1, specific for UAGUAAC, and RF-2, specific for UGA/UAA. In eukaryotes one such factor has been found, eRF-1. These factors act at the ribosomal A-site and require polypeptidyl-tRNA at the P-site. In bacteria the action of RF-1 and RF-2 are aided by the non-codon-specific RF-3 which binds to guanine nucleotides. In eukaryotes a similar factor, eRF-3, has been identified. The genes encoding RF-1 (*prfA*) and RF-2 (*prfB*) have been identified. Mutations in these genes often cause misreading of termination signals, increased frameshifting, and temperature-sensitive growth of the cells. Examples from *Escherichia coli*: RF-1, database code RFLECOLI, 360 amino acids (40.41 kDa); RF-2, database code RF2\_ECOLI, 365 amino acids (41.19 kDa). *See also* ribosome recycling factor.

**release-inhibiting factor or release-inhibiting hormone** any polypeptide that inhibits the release of a hormone or hormones. An example is somatostatin.

**releasing hormone or releasing factor** any of a group of peptide neurohormones that are synthesized in various distinct regions of the hypothalamus. They are released in nanogram amounts into the capillaries of the portal vessels of the median eminence of the hypothalamus, then carried to the anterior pituitary where they regulate the production and secretion in microgram amounts of the tropic hormones, e.g. thyrotropin, somatotropin, and the gonadotropins. In the anterior pituitary they act via the adenylate cyclase system and are then degraded by proteolysis.

**rem symbol:** rem; a non-SI unit of (radiation) dose equivalent, equal to 0.01 J kg<sup>-1</sup> of irradiated human (or other mammalian) tissue. It is being superseded by the sievert; 1 rem = 10<sup>-2</sup> sievert. [Acronym for roentgen equivalent man (or mammal).]

**REMI abbr. for restriction enzyme-mediated integration** (*see* insertional mutagenesis).

**remnant** a fragment of a molecule or other entity remaining after partial degradation especially chylomicron remnant.

**renal** pertaining to, or of, the kidney.

**renal rickets** a condition occurring in older children and characterized by the skeletal changes of rickets, due to impairment of renal function allowing excessive loss of calcium and phosphate into the urine.

**renaturation** the return of denatured macromolecules (protein, DNA, etc.) to the conformation they maintained before denaturation. In the case of proteins, reversible denaturation is brought about by disulfide reducing agents and urea, for nucleic acids by heat or salts. *See also* native state.

**renewal (of tissue)** *see* regeneration (def. 2).

**renin or angiotensin-forming enzyme or angiotensinogenase EC 3.4.23.15;** a labile proteolytic enzyme,  $M_r \approx 40\,000$ , formed from prorenin in plasma and kidney, and secreted into the blood by the kidney. It is also produced in relatively large amounts by the submaxillary gland of certain strains of mice. A glycoprotein aspartic endopeptidase, it is highly specific for the Leu-i-Leu bond in angiotensinogen, which it cleaves to generate angiotensin I. Despite its high specificity it resembles other eukaryotic aspartyl proteinases. Example, precursor from human: database code RENI\_HUMAN, 406 amino acids (45.01 kDa). It is a preproprotein; residues 1-23 are the peptide signal and 24-66 are the propeptide. 3-D structure is known. *Compare* rennin.

## renin-angiotensin system

**renin-angiotensin system** a system involved in the control of blood pressure. Renin, secreted into the blood by the kidney in response to osmotic changes, anoxia, or kidney trauma, acts on angiotensinogen to release angiotensin I (AI) (see angiotensin). Angiotensin-converting enzyme forms angiotensin II (All) from AI by release of His-Leu from the C-terminal end. All stimulates release of the mineralocorticoid aldosterone from the glomerulosa cells of the adrenal cortex. Various nonapeptide analogues of AI inhibit converting enzyme and are used in the treatment of renin-dependent hypertension. *See also* captopril. **rennet** an extract obtained from the stomachs of young mammals living on milk. It contains rennin (i.e. chymosin), an enzyme that clots milk and is used in cheese-making.

**rennin** an alternative name for chymosin (which is preferred because of possible confusion with renin). *See also* rennet.

**Reoviridae** a family of double-stranded RNA viruses (class III in the Baltimore classification) with a segmented genome, infecting vertebrates, arthropods, and plants. The virion consists of a "nonenveloped icosahedral particle, 60-80 nm across, and containing 10-12 segments of RNA together with RNA-directed RNA polymerase; the latter serves to transcribe the negative strand of each RNA molecule into mRNA. This family comprises six groups: the orthoreoviruses, orbiviruses, rotaviruses, cytorviruses, phytoreoviruses, and Fijivirus. No pathology is associated with the orthoreoviruses infecting humans, but rotaviruses cause gastroenteritis, and orbiviruses cause the disease blue tongue in sheep.

**reovirus** *see* Reoviridae.

**rep** an obsolete unit of absorbed dose of ionizing radiation of any kind, equal to the dose of radiation that, upon absorption by a given mass of living tissue, causes the same energy deposition as 1 roentgen of X- or gamma radiation, i.e. about 96 ergs per gram ( $0.0096 \text{ J kg}^{-1}$ ) of tissue. *See also* rad, rem. [Acronym for roentgen equivalent physical.]

**REP** abbr. for repetitive extragenic palindromic sequence.

**RepA** the protein product of the *Escherichia coli* gene *repA* which has a role in the replication of DNA in *E. coli*. Although the principal DNA helicase in *E. coli* is DnaB helicase, there is also a different 68 kDa monomeric protein, which has some helicase activity during certain life-cycle stages of the replication of single-stranded phages. The contribution of RepA protein to the host cell is less clear, but the rate at which *E. coli* replication forks propagate is reduced in *rep<sup>-</sup>* mutants.

**repairase** an enzyme concerned in the repair of an interrupted polynucleotide chain.

**repair enzyme** any of the enzymes making up the enzyme complex responsible for the excision of pyrimidine dimers which are formed on exposure of DNA to ultraviolet light, when adjacent pyrimidine residues on a DNA strand become covalently linked. Three enzymic activities are essential for the repair: (1) an enzyme complex comprising the three proteins encoded by the *uvrABC* genes (see *uvr*) that detects the distortion produced by the pyrimidine dimer; (2) the UvrABC enzyme complex also has another activity, described as a specific excinuclease, which cuts the damaged DNA strand eight nucleotides away from the dimer on the 5' side and four nucleotides away on the 3' side; (3) the 12-residue oligonucleotide excised by this specific excinuclease diffuses away and DNA polymerase I enters the gap to effect repair synthesis. Gaps are filled by DNA ligase. *See also* DNA repair enzyme, excision repair, recombinational repair, mismatch repair.

**repeated genes** *see* repetitive sequences.

**repeat-induced point (mutation)** *see* RIP.

**repeat sequence or repeat 1 (in DNA)** *see* repetitive sequences.

**2 (in proteins)** any sequence of the same amino-acid residue or group of amino-acid residues that is repeated in a polypeptide. Thus in some cases there are runs of glutamine or cysteine. In *Drosophila melanogaster* there is a protein with a string of 11 cysteine residues, and human androgen receptor protein has a string of 21 glutamine residues. In fact there are at present in

## replica plating

composite databases 44 proteins with this number of glutamine residues. In other proteins, e.g. tropocollagen, there is a regular sequence, except in this case for the last 20 amino-acid residues at each end of the chain. In tropocollagen every third residue is glycine usually followed by proline or hydroxyproline. The intrachain hydrogen bonds involve glycine. 3 the repeats of sugar residues often found in complex polysaccharides. repeat unit a major periodicity in the structure of a molecule as deduced from X-ray diffraction patterns.

**repetitive extragenic palindromic sequences or palindromic units** palindromic sequences in repetitive DNA in *Escherichia coli* and *Salmonella typhimurium*. These are never found within a coding sequence. They are topoisomerase substrates and potential transcription terminators.

**repetitive sequences** repeated sequences of nucleotides found in the DNA of eukaryotes. There are various types. (1) Satellite DNA typically consists of tandem (head-to-tail) repeats of a few hundred nucleotides. It is so called because those first discovered had an unusual ratio of bases that made it possible to separate the satellite DNA from the bulk of the cell DNA in a centrifuge. (2) Minisatellite DNA consists of shorter tandem repeats. The restriction fragment length polymorphisms linked to many genes have short sequences of bases in common. rDNA (see ribosomal DNA) probes for these sequences are useful in the preparation of a profile of the genome of an individual (fingerprinting). (3) Transposons (transposable elements) are also characterized by repeated sequences, often numbering several hundred copies. Primate DNA has large numbers of two types of transposable elements, L1 transposable elements and Alu sequences, which comprise about 300 bases. (4) Repeated genes for rRNA and histones are also found. In many cases repetitive sequences seem to be maintained solely by their ability to replicate within the genome (the 'selfish DNA hypothesis'). Rather than conferring benefits their behaviour can sometimes result in loss of fitness to the host, as in some human genetic diseases; mutations can arise due to insertion of transposable elements, to chromosomal rearrangements induced by recombination between repeated sequences, or to amplification of microsatellite sequences.

**replacement vector** a cloning vector in which part of the normal genome is replaced by foreign DNA. It contrasts with an insertion vector where the foreign DNA is merely incorporated into the normal genome. For example, a mutant of lambda phage, called  $\lambda^{gt}\text{-}\lambda\beta$ , contains only two *EcoRI* cleavage sites and so the middle segment of the DNA can be removed leaving 72% of the normal genome. A suitably long DNA replacement between the two ends of lambda DNA enables such a recombinant DNA molecule to be packaged into a lambda particle.

**replica** (*in electron microscopy*) a reproduction of the surface of an object. There are various ways by which the surface of an object, e.g. membrane of an organelle, may be examined by transmission electron microscopy by means of a replica. Such a replica may be obtained by evaporating a thin film of a heavy metal such as platinum on to the dried specimen. The metal is sprayed from an oblique angle in order to deposit a coating of uneven thickness because a shadow effect is created that gives the image a three-dimensional appearance. The organic material may be dissolved away to provide a replica of the surface of the specimen. Two other methods, freeze-etching and freeze-fracturing, employ frozen sections.

**replica plating** a technique for the production of identical patterns of bacterial colonies on a series of agar plates. The method uses velveteen or other fabric stretched on a pad, which is then pressed onto a plate of bacterial cultures so that some bacteria from each colony are transferred to the pad, preserving the spatial pattern of the colonies (in mirror image). If this pad is then pressed lightly onto a fresh culture plate, it will transfer colonies in the same formation to the new plate. This new plate may be prepared using media that will be selective for certain mutants, fermentation reactions, or anti-

biotic sensitivity. A similar technique can be used in the screening of hybridomas for antibody production.

**replicase** a loose term/or certain polymerase enzymes; e.g. certain viral RNA-directed RNA polymerases can be referred to as RNA replicases.

**replicate** 1 to make an exact copy of something, as in the replication of DNA. 2 (in electron microscopy) to make a replica.

**replication complex** the complex of replication proteins that are linked together as a single large unit, of total mass  $10^6$  daltons, that moves rapidly along the DNA during replication of DNA. It enables DNA to be synthesized on both sides of the replication fork in a coordinated and efficient manner. That part of the complex that contains DNA primase and DNA helicase is known as the primosome.

**replication-error mutation** a mutation that arises during DNA replication as a result of the incorrect copying of the sequence of nucleotides in the parent DNA. Probably fewer than one mistake occurs in  $10^9$  nucleotides added.

**replication fork** or replicating fork the Y-shaped region of a replicating DNA molecule or chromosome, resulting from separation of the DNA strands and in which synthesis of new strands takes place. The process requires the participation of helicases that open the duplex.

**replication of DNA** the means whereby new strands of deoxy-polynucleotides are synthesized. The structure of double-stranded DNA, with two strands of complementary base pairs, led Watson and Crick to propose a possible means of copying DNA: the two strands could unwind and each act as the template for a new strand, thus forming two helices, each containing one parental strand and one new one. The elegant Meselson-Stahl experiment demonstrated that DNA replication was indeed semiconservative. Other mechanisms of replication, 'conservative' and 'dispersive', have been proposed but there is no evidence that they occur. The helix of the double-stranded parental DNA must be unwound and this requires more than 20 proteins in a complex known as a primosome. All DNA-dependent DNA polymerases synthesize the new strands in the direction 5' to 3' using as substrates deoxynucleotide triphosphates with the production of pyrophosphate. The new strands are antiparallel to the parental template strand. At low resolution both strands of a double-stranded DNA appear to be synthesized in the same direction in spite of the fact that the polymerases only synthesize the strands in one direction. The problem is resolved by the fact that one strand, the leading strand (or continuous strand), is synthesized in a continuous fashion whereas the other strand, the lagging strand (or discontinuous strand), is synthesized discontinuously to give Okazaki fragments (1000-2000 nucleotides long in prokaryotes and 100-200 nucleotides long in eukaryotes) which are eventually joined by DNA ligase. The DNA ligases cannot start a chain and must rely on a priming device which is provided by RNA primase which again synthesizes an RNA primer in the direction 5' to 3' using nucleoside triphosphates as substrate. The continuous strand needs to be primed only once whereas the discontinuous strand must be primed repeatedly. Three principal DNA polymerases for *Escherichia coli* were discovered in the laboratory of A. Kornberg. DNA polymerase I, in addition to possessing synthetic activity *in vitro*, is also a 3'-5' exonuclease which gives it an editing function. It also has 5'-3' nuclease activity. DNA polymerase II participates in DNA repair but is not required for replication. DNA polymerase III is the predominant polymerase for replication of *E. coli* DNA *in vivo*. Eukaryotic cells have at least four DNA polymerases.

**replicative** able to be replicated. See also replicative form.

**replicative form abbr.: RF**; the intracellular form of viral nucleic acid that is active in replication. A single-stranded viral nucleic acid, be it RNA or DNA, is first converted into a double-stranded form - the replicative intermediate - to enable the viral strand to be replicated preferentially. In the case of a retrovirus a hybrid of RNA and DNA is formed.

**replicative intermediate** see replicative form.

**replicon** 1 a structural gene that controls the initiation and replication of DNA. 2 by association, the whole DNA sequence (such as the bacterial chromosome) that is replicated under the influence of a single replicon system.

**replisome** a replication complex hypothesized to account for the initiation of chromosome replication within a living cell.

**replitase** a particulate fraction that can be isolated from the nuclei of S phase Chinese hamster embryo fibroblasts and containing some of the enzyme activities required for DNA synthesis.

**reporter gene** a gene used to disclose the function of potential regulatory sequences. The sequences are placed in plasmids, upstream of the reporter gene; these chimeric plasmids are then introduced into cells and the expression of the reporter gene is measured as an index of the function of the regulatory sequences under the conditions being investigated. The *lacZ* ( $\beta$ -galactosidase) gene, the *CAT* gene (see chloramphenicol O-acetyltransferase), and the gene encoding firefly luciferase have been used in this way.

**reporter group** a chemical group that acts as a probe.

**repress** to check or restrain; the effect may be partial or total.

See repression, repressor.

**repressible** describing a metabolic reaction that is capable of undergoing repression.

**repression (in genetics)** the act of inhibiting gene expression.

An example is catabolite repression of the *lac* operon by glucose, mediated through binding of cyclic AMP to catabolite (gene) activator protein (CAP). By extension, the gene product itself (enzyme or other protein) and thus any associated metabolic reaction is said to be repressed. See also repressor.

**repressor (in genetics)** a molecule that specifically prevents the transcription of regulatory genes under control of an operator. When the repressor is bound to the operator, transcription cannot occur. An inducer can induce transcription by binding to the repressor to form a complex that has a low affinity for the operator. The classic example of a repressor is the lactose repressor protein, which controls the expression of the *lac* operon in *Escherichia coli*. The protein binds to a specific sequence of 21 nucleotide pairs (called the operator) that overlaps an adjacent RNA polymerase binding site (the promoter) at which RNA synthesis begins. In the presence of lactose, allolactose is formed, which binds to the repressor. This induces a conformational change that causes the repressor to loosen its hold on the DNA so that the gene is derepressed. In other examples, the binding of a signalling molecule may increase the affinity with which the repressor binds to the DNA; e.g. the *trp* operon, encoding enzymes that produce tryptophan in *E. coli* (see trp gene). See also repression.

**reproducibility** the ability to carry out a series of identical experiments to yield results that fall within a small range of error derived by statistical analysis (see standard deviation, standard error of the mean). The limits of error that are acceptable depend on the limitations of experimental technique and the inherent variability of the system under investigation.

**reproduction (in biology)** the production by an organism of new individuals that are more or less similar to itself. Reproductive strategies can be divided broadly into two categories: sexual reproduction, which requires the participation of male and female gametes and gives rise to genetic variation among the offspring; and asexual reproduction, which does not involve gametes and leads to the formation of offspring that are genetically identical to the parent. The latter takes various forms; examples include budding, fragmentation, parthenogenesis, spore formation, and vegetative reproduction.

**reptation** a term invoked to rationalize the movement and thermodynamics of linear polymers, dividing the chain conceptually into sections (reptons), which form the basis for statistical mechanical calculations of the relaxation time of the polymer and viscosity of polymer solutions.

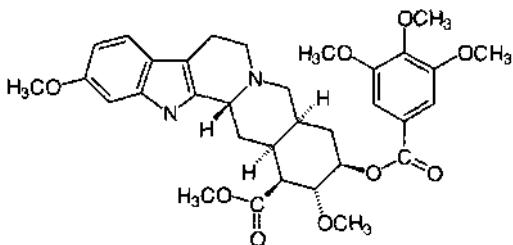

**repton** see reptation.

**RER abbr.** for rough endoplasmic reticulum.

**reseal**

**reseal** to join again the ends of ruptured components, as in, e.g., the resealing of plasma membranes after whole cells have been rendered permeable by various techniques, or of fractionated membrane fragments, which may reseal to form closed vesicles. The term can also refer to ligation of the cut ends of DNA after insertion of foreign DNA into a vector.

**reserpine** (*3P,16p,17a,18p,20a*)-11,17-dimethoxy-18[*(3,4,5*-trimethoxybenzoyl)oxy]yoimban-16-carboxylic acid methyl ester; an alkaloid isolated from the roots of certain species of *Rauwolfia* and noted for its antihypertensive and CNS depressant actions. These arise from its inhibition of the intraneuronal  $\text{Na}^+$ ,  $\text{Mg}^{2+}$ -ATPase pump, which maintains the neuronal vesicular stores of biogenic monoamines (**dopamine**, **norepinephrine**, and **serotonin**).

**reserve polysaccharide** any polysaccharide that is stored to provide an energy source at times of need. Examples are starch granules in plants, and glycogen granules in animals.

**Re/Si convention** a nomenclatural system for specifying the stereoheterotopic faces of a trigonal atom using the **sequence rule** in two dimensions. This is used to establish a priority sequence for the three ligands, e.g. of *Cabc*. The plane containing C and the first atoms of the ligands is then inspected from an arbitrarily chosen side. Starting with the highest priority ligand, it is determined whether the priority sequence is clockwise, hence *Re* (from Latin *rectus*, right), or counterclockwise, hence *Si* (from Latin *sinister*, left); e.g. for acetaldehyde,  $\text{CH}_3\text{CHO}$ , if the face inspected shows a clockwise ordering,  $\text{O} \rightarrow \text{CH}_3 \rightarrow \text{H}$ , that face is designated *Re*. There are a number of extensions of this general principle, and the specialist literature should be consulted for details.

**residence time** the averaged time that a site is occupied by any designated molecule.

**resident protein** see **luminal protein**.

**residual body** a membrane-lined cytoplasmic inclusion characterized by undigested residues (e.g. membrane fragments or whorls, ferritin-like particles). The term embraces **tellysosome** and (hypothetical) **post-lysosome**.

**residue** 1 any of the incorporated amino-acid moieties in a peptide or protein. 2 material that remains after any procedure to remove something.

**residue mass** the relative molecular mass of a residue; i.e. the sum of the **relative atomic masses** of all the atoms composing the residue.

**residue weight** the molecular weight of a residue; i.e. the sum of the **atomic weights** of all the atoms composing the residue.

**Residue mass** is the preferred term.

**resin** 1 or **rosin** any of a group of naturally occurring amorphous solids or semisolids, typically light yellow to dark brown in colour. Usually brittle and insoluble in water, they are found as plant exudates, often on trees such as pines and firs. 2 the polystyrene base of certain ion-exchange materials used in chromatography. The polystyrene is modified to carry sulfonic acid or carboxyl groups (cation exchangers), or primary or quaternary ammonium groups (anion exchangers).

**resistance** 1 the ability of a living organism, particularly a bacterium, to resist the effect of a disadvantageous environment or substance, especially an antibiotic. A bacterium may

**resonance hybrid**

possess one or more resistance plasmids. 2 see **electric resistance**.

**resistance donor** a strain of an organism, usually a bacterium, that is capable of transferring resistance, usually by conjugation, to a suitable recipient.

**resistance factor** abbr.: R factor; an alternative name for **resistance plasmid**.

**resistance plasmid** abbr.: R plasmid; a **plasmid** that carries genetic information for resistance to antibiotics or other antibacterial drugs. Other name: resistance factor (abbr.: R factor).

**resolution** 1 the degree of separation between two compounds being subjected to a transport method such as chromatography or sedimentation equilibrium (i.e. being resolved); complete resolution yields two compounds each uncontaminated by the other. 2 (in physics and biophysics) the extent to which closely juxtaposed objects can be distinguished as separate objects using an optical instrument, e.g. a microscope. The degree of resolution is dependent on the **resolving power** of the system. The fineness of detail with which objects can be seen is limited by the wavelength of light used. Only those objects similar in dimensions to the wavelength of the light (or larger) can be resolved. The wavelength of X-rays is from about  $10^{-8}$  m to  $10^{-11}$  m and they can thus be used to resolve structures at the atomic level. Thus a structure can be said to have been determined at  $3 \text{ \AA}$  resolution,  $7 \text{ \AA}$  resolution, etc.

**resolvase** an enzyme that, together with **transposase**, is involved in the replicative transposition of genetic elements in *Escherichia coli*. The 3' ends of the target chromosome, after the first cutting and splicing, serve as replicative primers for copying both the gaps and the two strands of the transposable element (which contains transposase) itself. Ligase action generates a cointegrate, a large circular structure containing both donor and target chromosomes with two freshly replicated copies of the transposable element. Resolvase now catalyses the site-specific recombination between the two elements, resulting in one copy of the transposable element inserted in each of the two chromosomes. Example, *tmpA* gene product from Tn3 which confers resistance for ampicillin; database code TNP3\_ECOLI, 185 amino acids (20.59 kDa); it contains a **helix-turn-helix** motif.

**resolving power** 1 (in chromatography) the power to resolve individual compounds (see **resolution** (def. I)). It depends on (1) the efficiency of the system employed; for columns this is given by the **theoretical plate** number; and (2) the relative affinities of different compounds for the stationary and mobile phases. 2 (in physics) a the ability of an optical instrument, e.g. a microscope or telescope, to produce separate images of objects placed close together, b the ability of a spectrometer to separate adjacent peaks in a spectrum.

**resonance** 1 (in physics) the induction or amplification of one vibration by another vibration of a periodicity equal to the natural oscillation frequency of the first, which is then said to resound. In an electronic circuit, resonance occurs when an applied emf equals the natural frequency of oscillation of the circuit (used, e.g., in tuning a radio receiver). 2 (in chemistry) a phenomenon shown by any molecular entity to which more than one **contributing structure** can be assigned, when these structures are of similar energy and differ only in the distribution of the valence electrons; the entity then oscillates between the two structures and adopts, in effect, an intermediate state. Resonance always results in a different distribution of electrons than would be the case if there were no resonance. See also **resonance energy**, **resonance hybrid**. 3 see **electron spin resonance spectroscopy**, **nuclear magnetic resonance**. -resonant adj.; resonate vb.

**resonance energy** the difference in energy of an actual molecule and the **contributing structure** of lowest energy.

**resonance hybrid** the structure that results when a chemical entity exhibits **resonance** (def. 2), such as occurs by the sharing of one or more electrons over several bonds. It has a lower en-

## resonance stabilization

ergy than any of the possible formal nonresonance contributing structures, giving additional stability of which the so-called resonance energy is a measure. A classic example is carbon dioxide, which may be represented by the Lewis formula for each as  $\ddot{\text{O}}\text{:OC}\text{:}\ddot{\text{O}}$ ,  $\text{:}\ddot{\text{O}}\text{:C}\text{:}\ddot{\text{O}}$ , and  $+\text{O}\text{:}\text{:C}\text{:}\ddot{\text{O}}^-$ . Compare mesomerism.

**resonance stabilization** or resodllnce stabilisation stabilization of molecular structure by resonance; *see also* resonance hybrid.

resonate *see* resonance.

re80rb to absorb again. -resorbent *ad.*; resorption *n.*; resorative *ad.*

resorcinol m-dihydroxybenzene; a compound used in the Seliwanoff test for ketoses.

re8orption *see* resorb.

**respiration** 1 the process of gaseous exchange between an organism and its environment. In plants, microorganisms, and many small animals, air or water makes direct contact with the organism's cells or tissue fluids, and the processes of diffusion supply the organism with dioxygen and remove carbon dioxide. In larger animals the efficiency of gaseous exchange is improved by specialized respiratory organs, such as lungs and gills, which are ventilated by breathing mechanisms. These organs possess respiratory surfaces, across which gases are exchanged with the blood or other transport medium. This then carries dioxygen to the body tissues, and removes carbon dioxide. 2 or oxidative metabolism the various energy-yielding reactions of cells or organisms that require oxygen as the final electron acceptor. *See* respiratory chain. -respiratory *ad.*

**respiratory burst** a phase of elevated metabolic activity, during which oxygen consumption increases, that occurs in neutrophils, monocytes, and macrophages shortly after phagocytosing material. This is associated with increased activity of the hexose monophosphate shunt and production of NADPH (*see* pentose phosphate pathway). An oxidase takes electrons from the NADPH and transfers them to  $\text{O}_2$  creating the reactive superoxide ( $0_2^-$ ) ion and  $\text{H}_2\text{O}_2$  in the vacuole. Patients with chronic granulomatous disease never produce a respiratory burst. In some cases this is due to lack of an essential cytochrome *b*. The patients suffer an accumulation of mononuclear cells at sites of chronic inflammation, forming granulomas.

**respiratory chain** or electron-transport chain the sequence of enzymes and other proteins within the mitochondrion and prokaryotic cell membranes by which substrates, including NADH and succinate, are oxidized by dioxygen. It is fundamental to tissue respiration (def. 2) which has the function of maintaining tissue metabolism through oxidative phosphorylation. The chain can be separated into a number of particles (*see* respiratory complex) each of which contains individual elements of the chain. The mechanism involves, in the case of NADH, removal by NADH dehydrogenase of a proton plus two electrons. In the case of succinate, there is a transfer of two hydride ions (i.e. two protons plus two electrons) by succinate dehydrogenase to the enzyme-bound FAD; other flavoproteins can similarly oxidize fatty acyl-CoA or p-hydroxybutyrate or  $\alpha$ -glycerophosphate. The protons are initially released to the intermembrane space, and the electrons are transferred by the appropriate flavoprotein to ubiquinone, from which they are transferred singly in sequence to cytochrome *b*, cytochrome  $c_1$ , cytochrome *c*, and cytochrome *a/a3* at which point they reduce molecular oxygen to promote formation of water with the protons that were formed earlier. Many other components are also involved. In tightly coupled mitochondria, the protons released to the intermembrane space reach the mitochondrial matrix (the space in which they react with molecular oxygen) by transfer through the inner mitochondrial membrane by the  $\text{F}_{0}\text{F}_{1}$  complex of the mitochondrial ATPase (*see*  $\text{H}^+$ -transporting ATP synthase), with concomitant phosphorylation of ADP to ATP. *See also* chemiosmotic coupling hypothesis.

**re8piratory complex** any of several groups of physically associated components of the respiratory chain. The concept arose

## response coefficient

during experiments to purify individual components, when it was found that membrane particles could be isolated each with a consistently characteristic composition. Four main complexes have been identified: complex I, which contains primarily NADH dehydrogenase; complex II, which contains succinate dehydrogenase; complex III, which contains cytochromes *b* and *c*; and complex IV, which contains cytochrome *a/a3* together with copper-containing proteins. Complexes I, II, and III all contain additionally a number of proteins rich in iron and sulfur. The  $\text{F}_0$  and  $\text{F}_1$  subunits of the ATPase associated with the respiratory chain have been termed complex V (*see*  $\text{H}^+$ -transporting ATP synthase). *See also* complex I, II, III, IV.

**re8piratory control** the regulation, in coupled mitochondria, of the rate of oxidative phosphorylation by the level of ADP. As the ADP level increases, and the ATP level falls, electron flow through the respiratory chain and coupled ATP synthesis are enhanced. The respiratory control ratio, or respiratory control index, represents the ratio of the rate of oxygen consumption of mitochondria in the presence of both substrate and ADP to the rate in the presence of substrate but the absence of ADP; i.e. the ratio of the rate in respiratory state 3 to respiratory state 4 (*see* respiratory state).

**re8piratory pigment** any of a number of pigmented proteins, associated with respiratory processes, that derive their colour from a prosthetic group, usually heme in red proteins such as cytochrome *c*, or flavin nucleotides in flavoprotein dehydrogenases, which are yellow.

**respiratory quotient** or **respiratory ratio** *abbr.*: RQ; a ratio of the rate of carbon dioxide evolution by any cell, tissue, or organism to its rate of dioxygen uptake.

**respiratory state** or **state of the respiratory chain** anyone of the possible steady states of the phosphorylating **respiratory** chain in mitochondria. In state 1 both ADP and respiratory substrates are lacking. State 2 is a 'standard state' in which ADP has been added to exhaust the endogenous respiratory substrate; in state 2' substrate has been added to exhaust the endogenous ADP. In state 3, the 'active' state of rapid respiration, all required components are present and the respiratory chain itself is the rate-limiting factor. State 4, an anaerobic 'resting' state, is characterized by a low respiration rate. In state 5, only oxygen is lacking, the respiration rate then being at zero.

	State	[ $\text{O}_2$ ]	[ADP]	Substrate level	Respiration rate	Rate-limiting factor
1	>0	low	low	slow	ADP	
2	>0	high	0	slow	substrate	
2'	>0	low	high	slow	ADP	
3	>0	high	high	fast	respiratory chain	
4	>0	low	high	slow	ADP	
5	0	high	high	0	$\text{O}_2$	

**respirometer** an instrument for measuring the uptake of oxygen during incubation experiments. The Barcroft apparatus and the Warburg apparatus were examples of this type of instrument. **response** the events brought about by a stimulus, especially in a cell, tissue, or organism. *See* stimulus-response coupling, sensitization, desensitization.

**response coefficient symbol:** *R*; an overall measure of the control exercised by a specific enzyme inhibitor, at its concentration, *I*, on the overall flux, *F*, of a multienzyme system. Hence,

$$R_I^F = (\partial F/F)/(\partial I/I)$$

or

$$R = \text{fractional change in flux}/\text{fractional change in inhibitor.}$$

A response coefficient can also be determined for the effect of *Ion* the concentration of a metabolite *S*. Thus

## response element

$$R_I^S = (\partial S/S) / (dI/I)$$

It is the product of the elasticity coefficient and the flux control coefficient.

**response element** abbr.: RE; a DNA sequence (sometimes called a 'module') that is common to promoters/enhancers of genes whose expression is coordinately regulated (*see* coordinate induction/repression). Examples: the estrogen response element (ERE) has the consensus sequence GGTCAANNTG[A/T]GCC; the glucocorticoid response element (GRE) has the consensus sequence TGGTACAAATGTTCT; the heat-shock response element (HSE) has the consensus sequence GNNGAANNTCC-NNG; the metal response element (MRE) has the consensus sequence CGNCCCCGGNCNC; the serum response element (SRE) has the consensus sequence CATATTAGG; and the thyroid response element (TRE), which is common to several enhancers, has the consensus sequence TGACTCA.

**response time** the interval between initiation of a process and the commencement of the action that it induces.

**responsiveness** (*in physiology*) the ability of a cell, tissue, or organ to undergo a response. Maximal response normally corresponds to the healthy *in vivo* state, so that the degree of response is an indication of the integrity of the preparation. However, negative regulators may be removed during tissue preparation, thus giving enhanced activity *in vitro*.

**restin** Reed-Sternberg cell intermediate filament-associated protein; *other name*: cytoplasmic linker protein-170 0.2 (abbr.: CLIP-170); a protein that is highly expressed in such cells in Hodgkin's lymphoma and having a large coiled-coil a-helical domain similar to those in myosins. Example from human: database code REST\_HUMAN, 1427 amino acids (160.81 kDa).

**resting potential** the potential difference across the membrane of a cell in the unstimulated state. *See also* membrane potential.

**resting state** an inactive or unstimulated state, especially of a cell. *See also* cell-division cycle.

**restricted DNA** DNA that has been cut by a restriction endonuclease within a bacterium; bacteria are protected from the propagation within them of foreign DNA, usually viral DNA, by the possession of restriction endonucleases which degrade the invading DNA. Each nuclease recognizes a specific sequence of 4–8 nucleotides in the DNA. The cleaved sequences, where they occur in the genome of the bacterium itself, are protected from cleavage by methylation at the amino group of an adenine, or either the 5 position of a cytosine or the amino group of a cytosine. The newly replicated strand of the bacterial host DNA, which is protected from degradation by the methylated parent strand with which it forms a duplex, is modified before the next cycle of replication (*see* restriction-modification system). Such sequences in the viral DNA are usually not so methylated and hence are degraded first by the restriction enzymes and then by bacterial exonucleases. Invading DNAs are only rarely modified and enabled to reproduce in their new host. Its progeny are, however, no longer modified in the way that permits them to propagate. *See also* host-controlled modification.

**restricted phage** or **restricted bacteriophage** *see* restricted virus.

**restricted virus** a virus whose host range is limited by host-controlled modification so that when it infects a related but non-identical host cell its DNA is degraded by the new host cell's restriction endonucleases.

**restriction** (*in molecular biology*) the action or use of restriction endonucleases. *See also* restrictive.

**restriction analysis** another term for restriction mapping.

**restriction endonuclease** or **restriction enzyme** or **restriction nuclease** any of a group of enzymes, produced by bacteria, that cleave molecules of DNA internally at specific base sequences. They, therefore, act to 'restrict' the replication of foreign, usually viral, DNA entering the bacterial cell (*see* restricted DNA). Some of them also methylate the host bacterial

## restriction mapping

DNA to protect it from degradation. There are three known types of restriction enzymes. Types I and III each carry activity for both the endonuclease and methylase function whereas type II enzymes do not carry the methylase activity. Type I enzymes cleave the DNA at a random site located at least 1000 bp from the recognition sequence, type III do so 24–26 bp distant from the recognition site. In contrast type II enzymes cleave DNA at specific sites within the recognition sequence. This makes type II enzymes indispensable for DNA manipulation. Around 2500 species of type II restriction enzymes with some 200 differing sequence specificities have been characterized. A restriction endonuclease is named by the first letter of the genus of the bacterium that produced it and the first two letters of its species, followed by its serotype or strain designation, and a roman numeral if the bacterium contains more than one type of restriction enzyme. Type I (EC 3.1.21.3) restriction and modification enzymes are complex, multifunctional systems that require ATP, S-adenosyl methionine, and Mg<sup>2+</sup> as cofactors; in addition to their endonucleolytic and methylase activities, they are potent DNA-dependent ATPases. The subunit composition, three subunits designated R, M, and S, is similar to that of ATPases. They catalyse the endonucleolytic cleavage of DNA to give random double-stranded fragments with terminal 5'-phosphates; ATP is simultaneously hydrolysed. Example, R protein from *Escherichia coli*, enzyme *EcoR124/3*: database code TIR1\_ECOLI, 1033 amino acids (119.52 kDa). Type II enzymes have activity as site-specific deoxyribonucleases (EC 3.1.21.4), which catalyse the endonucleolytic cleavage of DNA to give specific double-stranded fragments with terminal 5'-phosphates; Mg<sup>2+</sup> is a cofactor. Example from *E. coli*, enzyme *EcoRV*: database code T2E5\_ECOLI, 244 amino acids (28.49 kDa). Such enzymes are the basis of restriction mapping. Type III enzymes have activity as site-specific deoxyribonucleases (EC 3.1.21.5). The protein has two subunits, products of the *res* (from 'restriction') and *mod* (from 'modification') genes; these are respectively, responsible for binding the system-specific DNA recognition site in the restriction and the methylation of one of the adenosyl residues in the recognition site. A list of restriction endonucleases is given in Appendix F. *See also* restriction-modification system.

**restriction enzyme** an alternative name for restriction endonuclease.

**restriction fragment** a fragment of DNA produced by the action of a restriction endonuclease. It usually refers to the product of a type II enzyme that recognizes specific base sequences in double-helical DNA and cleaves both strands of the duplex at specific sites.

**restriction fragment length polymorphism** abbr.: RFLP; polymorphism within a population of organisms of the size of the fragments of DNA produced as the result of the action of a type II restriction endonuclease. It results from a corresponding polymorphism of restriction sites in the genome, due to slight differences in base sequence between individual members of the population. RFLP is exploited in constructing physical maps of the genome, and widely used for localizing specific genes and detecting genetic differences between closely related individuals. The analysis of restriction fragments can reveal the presence of a mutation that may itself cause disease or be closely linked to one that does; for example, genetic diseases such as sickle-cell anaemia, cystic fibrosis, and Huntington's disease can be detected by RFLP analyses. *See also* restriction mapping.

**restriction map** a pattern obtained as the result of restriction mapping.

**restriction mapping** the use of type II restriction endonucleases to cleave genomic or other DNA to produce a characteristic pattern of fragments. The fragments are resolved by gel electrophoresis and visualized. Every DNA molecule produces a unique pattern, which accords with the specificity of the particular restriction enzyme. By comparing the patterns ob-

tained from two or more different DNAs, differences between closely similar DNA molecules, such as arise from mutations, may be detected. The use of DNA probes, such as rDNA, to identify particular fragments may often be of value.

**restriction-modification system** any system whereby host DNA is methylated to render it resistant to the action of the cell's restriction endonucleases (*see* restricted DNA); methylation involves the adenine or cytosine residues at the restriction sites. Several enzymes have been implicated in this action: (1) EC 2.1.1.72; *recommended name*: site-specific DNA-methyltransferase (adenine-specific); *other names*: N-6 adenine-specific DNA methylase; modification methylase; it catalyses a reaction between S-adenosyl-L-methionine and DNA adenine to form S-adenosyl-L-homocysteine and DNA 6-methylaminopurine. (2) Another type is EC 2.1.1.73; *recommended name*: site-specific DNA-methyltransferase (cytosine-specific); *other names*: C-5 cytosine-specific DNA methylase; modification methylase; it catalyses a reaction between S-adenosyl-L-methionine and DNA cytosine to form S-adenosyl-L-homocysteine and DNA 5-methylcytosine. Examples: (1) *EcoRV* methylase from *Escherichia coli*; database code MTE5\_ECOLI, 298 amino acids (34.60 kDa); (2) *EcoP15* mod gene product of a type III system (*see* restriction endonuclease); this methylates one of the A residues in 5'-CAGCAC-3'; it is a homotetramer; database code T3MO\_ECOLI, 645 amino acids (74.22 kDa).

**restriction negative** describing an organism that does not contain any restriction endonuclease.

**restriction site** a sequence of bases in a DNA molecule that is recognized by a restriction endonuclease.

**restrictive** 1 describing a strain or line of cells that does not permit the replication of a particular viral DNA, and is thus resistant to infection. 2 describing a set of conditions, such as a temperature range, in which a mutant phenotype is expressed, thus limiting the growth of the organism or causing its death. *Compare* permissive. *See also* conditional lethal mutation, temperature-sensitive mutation.

**restrictive conditions** *see* conditional lethal mutation.

**restrictive temperature** *see* temperature-sensitive mutation.

**restrictocin** an antitumour polypeptide, M<sub>r</sub> 16 000, from *Aspergillus* spp. It cleaves the large RNA of the eukaryotic 60S ribosomal subunit and inhibits protein synthesis in picornavirus-infected cells.

**RET** a human transforming oncogene derived through fibroblast transfection with T-cell lymphoma DNA. It encodes two forms of receptor tyrosine kinases of unknown ligand; the cytoplasmic oncogenic forms (*p76<sup>RET</sup>*, *p81<sup>RET</sup>*) are constitutively phosphorylated on tyrosine; they form homo- and heterodimers, and have autoprophosphorylation activity. A number of variants have been associated with multiple endocrine neoplasia and Hirschprung's disease. Example (precursor): database code RET\_HUMAN, 1114 amino acids (124.32 kDa).

**retentate** or dialysis residue or residue (*in* dialysis) the moiety of the dialysed material that has not traversed the membrane; the liquid containing this moiety (which may not still be entirely in solution). Some authorities prefer the term non-diffusible material.

**retention coefficient** (*in column chromatography*) the ratio of the void volume to the elution volume for a specific solute. It is a measure of the partition of the solute between the column material and the solvent, and is independent of column size.

**retention time** the time taken by a compound to traverse the length of a gas-liquid chromatography column. The retention time is a characteristic of each compound under defined conditions. It can be used to aid in identification within a series of homologues, e.g. fatty acids, which are characterized by their carbon number derived from the retention time.

**retention volume** a parameter of liquid chromatography, related to the volume at which each compound elutes under defined conditions.

**reticulate** 1 or reticular resembling a net; in the form of a net-

work. 2 to create in the form of a net or network. -reticulation n.

**reticulocalbin** a Ca<sup>2+</sup>-binding luminal protein of the endoplasmic reticulum. It has six EF-hands, a 20-residue N-terminal signal sequence, and the C-terminal sequence HDEL. Example (precursor) from mouse: database code RCALMOUSE, 325 amino acids (38.07 kDa).

**reticulocyte** an immature erythrocyte that is capable of protein synthesis, most of the protein synthesized (about 90%) being hemoglobin. It retains intracellular organelles, including mitochondria, and histologically stains for the presence of ribosomes. The name implies misleadingly that it has a reticulum (def. 1), which is characteristic of cells that secrete protein, a function not possessed by the reticulocyte.

**reticulocyte lysate** the preparation obtained by suspending reticulocytes in distilled water so that the cells are lysed by osmotic shock. The reticulocytes are usually obtained from rabbits in which reticulocytosis has been induced by the administration of phenylhydrazine. The residual RNA is usually removed by the addition of a ribonuclease that is calcium-dependent and is thereby inactivated by the addition of EDTA. Such a lysate is often used for the *in vitro* translation of added mRNA.

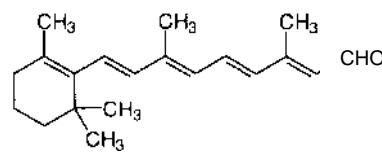

**reticulocytosis** enhanced levels of reticulocytes in the blood, often due to experimentally-induced increased production. *See also* reticulocyte lysate.

**reticuloendothelial system** *a former name for* mononuclear phagocyte system.

**reticulum** 1 the endoplasmic reticulum, a netlike structure of membranes found in the cytoplasm. 2 the most anterior chamber of the ruminant stomach.

**retina** the light-sensitive layer lining the inside of the posterior wall of the eye in vertebrates and some classes of molluscs. The inner nervous layer of the vertebrate retina is transparent and contains photoreceptive cone cells and/or rod cells together with their associated nerve cells and fibres, glia, and blood vessels; the outer layer, next to the choroid, is darkly pigmented and prevents back-reflection of light.

**retinal** 1 pertaining to the retina. 2 *the recommended trivial name for* (2E,4E,6E,8E)-3,7-dimethyl-9-(2,6,6-trimethylcyclohex-1-en-1-yl)nona-2,4,6,8-tetraen-1-al; *other names*: retinal; retinaldehyde; vitamin A aldehyde; vitamin Al aldehyde; retinene; retinenol; a compound that plays an important role in the visual process in most vertebrates (*compare* 3,4-didehydroretinal). In the retina this (all-E)-isomer, commonly distinguished as *all-trans-retinal*, is converted by retinal isomerase to its (2E,4Z,6E,8E)-stereoisomer, generally termed 11-cis-retinal, which then combines (as a Schiff's base) with an opsin to form (in cone cells) iodopsin or (in rod cells) rhodopsin. Interaction with a photon brings about dissociation of iodopsin or rhodopsin, to regenerate all-trans-retinal and the opsin, thereby completing the visual cycle. Retinal is formed in the retina by enzymic oxidation of retinol; in addition, most vertebrates can convert dietary α-, β-, and γ-carotenes to retinal by oxidative cleavage of the polyisoprenyl chain at its midpoint. [*Note*: (1) The numbering system of the systematic name is different from that of the trivial name, the latter following the rules used for carotenoids. (2) The fuller name retinaldehyde is recommended if confusion with def. 1 may occur.]

*all-trans-retinal*

retinal,

**retinal**, (*sometimes*) an alternative name for **retinal** (def. 2) (especially to distinguish it from **retinal2**; not recommended).

*retinal12* (sometimes) an alternative name for 3,4-didehydroretinal (especially to distinguish it from retinal!; not recommended).

retinal cone *see* cone cell.

retinaldehyde *see* retinal.

retinal isomerase EC 5.2.1.3; systematic name: *all-trans*-retinal II-*cis*-*trans*-isomerase; other name: retinene isomerase; an enzyme that catalyses the conversion of all-trans-retinal to II-*cis*-retinal. Example from *Todarodes pacificus* (Japanese flying squid); database code REIS\_TODPA, 301 amino acids (33.45 kDa). See also retinal (def. 2).

retinal rod *see* rod cell.

*retinene or retinenet an alternative name for retinal (def. 2) (not recommended).*

*retinene2* an alternative name for 3,4-didehydroretinal (not recommended).

retinene isomerase *an alternative name for* retinal isomerase.

retinitis pigmentosa a relatively common genetic disorder which in humans affects 1 in 4000 people and is caused by the premature death of photoreceptors. The result is progressive night blindness, contraction of the visual field and finally complete loss of sight. One form of autosomal dominant disease results from an abnormality on chromosome 3. In this, there is a single amino-acid substitution in the rhodopsin molecule caused by a base transversion of C to A, which results in the change of a proline to a histidine residue at position 23 in the opsin molecule, causing the characteristic retinal degeneration. Another severe form of the disease, affecting up to around 20% of some populations, is X-linked; it usually becomes manifest within the first two decades of life and progresses to blindness within 10-20 years. The gene, named *RPGR*, for this form has now been found on the short arm of the X-chromosome. The predicted 90 kDa protein product of the *RPGR* gene bears significant homology to the RCC1 family. retinoate 1 the anion of retinoic acid. 2 any salt or ester of retinoic acid.

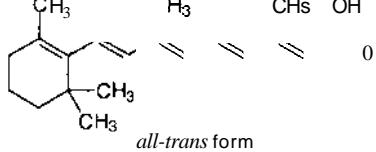

retinoblastoma a childhood cancer of the developing retina.

Retinoblastoma a childhood cancer of the developing retina. The offspring of surviving victims have a high incidence of this disease as well as several other types of malignancies. Retinoblastoma is associated with the inheritance of a copy of chromosome-13 from which a particular segment has been deleted. It develops through a mutation in a retinoblast (a retinal precursor cell). The affected chromosomal segment contains the *RB* gene which specifies a factor that restrains uninhibited cell proliferation. Thus the *RB* gene is a tumour suppressor gene. See also retinoblastoma protein.

**retinoblastoma protein** abbr.: pRb; the product of the retinoblastoma gene, RB. pRb is a 105 kDa DNA-binding protein that is localized in the nucleus of normal retinal cells but absent in retinoblastoma cells. The protein is phosphorylated in the cell cycle by protein kinase CDC2. It appears that the interaction of pRb with various transcription factors suppresses cellular proliferation. Example: database code RB\_HUMAN, 928 amino acids (106.04 kDa).

**retinoic acid** ( $\text{C}_{20}\text{H}_{30}$ ) ( $12-\text{d}$ ). The recommended trivial name for (*2EAE,6E,SE*)-3,7-dimethyl-9-(2,6,6-trimethylcyclohex-1-en-1-yl)nona-2A,6,S-tetraenoic acid; other names: tretinoin; vitamin A acid; vitamin A<sub>1</sub> acid; it is formed from retinal by enzymic oxidation in kidney and other tissues, and is active in preventing some, but not all, of the symptoms of vitamin A deficiency. It is a morphogen and regulator of differentiation during embryogenesis. See also retinoic acid receptor, vitamin A.

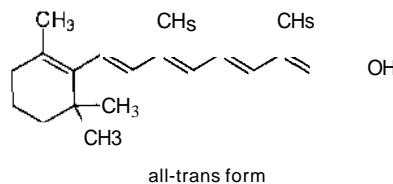

CH<sub>3</sub>COOH + H<sub>2</sub>O → CH<sub>3</sub>COO<sup>-</sup> + H<sub>3</sub>O<sup>+</sup>

retinoic acid receptor a nuclear receptor for retinoic acid that mediates its effects on cells. These receptors bind retinoic acid and directly regulate gene expression. The proteins belong to the steroid/thyroid/retinoic acid family of nuclear receptors for hormones. The ligand-binding domain is in the C-terminal region, the zinc-finger DNA-binding domain in a central region, and a function-modulating domain in the N-terminal region. Binding of hormone induces changes in receptor conformation that control transcriptional activation and repression, and also regulates homo- or heterodimerization. In the absence of ligand, these receptors repress basal gene expression, probably through co-repressor proteins.  $\alpha$ ,  $\beta$ ,  $\gamma$  and  $\delta$  types of receptor are known. Example,  $\alpha$ -I receptor from *Mus musculus*: database code RRALMOUSE, 462 amino acids (50.73 kDa).

**retinoid** any member of a class of isoprenoids, whether naturally occurring or not, that contain or are derived from four prenyl groups linked in a head-to-tail manner. All retinoids may formally be derived from a monocyclic parent compound with 20 carbon atoms containing five carbon-carbon double bonds and a functional group at the terminus of its acyclic moiety.

**retinol** the recommended trivial name and international nonproprietary name for (2E,4E,6E,8E)-3,7-dimethyl-9-(2,6,6-trimethylcyclohex-1-en-1-yl)nona-2,4,6,8-tetraen-1-ol; other names: retinol]; vitamin A; vitamin A<sub>1</sub>; vitamin A alcohol; vitamin A<sub>1</sub> alcohol; axerophthol; axerol; the predominant form of vitamin A in higher vertebrates and marine fishes (*compare* 3,4-dihydroretinol). It is stored primarily in the liver, almost entirely as the ester, retinyl palmitate.

retinoyl the acyl group formally derived from retinoic acid.

retinyl the alkyl group formally derived from retinol by loss of its hydroxyl group.

*retro+prefix* signifying backwards, or in the reverse direction.

retroendocytosis the process by which some particles, e.g. low-density lipoproteins, are released, after receptor-binding and endocytosis, back into the medium rather than being degraded within lysosomes.

**retrogene** a segment of DNA that has arisen by reverse transcription of the genetic material in an RNA virus (retrovirus) and incorporation of the DNA so formed into the host cell's genomic DNA.

**retrogradation** the spontaneous irreversible change of a liquid colloidal solution to an insoluble or gelled state. The term is used especially of aqueous amylose solutions in which micro-crystalline precipitates of aligned, hydrogen-bonded amylose molecules occur on standing.

**retrograde** 1 moving backwards; reverse or inverse; tending towards a former state or condition; deteriorating. 2 to move backwards or in reverse, as in retrograde transport.

retrogress to move backwards or in a less favourable direction; to deteriorate or degenerate. -retrogression *n.*; retrogressive *adj.*

retroinhibition *an alternative name for feedback inhibition.*

retropepsin EC 3.4.23.16; a pepsin-type endopeptidase from HIV that catalyses the hydrolysis of Xaa-1-Xbb bonds, where Xaa is a hydrophobic residue, and Xbb is variable, but often is Pro. It is part of the polyprotein product of the *pol* gene. This polyprotein also contains reverse transcriptase and ribonucle-

**retroposon**

ase H. Example from HIV-1; database code NRL\_1HHP, 99 amino acids (10.78 kDa); 3-D structure known.

**retroposon or retrotransposon** a transposable element that uses a mechanism indistinguishable from part of a retroviral life cycle. Retroposons are present in a wide variety of organisms, such as yeast, *Drosophila*, and mammals. A good example is the Ty1 element of yeast: after the formation of a double-stranded DNA by reverse transcriptase it is integrated into a random site on the chromosome.

**retroregulation** the regulation of translation of messenger RNA (mRNA) by a sequence that is downstream of the region undergoing translation. For example, an mRNA of phage lambda carrying the sequence of gene *int* is not normally translated; mutation in a site called *sib*, located downstream of the *int* coding sequence, allows translation of the *int* mRNA.

**retrotransposon** *an alternative name for retroposon.*

Retrovir *see zidovudine.*

**retroviral oncogene** *see oncogene, retrovirus.*

**retrovirus or ribodeoxyvirus or RNA-DNA virus** any virus belonging to the family Retroviridae. This comprises single-stranded RNA animal viruses characterized by two unique features: firstly, their genome is diploid, consisting of two copies of the RNA; secondly, this RNA is transcribed by the virion-associated enzyme reverse transcriptase into double-stranded DNA. This double-stranded DNA, or provirus, can then integrate into the host genome and be passed from parent cell to progeny cell as a stably integrated component of the host genome. The virion is an enveloped, roundish particle, ≈100 nm in diameter, with a helical nucleocapsid containing 6 MDa of RNA, consisting of two identical molecules of ≈3 MDa each, joined to their 5' ends and hydrogen-bonded into loops (70S RNA), plus small (45S) RNA from the host. The genome is bounded at each end by long terminal repeat sequences and comprises at least three genes: *gag*, which encodes for the inner capsid protein; *pol*, which codes for a polyprotein containing retropepsin, ribonuclease H (*see* ribonuclease), and reverse transcriptase; and *env*, which codes for the spikes on the envelope. Members of a subfamily of retroviruses, known as the Oncovirinae (or the RNA tumour viruses), contain an additional oncogene, which confers on the virus the ability to form tumours in the host. These oncoviruses include the Rous sarcoma virus and other leukosis viruses of birds, and a number of viruses causing leukemia in various mammals (not in humans). Tumour-producing retroviruses have also been called oDcornaviruses, rousviruses, and leukoviruses. Other subfamilies include the Spumavirinae (spumaviruses) and the Lentivirinae (lentiviruses); HIV is a member of the latter. The retroviruses are in class VI of the Baltimore classification.

**reverse dialysis** a technique for the concentration of macromolecules in solution. The (dilute) solution is placed in a bag made of a semipermeable material, through which the macromolecules cannot pass but water and other small molecules can. The bag is placed in a bed of dry water-soluble polymer (which cannot enter the membrane) such as polyethylene glycol. Water, together with other small molecules, is then drawn out of the bag into the external phase until equilibrium is reached, thereby concentrating the solution of macromolecules in the bag. *Compare* dialysis.

**reversed phase or reverse phase** a system used in adsorption chromatography (often thin-layer or high-pressure liquid chromatography), in which the stationary phase consists of a material with a hydrophobic surface. In such a system, molecules migrate in order of polarity, the most polar migrating fastest. In column chromatography, mobile phases are used in a sequence commencing with more polar solvents and proceeding in decreasing order of polarity, the reverse of the sequence used in normal phase chromatography. The stationary phase often consists of silicic acid in which all hydrophilic groups are masked by silanization.

**reversed rocket immunoelectrophoresis** a variant of

**reversible competitive antagonist**

rocket immunoelectrophoresis in which antibodies are forced by electrophoresis through antigen-containing agarose gel, the heights of the 'rockets' so formed being related to the antibody concentrations. It is useful for titre determinations in large series of antibody samples.

**reverse genetics** *another name for positional cloning a term coined to describe the study of the biological consequences to an organism of artificial alteration of its DNA. The changes may be either gross (e.g. deletion, insertion, or transposition of segments of DNA effected by recombinant DNA technology) or limited to specific loci (e.g. base substitution through site-directed mutagenesis).*

**reverse gyrase** an ATPase enzyme with a DNA helicase-like domain and a type-I (DNAtopoisomerase in the same protein. It is able to induce positive supercoiling into DNA, a property of DNA that is found only in bacteria that express this enzyme. Example (deduced from DNA sequence) from *Sulfolobus acidocaldarius* (an archaeabacterium): database code SSOREVGYRA, 780 amino acids (87.38 kDa).

**reverse mutation** a heritable change in a mutant gene that restores a nucleotide sequence to that which obtained prior to mutation. *Compare* back mutation, reversion.

**reverse osmosis** the pressure-induced flow of solvent through a semipermeable membrane in a direction that enhances any existing difference in the activities (or concentrations) of the nonpermeant solutes on the two sides of the membrane (*compare* osmosis). The principle can be used in the preparation of purified water from tap water or sea water.

**reverse phase** *see* reversed phase.

**reverse pinocytosis** *see* exocytosis.

**reverse transcriptase** EC 2.7.7.49; *recommended name:* RNA-directed DNA polymerase; *systematic name:* deoxynucleoside-triphosphate: DNA deoxynucleotidyltransferase (RNA-directed); *other names:* DNA nucleotidyltransferase (RNA-directed); revertase. A DNA polymerase enzyme, found particularly in retroviruses and possibly in normal animal cells, that uses either DNA or RNA as a template. It catalyses a reaction between a deoxynucleoside triphosphate and DNA, to form pyrophosphate and DNA.+1; this protein also has ribonuclease H(RNase H) activity. When the single-stranded RNA of the retrovirus enters a cell, the enzyme first makes a DNA copy of one of the long terminal repeats of the viral genomic RNA strand using a tRNA as a primer. The stretch of RNA used as a template is then digested by the RNase H activity of the enzyme, releasing the newly synthesized stretch of DNA which then pairs with a complementary stretch of viral RNA to form a DNA-RNA hybrid. This is then used by the same enzyme to make a double-stranded DNA which circularizes and integrates into a host cell chromosome. Examples: (i) AZT-resistant variant of HIV enzyme, database code A47175, 559 amino acids (64.32 kDa); 3-D structures known for parts of the HIV enzyme (database codes NRL\_IHRHA2, NRL\_IHRHB2); (ii) from *Escherichia coli* retrone EC67: database code RT67\_ECOLI, 586 amino acids (67.16 kDa). Reverse transcriptase lacks a proof-reading exonuclease function and is highly error-prone. It can thus evolve even within a single patient, and this interferes with long-term therapy. Reverse transcriptase is used in cDNA technology to make cDNA from RNA. Telomerase is a template-bearing reverse transcriptase.

**reverse transcription** the process carried out by reverse transcriptase. *See also* transcription.

**reverse turn** (*in protein structure*) a structural feature that allows the peptide chain to turn back through about 180° by what is termed a beta bend.

**reversible competitive antagonist** (*in pharmacology*) an antagonist for which the rate of dissociation from its receptor is relatively high, such that by increasing the concentration of an agonist the receptor occupancy (def. 2) of the antagonist falls. At sufficiently high concentrations of agonist a maximal tissue response can be obtained, even in the presence of the an-

tagonist, such that the extent of antagonism is determined by the relative concentrations of agonist and antagonist.

**reversible inhibition** (of an enzyme or other system) a type of inhibition that occurs when the equilibrium between free inhibitor and the inhibitor-enzyme (or system) complex lies sufficiently far towards the free inhibitor state for the inhibitor to be readily removed, leaving an active enzyme (or system).

**reversible reaction** a reaction in which the equilibrium constant is such that the reaction can be made to proceed at a detectable rate in either direction under appropriate conditions. **reversion** the restoration, by a second mutation, of the genomic base sequence of a mutant virus or organism to that of the parental strain. Less strictly, any return to the original phenotype. *See also* back mutation, reverse mutation.

**reversion frequency** the proportion of the total number of cells in a population that undergo reversion.

**reversion spectroscope** a spectroscope in which two spectra alongside each other, one of which is reversed by optical means, are formed by the entering light. The two spectra may be moved longitudinally relative to each other by moving a micrometer screw. If two absorption bands are aligned when a particular substance, e.g. oxyhemoglobin, is viewed, the amount by which the screw has to be turned to align the same band when a mixture of the same substance and another with a similar absorption spectrum, e.g. carbonmonoxyhemoglobin, is viewed is related to the proportion of the second substance present.

**revertant** 1 a mutant that has partially or completely regained the wild-type phenotype. 2 a gene that has undergone reversion.

**revertase** *an alternative name for* reverse transcriptase.

**Reynolds number symbol:** *Re*; a nondimensional parameter of fluid motion through a cylindrical tube or past an obstruction. It is given by the expression  $vI/\nu$ , where *I* has the dimensions of length, *v* is the fluid's velocity, and  $\nu$  is the kinematic viscosity. In general, low Reynolds numbers show that viscous forces predominate in controlling the flow, while high Reynolds numbers indicate that inertial forces are more important. [After Osborne Reynolds (1842-1912), Irish physicist and engineer.]

**RF abbr.** for 1 release factor. 2 replicative form.

**R factor** 1 *abbr. for* resistance factor (i.e. resistance plasmid). 2 (*formerly*) *abbr. for* release factor.

**rfDNA** *see* DNA.

**RFPLP abbr.** for restriction fragment length polymorphism.

**R form** 1 *abbr. for* relaxed form (of a protein). 2 R-form (hyphenated) *abbr. for* rough form; describing bacterial colonies with a jagged perimeter.

**RGD** the amino-acid sequence Arg-Gly-Asp, which is present in fibronectin and some other extracellular matrix proteins and is recognized by some integrins that bind these proteins.

**RGK-2** *see* tonin.

**RH** the negative logarithm of the concentration (expressed as pressure in atmospheres) of hydrogen gas in equilibrium with a redox system; i.e.

$$rH = -\log[H_2].$$

Also,

$$rH = 2(E_hF)/(RTlnlO) + pH,$$

where *F* is the Faraday constant, *R* the gas constant, *T* the thermodynamic temperature, and  $E_h$  the redox potential at the pH of the system under study.

**Rh** 1 *abbr. for* Rhesus factor. 2 *symbol for* rhodium.

**Rha** *symbol for* rhamnose.

**Rhabdoviridae** a family of single-stranded RNA viruses infecting vertebrates, arthropods, amoebae, and plants, whose members are identified by their elongated rod or bullet-shaped appearance. The virions are 70-80 nm particles, covered with a lipid envelope. They contain negative-strand RNA together with RNA-dependent RNA polymerase, which transcribes the genome directly to mRNA - they are class IV viruses in the

Baltimore classification. Rhabdoviruses are usually transmitted by arthropods; they include the plant rhabdoviruses, the vesiculoviruses (e.g. the vesicular stomatitis virus of cattle), the lyssaviruses, which include the rabies virus, and sigma virus of *Drosophila*. [From Greek *rhabdos*, rod.]

**rhabdovirus** *see* Rhabdoviridae.

**L-rhamnosamine** 2-amino-2,6-dideoxy-L-mannose; an amino sugar that occurs in some bacterial lipopolysaccharides.

**rhamnose symbol:** *Rha*; 6-deoxy-L-mannose; a monosaccharide (hexose) that occurs commonly as a compound of plant glycosides, in polysaccharides of gums and mucilages, and in bacterial polysaccharides; it is also a component of some plant cell-wall polysaccharides, and frequently acts as the sugar component of flavonoids. Free rhamnose is also found in some plants. The D-enantiomer occurs in some bacterial capsular polysaccharides. *See also* L-rhamnose isomerase.

**L-rhamnose isomerase** EC 5.3.1.14; *systematic name:* L-rhamnose ketol-isomerase; an enzyme that catalyses the interconversion of L-rhamnose and L-rhamnulose. It initiates the catabolism of rhamnose. L-rhamnulose is then phosphorylated by rhamnulose kinase, EC 2.7.1.5, to L-rhamnulose-1-phosphate which is cleaved by rhamnulose-1-phosphate aldolase, EC 4.1.2.19, to glyceraldehyde phosphate and (S)-lactaldehyde. Example from *Escherichia coli*: database code RHA\_ECOLI, 419 amino acids (47.12 kDa).

**rhamnulose 6-deoxyfructose**; its formation by L-rhamnose isomerase initiates rhamnose catabolism.

**rheology** the science concerning the deformation and flow of matter. -rheological *adj.*

**rheoseme** or flow signal a chemical messenger or transmitter substance (other than a neurotransmitter) carried from a site of generation to site of action within a cell (e.g. a neuron) by cytoplasmic flow; a translocated bioseme or second messenger. **rheostat** a device in which a controllable resistance is introduced into an electrical circuit to vary the output to permit an apparatus to be regulated within desired limits.

**Rhesus factor abbr.:** *Rh*; a protein associated with the rhesus (Rh) system of blood groups in humans. The system was so designated as a result of the finding that rabbit and guinea-pig antibodies raised against erythrocytes from *Macacus rhesus* monkeys agglutinated erythrocytes from 85% of the random human population. Initially an antigen, designated D, was isolated from the erythrocytes of Rh-positive individuals; those lacking D were classified Rh-negative. Subsequently, another antigen, LW (Landsteiner-Weiner), was identified, which, although phenotypically similar to D, is encoded by a gene that segregates independently from Rh. C and E antigens have also been found. The antigenic determinant is associated with the protein structure. In hemolytic disease of the newborn due to rhesus incompatibility, antibodies from a Rh-negative mother, often formed during the birth of a previous Rh-positive child whose blood has entered the mother's bloodstream, pass across the placenta and cause destruction of fetal red cells.

**rhinovirus** any of a group of small RNA viruses belonging to the Picornaviridae family, members of which are responsible for the common cold in humans, and foot-and-mouth disease in cattle.

**Rhizobium** a genus of soil bacteria whose members reside in specialized root nodules of leguminous plants and set up a symbiosis. The bacteria are active in nitrogen fixation providing the plant with organic nitrogen and obtaining carbon compounds in return. Many if not all *Rhizobium* species contain plasmids, which enable them to colonize their host plant species.

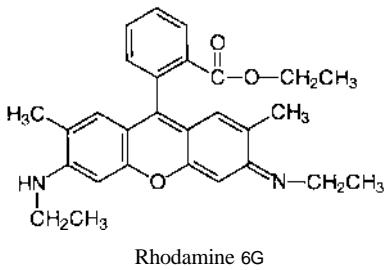

**rhizomorph** a stout, rootlike mass of hyphae, produced by some fungi, that serves to generate vegetative spread.

**rho symbol:** *p* (lower case) or *P* (upper case); the seventeenth letter of the Greek alphabet. For uses *see* Appendix A. *See also* rho protein, Rho protein.

**Rhodamine** any of a series of dyes based on 9-(2-carboxyphenyl)xanthine. Rhodamine 6G, N-[9-(2-carboxyethyl)phenyl]-

## rhodanese

6-(diethylamino)-3H-xanthen-3-ylidene]ethylethanamine, is used as a spray to reveal lipids as pink fluorescent spots after thin-layer chromatography.

**rhodanese** EC 2.8.1.1; *recommended name*: thiosulfate sulfur-transferase; *systematic name*: thiosulfate:cyanide sulfur-transferase; *other names*: thiosulfate cyanide transsulfurase; thiosulfate thiotransferase. An enzyme that catalyses the displacement of sulfite from thiosulfate by cyanide ion, forming sulfite and thiocyanate and thus detoxifying cyanide. It is of interest structurally in having two domains of closely similar conformation yet very different sequence. Example from *Gallus gallus* (chicken): database code THTR\_CHICK, 289 amino acids (32.25 kDa). [From the use of rhodanate as a name for thiocyanate.]

**rhodanide** any of a group of thiocyanates produced by the metabolism of mustard-oil glycosides (glycosinolates) in damaged leaf tissues.

**rhodium symbol**: Rh; a silvery-white metallic transition element of group VIII of the (IUPAC) periodic table; atomic number 45; relative atomic mass 102.9. It occurs mainly in oxidation state III. A rare member of the platinum metals, it possesses marked properties of nobility, being, e.g., resistant to nitric acid and aqua regia.

**rhodo+** or (*before a vowel*) **rhod+** *comb. form* indicating a red colour, or the odour of a rose. [From Greek *rhodos*, rose.]

**rhodopsin** or visual purple a brilliant purplish-red, light-sensitive visual pigment found in the rod cells of the retinas of most vertebrates (exceptions being freshwater and migratory fish and some amphibians). It is a seven-transmembrane-domain protein homologous to other members of the G-protein-linked receptor family. It consists of a rod-type opsin combined (as a 8chiffs base) with 11-cis-retinal (*see* retinal). It has an absorption maximum at  $\approx 500$  nm. *Compare* porphyropsin. A single amino-acid substitution in the rhodopsin molecule causes one form of retinitis pigmentosa in humans. *See also* bacteriorhodopsin, halorhodopsin, slow-cycling rhodopsin.

**rho factor** an alternative name for rho protein.

**rho protein** or (*sometimes*) rho factor a bacterial protein, an ATP-dependent helicase, that facilitates transcription termination. Binding of rho to the nascent RNA is followed by activation of rho's RNA-dependent ATPase activity, and release of the mRNA from the DNA template; it recognizes and binds to C-rich regions of the RNA transcript. In *Escherichia coli* this protein is the site of action of the antibiotic bicyclomycin, which binds to rho protein and inhibits its ATPase activity. Example from *E. coli*: database code RHO\_ECOLI, 419 amino acids (46.95 kDa). *Compare* Rho protein.

**Rho protein** a small Ras-related GTPase (*see* RAS*j*), involved in controlling the polymerization of actin into filaments, and subsequent organization. **RHOB** is an early response gene transiently induced in fibroblasts by platelet-derived growth factor or epidermal growth factor; its overexpression can be tumorigenic. *Compare* rho protein.

**RI abbr.** for refractive index.

**RIA abbr.** for radioimmunoassay.

**Rib symbol** for ribose.

## ribonuclease

**ribaric acid** one of the pentarie acids. *See also* aldaric acid. **ribitol** or (*formerly*) adonitol a pentitol derived formally by reduction of the -CHO group of either D- or L-ribose. It is a meso compound and does not require a D or L configurational descriptor. It occurs free in some plants and is a component of riboflavin.

**ribitol teichoic acid** a complex polymer of ribitol residues linked by phosphate groups, substituted by glucosyl or acetylglucosamine residues and ester-linked to D-alanine. It is found in the walls of Gram-positive bacteria.

**ribo+** *comb. form* 1 of, relating to, or containing ribose, especially as opposed to deoxyribose. 2 containing a ribose residue linked through its anomeric carbon. It is used also in riboflavin, inappropriately, for a ribitol residue.

**ribo-** *prefix* (*in chemical nomenclature*) indicating a particular configuration of three contiguous >CHOH groups (as found in the acyclic form of D- or L-ribose). *See also* monosaccharide.

**ribocharin** an acidic protein specifically associated with the granular component of the nucleolus and nucleoplasmic 65S particles. These particles contain the nuclear 288 rRNA and may represent the precursor to the large ribosomal subunit.

**ribodeoxyvirus** (*sometimes*) any RNA virus that replicates via DNA; such viruses are now usually known as retroviruses. *Compare* deoxyribovirus.

**riboflavin** an alternative name for vitamin 8<sub>2</sub>.

**ribofuranosyl** an alternative term for ribosyl.

**ribonuclease abbr.**: RNase or (*sometimes*) RNAase; any of a group of nuclease enzymes that cleave phosphodiester bonds in chains of RNA. With the exception of RNase P, which is a ribozyme, they are all proteins. As in the case of other enzymes that hydrolyse macromolecules, RNases are classified according to whether they are exoribonucleases, catalysing sequential cleavage of mononucleotides from either a free 5' or 3' terminus, or both, or endonucleases, cleaving bonds within the polyribonucleotide chain. Endonucleases, which unlike exonucleases can cleave circular molecules of RNA, fall into further categories according to whether they cleave only specific sites or at any phosphodiester linkage. Enzymes that cleave RNA fall into eight subclasses: EC 3.1.13, exoribonucleases producing 5'-phosphomonoesters; EC 3.1.14, exoribonucleases producing other than 5'-phosphomonoesters; EC 3.1.15, exonucleases active with either ribo- or deoxyribonucleic acids and producing 5'-phosphomonoesters; EC 3.1.16, exonucleases active with either ribo- or deoxyribonucleic acids and producing other than 5'-phosphomonoesters; EC 3.1.26, endoribonucleases producing 5'-phosphomonoesters; EC 3.1.27, endoribonucleases producing other than 5'-phosphomonoesters; EC 3.1.30, endonucleases active with either ribo- or deoxyribonucleic acids and producing 5'-phosphomonoesters; and EC 3.1.31, endonucleases active with either ribo- or deoxyribonucleic acids and producing other than 5'-phosphomonoesters. Ribonucleases include enzymes having mechanisms of (A) phosphotransferases, (B) phosphodiesterases, or (C) phosphorylases. In group C are polynucleotide phosphorylase and polynucleotide pyrophosphorylase. The differences between groups A and B are more than pedantic. Thus the feature of group A is the involvement of the 2'-OH group in an intramolecular attack at the adjacent phosphodiester bond, in addition to a property for conferring specificity for one or more of the four bases. The nucleoside 2':3'-cyclic phosphates are obligate intermediate products. In group B, a direct attack of water on the 3':5'-phosphodiester bond is catalysed. This latter group includes, therefore, the enzymes that hydrolyse both RNA and DNA and those that cleave diester bridges in RNA to form only 5'-nucleotide products. Thus group A enzymes may be classed as cyclizing and group B enzymes as non-cyclizing. The group A enzymes do not depend for their activity on divalent cations whereas the group B enzymes require Mg<sup>2+</sup> or Ca<sup>2+</sup>. Within each group of enzymes there are many types, as described below.

Exoribonucleases catalyse the sequential cleavage of mono-

nucleotides from one or other, or both, ends of the polynucleotide. Exoribonuclease II EC 3.1.13.1; *other name*: ribonuclease II; reaction: exonucleolytic cleavage in the 3'- to 5'-direction to yield 5'-phosphomononucleotides. Exoribonuclease H EC 3.1.13.2; reaction: exonucleolytic cleavage to 5'-phosphomonooester oligonucleotides in both 5'- to 3'- and 3'- to 5'-directions. Example from *E. coli*: database code RNB\_ECOLI, 644 amino acids (72.4 kDa). Poly(A)-specific ribonuclease EC 3.1.13.4; reaction: exonucleolytic cleavage of poly(A) to 5'-AMP. Yeast ribonuclease EC 3.1.14.1; reaction: exonucleolytic cleavage to 3'-phosphomononucleotides.

Endoribonucleases cleave the polynucleotide internally. This first group (sub-subclass EC 3.1.26) produce exclusively 5'-phosphomonooesters. *Physarum polycephalum* ribonuclease EC 3.1.26.1; reaction: endonucleolytic cleavage to 5'-phosphomonooester. Ribonuclease alpha EC 3.1.26.2; reaction: endonucleolytic cleavage to 5'-phosphomonooester. Ribonuclease III EC 3.1.26.3; *other names*: RNase O; RNase D; reaction: endonucleolytic cleavage to 5'-phosphomonooester. Example from *Rhodobacter capsulatus*: database code RCLEPRNCG, 265 amino acids (28.8 kDa). Ribonuclease H EC 3.1.26.4; *other names*: endoribonuclease H (calf thymus); calf thymus ribonuclease H; reaction: endonucleolytic cleavage to 5'-phosphomonooester; required for removing RNA from Okazaki fragments; see also RNA-directed DNA polymerase. Ribonuclease P EC 3.1.26.5; reaction: endonucleolytic cleavage of RNA, removing 5'-sequence of extra nucleotides from tRNA precursor; it is a ribozyme; see RNase P. Ribonuclease IV EC 3.1.26.6; *other names*: endoribonuclease IV; poly(A)-specific ribonuclease; reaction: endonucleolytic cleavage of poly(A) to fragments terminated by 3'-hydroxyl and 5'-phosphate groups. Example from yeast: PAN1\_YEA8T, 1480 amino acids (160 kDa). Ribonuclease P4 EC 3.1.26.7; reaction: endonucleolytic cleavage of RNA, removing 3'-sequence of extra nucleotides from tRNA precursor. Ribonuclease M5 EC 3.1.26.8; *other name*: 58 rRNA maturation nuclease; reaction: endonucleolytic cleavage of RNA, removing 21 and 42 nucleotides, respectively, from the 5'- and 3'-termini of a 58 rRNA precursor. Ribonuclease (poly(U)-specific) EC 3.1.26.9; reaction: endonucleolytic cleavage of poly(U) to fragments terminated by 3'-hydroxyl and 5'-phosphate groups. Ribonuclease IX EC 3.1.26.10; reaction: endonucleolytic cleavage of poly(U) or poly(C) to fragments terminated by 3'-hydroxyl and 5'-phosphate groups.

The second group of endoribonucleases (sub-subclass EC 3.1.27) yield products other than 5'-phosphomonooesters. Ribonuclease T2 EC 3.1.27.1; *other name*: ribonuclease II; reaction: two-stage endonucleolytic cleavage to 3'-phosphomononucleotides and 3'-phosphooligonucleotides with 2',3'-cyclic phosphate intermediates. Example (glycoprotein precursor) from *Aspergillus oryzae*: database code RTN2\_A8POR, 276 amino acids (30.71 kDa); residues 1-17 are the signal. *Bacillus subtilis* ribonuclease EC 3.1.27.2; reaction: endonucleolytic cleavage to 2',3'-cyclic nucleotides. Ribonuclease T1 EC 3.1.27.3; *other names*: guanylribonuclease; *Aspergillus oryzae* ribonuclease; ribonuclease NI; ribonuclease N2; reaction: two-stage endonucleolytic cleavage to 3'-phosphomononucleotides and 3'-phosphooligonucleotides ending in G-p with 2',3'-cyclic phosphate intermediates. Database code NRL\_5RNT, 104 amino acids (11.08 kDa); 3-D structure known, including bound intermediate. Ribonuclease U2 EC 3.1.27.4; reaction: two-stage endonucleolytic cleavage to 3'-phosphomononucleotides and 3'-phosphooligonucleotides ending in Ap or Gp with 2',3'-cyclic phosphate intermediates. Example from the smut fungus, *Ustilago sphaerogena*: database code RNU2\_U8TSP, 113 amino acids (12.26 kDa). Pancreatic ribonuclease EC 3.1.27.5; *other names*: ribonuclease; ribonuclease I; ribonuclease A; reaction: endonucleolytic cleavage to 3'-phosphomononucleotides and 3'-phosphooligonucleotides ending in Cp or Up with 2',3'-cyclic phosphate intermediates. Example (bovine): database

code NRL\_3RN3, 124 amino acids (13.68 kDa); 3-D structure known. *Enterobacter* ribonuclease EC 3.1.27.6; reaction: endonucleolytic cleavage to 3'-phosphomononucleotides and 3'-phosphooligonucleotides with 2',3'-cyclic phosphate intermediates. Example (precursor) from *E. coli*: database code RNLECOLI, 268 amino acids (29.58 kDa); residues 1-23 are the signal sequence. Ribonuclease F EC 3.1.27.7; reaction: endonucleolytic cleavage of RNA precursor into two, leaving 5'-hydroxyl and 3'-phosphate groups. Ribonuclease V EC 3.1.27.8; *other name*: endoribonuclease V; reaction: hydrolysis of poly(A), forming oligoribonucleotides and ultimately 3'-AMP. Compare deoxyribonuclease.

**ribonuclease 1 abbr.:** RNA; any anionic form of ribonucleic acid. 2 any salt of ribonucleic acid.

**ribonucleic acid abbr.:** RNA; *former names*: pentose nucleic acid (*abbr.*: PNA); ribose nucleic acid; yeast nucleic acid. See RNA.

**ribonucleoprotein abbr.:** RNP; any conjugated protein that contains RNA as the nonprotein moiety. Various specific kinds of RNP are listed with their abbreviations at RNP.

**ribonucleoside** any nucleoside (def. 1) in which the glycoside moiety is p-o-ribofuranose. The link is from C-1 of ribose to N-9 of a purine or to N-1 of a pyrimidine. To distinguish between the numbering systems of the base and sugar, the numbers of the sugar atoms are characterized by the addition of 'prime', i.e. 1' to 5'. The various products have trivial names, e.g. adenosine, guanosine, cytidine, and uridine. Strictly, the term ribonucleoside should be confined to structures occurring in nucleic acids, but it can be used for any base-ribose compound. By extension, it can be applied to pseudouridine (which occurs in tRNA) with a C-C link between ribose and uracil.

**ribonucleoside-diphosphate reductase** *the recommended name for* nucleoside-diphosphate reductasa.

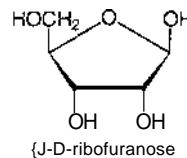

**ribonucleoside-triphosphate reductase** *the recommended name for* nucleoside-triphosphate reductase.

**ribonucleotide** any ribonucleoside in ester linkage to phosphate, commonly at the 5' position of the ribose moiety, although some 2'- and 3'-esters and some (cyclic) 2',3'-, or 3',5'-diesters are known. The 5'-ribonucleotides are metabolically important; they may be esters of [mono]phosphate, diphosphate, or triphosphate, e.g. guanosine 5'-(mono)phosphate, cytidine 5'-diphosphate, adenosine 5'-triphosphate. See nucleotide.

**ribonucleotide reductase** any enzyme that catalyses the reduction of ribonucleotides to deoxyribonucleotides during biosynthesis. See nucleoside-diphosphate reductase, nucleoside-triphosphate reductase.

**ribophorin** either of two types of protein, ribophorins I and II, that form two essential subunits of N-oligosaccharyltransferase. They were originally isolated as ribosome-binding proteins of rough endoplasmic reticulum. Examples from human: ribophorin I: database code RIB1\_HUMAN, 607 amino acids (68.57 kDa); ribophorin II: database code RIB2\_HUMAN, 631 amino acids (69.30 kDa).

**ribose symbol:** Rib; *ribo-pentose*. The D enantiomer, as {J-o-ribofuranose, forms the glycone moiety of all ribonucleosides, ribonucleotides, and ribonucleic acids, and also of ribose phosphates, various glycosides, some coenzymes, and some forms of vitamin B<sub>12</sub>.

**ribose nucleic acid** *a former name for* ribonucleic acid.

**ribose-S-phosphate epimerase** EC 5.3.1.6; *systematic name*: 0-ribose-5-phosphate ketoI-isomerase; *other names*: phospho-

## ribose-phosphate pyrophosphokinase

pentoisomerase; phosphoriboisomerase. An enzyme that catalyses the reaction:

It is an enzyme of pentose metabolism, especially the pentose phosphate pathway. Example from *Escherichia coli*: database code RP1A\_ECOLI, 219 amino acids (22.83 kDa).

**ribose-phosphate pyrophosphokinase** EC 2.7.6.1; *other name*: phosphoribosyl pyrophosphate synthetase (*abbr.*: PRS); an enzyme that catalyses the formation of 5-phospho-a-D-ribose-1-diphosphate (*abbr.*: PRPP; *other name*: phosphoribosyl pyrophosphate) from ATP and D-ribose 5-phosphate with release of AMP; it is Mg<sup>2+</sup>-dependent. PRPP is an intermediate in the biosynthesis of histidine and tryptophan, and in the *de novo* biosynthesis of purines and pyrimidines. The enzyme has a well-conserved sequence. Examples: in human there are two isoforms: PR8-II (also in rat); database code KPRL\_HUMAN, 317 amino acids (34.66 kDa); PRS-II: database code KPR2\_HUMAN, 317 amino acids (34.60 kDa).

riboside the product of the formation of a glycosidic bond between ribose and another group, either through the nitrogen of an amine or a hydroxyl group, i.e. via N- or O-glycosidic linkages. *See also* pseudouridine. Compare ribonucleoside.

**ribosomal DNA** *abbr.*: rDNA; the DNA of the genes coding for ribosomal RNA (*see* ribosome).

**ribosomal protein** *abbr.*: r-protein; any of the protein components of the ribosomal subunits. They are typically small, and some are basic. Ribosomal proteins are referred to as S (small subunit) proteins and L (large subunit) proteins; in *Escherichia coli* there are 21 S proteins, designated S1-S21, and 34 L proteins, designated L1-L34. In eukaryotes (e.g. rat liver) there are 33 S proteins and 49 L proteins. *See also* ribosome.

**ribosomal RNA** *abbr.*: rRNA; *see* ribosome.

ribosome an intracellular organelle, about 200 Å in diameter, consisting of RNA and protein. It is the site of protein biosynthesis resulting from translation of messenger RNA (mRNA). It consists of two subunits, one large and one small, each containing only protein and RNA. Both the ribosome and its subunits are characterized by their sedimentation coefficients, expressed in Svedberg units (*symbol*: S). Hence, the prokaryotic ribosome (70S) comprises a large (50S) subunit and a small (30S) subunit, while the eukaryotic ribosome (80S) comprises a large (60S) subunit and a small (40S) subunit. Several ribosomes may bind to one mRNA to form a polysome. Two sites on the ribosomal large subunit are involved in translation, namely the aminoacyl site (A site) and peptidyl site (P site). Ribosomes from prokaryotes, eukaryotes, mitochondria, and chloroplasts have characteristically distinct ribosomal proteins. Prokaryotic ribosomes contain 35-45% protein, while eukaryotic ribosomes contain 50% protein. Ribosomal RNA (rRNA) is RNA that forms part of the ribosomal structure. In prokaryotes, a 30S ribosomal subunit contains one 16S RNA molecule with associated proteins, while a 50S subunit contains one 5S and one 23S RNA molecule. In eukaryotes, the 60S subunit contains one 28S, one 5.85, and one 55 RNA molecule, while the 40S subunit contains one 18S RNA molecule. The structures are known. In *Escherichia coli*, the rRNAs are synthesized as part of a large transcript containing transfer RNA (tRNA) molecules, which is then cleaved during processing. In eukaryotes, the genes for the 5.88, 18S, and 28S molecules reside in the nucleolus, and code for a 405 transcript, which is then cleaved during processing; this includes splicing that occurs in the absence of protein. The gene for the 5S rRNA is a separate transcription unit outside the nucleolus. *See also* mRNA binding site, protein biosynthesis.

**ribosome-inactivating protein** *abbr.*: RIP; any of a group of proteins, obtained from plants, that inactivate eukaryotic ribosomes. They are of two types. Type I proteins have a single chain, and include agrostin, dianthrin, dodecandrin, gelonin, luffin, nomordin, saporin, and tritin. They are enzymes, EC

## ribothymidylic acid

3.2.2.22, that catalyse endohydrolysis of the N-glycosyl bond at one specific adenosine on 28S rRNA. They are plant protein toxins and possibly have antiviral activity. Examples: luffin, from the smooth loofah, *Luffa cylindrica*, has two subunits; precursor sequences: database code RIPA\_LUFCY, 277 amino acids (30.18 kDa), and database code RIPB\_LUFCY, 250 amino acids (27.26 kDa); saporinD-2 from *Saponaria officinalis*: database code RIP2\_SAPOF, 292 amino acids (32.77 kDa); the protein from wheat is called tritin, database code S33631, 275 amino acids (29.58 kDa); that from *Phytolacca dodecandra* is dodecandrinD, fragmentary data in database code S32971. Type II ribosome-inactivating proteins are enzymes with a similar action to the type I proteins, but have an additional covalently bound chain with lectin properties. They include abrin, modeccin, ricin, viscumin, and volvensin.

**ribosome recycling 'actor** *abbr.*: RRF; *formerly known as* ribosome releasing factor; a factor which, in bacteria is required for the recycling of ribosomes through decomposition of the termination complex following release-factor-mediated release of the completed polypeptide chain from the peptidyl tRNA. Example from *Escherichia coli*: database code RRF\_ECOLI, 185 amino acids (20.61 kDa).

**ribosyl** or **ribofuranosyl** any glycosyl group formally derivable from the α- or the β-furanose forms of D- or L-ribose. (The pyranose forms of ribose are exhibited only by the uncombined sugar.)

**ribosylate** to add a ribosyl residue. Compare ADP-ribosylation.

**ribosylthymine** *an alternative name for* ribothymidine.

**ribosylthymine monophosphate** *an alternative name for* ribothymidine monophosphate.

**ribosylthymine phosphate** *an alternative name for* ribothymidine phosphate.

**ribothymidine** or **ribosylthymine symbol**: T or Thd; 5-methyluridine; thymine riboside; 1-p-D-ribofuranosyl-5-methyluracil; a rare ribonucleoside, found as a minor component of many species of transfer RNA, where it is present as a residue of its 5'-phosphate. *See also* ribothymidine 5'-phosphate. Compare thymidine.

**ribothymidine monophosphate** or **ribosylthymine monophosphate abbr.**: TMP; *the common name for* any ribothymidine phosphate, particularly for ribothymidine 5'-phosphate.

**ribothymidine phosphate** or **ribosylthymine phosphate** ribothymidine monophosphate or ribosylthymine monophosphate (*abbr.*: TMP); any phosphoric monoester or diester of ribothymidine. Of the three possible monoesters - the 2'-phosphate, the 3'-phosphate, and the 5'-phosphate – and the two possible diesters – the 2',3'-phosphate and the 3',5'-phosphate – only ribothymidine 5'-phosphate is of any significance (the locant therefore being omitted if no ambiguity may arise).

**ribothymidine 5'-phosphate** or **ribosylthymine 5'-phosphate** or **5'-ribotbymidylc acid symbol**: Thd5'P or PT; *the alternative recommended names for* ribothymidine monophosphate or ribosylthymine monophosphate (*abbr.*: TMP); 5'-ribothymidyl phosphate; thymine riboside 5'-(dihydrogen diphosphate); thymine (mono)ribonucleotide. (The locant is commonly omitted if there is no ambiguity as to the position of phosphorylation.) A residue of ribothymidylic acid occurs in many species of transfer RNA, where it is formed *in situ* by methylation of the uracil moiety of an existing uridylic acid residue. This modification is effected by tRNA (uracil-5)-methyltransferase (EC 2.1.1.35), the methyl group being derived from S-adenosyl-L-methionine.

**ribothymidylate** 1 either the monoanion or the dianion of ribothymidylic acid. 2 any mixture of ribothymidylic acid and its anions. 3 any salt or ester of ribothymidylic acid.

**ribothymidylic acid** *the trivial name for* any phosphoric monoester of ribothymidine. The position of the phosphoric residue on the ribose moiety of a given ester may be specified by a prefixed locant - *see* ribothymidine phosphate. However, 5'-ribothymidylic acid is the ester commonly denoted, its locant usually being omitted if no ambiguity may arise. 5'-ribo-

**ribothymidyl**

thymidylic acid is also an alternative recommended name for ribothymidine 5'-phosphate.

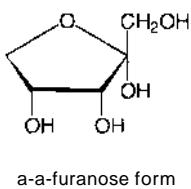

**ribothymidyl** the ribothymidine[mono]phospho group; the acyl group derived from **ribothymidyl acid**.

**ribovirus** an alternative name for **viroid**.

**ribozyme** an RNA molecule with catalytic activity. Such activity was first discovered by Sidney Altman in 1981 for **RNase P**. Thomas R. Cech in 1982 discovered the catalysis by RNA of the reactions involved in the **splicing** of ribosomal RNA from *Tetrahymena*. In this reaction a 414-nucleotide **intron** is removed from a 6.4 kb precursor to yield the mature 26S rRNA molecule. A guanosine nucleotide is essential in the reaction, binding to the RNA and then attacking the 5' splice site to form a phosphodiester bond with the 5' end of the intron. After further reactions the 414-nucleotide intron is released and undergoes two further splicing reactions to produce a linear RNA of 395 nucleotides which has lost 19 nucleotides and is named L19. L19 is catalytically active and is a true enzyme acting both as a nuclease and a polymerase. The rate of conversion of a pentacytidylate into longer and shorter oligomers is about  $10^{10}$  times the uncatalysed rate. Mg<sup>2+</sup> plays an essential role. Much smaller ribozymes have been demonstrated, e.g. the **viroids** which infect plants and undergo self-splicing after replication. Comparisons of nucleotide sequences in the vicinity of specific cleavage sites suggest that the active site has a **hammerhead** secondary structure consisting of three helical regions radiating from a central core of unpaired nucleotides. mRNA precursors in the mitochondria of yeast and fungi also undergo self-splicing as do some RNA precursors in chloroplasts. Such reactions can be classified according to the nature of the unit that attacks the upstream splice site. Group I are mediated by a guanosine cofactor. In group II the attacking moiety is the 2'-OH of a specific adenylate of the intron. Such reactions resemble those that occur in the **spliceosomes**. The work on ribozymes has a special interest in respect of theories on the origin of life because those interested in the origin of life on earth favour the idea that the first macromolecules were composed of RNA. The fact that RNA can catalyse reactions lends support to their views. See also **ribonuclease**.

**Rib5'ppA** symbol for adenosinediphosphoribose (alternative to *AdoPPRib* or *A5'pp5Rib*).

**o-ribulose** a nonsystematic name for the ketopentose *D*-erythro-2-pentulose.

**D-ribulose 1,5-bisphosphate** abbr.: RBP or RuBP; former name: ribulose diphosphate (abbr.: RDP or RuDP); a key metabolite of the **reductive pentose phosphate cycle**. It is formed in a reaction in which ribulose 5-phosphate is phosphorylated by ATP, catalysed by phosphoribulokinase, EC 2.7.1.19, and is a substrate of **ribulose-bisphosphate carboxylase**.

**ribulose-bisphosphate carboxylase** EC 4.1.1.39; systematic name: 3-phospho-D-glycerate carboxy-lyase (dimerizing); other names: ribulose-bisphosphate carboxylase/oxygenase (abbr.: Rubisco); the key enzyme in the fixation of *CO<sub>2</sub>* in the **reductive pentose phosphate cycle**; a copper protein. One molecule of D-ribulose 1,5-bisphosphate reacts with one molecule of *CO<sub>2</sub>* to yield two molecules of 3-phospho-D-glycerate, which can be converted into a hexose product (fructose 6-phosphate). If, as is possible, D-ribulose 1,5-bisphosphate reacts with *O<sub>2</sub>* instead of *CO<sub>2</sub>*, the products are one molecule each of 3-phospho-D-glycerate and 2-phosphoglycolate. This

**rifamycin**

enzyme comprises up to 50% of leaf proteins and is the most abundant protein in the biosphere. Examples, all from tomato: large chain precursor: database code RBL\_LYCES, 477 amino acids (52.62 kDa); small chain I precursor (less 17): database code RBSLLYCES, 181 amino acids (20.28 kDa); small chain 2a precursor (less 5): database code RBS2\_LYCES, 180 amino acids (20.25 kDa); small chain 3a/3c precursor: database code RBS3\_LYCES, 180 amino acids (20.21 kDa); small chain 3b precursor: database code RBS4\_LYCES, 180 amino acids (20.19 kDa).

**D-ribulose 5-phosphate** the 5-phosphate ester of D-ribulose; it is a component of the **pentose phosphate pathway**, the product of 6-phosphogluconate dehydrogenase. It is converted to ribulose 1,5-bisphosphate in the **reductive pentose phosphate cycle** of photosynthesis.

**L-ribulose-phosphate 4-epimerase** EC 5.1.3.4; an enzyme that catalyses the reaction:

Example: *araD* gene product from *Escherichia coli*: database code ARAD\_ECOLI, 231 amino acids (25.49 kDa).

**Richner-Ranhart syndrome** see **tyrosine transaminase**.

**ricin** a highly toxic lectin obtained from the seeds of the castor oil plant, *Ricinus communis*. It is a 493 amino-acid glycoprotein dimer comprising an A chain (*M<sub>r</sub>* 66 000) and a B chain (*M<sub>r</sub>* 34 000) linked by a disulfide bond. Ricin binds to the cell via interaction between the B chain and galactose groups on cell-surface receptors; then the disulfide bond is cleaved allowing the A chain to enter the cell. The A chain then binds to the proteins of the 60S ribosomal subunit, apparently in the region of binding of elongation factors eEF-1 and eEF-2, thereby halting protein translation. Protein from *R. communis* (precursor): database code RICL\_RICCO, 576 amino acids (64.09 kDa). See also **abrin**, **ribosome-inactivating protein**.

**rickets or rachitis** a disturbance of calcium (and phosphate) metabolism in young growing animals (including humans), resulting from a deficiency of **vitamin D** or of its activation. It is characterized by softening of the bones and skeletal deformities, particularly bowing of the legs.- **rachitic** adj.

**RID** abbr. for radial immunodiffusion.

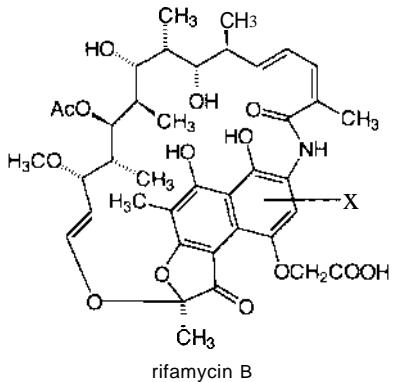

**RIEP** abbr. for rocket immunoelectrophoresis.

**Rieske protein** EC 1.10.99.1; recommended name: plastoquinol-plastocyanin reductase; systematic name: plastoquinol:oxidized-plastocyanin oxidoreductase; one of the four subunits of the cytochrome *b<sub>6</sub>-f* complex. An enzyme that catalyses a reaction between plastoquinol-1 and two molecules of oxidized plastocyanin to form plastoquinone and two molecules of reduced plastocyanin. It is a high-potential 2Fe-2S protein. Example, precursor from tobacco: database code UCRLTOBAC, 228 amino acids (24.12 kDa). Apart from the Rieske protein the subunits of the *b<sub>6</sub>f* complex consist of **cytochromes b<sub>6</sub>** and f and a 17 kDa peptide; it is similar to other iron-sulfur proteins (e.g. in mitochondria) and has three motifs.

**rifampicin or rifampin** an antibiotic, *M<sub>r</sub>* 823, obtained as a semisynthetic derivative of rifamycin B, from which it differs only in the substituents on the ring marked X in the structure for that compound. It acts by inhibiting bacterial transcription, and is effective in sensitive bacteria (see **rifamycin**) at extremely low concentrations (0.01 µg ml<sup>-1</sup>) while having no effect on eukaryotic transcription at 10<sup>4</sup> times that dose. Mitochondrial and chloroplast transcription may be affected at higher doses. It is stable when stored dry at 4 °C in the absence of light. In addition to its use as an antibiotic it has application in molecular biology as an agent for removing plasmids from bacteria in a process known as **plasmid curing**.

**rifamycin** any of a group of closely related anti-transcription antibiotics produced by *Streptomyces mediterranei* that are active against Gram-positive bacteria and *Mycobacterium tuberculosis* but are much less effective against Gram-negative organisms. Chemically and functionally they are closely re-

lated to the streptovaricins, and collectively the two groups are referred to as ansamycins – they are characterized by a chromophoric naphthohydroquinone nucleus spanned by a long aliphatic bridge. The mode of action of ansamycins involves inhibition of bacterial but not eukaryotic RNA synthesis via binding to the  $\beta$  subunit of bacterial DNA-dependent RNA polymerase and prevention of chain initiation; chain elongation is not affected once the initiation of RNA chain synthesis progresses beyond the third diester bond.

**rigid** (*in lipid biochemistry*) a term sometimes used to describe the ordered phase of a lipid bilayer below the phase transition temperature. *See* phase transition (of lipids).

**Rimington, Claude** (1903-93), British biochemist, distinguished for porphyrin research. With two coauthors he suggested (1968) that the British king, George III, suffered from variegate porphyria at a time preceding and during the American revolution. The hypothesis remains unproven and the cause of the king's deranged personality remains unknown.

**rimorphin** a 13-residue peptide that is a major Leu-enkephalin-containing peptide in tissues that contain dynorphin and  $\alpha$ -neo-dynorphin. It yields three enkephalin sequences.

**ring closure** the formation of a covalent bond that converts a linear molecule into a ring structure.

**Ringer, Sydney** (1835-1910), British physician and physiologist who devised Ringer's solution.

**Ringer-Locke solution** a less common name for Locke's solution.

**Ringer's solution** or **Ringer solution** any of a number of aqueous solutions of mixed inorganic salts, of composition determined empirically by Ringer or adapted therefrom, that have been useful as fluid replacements *in vivo* Dr in place of serum as perfusing Dr suspending media for organs, tissues, or cells *in vitro*. Ringer's own mixtures (reported over the period 1882-87) were devised mostly for maintaining normal contractility of perfused isolated frog heart. One of the most effective solutions contained (in g L<sup>-1</sup>, approx.) NaCl (7.0), KCl (0.04), CaCl<sub>2</sub> (anhydrous, 0.09), and NaHCO<sub>3</sub> (0.5). *See also* Krebs' mammalian Ringer, Locke's solution, Tyrode's solution.

**Ringer-Tyrode solution** a less common name for Tyrode's solution.

**RING finger** a zinc finger motif defined as

and present in a family of nuclear proteins.

**ring opening** the breaking of a bond that converts a ring structure to an open-chain form.

**RIP** abbr. for 1 repeat-induced point (mutation); a phenomenon found in *Neurospora*; when more than one copy of a DNA sequence is present in a haploid genome that goes through a cross, both ectopic and endogenous copies are subject to point mutation at a high rate. RIP occurs in the dikaryotic ascogenous hyphae. Because transformation of *Neurospora* typically leads to gene amplification, RIP provides a highly efficient

and selective method of introducing mutations *in vivo* in any gene cloned *in vitro*. 2 ribosome-inactivating protein.

**RISBASES** proteins that have sequence similarity with members of the ribonuclease family but are thought not to function as ribonucleases. Examples are bovine seminal RNase and angiogenin. [From ribonuclease with special biological action.]

**RIST** abbr. for radioimmunosorbent test.

**ristocetin** a glycopeptide antibiotic complex from *Nocardia lurida*. Ristocetin A, M<sub>r</sub> 2066, acts primarily on Gram-positive bacteria by inhibiting the biosynthesis of peptidoglycans, the mucopeptides of bacterial cell walls. Clinically, it is particularly useful against infections of the gut when administered by injection; however, it is ineffective when taken orally, and has toxic side effects including kidney damage.

**Rittenberg tube** an evacuable two-legged tube provided with a stopcock and used for the conversion of <sup>15</sup>N-labelled ammonium salts into dinitrogen prior to mass-spectrometric analysis. It has been jocularly known, especially in Israel, as Rittenberg's trousers. [After David Rittenberg (1906-70), US biochemist.]

**R loop** the structure formed when an RNA of complementary sequence stably base pairs with one of the DNA strands of double-stranded DNA, as happens at the start of transcription.

**r.m.m.** abbr. for relative molecular mass.

**RMS** abbr. for root mean square.

**Rn** symbol for radon.

**RNA** abbr. and common name for ribonucleate (def. I) or ribonucleic acid; one of the two main types of nucleic acid, consisting of a long, unbranched macromolecule formed from ribonucleotides, the 3'-phosphate group of each constituent ribonucleotide (except the last) being joined in 3',5'-phosphodiester linkage to the 5'-hydroxyl group on each ribose moiety of the next one. The presence of a free 2'-hydroxyl group on each ribose moiety renders these phosphodiester bonds susceptible to hydrolytic attack by alkali, in contrast to those of DNA. The RNA chain has polarity, with one 5' end and one 3' end. Two purines, adenine and guanine, and two pyrimidines, cytosine and uracil, are the major bases usually present. In addition, minor bases may occur; transfer RNA, however, contains unusual bases in relatively large amounts. The sequence of bases carries information, whereas the sugar and phosphate groups play a structural role. RNA is fundamental to protein biosynthesis in all living cells. Messenger RNA (mRNA) is responsible for carrying the coded genetic 'message', transcribed from DNA, to sites of protein assembly at the ribosomes. The latter are composed of ribosomal RNA (rRNA) plus proteins. A third species, transfer RNA (tRNA), is instrumental in importing amino acids to the assembly site, according to instructions carried by mRNA. In some viruses, RNA is the genetic material instead of DNA. Specific forms, functions, molecules, or preparations of RNA may be designated by prefixes or suffixes, thus: A-RNA or RNA-A, A-form of RNA; cRNA, complementary RNA; dsRNA, double-strand(ed) RNA; hnRNA or H-RNA or HnRNA, heterogeneous nuclear RNA; mRNA, messenger RNA; miRNA, messenger-RNA-interfering complementary RNA; mtRNA, mitochondrial RNA; nRNA, nuclear RNA; rRNA, ribosomal RNA; sRNA or S-RNA, soluble RNA; seRNA, small cytoplasmic RNA; snRNA, small nuclear RNA; snoRNA, small nucleolar RNA; ssRNA, single-strand(ed) RNA; tRNA, transfer RNA; tcRNA, translational-control RNA; Z-RNA or RNA-Z, Z-form of RNA.

**RNA adenylating enzyme** see polynucleotide adenylyltransferase.

**RNAase** (sometimes) abbr. for ribonuclease; RNase is more usual.

**RNA-dependent DNA polymerase** another name for RNA-directed DNA polymerase (*see* reverse transcriptase).

**RNA-dependent RNA replicase** see RNA-directed RNA polymerase.

**RNA-directed RNA polymerase** EC 2.7.7.48; other name: RNA nucleotidyltransferase (RNA-directed); an enzyme that

catalyses a reaction between a nucleoside triphosphate and RNA. to form RNA.+<sub>1</sub> and pyrophosphates; it is required for the replication of RNA viruses; in the case of eukaryotic viruses, the enzyme normally comprises several subunits. Example from influenza virus (strain Ann Arbor), subunit P1 (or PBI): database code RRPLIAANN, 757 amino acids (86.34 kDa); subunit P2 (or PAI: database code RRP2\_IAANN, 716 amino acids (82.71 kDa); subunit P3 (or PB2): database code RRP3\_IAANN, 759 amino acids (85.99 kDa).

**RNA-DNA virus** *a former name for retrovirus.*

**RNA helicase** an ATP-dependent enzyme that is similar to DNA helicase except that its substrate is RNA. Example *dbpA* gene product (*Escherichia coli*) specific for 23S rRNA: database code DBPA\_ECOLI, 457 amino acids (49.13 kDa).

**RNA ligase** IATP) EC 6.5.1.3; *other name:* polyribonucleotide synthase (ATP); an enzyme that catalyses the reaction:

Example from bacteriophage T4: database code RLIG\_BPT4, 374 amino acids (43.46 kDa). Example, tRNA ligase from yeast: database code TRNL\_YEAST, 827 amino acids (95.23 kDa).

**RNA polymerase** any enzyme that utilizes ATP, GTP, CTP, and UTP to synthesize RNA from a DNA or RNA template. DNA-dependent RNA polymerases include (i) the enzymes responsible for transcription of DNA and (ii) primases, which synthesize the RNA primers required for replication of DNA. An RNA-directed RNA polymerase (replicase or RNA synthetase) is involved in the replication of RNA viruses.

DNA-dependent (or DNA-directed) RNA polymerase (EC 2.7.7.6); *other name:* RNA nucleotidyltransferase (DNA-directed); it catalyses a reaction between a nucleoside triphosphate and RNA. to form RNA.+<sub>1</sub> and pyrophosphate. This EC class number includes the following examples.

In prokaryotes there is a single DNA-dependent RNA polymerase which transcribes all classes of DNA. The core *Escherichia coli* enzyme is composed of three types of subunit,  $\alpha$ ,  $\beta$ , and  $\beta'$ , and has the composition  $\alpha_2\beta\beta'$ ; the holoenzyme contains an additional  $\sigma$  subunit or sigma factor. The core enzyme has a general affinity for DNA; sequence-specific DNA binding is conferred by the sigma factor which is responsible for promoter recognition and transcription initiation. Different sigma factors recognize different promoters. Following transcription initiation, the sigma factor dissociates from the core enzyme. The functions of the individual subunits are not fully understood. The  $\beta$  subunit is probably involved in binding ribonucleotide substrates; it is the target for rifamycin and streptolydigin antibiotics. The  $\beta'$  subunit may bind template DNA. Examples:  $\alpha$  subunit from *E. coli* (identical in *Salmonella typhimurium*): database code RPOA\_ECOLI, 329 amino acids (36.47 kDa);  $\beta'$  subunit from *E. coli*: database code RPOC\_ECOLI, 1407 amino acids (154.98 kDa).

Phage RNA polymerases are much smaller and simpler than bacterial ones: the polymerases from phage T3 and T7 RNA, e.g., are single polypeptide chains of <100 kDa. Example from phage T3: database code RPOL\_BPT3, 884 amino acids (98.68 kDa).

Eukaryotes have three types of DNA-dependent RNA polymerase in the nucleus, each producing a different type of RNA. RNA polymerase I, located in the nucleolus, synthesizes precursors of most ribosomal RNAs; RNA polymerase II, located in the nucleoplasm, synthesizes messenger RNA precursors; and RNA polymerase III, also located in the nucleoplasm, synthesizes the precursors of 5S rRNA, the transfer RNAs, and other small RNAs. These enzymes can be distinguished by their sensitivity to u-amanitin (see amanitin); class I enzymes are not inhibited by this octapeptide, whereas class II enzymes are rapidly inhibited by low concentrations; the sensitivity of class III enzymes varies depending on species. RNA polymerase I has 13 subunits totalling over 600 kDa; it recog-

nizes a single type of promoter and requires at least two ancillary factors, UBFI and SL1; it accounts for 50-70% of the RNA polymerase activity in eukaryotic cells. RNA polymerase II from all sources contains two large subunits of 215 and 139 kDa and several smaller polypeptides. The 215 kDa subunit has homology with the prokaryotic  $\beta'$  subunit and contains a C-terminal domain (CTD) with multiple repeats of the consensus sequence YSPTSPS; the CTD is involved in initiation. The 139 kDa subunit has homology with the bacterial  $\beta$  subunit; the third largest subunit is related to the bacterial  $\alpha$  subunit. Example of the latter: database code RPB3\_YEAST, 318 amino acids (35.24 kDa). Three of the remaining subunits are common to RNA polymerases I, II, and III. Example: database code RPB5\_YEAST, 215 amino acids (25.05 kDa). Most promoters used by RNA polymerase II contain the TATA box, which is recognized by the TATA-binding protein (TBP), a component of the transcription factor TFIID. Several other accessory factors are required for transcription by RNA polymerase II. RNA polymerase III has 14 subunits totalling 700 kDa. The promoters it uses may be upstream of the transcribed gene (for snRNAs) or within the gene (for tRNAs and 5S RNA). Three accessory factors, TFIIA (a zinc-finger protein), TFIIB, and TFIIC, are involved in transcription from internal promoters. Examples: 47 kDa subunit of RNA polymerase III: database code RPC4\_YEAST, 424 amino acids (46.89 kDa); 40 kDa subunit common to polymerases I and III; database code RPC5\_YEAST, 335 amino acids (37.64 kDa).

Mitochondria and chloroplasts also contain RNA polymerase activity that synthesizes the RNAs required for mitochondrial and chloroplast protein synthesis. Polymerases from these organelles are smaller than the nuclear enzymes and more like prokaryotic RNA polymerases.

[RNA-polymerase]-subunit kinase EC 2.7.1.141; *other name:* CTD kinase (abbr. for C-terminal domain kinase); an enzyme that catalyses a reaction between ATP and [DNA-directed RNA polymerase] to form phospho-[DNA-directed RNA polymerase] and ADP.

RNase *usual abbr. for* ribonuclease; compare RNAase.

RNase MRP a site-specific endoribonuclease for mitochondrial RNA processing (hence 'MRP'). It contains an essential RNA component and cleaves mitochondrial RNA (mtRNA) transcripts that are complementary to the D-loop region of vertebrate mtDNA.

RNase P a catalytic activity responsible for the formation of the 5'-phosphate terminus of tRNA, by cleaving a sequence of bases from the 5' end of a primary transcript, as a first step in the formation of pre-tRNA. The activity resides in the RNA moiety of a complex consisting of 86% RNA and 14% protein by weight. It was the first nonprotein enzymic activity to be discovered, by Albnan - and is an example of a ribozyme. See also ribonuclease.

RNA synthetase an RNA-directed RNA polymerase.

RNA tumour virus a common designation for retrovirus, as this is the only group of RNA viruses known to cause cancer.

RNP *abbr. for* ribonucleoprotein. Specific kinds of RNP may be designated by prefixes, thus: hnRNP, heterogeneous nuclear ribonucleoprotein; scRNP, small cytoplasmic ribonucleoprotein; snRNP, small nuclear ribonucleoprotein.

Roberts, Richard J. (1943- ), British molecular biologist; Nobel Laureate in Physiology or Medicine (1993) jointly with P. A. Sharp 'for their discovery of split genes'.

Robinson, (Sir) Robert (1886-1975), British organic chemist; Nobel Laureate in Chemistry (1947) 'for his investigations on plant products of biological importance, especially the alkaloids'.

Robison ester *an old name for* o-glucose 6-phosphate. Compare Neuberg ester. [After R. Robison, British chemist (1883-1941).]

Rochelle salt potassium sodium tartrate tetrahydrate; it is used as a constituent of Fehling's solution. [After La Rochelle, French port.]

## rocket immunoelectrophoresis

rocket immunoelectrophoresis *abbr.*: RIEP; a one-dimensional electroimmunodiffusion, *also known as* electroimmunoassay, used for quantitative analysis of proteins. Exact volumes of protein (antigen) solution are applied in an agarose gel of uniform thickness containing the corresponding antibody. An electric field causes the migration of both antigen and antibody. They react to form elongated curved precipitation lines, known as rockets because of shape, which are proportional in size to the amount of antigen. *See also* crossed immunoelectrophoresis.

Hodbell, Martin (1925-98), US biochemist; Nobel Laureate in Physiology or Medicine (1994) jointly with A. G. Gilman 'for their discovery of G-proteins and the role of these proteins in signal transduction in cells'.

rod cell *or* rod a rod-shaped cell that is one of the two types of light-sensitive cell of the vertebrate retina. Rod cells contain rhodopsin or (in freshwater and migratory fish and some amphibians) porphyropsin, and are responsible for vision in dim light. They occupy all of the margin of the retina and are absent from the fovea. Each rod photoreceptor is a highly specialized cell with an outer and inner segment, a cell body, and a synaptic region where the rod passes a chemical signal to retinal nerve cells. The phototransduction apparatus is in the outer segment, which contains a stack of disks, each formed by a closed stack of membrane in which rhodopsin molecules are embedded. The plasma membrane surrounding the outer segment contains cyclic-GMP-gated Na<sup>+</sup> channels. These are kept open in the dark by cyclic GMP molecules bound to the channels. Metarhodopsin II, an activated form of rhodopsin resulting from interaction with a photon, activates transducin, a G-protein, which then activates a cyclic GMP phosphodiesterase, reducing the cellular level of cyclic GMP to initiate a nerve impulse in the optic nerve. *Compare* cone cell.

rod gel a gel used in a form of polyacrylamide gel electrophoresis, in which the gel is cast in cylindrical glass tubes. Now largely superseded by slab-gel electrophoresis.

roentgen *a variant spelling of* roentgen.

rolling circle a mechanism for the replication of circular double-stranded DNA. One strand is nicked, then, using the unbroken strand as a template, the DNA is replicated around the circle. Replication does not cease when one circumference has been replicated, but continues around the circumference several more times (hence the name 'rolling'). Consequently, multimers of the replicon are produced in a long single strand with the appearance of a tail; this may then be cut into unit replicons, or into multimers containing tandemly repeated copies of the original unit; these may remain as single strands or be transcribed to yield a complementary strand.

rontgen *or* roentgen symbol R; the unit of exposure (def. 3) to X- or gamma radiation, expressed in terms of the amount of ionization caused in air. Defined originally (1928, 1937) as that quantity of radiation having a corpuscular emission per 0.001293 gram of air (equivalent of 1 cm<sup>3</sup> of dry air at stp) producing, in air, ions carrying one electrostatic unit quantity of electricity of either sign. Expressed in SI units, 1 R causes the production in air of ions (of one sign) carrying a charge of 2.58 × 10<sup>-4</sup> C kg<sup>-1</sup>; this corresponds to the formation of 1.61 × 10<sup>15</sup> ion-pairs per kg of air and to an absorption of energy by air equal to 0.00869 J kg<sup>-1</sup>. The energy absorption by water or tissue from 1 R of X- or gamma-radiation is about 0.0096 J kg<sup>-1</sup>. Prior to 1956, the roentgen was used in clinical work to express both exposure and absorbed dose. *See also* rad (def. 2), rem, rep. [After Wilhelm Konrad von Rontgen (1845-1923), German physicist, discoverer of X-rays.]

roentgen equivalent man *or* roentgen equivalent man *see* rem.

roentgen equivalent physical *see* rep.

roentgen rays *a former name for* X-rays.

room temperature ambient temperature, often used for reactions that can be carried out on the bench without devices to maintain constant temperature. Normally within several degrees of 20°C.

## rotenone

root effect the lowering of ligand affinity and of cooperativity of ligand binding (in hemoglobin) brought about by a low pH. (After R. W. Root who reported it in 1931.)

root mean square *abbr.* RMS; the positive square root of the mean of the squares of a series of values of  $x_i$ :

$$\text{RMS value} = \sqrt{\frac{(x_1^2 + x_2^2 + \dots + x_n^2)}{n}}$$

*Compare* standard deviation.

HOS *abbr.* for rod outer segment; *see* rod cell.

ROB a gene family encoding receptor-like tyrosine kinases of unknown function; *voros* is the oncogene of the acutely transforming avian sarcoma virus UR2 (named after the University of Rochester). The vertebrate gene product, Ros, has close similarity to the *Drosophila* Sevenless protein; it appears to be associated with a phosphoinositide response (*see* phosphatidyl-inositol cycle); Ros-1 is a member of the Src family. Example from chick: database code KROS\_CHICK.

rosetting a method of isolating cells by allowing them to associate with red blood cells. For example, lymphocytes become surrounded with red cells, forming a 'rosette', and may then be isolated by sedimentation through Ficoll gradients.

rota-evaporate to evaporate a solution in a rotating round-bottomed flask in a temperature-controlled water bath, using an apparatus that can at the same time apply a vacuum to the flask interior. -rota-evaporation *n.*

rotamer *see* rotational isomer.

rotary evaporator an apparatus used for flash evaporation; *see also* rota-evaporate.

rotational correlation time *see* correlation time.

rotational diffusion rotation of a solute molecule around its centre of mass as a result of Brownian movement.

rotational frictional coefficient *see* frictional coefficient.

rotational isomer molecules of identical configuration may be distinguished as having different conformations after rotation about a bond. If an assembly of atoms X-A-B-Y (X and Y not being collinear with A-B) is viewed along the axis A-B, the X-A and B-Y bonds will make an angle with each other which may be 0° (superposition), 180° or some intermediate angle. This angle is termed the torsion angle, designated  $\phi$  or  $\psi$ . Conformations are then described as synperiplanar (*sp*), synclinal (*sc*), anticlinal (*ac*) or antiperiplanar (*ap*) according as the torsion angle is within ±30° of 0°, ±60°, ±120°, or ±180°, respectively. Formerly, the terms *cis*, *gauche* and *trans* were in use for synperiplanar, synclinal and antiperiplanar respectively.

rotational strength *or* rotatory strength symbol: R; an index of the degree to which an absorption band exhibited by an optically active solute displays circular dichroism. It may be evaluated for the absorption band in question by means of the expression:

$$R = 2.296 \times 10^{-44} \int \left( \frac{\Delta \varepsilon_{\lambda}}{\lambda} \right) d\lambda$$

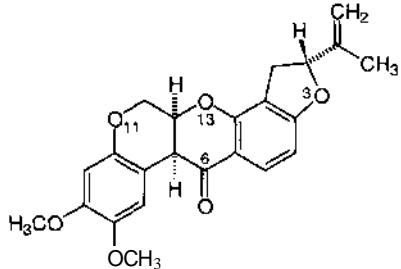

where  $\lambda$  is a wavelength of observation and  $\Delta \varepsilon_{\lambda}$  is the difference between the molar (decadic) absorption coefficients of the left and right circularly polarized light beams at that wavelength. Rotational strength is thus essentially the absorption coefficient difference integrated over the entire absorption band.

rotation axis a crystal or an oligomeric protein molecule is said to possess an *n-fold* rotation axis if it presents exactly the same appearance after a rotation about that axis of 360°/*n*. *Compare* screw axis.

rotation-reflection axis *see* symmetry.

rotenone an insecticidal material and the active principle in derris. It is present in plants of the genera *Derris*, *Lonchocarpus*, *Tephrosia*, and *Mundulea*; these plants were used by indigenous peoples as fish poisons (*Derris* in Asia, *Lonchocarpus* in South America, and *Tephrosia* more extensively). Rotenone inhibits mitochondrial respiration on the oxygen side of the nonheme iron of NADH dehydrogenase. Extracts of rotenone-

containing plants are used as insecticidal sprays and dusts (derris dust). Compare piericidin A.

**Rot value or Rot value** a measure of the kinetic complexity of RNA based on its hybridization ability. The notation is a modification of *Rot*, where  $R_o$  is the initial RNA concentration and  $t$  is time. It is analogous to the *Cot* value (see  $C_0t$ ) for DNA.  $Rot_y$  is the value corresponding to half complete association between complementary polynucleotides.

**rough endoplasmic reticulum abbr.:** RER; a region of the endoplasmic reticulum associated with ribosomes and involved in the synthesis of secreted and membrane-bound proteins. The nascent protein destined for secretion with its signal peptide associates with a receptor for the signal recognition particle and then translocates through the RER lipid bilayer by means of a group of proteins known as a translocon, which includes TRAM. The signal peptide is removed by the signal peptidase. The process is aided by heat-shock proteins, which serve as chaperones.

**Round-up** see glyphosate.

**rousavirus** see retrovirus.

**rP** the negative decadic logarithm of the molar concentration of inorganic phosphate; i.e.  $rP = -\log[P_i]$ . If, for the equilibrium

$$K = [X][Pi]/[XP]$$

then

$$rP = -\log K - 10g([XP]/[X]).$$

**RP-HPLC** abbr. for reversed phase high-pressure liquid chromatography; see reversed phase.

**R plasmid** abbr. for resistance plasmid.

**r-protein** abbr. for ribosomal protein.

**RP-TLC** abbr. for reversed phase thin-layer chromatography; see reversed phase.

**RQ** abbr. for respiratory quotient.

**RRM** abbr. for RNA recognition motif; a conserved 80-amino-acid sequence motif present in members of a family of proteins that bind RNA. It has a  $\beta$ - $\alpha$ - $\beta$ - $\beta$ - $\alpha$ - $\beta$  structure.

**rRNA** abbr. for ribosomal RNA; see ribosome.

**(RS)-** prefix (in chemical nomenclature) denoting a racemate containing a single chiral centre. See sequence rule.

**R segment** abbr. for repeat segment; part of retroviral RNA consisting of direct repeats i.e. repeats having the same orientation; the size of the repeated segments varies in different strains of virus, from 80 to 100 nucleotides.

**R/S convention** the system of configuration specification of chiral compounds based on the sequence rule.

**RSKG-5** see tonin.

**R state** see Rform.

**rtDNA** (sometimes) abbr. for recombinant DNA; use not recommended.

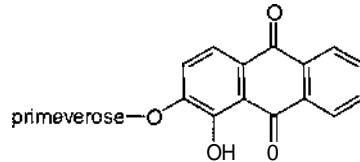

**RTP symbol** for any unspecified purine nucleoside 5'-triphosphate.

**Ru symbol** for ruthenium.

**RU-486** or RU-38486 mifepristone; 11,B-(4-dimethylaminophenyl)-17,B-hydroxy-17a-prop-1-ynylestra-4, 9-dien-3-one; a steroidal progesterone-receptor antagonist that prevents implantation of a fertilized ovum in the uterus. It is an effective contraceptive even when taken after coitus.

**rubber** a *cis*,I,4-polyisoprene with  $M$ , varying from about  $1 \times 10^5$  to  $1 \times 10^6$ , representing polymers of about 1500 to 60000 isoprene residues. It is found in the latex of about 300 different flowering plants, but only *Hevea brasiliensis* is a commercial source. A nonelastic rubber from *Manilkara bidentata* latex is known as balata. It is a *trans*-I,4-polyisoprene.

**ruberythric acid** the glycoside; 2-alizarin ,B-D-primeveroside, a major component of the plant dyestuff madder.

**rubidium symbol:** Rb; a silvery-white metallic element of group I of the IUPAC periodic table; atomic number 37; relative atomic mass 85.48.

Highly reactive, it must be stored in an inert atmosphere.  $Rb^+$  may be used experimentally as a  $K^+$  analogue (sometimes as substitute, other times as competitor).

**Rubisco** abbr. for ribulose-bisphosphate carboxylase.

**RuBP** abbr. for ribulose 1,5-bisphosphate.

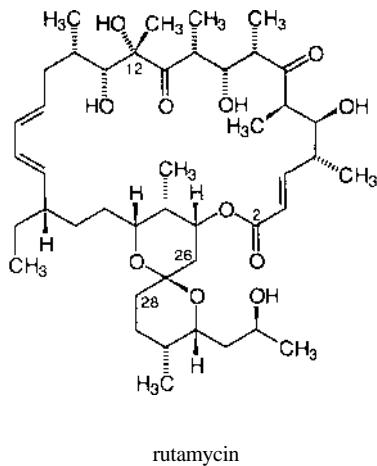

**rubredoxin** abbr.: Rd; any of a group of bacterial iron-sulfur proteins that are small, highly conserved, contain non-heme iron, and are nonenzymic. They lack acid-labile sulfur, and are characterized by having either one or two iron atoms each entirely in mercaptide coordination, i.e. surrounded by four cysteine residues or sulfur-containing ligands. They are electron acceptors for, e.g., hydrogenase-linked redox processes and hydroxylase systems. Rubredoxins of  $M$ , 6000-19000 have been found in a number of bacteria. The ferric form is intense red, the ferrous form is colourless. Example from *Alcaligenes eutrophus*: database code RUBR\_ALCEU, 78 amino acids (8.64 kDa). Compare ferredoxin.

**rudimentary** a gene that in *Drosophila* is the equivalent of *pyr-1* in a number of other eukaryotes. It encodes a CAD protein. ruffled edge or ruffling the appearance of the leading edge of a moving cell in culture, caused by the extension of microspikes and lamellipodia, which when not attached to the substratum have the appearance of ruffles in flimsy dress fabric.

**Russell's viper venom** the venom of Russell's viper, *Vipera russelii*, a snake of SE Asia. It is used experimentally as a source of several enzymes especially phospholipases, proteases, and ribonucleases.

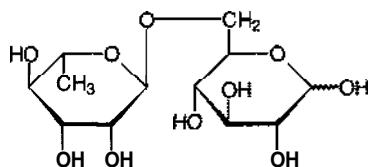

**rusticyanin** a blue copper-containing single-chain polypeptide obtained from a thiobacillus. It undergoes reduction during oxidation of  $Fe^{2+}$  with dioxygen. It is stable in acid, labile in alkali, and contains no arginine. Example from *Thiobacillus ferrooxidans*: database code RUSI\_THIFE, 154 amino acids (16.38 kDa).

**rutamycin** or oligomycin D 26-demethyloligomycin A; an anti-fungal agent that has no significant activity against bacteria but is strongly inhibitory to a limited number of yeast and other fungal species. It acts by inhibiting mitochondrial ATPase  $F_1$ , preventing phosphoryl group transfer, but has no effect on isolated  $F_1$  units. (Illustrated on p. 581.) See also oligomycin.

**ruthenium red** ruthenium oxychloride ammoniated;  $[(\text{NHJ})_5\text{-Ru-O-(NHJ)}_4\text{-O-Ru-(NHJ)}_5]\text{Cl}_6 \cdot 4\text{H}_2\text{O}$ . A brownish-red, water-soluble inorganic compound, used in microscopy and electron microscopy as a stain for acid mucopolysaccharides. It inhibits the influx of  $\text{Ca}^{2+}$  ions into mitochondria at extremely low concentrations.

**rutinose** the disaccharide, 6-O-p-L-rhamnosyl-D-glucose; it occurs in some glycosides, e.g. rutin, the 3'-rutinoside of quercetin.

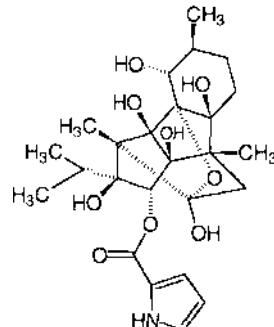

**Ružička, Leopold** (1887-1976), Croatian-born Swiss chemist; Nobel Laureate in Chemistry (1939) 'for his work on polymethylenes and higher terpenes' [prize shared with A. F. J. Butenandt].

**$R_B$  value or relative band rate or relative band speed** (*in chromatography*) symbol:  $R_u$ ; the ratio of the distance travelled by a zone of the substance of interest to the distance simultaneously travelled by a reference substance B. See also  $R_v$  value.

**$R_f$  value or  $R_F$  value or band rate or band speed** symbol:  $R_f$  or  $R_F$ ; (*in chromatography*) the ratio of the distance travelled by the

centre of a zone of the substance of interest to the distance simultaneously travelled by the mobile phase. In paper and thin-layer chromatography, it is generally determined from the distance travelled by the substance from the origin and the distance travelled by the eluent front from the same point. [From 'rate relative to front'.]

**ryanodine** an alkaloid with insecticidal activity, isolated from *Ryania speciosa*. See also ryanodine receptor.

**ryanodine receptor** abbr.: RYR; any of a group of receptor proteins that bind ryanodine. They were first discovered in muscle, but subsequently identified in other cell types. Their natural role is to function as intracellular  $\text{Ca}^{2+}$ -release channels. In muscle, they provide communication between transverse tubules (**T-tubules**) and sarcoplasmic reticulum (SR); contraction of skeletal muscle is triggered by release of  $\text{Ca}^{2+}$  from SR following depolarization of T-tubules. The  $\text{Ca}^{2+}$  channel is modulated by  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ , and calmodulin. Three types are known: RYR1, the skeletal muscle type; RYR2, the cardiac muscle type; and RYR3, a highly truncated protein found in some nonmuscle cells. Cyclic ADP-ribose activates the RYR2 but not the RYR1 receptor. In muscle the receptors are integral transmembrane glycoproteins, probably tetrameric; the C-terminal region is on the SR lumen side of the membrane, while the N-terminal region (the major part of the molecule for RYR1 and 2) protrudes into the cytosol. Deficiency is associated with malignant hyperthermia. Example, skeletal muscle type from human: database code RYNR\_HUMAN, 5032 amino acids (563.79 kDa).

**RYN method** a method for determining the plausibility of an **open reading frame**. A computational analysis of the sequence determines the frequency of the favoured codons R (purine), Y (pyrimidine), and N (anything). If these are found to be in the proportions expected from that normally found, it lends support to the fact that the correct **reading frame** has been selected, and that the open reading frame is correct.

**RYR** abbr. for ryanodine receptor.

# 5s

**s** symbol for 1 second (deL I). 2 solid state (in a chemical equation). 3 atomic orbital corresponding to an orbital angular momentum quantum number ( $l$ ) = 0. 4 singlet (in nuclear magnetic resonance spectroscopy). 5 strong absorption (in infrared spectroscopy).

**s** symbol for 1 sedimentation coefficient. 2 solubility. 3 (in monosaccharide nomenclature) the septanose form; it is suffixed to the symbol for the corresponding monosaccharide; e.g. glucoseptanose is symbolized as Glcs. 4 specific entropy (i.e. entropy/mass). 5 spin quantum number.

**s-** abbr.: for sec-.

**5** symbol for 1 sulfur. 2 siemens. 3 Svedberg unit (SW.20 is the symbol under standard conditions). 4 a residue of the  $\alpha$ -amino acid L-serine (alternative to Ser). 5 a residue of an incompletely specified base in a nucleic-acid sequence that may be either cytosine or guanine. 6 a residue of the ribonucleoside thiouridine when the position of the thiol group in its thiouracil moiety is unknown or unspecified (alternative to sU or Srd). 7 substitution (reaction mechanism).

**25** symbol for a residue of the ribonucleoside 2-thiouridine (alternative to S2U); see thiouridine.

**45** symbol for a residue of the ribonucleoside 4-thiouridine (alternative to s4U); see thiouridine.

**5<sub>N'</sub>** abbr. for unimolecular nucleophilic substitution.

**5<sub>N2</sub>** abbr. for bimolecular nucleophilic substitution.

**5<sub>W.20</sub>** see S (deL 3).

**S** symbol for 1 entropy. 2 spin quantum number (of a system). 3 strangeness quantum number. 4 area (alternative to A).

**S** stereochemical descriptor denoting *sinister*; i.e. the absolute configuration of a chiral compound in which the priority (obtained using the Cahn-Ingold-Prelog sequence rules) of the substituent groups on the chiral centre decreases in an anti-clockwise (left-handed) direction. For use as a prefix in chemical nomenclature, the descriptor is placed in parentheses and connected with a hyphen; e.g. (S)-alanine. For chiral compounds in which the relative but not the absolute configuration is known, *sinister* configuration is denoted by the prefix (S<sup>\*</sup>). See sequence rule. Compare R.

**S-**prefix (in chemical nomenclature) denoting substitution on a sulfur atom in a compound; a particular sulfur atom may be specified by a right superscript.

**-S** conformational descriptor designating the skew conformation of a six-membered ring form of a monosaccharide or monosaccharide derivative. Locants of ring atoms that lie on the side of the structure's reference plane from which the numbering appears clockwise are indicated by superscripts preceding the letter, and those that lie on the other side of the reference plane by subscripts following the letter; e.g. 1,2-O-ethylidene-a-O-glucopyranose-'S'. See also conformation.

**s.a.** abbr. for specific activity.

**5AA** abbr. for serum amyloid A; see amyloid A protein.

**5ABP** abbr. for secretory actin-binding protein.

**saccharase** the trivial name for any of a group of widely distributed hydrolases that attack the fructose (fructosaccharases) or glucose (glucosaccharases) end of appropriate oligosaccharides, liberating fructose or glucose respectively. The term is also used as an alternative trivial name for invertase (which is both a fructosaccharase and a glucosaccharase). saccharate see glucarate.

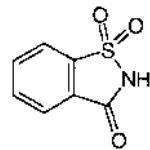

**saccharic acid** 1 an old name for aldaric acid. 2 an old name for glucaric acid; see glucarate.

**saccharide** any carbohydrate; the term is applied especially to the simple sugars, i.e. the monosaccharides, disaccharides, and short-chain oligosaccharides. See also polysaccharide.

**saccharification** the hydrolysis of sugar derivatives or complex carbohydrates to soluble, fermentable sugars.

**saccharimeter** an instrument for measuring the amount of sugar in a solution, especially a polarimeter used for such a purpose. Compare saccharometer.

**saccharin** 2,3-dihydro-3-oxobenzisosulfonazole; O-sulfonylbenzimid; an artificial, nonnutritive sweetening agent that is several hundred times sweeter than sucrose. It is often used as its more soluble sodium salt. Its carcinogenicity has been extensively studied. Rats receiving high doses produced tumours of the urinary tract but there is no clear-cut evidence of such an effect in humans.

**saccharogenesis** the process of producing soluble, fermentable sugars from a complex carbohydrate. -saccharogenic adj.

**saccharogenic method** a method for assaying amylase and similar enzymes that hydrolyse polysaccharides. It depends on determination of the amount of simple sugar product formed by the enzyme.

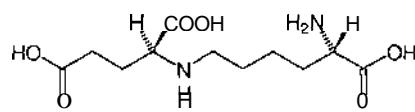

**saccharometer** an instrument for measuring the amount of sugar in a solution, especially a hydrometer specially calibrated for the purpose. Compare saccharimeter.

**Saccharomyces** a genus of budding yeasts that reproduce asexually by budding or sexually by conjugation. They are used especially as simple model organisms in the study of eukaryotic cell biology, and in genetic engineering. *Saccharomyces cerevisiae* is used commercially in bread-making and in the production of alcoholic beverages and industrial alcohol. It is able to divide vegetatively in either the haploid or diploid phase. This permits the isolation of recessive mutations in the haploids and complementation testing in the diploids. Transformation procedures that permit DNA uptake by either protoplasts or whole yeast cells have been developed and a wide range of cloning vectors constructed. In cases where a recombinant glycoprotein is desired, yeast has proved very useful since it can, unlike bacteria, effect post-translational glycosylation. It has been used for the production of a vaccine for hepatitis B.

**saccharopine** N<sup>6</sup>-(I,3-dicarboxypropyl)-L-lysine; an intermediate in the aminoacidic pathway for lysine biosynthesis (e.g. in *Saccharomyces* spp., hence the name) and for lysine catabolism (e.g. in mammalian liver). The reactions involved are:

they are catalysed by saccharopine dehydrogenases, which are characterized as lysine-forming or glutamate-forming, and require either NAD+/NADH or NADP+/NADPH as coenzyme; see saccharopine dehydrogenase (NAD, L-glutamate-forming) and saccharopine dehydrogenase (NAD, L-lysine forming).

**saccharopine dehydrogenase (NAD-)** L-glutamate-forming) EC 1.5.1.9; an enzyme of the pathways for the synthesis and degradation of lysine. It catalyses the oxidation by NAD+

## saccharopine dehydrogenase

of  $N^6$ -(L-1,3-dicarboxypropyl)-L-lysine to L-glutamate and 2-amino adipate 6-semialdehyde with formation of NADH. There is a second saccharopine dehydrogenase with the same reaction mechanism, in which the coenzyme is NADP $^+$ : EC 1.5.1.10, saccharopine dehydrogenase (NAPD $^+$ : L-glutamate-forming). See also saccharopine.

saccharopine dehydrogenase INAD $^+$ , L-Lysine-forming) EC 1.5.1.7; other name: lysine-2-oxoglutarate reductase; an enzyme of the pathways for the synthesis and degradation of lysine. It catalyses the reaction between L-lysine, 2-oxoglutarate, and NADH to form  $N^6$ -(L-1,3-dicarboxypropyl)-L-lysine (saccharopine), NAD $^+$ , and H $_2$ O. Example from *Yarrowia lipolytica* (formerly *Candida lipolytica*): database code LYS 1\_YARLI, 369 amino acids (40.57 kDa). See also saccharopine.

saccharose an old name for sucrose.

safety cabinet a cabinet providing an area at bench level in which pathogenic agents may be handled or stored while preventing their entry into the atmosphere outside the cabinet; at the same time, sterility within the cabinet is normally ensured. Usually the cabinet is ventilated with a stream of air, which is extracted through a filter system that traps any pathogens. There are several grades of safety, the highest grades being for the more potentially hazardous materials; in the lowest grade, there is an inward flow of air through the front aperture; a higher grade cabinet is ventilated by a downward flow of filtered air, extracted so as to ensure also an inward flow through the front aperture, the extracted air being recirculated through the filter; in the highest grade, there is no front aperture, the operator manipulating the interior components using gloves mechanically sealed into the front of the cabinet.

**SAH** abbr. for S-adenosyl-L-homocysteine; see S-adenosylhomocysteine.

**SAICAR** or **SACAIR** abbr. for 1-(5-phosphoribosyl)-5-amino-4-(N-succinocarboxamide)-imidazole.

**SAICAR synthetase** see phosphoribosylaminoimidazole-succinocarboxamide synthase.

**Sakaguchi test** a test for guanidines; in alkaline solution they give a red colour with the Sakaguchi reagent, which contains a-naphthol and sodium hypochlorite. Arginine undergoes this reaction, as do arginine-containing proteins.

**Sakmann**, Bert (1942- ), German physiologist; Nobel Laureate in Physiology or Medicine (1991) jointly with E. Neher 'for their discoveries concerning the function of single ion channels in cells'.

**salbutamol** other name: albuterol; 4-hydroxy-3-hydroxymethyl-a-[tert-butylamino)methyl]-benzyl alcohol, al-[[I, I-dimethylethyl]amino)methyl]-4-hydroxy-1,3-benzenedimethanol; a  $\beta$ -adrenergic agonist. The modification of the catechol ring by introduction of the hydroxymethyl group enhances the  $\beta_2$ -adrenoceptor activity by a factor of about 60 compared with isoproterenol.

**salicylic acid** 2-hydroxybenzoic acid; a white, crystalline, sweet-tasting substance, slightly soluble in water; its esters are found in bark of sweet birch and wintergreen, the leaves of which are used as a topical keratolytic and antifungal agent. It serves as a natural inducer of heat production ('calorigen') in *Arum* lilies, and has a broad regulatory role in plants. Its *O*-acetyl derivative is aspirin.

## salt bridge

saline 1 of, concerned with, or containing common salt (sodium chloride). 2 of, or containing, salts of alkali metals or magnesium. 3 an aqueous solution of sodium chloride and (sometimes) other salts, of defined osmolarity, prepared for intravenous injection or perfusion; usually 0.9% w/v sodium chloride. See also physiological saline.

**saliva** the mixed secretions of the salivary glands and of the mucous membrane of the mouth. It contains an a-amylase (ptyalin), mucin, various inorganic ions, urea, buffers, lysozyme, etc., and has a pH near 7. It is secreted in response to food, which it serves to moisten and lubricate; the amylase may bring about some hydrolysis of ingested starch. See also sialic. -salivary adj.

**salivary gland** any of the various glands that discharge saliva into the mouth. In humans there are three pairs: the parotid, sublingual, and submaxillary glands. In snakes they include the venom glands.

**salivary juice** the collective secretions of the salivary glands; i.e. saliva. Its secretion was studied by Pavlov and led him to the discovery of the conditioned reflex.

**Salkowski test** a test for the presence of cholesterol. When concentrated sulfuric acid is added to a chloroform solution of cholesterol, the chloroform layer shows a red to blue colour and the acid layer shows a green fluorescence. [After Ernst Leopold Salkowski (1844-1923), German physiological chemist.]

**salmine** a 6-7 kDa protamine, found in salmon sperm.

**salmon** common name for a number of fish of the family Salmonidae which live in coastal waters of the North Atlantic and North Pacific and breed in rivers. The flesh of these fish is comparatively rich in oils with a high content of long-chain *n*-3 fatty acids; typical composition (major fatty acids, expressed as % of total fatty acids): 16:0, 10; 16:I(n-7), 5; 18:0,4; 18:I(n-9), 24; 18:2(n-6), 5; 18:3(n-3), 5; 20:I(n-9), 1; 20:4(n-6), 5; 20:5(n-3), 5; 22:6(n-3), 17.

**Salmonella** a genus of rod-shaped, motile, aerobic bacteria including the agents responsible for typhoid fever (*S. typhi*), some types of food poisoning, and other enteric diseases.

**Salmonella mutagenesis test** or Ames test a method of screening chemicals for carcinogenicity, in which their mutagenic effect on selected strains of *Salmonella typhimurium* is evaluated -- there being a high correlation between mutagenicity and carcinogenicity for substances of known action. The strains of *S. typhimurium* used are normally those that require histidine. They are plated out on histidine-deficient medium after being mixed with the potential mutagen. Mutations brought about by the test substance which reverse the defect in their ability to synthesize histidine are revealed by colonies growing on the plate.

**salt** 1 any member of a class of compounds formed, together with water, by reaction of an acid with a base (most commonly an inorganic acid and metallic base). 2 or common salt sodium chloride.

**saltation** 1 the action of jumping or leaping. 2 proceeding in a discontinuous manner by leaps interspersed by periods of rest. 3 an irreversible and inherited change in a cell or organism due to mutation. -saltatory adj.

**saltatory conduction** the passage of a nerve impulse across a gap, as between the nodes of Ranvier in a myelinated nerve fibre.

**saltatory evolution** evolution by sudden changes or by periods of active change with intervening inactive periods.

**saltatory replication** a hypothetical, sudden lateral replication of DNA thought to be responsible for the production of families of similar nucleotide sequences.

**salt bridge** 1 a tube, usually closed with porous plugs, that is filled with a solution of a salt (often potassium chloride, commonly saturated) and used to obtain electrical contact between two electrolytic half-cells without intermingling of their respective electrolytes. 2 any electrostatic bond between positively and negatively charged groups on amino-acid residues

## salt fractionation

saponin

of a protein, that contributes to the stability of the protein structure.

**salt fractionation** the differential precipitation of proteins (or nucleic acids) from solution by the addition of neutral salts, often ammonium sulfate. *Compare* salting out.

**salting in** the increase in the solubility of certain proteins (e.g. globulins) and dipolar ions (e.g. cystine) produced in solutions of low ionic strength by an increase in the concentration of neutral salts.

**salting out** the decrease in the solubility of proteins, gases, uncharged molecules, and, in sufficiently concentrated solutions, electrolytes, produced in solutions of high ionic strength by an increase in the concentration of neutral salts.

**salting-out chromatography** a method of chromatography whereby water-soluble organic compounds are separated by ion-exchange chromatography by use of an aqueous salt solution as eluent.

**salting-out constant symbol:**  $K_s$ ; the slope of the straight line relating the logarithm of the solubility of a substance in neutral salt solutions and the ionic strength. It is given by

$$K_s = -[\log(s/s^*)]/I,$$

where  $s$  is the solubility in mol dm<sup>-3</sup> at ionic strength  $I$ , and  $s^*$  is the hypothetical solubility at zero ionic strength.

**salt link or salt linkage** an ionic bond.

**salvage pathway** any metabolic pathway that utilizes compounds formed in catabolism for biosynthetic purposes, despite these compounds not being intermediates in the corresponding normal biosynthetic pathways. Thus, free purine and pyrimidine bases may be converted to the corresponding ribonucleotides. In the case of purines, the ribose phosphate moiety of 5-phospho-a-D-ribosyl diphosphate (I) is transferred to the purine; thus

*See also* purine biosynthesis.

**SAM abbr.** for S-adenosylmethionine.

**SAMase** a trivial name for S-adenosylmethionine cleaving enzyme (S-adenosylmethionine hydrolase; EC 3.3.1.2).

**same-sense mutation** an alternative name for silent mutation.

**sample** a small, separated portion of the whole. In experimentation it is often essential that the sample be fully representative of the characteristics of the whole (and always so for a statistical sample).

**sample applicator** a device to aid application of samples to chromatography plates, etc.

**sample well** a hole cut in an electrophoresis gel in which the sample to be analysed is placed.

**sampling error (in statistical analysis)** the chance difference between a measurement obtained from a sample and the corresponding measurement obtained from the whole population.

**Samuelsson, Bengt Ingemar** (1934- ), Swedish biochemist; Nobel Laureate in Physiology or Medicine (1982) jointly with S. K. Bergstrom and J. R. Vane 'for their discoveries concerning prostaglandins and related biologically active substances'.

**sandwich assay or sandwich technique** a type of immunoassay in which antibody against the antigen to be assayed is bound to a solid surface (e.g. plastic). After addition of solution containing antigen the fixed antigen is washed. A second antibody, which is radioactive or fluorescent, is added, sandwiching the antigen; after removal of excess, the amount of bound label is determined. The second antibody may be specific for a different epitope on the antigen, thus enhancing overall specificity, or for the first antibody bound to an antigen.

**sandwich complex** a 2:1 macrocycle:cation complex in which the metal ion is held between two parallel macrocyclic complexes.

**sandwich technique** an alternative name for sandwich assay.

**sandwich test** an immunohistochemical procedure employing a sandwich assay to detect an antibody within a cell.

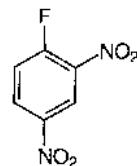

**Sanfilippo syndrome A** an alternative name for mucopolysaccharidosis type IIIA.

**Sanfilippo syndrome B** an alternative name for mucopolysaccharidosis type IIIB.

**Sanger, Frederick** (1918- ), British biochemist, protein chemist, and nucleic-acid chemist; Nobel Laureate in Chemistry (1958) 'for his work on the structure of proteins, especially that of insulin'; Nobel Laureate in Chemistry (1980) jointly with W. Gilbert 'for their contributions concerning the determination of base sequences in nucleic acids' [prize shared with P. Berg].

**Sanger's method** 1 (for identifying and estimating N-terminal amino-acid residues of polypeptides and proteins) a method in which free unprotonated amino groups react with 1-fluoro-2,4-dinitrobenzene (FDNB). The dinitrophenylamino groups formed are stable to the acid used to hydrolyse the peptide bonds; the yellow arylated (DNP-) amino acids so released can then be identified by chromatography and estimated spectrophotometrically. 2 (for polypeptide and protein sequencing) a general method for deriving the primary sequence of a polypeptide chain, based on selective hydrolytic degradation of the chain into smaller peptides. The sequence of each smaller peptide may then be found by use of FDNB to label its N-terminal amino acid, together with total hydrolysis to give the amino-acid composition and further stepwise degradation by use of carboxypeptidase or by Edman degradation. By selection of different degradation procedures to ensure overlap of sequences between the various smaller peptides, the overall sequence of the starting material may be determined. 3 (for DNA sequencing) an alternative name for chain-termination method.

**Sanger's reagent** 2,4-dinitrofluorobenzene (abbr.: DNFB); 1-fluoro-2,4-dinitrobenzene (abbr.: FDNB); a substance used in structural protein chemistry to arylate free amino groups. See Sanger's method (def. 1,2).

**sapecin** an insect defensin that is active against (mainly Gram-positive) bacteria. It has a high affinity for cardiolipin. Example (precursor includes presumed signal of unknown length) from *Sarcophaga peregrina*: database code SAPE\_SARPE, 94 amino acids (9.90 kDa).

**sapogenin** any of the aglycon moieties of saponins; they may be steroids or triterpenes.

**saponifiable fraction** the portion of total lipid that, after treatment with hot alkali, is soluble in water and insoluble in ether.

**saponifiable lipid** any lipid that can be hydrolysed with alkali to give soap (fatty-acid salts) as one product; they include any glycolipid, cholesterol ester, or sphingolipid.

**saponification** the hydrolysis of an ester by an alkali to give the alcohol and salt of the acid. Originally the term meant the hydrolysis of a neutral fat by alkali (e.g. potassium hydroxide) into glycerol and a soap. *-saponify vb.*

**saponification equivalent** the amount in grams of an ester that consumes one gram-equivalent of alkali in saponification. *Compare* saponification number.

**saponification number** the number of milligrams of potassium hydroxide consumed in the complete saponification of one gram of any particular fat, oil, or wax. *Compare* saponification equivalent.

**saponin** any member of a large group of glycosides, widely distributed in plants, that are powerful surfactants. Each saponin

**saponin detoxifying enzyme**

consists of an aglycon moiety (i.e. sapogenin), which may be a steroid or a triterpene, and a sugar moiety, which may be glucose, galactose, a pentose or methylpentose, or an oligosaccharide. All saponins foam strongly when shaken with water. They are membrane-active, powerful hemolytic agents and may be used at low concentrations to penetrate cells. They are thus highly toxic on injection, but not on ingestion as they are not absorbed through the gut. *See also* digitonin.

**saponin detoxifying enzyme** an enzyme of unknown mechanism that acts, as the name implies, to prevent activity of anti-fungal saponins. Example from *Gaeumannomyces graminis avenacinase* (the so-called take-all fungus, an extreme pathogen of cereals): database code GGU17568, 637 amino acids (68.66 kDa).

**sapor** that which is sensed by taste; any quality relating to taste or savour. -saporific or savorous *adj.*

**saporin** a type I ribosome-inactivating protein, EC 3.2.2.22, from the soapwort *Saponaria officinalis*.

**saposin** or sphingolipid activator protein any of a group of peptide cofactors of enzymes for the lysosomal degradation of sphingolipids. They stimulate various enzymes, including glucosylceramidase, galactosylceramidase, cerebroside-sulfatase, a-galactosidase, p-galactosidase, and sphingomyelin phosphodiesterase. Saposins A to D are known. Deficiency of any may cause a mild form of a sphingolipidosis that normally results from deficiency of an enzyme the saposin activates. They contain characteristic domains known as saposin A-type or B-type domains. Example (precursor) from human: database code SAP\_HUMAN, 524 amino acids (58.04 kDa). Specific polypeptides derived from this (amino acids in the precursor sequence in brackets) are as follows: saposin A (60-142) together with saposin C (311-391) stimulate hydrolysis of glucosylceramide by p-glucosylceramidase (EC 3.2.1.45) and galactosylceramide by p-galactosylceramidase (EC 3.2.1.46). Saposin C deficiency causes a variant of Gaucher's disease. Saposin B (195-274) is a homodimer and forms a solubilizing complex with the substrates of the sphingolipid hydrolases; deficiency causes a variant of metachromatic leukodystrophy. Saposin D (405-486) is a specific activator of sphingomyelin phosphodiesterase (EC 3.1.4.12) and deficiency causes a variant of Tay-Sachs disease ( $G_{M2}$  gangliosidosis). *See also* swaposin.

**saprophyte** any plant, fungus, or microorganism that lives on dead or decaying organic matter. -saprophytic *adj.*

**sarafotoxin** any of several toxic peptides that have been purified from the burrowing asp, *Atractaspis engaddensis*, and that cause cardiac arrest when injected into mice, probably as a direct result of coronary vasospasm arising from their strong vasoconstrictor activity. All have 21 amino acids, with two pairs of half-cystine residues in identical positions and a hydrophobic tail with a C-terminal tryptophan residue. They have strong homology with endothelins and have endothelin receptor agonist action. Sarafotoxins S6A-E are synthesized as a precursor from *A. engaddensis*: database code SRTX\_ATREN, 543 amino acids (62.32 kDa). Sarafotoxin S6D has the sequence

CTCKDMTDKECLYFCHQDIIW.

*See also* bibracte.

**Saran Wrap** proprietary name for a vinylidene chloride copolymer cling-film used for gel drying, food storage, and other purposes.

**$\alpha$ -sarcin** a cytotoxin produced by *Aspergillus giganteus*. It has ribonuclease activity, specific for purines in both single-stranded and double-stranded RNA. It inhibits protein synthesis, cleaving a single phosphodiester linkage between guanosine and adenosine residues in 28S rRNA in the 60S' subunit of the eukaryotic ribosome, resulting in loss of 393 nucleotides from the 3' end of 28S rRNA. This single site of action in the intact ribosome contrasts with its action on purified 28S rRNA, in which it causes extensive degradation, cut-

**sarcosome**

ting on the 3' side of every adenine or guanine. Example (precursor): database code RNAS\_ASPGI, 177 amino acids (19.72 kDa), residues 1-27 being the signal, and 28-177 the enzyme. **sarcolemma** the outer membrane of a muscle fibre. It consists of the plasma membrane, a covering basement membrane (about 100 nm thick and sometimes common to more than one fibre), and the associated loose network of collagen fibres. The term was originally used by light microscopists to designate the line visibly marking the outer fibre edge.

**sarcoma** a malignant tumour of connective tissue or of its derivatives. -sarcomatous *adj.*

**sarcomere** the functional unit of a myofibril of vertebrate muscle, about 2.3  $\mu\text{m}$  long. In striated muscle the sarcomeres of many parallel myofibrils are positioned such that myosin thick filaments are aligned in register across the myofibril (having a dense appearance in microscopic preparations), as also are the actin thin filaments (which have a lighter appearance), resulting in the alternation of light, isotropic bands known as I bands, and dark, anisotropic bands known as A bands; the I band is bisected by a very dense, narrow Z line, while the central, less dense region of the A band is known as the H zone, which in turn is bisected by the dark M line, or midline, the location of specific proteins that link adjacent thick filaments to each other. The Z lines are due to attachment sites for thin filaments. **sarcoplasm** all of the contents of a muscle fibre except nuclei. The sarcoplasm is pervaded by the sarcoplasmic reticulum. *Compare* cytoplasm. -sarcoplasmic *adj.*

**sarcoplasmic reticulum** abbr.: SR; a fine reticular network of membrane-limited elements that pervades the sarcoplasm of a muscle fibre. Like the endoplasmic reticulum the SR is continuous over large portions of the cell, it has a large surface-to-volume ratio, and is continuous with and/or homologous to the nuclear envelope. At the level of the I band (*see* sarcomere), the SR forms dilated sacs, or cisternae. Opposite the I bands and Z lines of every sarcomere there are always two SR terminal sacs that face each other across a narrow space, through which run T-tubules. At the level of the A-I junction longitudinally orientated SR sacs run along the fibril, forming a palisade around the A band. The SR contains a  $\text{Ca}^{2+}$ -translocating ATPase that moves  $\text{Ca}^{2+}$  into the SR during ATP hydrolysis; ATP resynthesis is associated with movement of  $\text{Ca}^{2+}$  out of the SR vesicles.

**sarcosine** N-methylglycine; an intermediate in the conversion of choline, via betaine and dimethylglycine, to glycine, and in the synthesis of choline from glycine. *See also* sarcosinemia. **sarcosine dehydrogenase** EC 1.5.99.1; a flavoprotein enzyme that catalyses the reaction:

The flavin is FMN.

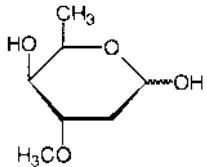

**sarcosinemia** or (*esp. Brit.*) sarcinaemia a rare inherited metabolic disease of humans, also found in ethylnitrosourea-induced mutants of mice, giving elevated plasma and urine levels of sarcosine. It may be accompanied by mental retardation or psychiatric disturbances. Primary sarcosinemia results from deficiency of sarcosine dehydrogenase (EC 1.5.99.1). Sarcosinemia may also be found in folate deficiency (*see* folic acid) in humans and in glutaric aciduria type II, but in primary sarcosinemia elevated levels of other organic acids are not found. Inheritance is probably autosomal recessive.

**sarcosome** a subcellular organelle found in muscle tissue that has essentially the same biochemical properties as a mitochondrion in other tissues. In muscles with intermittent activity, sarcosomes are found at the level of the I bands (*see* sarcomere); such muscles include skeletal muscles of vertebrates and invertebrates whose metabolism during activity is largely anaerobic. In muscles required to perform sustained activity, such as bird and insect flight muscles and vertebrate heart muscle, sarcosomes are found at the level of the A bands; these muscles have predominantly aerobic metabolism.

sarcotubule *another name for* Ttubule.

sarin methylphosphonofluoridic acid I-methylethyl ester; an organophosphate (def. 2) that inhibits acetylcholinesterase and other serine esterases. It is a military nerve gas but is useful in the treatment of leprosy and has some effect on AIDS.

**o-sarmentose** 2,6-dideoxy-3-O-methyl-D-xylo-hexose; a substance found as a component of some cardiac glycosides.

**satellite DNA** a fraction of DNA, present in most eukaryotic cells in amounts of up to 10% or more of total DNA, with a highly repetitive nucleotide sequence. Its base composition differs sufficiently from the bulk of the DNA to give rise to a 'satellite' band having a different buoyant density when DNA preparations, following shear force degradation, are centrifuged in cesium chloride density gradients. For instance, mouse satellite DNA contains about a million copies of a repeating sequence of approximately 300 base pairs with a lower (G+C) content than that of the moderately repetitive and unique DNA sequences. *See also* minisatellite.

**satellite RNA** small RNAs ( $\approx 350$  bases) also called virusoids, found in plants; they are encapsidated by some plant viruses. *See also* ribozyme.

**satellite virus** a small virus that occurs in association with another virus, upon which it is dependent. An example is satellite tobacco mosaic virus (STMV). This  $172\text{ \AA}$  diameter particle encloses a 1059 nucleotide RNA that encodes only two proteins, the 159-residue viral coat protein and a 58-residue protein of unknown function. STMV can only multiply in cells that have been coinfecte with tobacco mosaic virus. This is the only known example of such a parasitic relationship between a spherical virus and a rod-shaped virus.

**saturable** capable of undergoing saturation (def. 5). -saturability *n.*

**saturated fatty acid** any fatty acid in which the carbon-carbon bonds of the alkyl chain are exclusively single bonds. The predominant naturally occurring saturated fatty acids are palmitate and stearate; others include laurate, myristate, arachidate (*see* arachidic acid), behenate (*see* behenoyl), lignocerate, and cerotate (*see* ceretyl). All saturated fatty acids can be derived metabolically from acetyl-CoA, both in animals and plants. *See also* fatty-acid nomenclature.

**saturates** *an informal term for* saturated fatty acids.

**saturation** 1 (of a chemical compound) the point at which all the valence bonds of the component atoms are satisfied, especially the state of an organic compound that contains only single carbon-carbon bonds. 2 (of a solution) the state in which it has the greatest concentration of the solute that can remain in stable equilibrium with undissolved solute at a given temperature and pressure. 3 (of a gas) the state in which there is the greatest concentration of the vapour associated with a liquid or solid that can remain in stable equilibrium with unvaporized liquid or solid, respectively, at a given temperature and pressure. 4 (of an active site of an enzyme or transporter) the point at which the site is fully occupied with ligand. Saturable enzyme or receptor systems exhibit hyperboliform or sigmoid curves of activity versus concentration (*see* saturation kinetics). 5 the act or process of bringing to or towards saturation; especially the addition of hydrogen to triple and double bonds.

**saturation analysis or binding assay** a development of isotope dilution analysis used for the measurement of very low concentrations of biologically potent substances (e.g. a specified hor-

mone) in small samples of complex mixtures such as biological fluids. The essential steps of the technique are: (1) the substance, S, is allowed to react with a fixed amount of a specific binding agent under conditions such that the latter is always fully saturated with S; (2) the partitioning of S between the free and bound states is determined by the use of an indicator and by physical separation of the free from the bound form; and (3) the distribution of the indicator is compared with distributions obtained using a series of known amounts of S. The indicator is a labelled form of pure S, the label commonly being a radioisotope of high specific activity; alternatively, fluorescent, enzymic, or other labels may be used if they give the required sensitivity. The specific binding agent is generally an antibody (usually tailor-made), as in enzyme immunoassay, fluoroimmunoassay, or radioimmunoassay, or a naturally occurring macromolecular carrier or cellular receptor substance, as in competitive protein-binding assay.

**saturation fraction symbol:**  $y$ ; the ratio of the concentration of bound ligand to the total concentration of the binding agent. Hence, in a binding reaction where a compound P binds X to form PX, then  $y = [PX]/[P_{\text{total}}]$ . A plot of  $y$  against  $[X]$  is known as the adsorption isotherm for this system.

**saturation kinetics** the kinetics of a reaction (or of mediated transport) when the velocity of the reaction (or of the transport) increases to a maximal value (plateau) as the concentration of the reactant (or of a component being transported) is increased.

**saturation ratio or cooperativity index symbol:**  $R_s$ ; (of an allosteric protein) the ratio of the concentration of the substrate (or other small molecule) necessary to produce 90% to that required to produce 10% saturation of the specific sites on a protein. It is a convenient measure of the extent of cooperativity. *See also* cooperative ligand binding.

**saxitoxin abbr.:** STX; a paralytic poison, produced by the marine dinoflagellates *Gonyaulax catenella* and *G. excavata*. It can be accumulated by shellfish, making them toxic when eaten. Its action is similar to that of tetrodotoxin, with which it competes for sodium channels.

**Sb symbol for antimony.**

**SBH abbr. for sequencing by hybridization;** a hypothetical method yet to be implemented for the very rapid sequencing of DNA. It is based on the idea of having all possible octamers (there are 63 536) on a small hybridization screen called a DNA chip. As the octamers form nested arrays, a DNA fragment (of a few hundred bases) would only hybridize to some of these and the sequence could be deduced computationally.

**SBS model or SBS abbr. for side-by-side model.**

**se abbr. for synclinal** (def. 2).

**s.c. abbr. for subcutaneous.**

**Sc 1 symbol for scandium.** 2 abbr. for secretory component (*see* secretory piece).

**SCAD abbr. for short-chain acyl-CoA dehydrogenase or butyryl-CoA dehydrogenase;** *see* beta-oxidation system.

**scaffolding protein** any of a group of proteins that have specific binding sites and are instrumental in determining the structure and assembly of large three-dimensional structures such as a virus. Such proteins are integral to the self-assembly doctrine elaborated by Caspar and Klug.

**scalar** 1 a physical quantity, such as mass or time, that is characterized only by its magnitude and does not contain any concept of direction. 2 describable by a number representing a point on a scale undirected in space. *Compare* tensor, vector (def. 1).

**scaler** an electronic circuit or device that counts electrical pulses by aggregating the pulses and giving one output pulse for a predetermined number of input pulses.

**SCAMP abbr. for secretory carrier membrane protein;** it is a  $\text{Ca}^{2+}$ -binding protein with leucine zipper and zinc finger motifs. SCAMPs are widely distributed as components of post-Golgi membranes. They function in the mechanisms for recycling proteins between the Golgi and the cell surface. Ex-

**scanner**

ample from rat, SCAMP 37: database code S37395, 338 amino acids (37.96 kDa).

**scanner** an instrument or device used to measure or sample the distribution of some quantity or condition in a particular system, area, or region, e.g. to measure the distribution of colour or radioactivity on a chromatogram or electrophoretogram, or to measure the radial distribution of light absorbance in a cell in an ultracentrifuge.

**scanning electron microscope** abbr.: SEM; see **electron microscope**.

**scanning proton microprobe** an instrument in which a sample is bombarded by a high-energy (1-4 MeV) proton beam, causing emission of X-rays that can be characteristically attributed to certain elements. The technique permits the detection of elements down to about 1 ppm.

**Scatchard plot** a method of analysis of the binding of ligand to a macromolecule (or receptor), based on the **Scatchard equation**,  $\bar{v}/[L] = (n - \bar{v})K$ , where  $\bar{v}$  is the average number of ligand molecules bound per binding macromolecule,  $[L]$  is the free ligand concentration,  $n$  is the number of binding sites on the macromolecule and  $K$  is the intrinsic association constant. A plot is made of  $\bar{v}/[L]$  on the y-axis and  $\bar{v}$  on the x-axis. If the binding sites are identical and independent, a straight line is obtained of slope  $-K$  with intercepts on the x-axis of  $n$  and on the y-axis of  $Kn$ . If there is interaction between the binding sites, or there are several classes of independent sites, the plot is not linear. [After George Scatchard (1892-1973), US physical chemist.]

**scatter** to disperse in random direction(s) by impact or other interaction, especially light, electrons, neutrons, or X-rays. The measurement of scattered rays or particles may lead to useful analysis, as in **light scattering**.

**scatter diagram** a graph upon which two measured characteristics of each individual of a population are represented by one dot.

**scavenger** (in chemistry) a substance that reacts with (or otherwise removes) a trace component, such as a trace metal ion, or that traps a reactive **reaction intermediate**.

**SCF** abbr. for stem cell factor.

**Schally, Andrew** Victor (1926- ), Polish-born US biochemist and physiologist; Nobel Laureate in Physiology or Medicine (1977) jointly with R. Guillemin 'for their discoveries concerning the peptide hormone production of the brain' [prize shared with R. Yalow].

**Schardinger dextrin** a former name for **cyclodextrin**. [After Franz Schardinger (1853-1920), who first described such compounds in 1908.]

**Schardinger enzyme** an alternative name for **xanthine oxidase**.

**Schardinger reaction** the decolorization of Methylene Blue by milk in the presence of formaldehyde; the reaction is catalysed by **xanthine oxidase** (or Schardinger enzyme) in the milk.

**Schatz, Albert** (1920- ), PhD student of S. A. Waksman, legally recognized as the co-discoverer of **streptomycin**.

**Scheie syndrome** an alternative name for **mucopolysaccharidosis I S**. [After Harold G. Scheie (1909- ).]

**Schiff, Hugo** (1834-1915), German chemist who devised the reagent for aldehydes known as **Schiff reagent**.

**Schiff base** or Schiff's base any **imine** having the more limited general structure  $R_2C=NR'$  where R may be any organyl group or H and R' is any organyl group. It may be formed by condensation of the carbonyl group of an aldehyde or ketone with the amino group of a primary amine according to the equation:

Often considered to be synonymous with **azomethine**.

**Schiff reagent** a solution of leucofuchsin - fuchsin bleached with sulfuric acid - that produces a red colour when reacted with an aldehyde. The reagent is used in the **hulgen reaction** and the **periodic acid-Schiff reaction**.

**Schiff test** 1 (for aldehydes) a test based on the red colour produced when aldehydes react with **Schiff reagent**. 2 (for uric

**Schoenheimer**

acid) a test based on the reduction of silver ions (silver nitrate solution) to metallic silver by uric acid in sodium carbonate solution. 3 (for urea) a test based on the formation of a purple colour when urea is treated with a concentrated solution of furfural in concentrated hydrochloric acid solution. Allantoin, but not uric acid, also gives a positive test.

**Schild equation** the expected relationship between the **concentration ratio**,  $r$ , and the concentration of a reversible competitive antagonist, B. It is given by  $r = [B]/K_B + I$ , where  $K_B$  is the dissociation equilibrium constant for the combination of B with the receptor. Compare **Gaddum equation**. [After Heinz Otto Schild (1906-84), Austrian-born British pharmacologist.]

**Schild plot** a plot of  $\log(\text{concentration ratio} - 1)$  versus  $\log$  concentration of antagonist. For a reversible competitive antagonist the plot has a gradient of I. The intercept on the abscissa then defines the concentration of antagonist required to reduce the response of the target tissue (or organism) by half (the dissociation equilibrium constant:  $-\log K_B = pA_2$  when the slope is exactly unity and there are no complicating factors; see  $pA_2$ ).

**Schilling test** a test for cobalamin (vitamin  $B_{12}$ ) malabsorption that depends on the oral administration of  $^{57}\text{Co}$  or  $^{58}\text{Co}$  labelled **cyanocobalamin** and measurement of the urinary excretion of the radioactive label during the ensuing 24 hours. [After Robert Frederick Schilling (1919- ), US hematologist and nutritionist.]

**schizophrenia** any of a group of mental disorders characterized by a special type of personality disintegration, random thought processes, and impaired relation to reality. The biochemical basis of the disease remains enigmatic. Antipsychotic (neuroleptic) drugs such as **chlorpromazine**, which are widely used in the symptomatic treatment of all forms of schizophrenia, are considered to act by blocking postsynaptic dopamine D<sub>2</sub> receptors, though most are not totally selective in this action. -schizophrenic adj., n.

**Schizosaccharomyces pombe** the fission yeast that is used to brew the African beer called *pombe*. The rod-shaped cells grow by elongation, and the spores germinate and divide as haploids. The arrangement of the membranous organelles, e.g. the Golgi apparatus, in fission yeast is closely similar to that of higher eukaryotes, in marked contrast to that of budding yeast. It is especially suitable for analysing the relationship between cell size and the cell cycle for two reasons: (1) the cells divide symmetrically, unlike budding yeast; and (2) the yeast grows in length but not in diameter.

**Schlesinger test** a qualitative test for **urobilin** in urine. The urobilinogen in the urine is first oxidized by iodine to urobilin, then a zinc-urobilin complex is formed by addition of zinc acetate in ethanol; the complex has a yellow-green fluorescence and an absorption band at 507 nm.

**Schlieren method** an optical method of exhibiting inhomogeneities in refractive index in transparent media, dependent on the deflection of a ray of light from its undisturbed path when it passes through a medium in which there is a solute inducing a gradient of refractive index normal to the ray. The curvature of the ray is proportional to the refractive-index gradient in the direction normal to the ray. It is used in biochemistry particularly in measurements of diffusion, sedimentation, and electrophoretic mobility of proteins and other substances. [From German *Schlier*, streak.]

**Schmidt-Thannhauser procedure** a method for the extraction and determination of DNA, RNA, and phosphoproteins. Material insoluble in dilute, cold trichloroacetic acid is dried, digested with alkali, and subsequently precipitated with a strong acid. The total phosphorus in the precipitate represents DNA, the soluble inorganic phosphorus represents the phosphoproteins, and the soluble organic phosphorus represents the RNA. [After Gerhard Schmidt (1901-81) and Siegfried Joseph Thannhauser (1885-1962), German-born US biochemist.]

**Schoenheimer, Rudolf** (1898-1941), German-born US biochemist; a leader in early work with isotopic tracers ( $^2\text{H}$  and  $^{15}\text{N}$ ) that led him (with colleagues) to put forward the concept

## Schultz-Dale reaction

screen

of the dynamic state of body constituents, which became an important principle in metabolic regulation.

**Schultz-Dale reaction** an *in vitro* anaphylactic reaction in which the uterus or ileum of a sensitized animal (guinea pig) contracts specifically when a small amount of the sensitizing antigen is added to the bathing medium. The reaction is caused by histamine and similar substances that are released when the antigen combines with cellular antibody. [After H. H. Dale.]

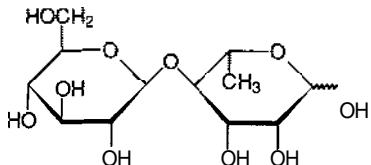

**SChiltz-Borrisow rule** or Schiitz law an empirical rule according to which the velocity of an enzyme reaction is proportional to the square root of the enzyme concentration. It was first developed for pepsin but applies only to the crude enzyme under certain limited conditions; similar results have been obtained with some other proteinases. The effect is due to the presence of a reversibly dissociating pepsin inhibitor in crude pepsin preparations.

**Schwann cell** a uninucleate cell of the neurilemma surrounding a myelinated neuronal axon that is responsible for the formation and maintenance of the myelin sheath in peripheral myelinated neurons. [After Theodor Schwann (1810-82), German anatomist and physiologist.]

**Schwannommin** see merlin.

**SCIF abbr.** for secondary cytotoxic T-cell-inducing factor (i.e. interleukin 2).

**scillabiose** the disaccharide 4-O-P-D-glucopyranosyl-L-rhamnose; it occurs in a glycoside of *Scilla maritima*.

**scinderin** or adseverin a  $\text{Ca}^{2+}$ -dependent cytosolic actin filament severing protein present in chromaffin cells, platelets, and a variety of secretory cells. Example (bovine): database code BBSCINDE, 715 amino acids (80.68 kDa).

**scintillant** 1 (of a phosphor) exhibiting scintillation. 2 *ajargon term for* scintillator.

**scintillate** 1 to give off sparks, to sparkle. 2 (of a phosphor) to emit quanta of light discontinuously, by fluorescence, when struck by a charged particle or a high-energy photon.

**scintillation** 1 the act of scintillating. 2 the flash of light produced in a phosphor when it is struck by a charged particle or a high-energy photon.

**scintillation autoradiography** an alternative term for fluorography (def. 2).

**scintillation cocktail** or **scintillation fluid** any mixture, containing a scintillator, to which beta emitters can be added for the purpose of scintillation counting; the radiation excites the scintillator to emit light. Many scintillation cocktails are based on hydrophobic solvents, since for the most part scintillators sparingly soluble in aqueous solutions have been used. The first scintillator to be widely used was 2,5-diphenyloxazole (PPO), often used in conjunction with 1,4-bis(5-phenyl-2-oxazolyl)benzene (PoPoP), which is excited by the light emitted by PPO to emit light of a higher wavelength more suitable for measurement. Subsequently many other scintillators, especially biodegradable compounds and others more compatible with water, have been developed. See also biphenylphenyloxadiazole, bismethylstyrylbenzene.

**scintillation counter** an instrument for the detection and measurement of the intensity of high-energy radiation. Instruments for detecting gamma radiation contain a detector, normally a crystal of sodium iodide containing a small amount of thallium, and this is encased in a metal 'top hat' lined with a

white reflector, the open end being sealed with Perspex. When the sodium iodide absorbs  $\gamma$  rays it emits a flash of light. For the counting of  $\beta^-$  emissions, the radioactive substance is dissolved or suspended in a scintillation cocktail contained in a glass or plastic vial, which is inserted into a chamber in the counter. Sometimes a solid scintillant is used for this also, e.g., for the effluent from chromatography columns. In the case of both types of instrument, the flashes of light produced are detected by a photomultiplier and converted into pulses of electric current which may be counted by an electronic counter. scintillation fluid an alternative term for scintillation cocktail. scintillation spectrometer another name for scintillation counter.

**scintillator** or **scintillant** any phosphor that fluoresces when struck by a charged particle or a high-energy photon. See scintillation cocktail.

**scintillon** a subcellular, crystal-like structure, found in bioluminescent organisms, that emits light on acidification in the presence of oxygen.

**scissile** capable of being split easily or cut smoothly, especially of an easily cleaved chemical bond.

**scission** a division or splitting; an act of dividing a nonisometric object orthogonally to its longest axis, especially a chemical bond or a fibrous molecule; cleavage (def. 2).

**scleral** pertaining to the sclera, the fibrous outer layer of the eyeball.

**scleroprotein** any of a group of simple, generally fibrous proteins that are insoluble in aqueous solutions; examples include keratin and silk fibroin.

**sclerosis** hardening of a tissue as a sequel to inflammation; especially an increase of connective tissue in the nervous system. See also arteriosclerosis. -sclerotic ad.

**scopolamine** see hyoscine.

**scorbutic** of, pertaining to, or affected with scurvy.

**scotophobin** a IS-residue peptide that accumulates in the brains of rats trained to avoid the dark; administration is said to elicit a similar response in untrained animals. It is thought to be the first memory-directing substance isolated and identified.

**scotopia** adaptation to darkness; the adjustment of the eye to vision in dim light or the dark. It is considered to involve mainly retinal rod cells. Compare photopia. —**scotopic** ad.

**scotopsin** an opsin that is the apoprotein of a rhodopsin.

**SCP abbr.** for single-cell protein.

**scrapie** a spongiform encephalopathy of sheep and goats, and the first to be identified of a group once thought to be 'slow virus' infections occurring naturally and caused by an unconventional agent. Scrapie has similarities to two other animal diseases, transmissible mink encephalopathy and bovine spongiform encephalopathy, and three transmissible human dementias, kuru, Creutzfeldt-Jakob disease, and Gerstmann-Striussler syndrome. All these diseases are now accepted as being caused by alterations in the prion proteins in the nervous system. The disease has been known since its first reported occurrence in merino sheep in Spain in 1732, which was rapidly followed by reports of other cases in Britain and Germany. The incubation period for the scrapie agent is usually 1-3 years. Different breeds of sheep exhibit markedly different susceptibilities to scrapie. As many as 20 different strains of scrapie agent, each with distinct properties in terms of incubation period in a given host and location of damage within the brain have been identified and transferred to mice. It would appear that the strains are passed to the progeny, so any explanation of the nature of the infective agent and process must take this into account.

**screen** 1 to protect from; esp. from harmful agents or radioactivity using sheets of lead, glass, or plastic; or from radiofrequency interference using a copper sheath or wire net. 2 to sift data, often using a limited or general assay, for selection of a particular phenomenon or result; samples selected by preliminary screening can be isolated for more detailed study. 3 (*in clinical chemistry*) to carry out any diagnostic procedure on a

## screw axis

large cohort of patients with a view to detecting hitherto asymptomatic disease; *see also* genetic screening. 4 any device or material that acts to screen.

**screw axis** a crystal or an oligomeric protein molecule is said to possess an n-fold screw axis if it presents exactly the same appearance after rotation about that axis of  $360^\circ/n$  coupled with a translation parallel to the axis. *Compare* rotation axis.

**scRNA** abbr. for small cytoplasmic RNA.

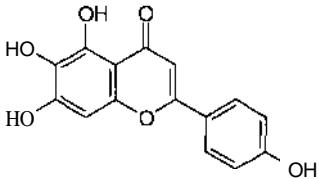

**scRNP** abbr. for small cytoplasmic ribonucleoprotein.

**scurvy avitaminosis C**; a deficiency disease caused by lack of ascorbic acid (vitamin C) in the diet. It is characterized by anemia, sponginess and ulceration of the gums, hemorrhages into the skin and subcutaneous tissues, and delayed wound healing.

**scute** a gene in *Drosophila* for AS-C protein.

**scutellarin** EC 3.4.21.60; *other name*: taipan activator (being from the venom of the taipan (snake), *Oxyuranus scutellatus*). An enzyme that catalyses the selective cleavage of Arg-I-Thr and Arg-I-Ile in prothrombin to form thrombin and two inactive fragments; its specificity is similar to that of factor Xa (*see* blood coagulation). *Compare* scutellarin.

**scutellarein** 4',5,6,7-tetrahydroxyflavone; the aglycon of scutellarin. *Compare* scute/arin.

**scutellarin** the glucuronide of scutellarein, from *Scutellaria* spp. *Compare* scutelarin.

**scyrr colloquialism** for scRNP (i.e. small cytoplasmic ribonucleoprotein).

**SD abbr.** for standard deviation.

**SOS abbr.** for sodium dodecyl sulfate.

**SO sequence abbr.** for Shine-Dalgarno sequence.

**SOS-PAGE abbr.** for SDS-polyacrylamide gel electrophoresis.

**SOS-polyacrylamide gel electrophoresis or SDS gel electrophoresis abbr.**: SDS-PAGE; a rapid and inexpensive method for resolving a protein into its subunits and determining their relative molecular masses ( $M_r$  values), based on the ability of sodium dodecyl sulfate to cause dissociation of oligomeric proteins and to bind to the subunits to form complexes of constant charge-to-mass ratio. On zone electrophoresis in polyacrylamide gel, such complexes often have mobilities directly related to their  $M_r$  values, which, if unknown, may thus be obtained by comparison with standards. *Other name*: detergent gel electrophoresis.

**Se symbol** for selenium.

**SE abbr.** for standard error; *see* standard error of estimate of the mean.

**SEA** a gene family encoding membrane receptor tyrosine kinases having strong homology with the insulin receptor family. The acutely transforming virus, avian erythroblastosis virus (*abbr.*: AEV) strain 13, contains the oncogene *v-sea*; this transforms fibroblasts and erythroblasts, but not avian myeloid cells. Sea, the product of *c-sea*, the cellular homologue of *v-sea*, phosphorylates She (*see* SHe) on tyrosine residues. Example from AEV strain 13: database code KSEA\_AVIET, 370 amino acids (41.70 kDa).

**sealase** *a former name* for DNA ligase (ATP); *see* DNA ligase.

**sea-urchin-hatching proteinase** *see* envelysin.

**sebaceous gland** any of the single or branched glands in the skin that produce the oily substance, sebum. They open into the hair follicles.

**sebum** the oily secretion of the sebaceous glands in the skin. It

## secondary hyperlipidemia

contains lipids such as waxes, squalene, and triacylglycerols; the triacylglycerols are broken down by anaerobic bacteria during secretion to form fatty acids. Sebum helps to form an effective barrier against water loss.

**sec symbol** for secant (def. I).

**sec. abbr.** and *obsolete symbol* for second (def. I).

**sec-** *abbr.*: *so*; *prefix* (*in chemical nomenclature*) signifying secondary (def. Ia).

**secant** 1 *abbr.* and *symbol*: sec; the reciprocal of the cosine of an angle. 2 a straight line cutting a curve at two or more points.

**seco- prefix** (*in chemical nomenclature*) denoting cleavage of a ring with addition of one or more hydrogen atoms at each terminal group thus created. The numbering of the skeletal atoms of the parent molecule is retained.

**seco-carotenoid** a carotenoid in which one of the rings has undergone fission by breakage of a carbon-carbon bond; e.g. semi-p-carotene (5,6-seco-p-p-carotene-5,6-dione).

**second** 1 *symbol*: s; the SI base unit of time, equal to the duration of 9 192 631 770 periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the caesium-133 atom. 2 *symbol*: " a unit of plane angle equal to  $1/60$  of a minute; i.e. 4.848 14 microradian ( $1/648\ 000$  rad). *See* angle (def. 1).

**secondary** (*in chemistry*) 1 a *prefix*: sec- (*abbr.*: so); describing an alkyl compound (e.g. an alkanol) in which the functional group (e.g. a hydroxyl group) is attached to a carbon atom linked to two others. b describing the carbon atom bearing the functional group in such a compound. 2 describing an amide or amine in which two appropriate groups are attached to a nitrogen atom. 3 describing a salt formed by replacing two of the ionizable hydrogen atoms of a tribasic acid by one or two other cations of appropriate valency. *Compare* primary, tertiary.

**secondary bond** a *loose term to describe* any of the weak attractive forces between atoms and/or molecules, especially when these stabilize a three-dimensional structure. It includes hydrogen bonds, hydrophobic interactions, and van der Waals forces. **secondary cell wall deposition** (*in plants*) the deposition of microfibrils and noncellulosic polysaccharides on the primary cell wall. It provides additional conducting and supporting tissue and frequently makes up the greater part of the mature cell wall.

**secondary charge effect** an effect seen in the hydrodynamic study of charged macromolecules when the positive and negative ions of the supporting electrolyte have different sedimentation (or diffusion) coefficients, leading to the establishment of local electric fields due to charge separation. These local fields act as an additional force on the macromolecules, either accelerating or retarding their movement.

**secondary cytotoxic T cell-inducing factor abbr.**: SCIF; *an alternative name* for interleukin 2.

**secondary deficiency** a nutritional deficiency occurring when the dietary content of some essential nutrient is known to be adequate in normal conditions. It may be caused by a failure of absorption from the gut due to disease, diminished synthesis of a vitamin by the intestinal flora during treatment with an antibacterial agent, or increased requirement, e.g. in pregnancy.

**secondary electron** an electron emitted from a solid as a result of the impact of another electron. If the energy of the incident primary electron is sufficient, more than one secondary electron may be emitted, an effect exploited in an electron multiplier. *See also* photomultiplier.

**secondary emission** the phenomenon of emission of secondary electrons.

**secondary F'-containing strain** *see* F plasmid.

**secondary fluor** a second fluorescent agent that absorbs the fluorescent light emitted by a primary fluor and is thus excited to emit light at a higher wavelength, which may be more convenient for detection.

**secondary hyperlipidemia** *see* hyperlipidemia.

**secondary immune response**

**secondary immune response** an immune response to an immunogen to which an animal has previously been exposed and to which its lymphoid tissue has been primed. It consists characteristically of the rapid production of large amounts of antibody over a few days, following which the level of antibody slowly declines in an exponential manner. *Compare* primary immune response.

**secondary lysosome** or phagolysosome a lysosome that contains not only the specific acid hydrolases but also their substrates taken up from the environment or sequestered from the cell's own cytoplasm. Secondary lysosomes are formed by fusion of a primary lysosome with a phagosome or a vesicle containing endocytosed matter. *Compare* telolysosome.

**secondary messenger** a variant form of second messenger.

**secondary metabolism** the formation of end products of metabolism - secondary metabolites - that often have no readily apparent use in the producing organism.

**secondary metabolite** any of a group of chemically very diverse natural products that have a restricted taxonomic distribution, usually possess no immediately obvious function in cell growth, and are often (but not always) synthesized by cells that have stopped dividing; typically they exist as members of closely related chemical families, usually of  $M_r < 1500$ , but some bacterial toxins are considerably larger. An example of a secondary metabolite is penicillin.

**secondary response** see secondary immune response.

**secondary structure** 1 (of a protein) the arrangements of the polypeptide chain that form more-or-less regular hydrogen-bonded structures, in particular  $\alpha$ -helical and  $\beta$ -pleated sheet structures; *see* alpha helix, beta strand. 2 (of a nucleic acid) the arrangement of one or two polynucleotide chains in bihelical structures, stabilized by hydrogen bonds between complementary bases (*see* complementary base sequence); *compare* clover-leaf structure. *See also* primary structure, quaternary structure, tertiary structure.

**second law of thermodynamics** *see* thermodynamics.

**second messenger** or **secondary messenger** a mediator that is caused to accumulate in an effector (target) cell by the action of a hormone, growth factor, or other agonist, and that brings about the action of that agonist on the cell. The major second messenger systems are currently recognized to include: synthesis of cyclic AMP by adenylate cyclase (the first of such systems to be discovered); synthesis of cyclic GMP by guanylate cyclase; opening of ion channels; the phosphoinositide system, (*see* phosphatidylinositol cycle) involving activation of phosphoinositide-specific phospholipase C (*see* phospholipase), or 1-phosphatidylinositol 3-kinase; and protein phosphorylation by serine/threonine-specific or tyrosine-specific protein kinases. An important component in several of these systems involves coupling of activated receptor to the effector system through a G-protein.

**second-order rate constant** *see* rate constant.

**second-order reaction** *see* order of reaction.

**seco-steroid** a steroid in which one of the rings has undergone fission by breakage of a carbon-carbon bond.

**secretagogue** or **secretogogue** an agent that stimulates secretion (usually of a named hormone, juice, or other glandular product). *See also* +agonue.

**secretase** a type of enzyme that cleaves the extracellular domain of a number of membrane proteins of type I or type II topology, releasing the extracellular part of the protein into the circulation. Cleavage normally occurs close to the extracellular face of the membrane. Proteins on which secretases act include Alzheimer's amyloid precursor protein, angiotensin converting enzyme, transforming growth factor- $\alpha$ , and the tumour necrosis factor ligand and receptor superfamilies. Secretase activity is inhibited by a number of metalloproteinase inhibitors, suggesting that secretases may be metalloproteinases. **secrete** to elaborate and emit a secretion from a cell or, particularly, from a gland.

**secretin** a digestive hormone, discovered in 1902 by William

**secretory protein I**

Maddock Bayliss (1860-1924, British biologist) and Ernest Henry Starling (1866-1927, British physiologist) (the first hormone to be discovered). It has the sequence (human):

(3.04 kDa), and is formed from a 134-amino-acid precursor, which is synthesized in specific endocrine cells, S cells, in the mucosa of the small intestine. It stimulates the release of bicarbonate, enzymes, and potassium ions from the pancreas and stimulates the secretion of enzymes and electrolytes in the gut; it also inhibits HCl production by the stomach. Secretin lends its name to a superfamily that on structural grounds includes gastric inhibitory peptide, GHRH, glucagon, peptide HI, and vasoactive intestinal polypeptide. Example of precursor from *Mus musculus*: database code SECR\_MOUSE, 133 amino acids (14.91 kDa).

**secretin receptor** any of several membrane proteins that bind secretin and mediate its intracellular effects. These are seven-transmembrane-domain, G-protein-coupled, adenylate cyclase stimulating receptors, not structurally related to other G-protein-coupled receptors. Example from human (precursor): database code SCRC\_HUMAN, 440 amino acids (50.23 kDa).

**secretion I** the process of elaborating, segregating, and emitting a substance or juice from a cell, organ, or organism; e.g. the secretion of insulin by the B cells of the islets of Langerhans, or the secretion of urine by the kidneys. At the cellular level there are three basic types of secretion: apocrine, holocrine, and merocrine. 2 a product of secretion (def. I) from a cell, organ, or organism.

**secretogogue** a variant spelling of secretagogue.

**secretogranin I** another name for chromogranin B (*see* chromogranin).

**secretor** any person who secretes water-soluble glycoproteins with A, B, or H blood-group specificities into their mucous secretions, e.g. saliva and gastric juices. Over 80% of humans are secretors, their status being determined by the allelic constitution of a secretor gene in their genomes.

**secretor gene** a gene determining secretor phenotype in humans. Whether a person is a secretor or nonsecretor is determined by a pair of allelic genes, *Se* and *se*. Secretors are either *SelSe* or *Selse* while nonsecretors are *se/se*. These alleles occur at a different locus from the ABO locus and do not affect the A, B, and H specificities of the red blood cells.

**secretory** describing a molecule or molecular fragment destined for secretion from a cell, such as secretory protein, polypeptide, etc.

**secretory actin-binding protein** abbr.: SABP; also called prolactin-inducible protein; gross cystic disease fluid protein 15; a glycoprotein that has been isolated in several different studies (as the alternative names indicate) but whose function remains unknown. As the prolactin-inducible protein, it was identified as a highly specific and sensitive marker of primary and metastatic breast cancer. Example from human (precursor): database code SABP\_HUMAN, 146 amino acids (16.55 kDa).

**secretory component** another name for secretory piece.

**secretory granule** a small subcellular vesicle, surrounded by a single-layered membrane, that is formed from the Golgi apparatus and contains a highly concentrated protein destined for secretion. Secretory granules move towards the periphery of the cell, their membranes fuse with the cell membrane, and their protein load is exteriorized. Processing of the contained protein may take place in secretory granules. *Compare* zymogen granule.

**secretory piece** (abbr.: SP) or **secretory component** (abbr.: Sc) the 58 kDa polypeptide that joins together the two identical monomers comprising the secretory form of immunoglobulin A. It has strong affinity for mucus, thus prolonging retention of IgA on mucous surfaces, and may protect this class of immunoglobulin against proteolytic destruction in the digestive tract. *Other names:* T chain; transport piece.

**secretory protein I** abbr.: SP-I; a glycoprotein of the parathyroid gland that is co-secreted *in vitro* with parathyrin. It consists

## sector

of at least two homologous glycoproteins of similar size ( $M_r$  72 000 and 70 000), related to chromogranin A (see chromogranin).

**sector** any portion of a circle bounded by two radii and the included arc. -sectoral adj.

**sector cell** or sector-shaped cell a cell used in an analytical ultracentrifuge to contain the sample. It is sector-shaped when viewed parallel to the rotation axis. Since the accelerating force is radial, sedimenting molecules move along radii and this cell shape minimizes the collision of sedimenting molecules with the cell walls.

**sediment** 1 to undergo sedimentation. 2 the accumulation of material resulting from sedimentation.

**sedimentation** the setting of solid particles (or solute) through a liquid (or solution) under the influence of a gravitational or centrifugal field.

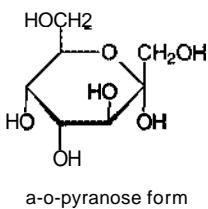

**sedimentation coefficient symbol:**  $s$ ; the rate of sedimentation of a particle in an ultracentrifuge or other system. For a particle or solute sedimenting in a system at constant applied field, temperature, and pressure,  $s = vla$ , where  $a$  is the acceleration of free fall or centrifugation and  $v$  is the velocity of sedimentation. In centrifugation  $s = vlw^2r$ , where  $\omega$  is the angular velocity in rad s<sup>-1</sup> and  $r$  is the distance of the particle or solute from the axis of rotation. It has the dimensions of time. The sedimentation coefficients of macromolecules and cellular particles are often expressed in svedbergs.

**sedimentation equilibrium** a technique in which compounds of interest are centrifuged for a period sufficiently long for the system to come to equilibrium. The technique has a number of applications. In one, used for molecules that have a density greater than the solvent, centrifugation is carried out at relatively slow speeds so that sedimentation of the molecule is slow enough to be counterbalanced by diffusion. At equilibrium, the concentration is lower at the meniscus and higher at the bottom of the cell, but is unchanging. The relative molecular mass,  $M_r$ , of the compound in question, often a protein, can be calculated from the expression:

$$M_r = 2RT \ln(c_2 I c_1) / l w^2 (l - vp)(r_2^2 - r_1^2)$$

where  $R$  is the gas constant,  $T$  is the thermodynamic temperature,  $v$  is the specific volume of the component,  $\rho$  is the density of the solution,  $\omega$  is the angular velocity of the rotor, and  $c_1$  and  $c_2$  are the concentrations of the component at distances  $r_1$  and  $r_2$  from the centre of rotation. Ideally, determinations should be done at several concentrations and extrapolated to zero concentration.

**sedoheptulose** a nonsystematic name for D-alstro-2-heptulose.

**sedoheptulose-bisphosphatase** EC 3.1.3.37; a chloroplast enzyme of the reductive pentose phosphate cycle that catalyses the reaction:

Example from *Arabidopsis thaliana* (precursor): database code SI7P\_ARATH, 393 amino acids (42.41 kDa).

**sedoheptulose '-phosphate** the 7-phosphate ester of sedoheptulose; it is a component of the pentose phosphate pathway. **Seebeck effect** the phenomenon whereby an electromotive force is generated in a circuit containing junctions between

## selectively labelled

dissimilar metals if these junctions are not all at the same temperature. See thermocouple. Compare Peltier effect. [After Thomas Johann Seebeck (1770-1831), Estonian-born German physicist.]

**segmentation** 1 (of an ovum) see cleavage (def. 3). 2 (of an animal's body) see metamerism.

**segregation (in genetics)** 1 the separation of homologous genetic elements (i.e. allele pairs) during meiosis in diploid cells. 2 the separation of sister chromatids during mitosis; by extension, the separation of any two independent genetic elements during cell division in prokaryotes. 3 (of plasmids) the partitioning of plasmids into daughter cells at cell division. Naturally occurring plasmids contain a partitioning function, *par*, which ensures correct partitioning into the two daughter cells. **segresome** a membrane-bound, cytoplasmic aggregate of a dye, formed either by passage of the dye through the membrane of a pre-existing phagosome or lysosome, or by some process leading to the *de novo* formation of a membrane around the dye aggregate.

**Seitz filter** a filtration apparatus that removes microorganisms from a liquid. It formerly consisted of a flat pad of asbestos, or asbestos and cellulose, suitably mounted between the sample container and the receiving flask, filtration being assisted by reducing the pressure in the receiving flask. It has now been superseded by a sintered-glass filter. [After Seitz-Filter-Werke, T. and G. Seitz GmbH & Co., Bad Kreuznach, Germany.]

**selachyl alcohol** 3-(octadec-9-enyloxy)-1,2-propanediol; a 1-octadec-9-enyl ether of glycerol, and a hydrolysis product of ether lipids.

**selected-ion monitoring** or **mass fragmentography** or **molecular fragmentography** a type of gas chromatography/mass spectrometry in which the intensities of one or more molecular or fragment ions selected from the mass spectrum of a particular compound are monitored continuously as a means of quantifying that compound.

**selectin** any of a group of leukocyte surface molecules that act as leukocyte adhesion molecules; they are classed as CD62 in the CD marker system. All have lectin family carbohydrate-binding domains and EGF-repeats, with four motifs. They are expressed on the surface of platelets and endothelial cells as well as leukocytes. E selectin (CD62E),  $M_r$  107–115 000 in various glycosylated forms, is expressed on endothelial cells, being induced by cytokines such as interleukin 1 $\beta$  and tumour necrosis factor  $\alpha$  in 3–6 hours. It mediates endothelial cell binding to neutrophils, monocytes, and some memory T cells. Example from human (precursor): database code LEM2\_HUMAN, 610 amino acids (66.58 kDa). L selectin (or lymph node homing receptor; CD62L),  $M_r$  74 000 (on lymphocytes), is constitutively expressed on monocytes, lymphocytes (thymocytes, NK cells), neutrophils, eosinophils, and basophils. It mediates the adherence of lymphocytes, neutrophils, and monocytes to endothelium, including that of lymphocytes to endothelial cells of high endothelial venules in peripheral lymph nodes. It binds to MadCAM and CD34. Example from human (precursor): database code LEM1\_HUMAN, 372 amino acids (42.14 kDa). P-selectin (or PADGEM; abbr. for platelet activation dependent granule external membrane protein),  $M_r$  140000, is expressed at the surface of activated platelets and endothelial cells, and is inducible within minutes by thrombin, histamine, or peroxides from  $\alpha$  granules of platelets or Weibel-Palade bodies of neutrophils. It mediates the adhesion of neutrophils and monocytes to platelets and endothelial cells. Example from human (precursor): database code LEM3\_HUMAN, 830 amino acids (90.74 kDa).

**selection (in microbiology)** a laboratory method in which a mixture of microorganisms is cultured under particular growth conditions that permit only cells with certain characteristics to survive, thereby enabling their isolation.

**selection pressure** the intensity with which natural selection operates; it is often measured by the change in gene frequency per generation due to the effects of natural selection.

**selectively labelled** indicating an isotopically labelled mol-

## selective medium

ecule in which the position(s) of the labelling is known, but the number of labelling nuclides at that (those) position(s) is not known; e.g. selectively labelled ethanol is designated as [1,2-<sup>2</sup>H]CH<sub>3</sub>-CH<sub>2</sub>-OH, which indicates that some, or all, of the hydrogen atoms on carbon atoms 1 and 2 are zH atoms.

**selective medium** a culture medium designed either to encourage or to inhibit the growth of certain types of organisms, especially microorganisms.

**selective theory of immunity** or **elective theory of immunity** any theory that ascribes to antigens a selective function in immunity by which antigens select cells genetically prepared to respond specifically and cause them to multiply and differentiate. They include the clonal-selection theory and the natural-selection theory of immunity. *Compare* instructive theory of immunity.

**selenium symbol:** Se; a metalloid element of group 16 of the (IUPAC) periodic table; atomic number 34; relative atomic mass 78.96. Its main oxidation states are -2, +2, +4, and +6, with properties similar to those of sulfur, but more metallic. It occurs in various allotropic forms (grey, red, black); the grey form shows some electrical conductivity, which is enhanced by light, and it is used in 'selenium cells' to measure light intensity. There are several isotopes, the most abundant being selenium-80 (mass 79.916; relative abundance 49.8%); others are selenium-74 (0.9%), selenium-76 (9.0%), selenium-77 (7.6%), selenium-78 (23.5%), and selenium-82 (9.4%). Radioactive isotopes are selenium-72, selenium-73, selenium-75, and selenium-79. Selenium is an essential trace element, required for the formation of selenoproteins, notably glutathione peroxidase. Gut absorption is poor, but selenium deficiency is rare (seen, e.g., in some parts of China with low soil selenium). The most obvious clinical feature of dietary deficiency is myopathy (especially cardiomyopathy). Measurement of red-cell glutathione peroxidase activity gives an index of selenium status.

**selenium-72** a radioactive nuclide of selenium, <sup>72</sup>Se, mass 71.927; it emits gamma radiation (0.046 MeV) and has a half-life of 8.4 days.

**selenium-73** a radioactive nuclide of selenium, <sup>73</sup>Se, mass 72.927; it emits a β<sup>+</sup> particle (1.32 MeV) and gamma radiation (0.361 Mev) and has a half-life on.1 h.

**selenium-75** a radionuclide of selenium, <sup>75</sup>Se, mass 74.923; it emits gamma radiation (0.481 MeV) and has a half-life of 118.5 days.

**selenium-79** a radionuclide of selenium, <sup>79</sup>Se, mass 78.918; it emits an electron (β<sup>-</sup> particle, 0.16 MeV), no gamma radiation, and has a half-life of 6.5 x 104 years.

**selenoamino acid** an amino acid in which selenium replaces a sulfur atom; *see* selenocysteine, selenomethionine.

**selenocysteine** H-Se-CH<sub>2</sub>-CH(NH<sub>2</sub>)-COOH; an essential component of glutathione peroxidase and some other proteins (*see* selenoprotein). For its synthesis, a special tRNA charged with serine responds to a UGA codon. The serine is converted to selenocysteine just before its use on the ribosome. It is assumed that the neighbouring base sequence indicates a special sense for this codon, which is normally a 'stop' codon.

**selenomethionine** CH<sub>3</sub>-Se-[CH<sub>2</sub>]<sub>2</sub>-CH(NH<sub>2</sub>)-COOH; a selenoamino acid used as an antimetabolite, competing with methionine; it is also found in proteins; *see* selenoprotein.

**selenoprotein** a protein containing selenium, almost invariably as selenocysteine, although selenomethionine can occur, apparently as a random substitute for methionine. Well-known selenoproteins include the mammalian glutathione peroxidases and tetraiodothyronine 5'-deiodinase, and bacterial formate dehydrogenases and glycine reductase.

**self** 1 the individuality of a person or thing; the totality of components intrinsic to an individual or thing. 2 (*in immunology*) the components of an individual's own tissues that can be distinguished from foreign substances by the individual's immune system, and towards which immunological tolerance is shown.

**self-absorption** the absorption of any emission by the emitting molecules.

## semantophoretic molecule

**self antigen** any (potentially) antigenic molecule originating in an individual that is recognized as nonforeign by the individual's immune system, and towards which immunological tolerance is normally shown. *See also* autoimmunity, self-tolerance.

**self-assembly** the formation of a complex entity from more simple, identical units without intervention from any external agency.

**self-assembly doctrine** a doctrine elaborated by Caspar and Klug to explain the assembly of small viruses and subcellular organelles. It is postulated that the structure assembles as a result of specific binding sites on proteins that interact to form a scaffold on which other components form.

**self-catabolite repression** repression of gene expression by a catabolite formed within the same organism.

**self-cloning** the cloning of a gene within the species from which it was derived, a technique that in some countries attracts less stringent government restrictions than when a gene is cloned in another species, being considered the less hazardous of the two approaches with respect to the genetic environment.

**self determinant** a determinant originating from the tissue of an organism and thus treated as self (def. 2) by the immune system of that organism (except in the case of autoimmune pathology; *see* autoimmunity).

**self-fertilization** the union of male and female gametes of the same organism.

**self-hybridization** hybridization between nucleic acids that exhibit complementarity.

**selfing** (*in microbiology*) the production of wild-type 'transductants' by infection of an auxotrophic strain with a transducing phage grown on the same auxotroph as the donor.

**selfish DNA hypothesis** a hypothesis put forward to account for the presence in eukaryotic genomes of large amounts of repetitive DNA (*see* repetitive sequences). Because there is no confirmatory evidence that much of such DNA serves any useful purpose for its host, this DNA has been termed selfish DNA or junk DNA, and is suggested to be a molecular parasite that, over many generations has disseminated itself throughout the genome. If this is true, it remains a mystery why natural selection has not eliminated 'selfish DNA'.

**self tolerance** the state in which the immune system of any particular individual lacks reactivity against potentially antigenic molecules originating within that individual. Self tolerance develops during perinatal life. *See also* acquired tolerance, autoimmunity, immunological tolerance.

**Seliwanoff test** a test for ketohexoses based on the production of a red colour when the sample is boiled with a solution of 0.05% w/v resorcinol in 3 M hydrochloric acid. The test relies on the fact that ketoses are dehydrated more rapidly than aldoses to yield furfural products. [After Feodor Fedorowitsch Seliwanoff (1859-1938), Russian chemist.]

**SEM** or **S.E.M.** 1 *abbr.* for standard error of estimate of mean. 2 *abbr.* for scanning electron microscope; *see* electron microscope.

**sem-5** the gene for Sem-5, sex muscle abnormal protein 5, in *Caenorhabditis elegans*. Sem-5 acts both in vulval induction and sex myoblast migration, and is linked in a signalling chain from tyrosine kinase receptors (e.g. EGF-type Let-23). It contains SH2 and SH3 domains (*see* SH domain) characteristic of tyrosine kinase binding proteins. Mutations of the sem-5 gene block signalling pathways from several tyrosine kinase receptors in the worm. Database code SEM5\_CAEEL, 228 amino acids (26.18 kDa).

**semantide** or **semantophoretic molecule** or **informational macromolecule** any of the different types of macromolecules that carry the information of the genes or a transcript (or a translation) thereof. The genes themselves are primary semantides, messenger RNA molecules are secondary semantides, and most polypeptides are tertiary semantides.

**semantophoretic molecule** an alternative name for semantide.

## semen

semen the fecundating fluid of male higher animals, consisting of spermatozoa suspended in seminal plasma – secretions of the accessory glands.

**semenogelin** one of two major gel-forming proteins of semen. These proteins have 80% of their amino-acid residues in common, and their genes are localized to the long arm of chromosome 20. They are hydrolysed by a kallikrein-like proteinase. Example (precursor) of the predominant human protein of this type, semenogelin 1: database code SEMI\_HUMAN, 462 amino acids (52.07 kDa).

semi+prefix 1 half. 2 partial or partially; intermediate.

**SEMI** abbr. for specific endogenous mitotic inhibitor; see chalone.

**semialdehyde** any of a class of organic compounds formed by the reduction of one carboxyl group of a dicarboxylic acid to an aldehyde group, as in glutamic semialdehyde.

**semiconductor** any material, e.g. germanium or silicon, whose electrical conductivity lies between that of conductors and insulators and increases with increasing temperature. Its crystal structure has atomic bonds that allow the conduction of electric current by either positive or negative carriers when the appropriate additives (dopants) are present.

**semiconservative replication of DNA** see replication of DNA.

**semiconstitutive mutant** a mutant in which negative regulation is partially lost, so that a gene is expressed in the absence of inducer, but at a lower level than in the fully constitutive mutation, yet in the presence of inducer the expression reaches the fully constitutive level. See also constitutive mutation.

**semi-micro** 1 describing or concerning something moderately small; applied to a scale of operation, an item of equipment, a quantity of material, etc. 2 (in analytical chemistry) a term originally used to indicate analysis of amounts of substance in the range 10–100 mg. Compare micro (def. I). See also micro-analysis.

**seminal** 1 a pertaining to seed, b of, or relating to, semen. 2 (of an experiment, idea, or publication) germinating new concepts; fundamentally original.

**seminal plasma** the suspending fluid in which semen is ejaculated.

**seminalplasmin** another name for caltrin.

**semiochemical** any chemical substance that delivers a message or signal from one organism to another. The two broad classes into which such substances are divided are known as pheromones and allelochemicals, depending on whether the information transfer occurs between, respectively, individuals of the same species (intraspecific) or between members of different species (interspecific). See also allomone, kairomone.

**semiotics functioning as sing.** 1 the practice of symptomatology; a term that became obsolescent, but has been reintroduced in connection with CT, NMR, and other imaging techniques. 2 the philosophical theory of signs and symbols, having three branches: syntactics, semantics, and pragmatics.

**semipermeable membrane** a membrane that allows the passage of only certain solutes, usually small molecules, but is freely permeable to solvent.

**semipolar double bond** an alternative name for dipolar bond.

**semiquinone** any free radical derived from a quinone or quinoid compound by the removal from it of a single hydrogen atom. Compare quinone.

**semisolid medium** (in cell culture) a medium of consistency between those of a solution and a full gel.

**semisynthesis** the partial synthesis of a chemical compound, especially a novel substance, by chemical orland enzymic modification of one isolated from natural sources or produced biotechnologically (e.g. by fermentation). The procedure has been applied with conspicuous success in the manufacture of new pharmaceuticals such as artificial penicillins and cephalosporins. -semisynthetic adj.

**semisystematic name** or semitrivial name (in organic-chemical nomenclature) a name of a molecular entity that has only a part of it used in a systematic sense; e.g. (meth)ane, (but)ene,

## Sephadex

(calci)diol (in each of which only the part of the name outside the parentheses is systematic). Most names in organic chemistry are of this type. Compare systematic name, trivial name.

**senescence** the process of ageing. -senescent adj.  
senile aged, to a point of severely decreased capability. -senility n.

**senna** a preparation of the dried leaves of *Cassia angustifolia* or *C. senna* used as a laxative. It contains glycosides of hydroxyanthracene (sennoside B), which are metabolized to purgative anthraquinones by colonic bacteria.

**sense DNA** see coding strand.

**sense strand** (of duplex DNA) see coding strand.

**sensitivity** 1 an index of the ability of any analytical method or other detection procedure to make quantitative determinations at very low levels. 2 (in metabolic control theory) the susceptibility of flux through a pathway to change in response to change in the level of one of the component enzymes, expressed quantitatively in terms of the flux control coefficient. An alternative meaning arises when an allosteric ligand acts at several points in a pathway, where a plot of the fractional modification in flux versus ligand concentration yields a sigmoidal curve for a positive effector; the sensitivity in this case can be derived from the slope of the sigmoidal curve.

**sensitivity coefficient** former name for flux control coefficient.

**sensitization** or sensitisation 1 enhanced reactivity to any treatment (such as exposure to an agonist) of any tissue, cell, or molecular system resulting from prior experience or treatment (often by the same agonist). 2 the conditioning of an animal by antigen in such a way that hypersensitivity reactions occur on subsequent exposure to the antigen. 3 the attachment of antibody to sheep red blood cells to make them susceptible to lysis by complement in the complement-fixation test. Red blood cells treated in such a way are commonly referred to as sensitized cells. -sensitize or sensitise vb.

**sensitizer** or sensitiser see allergen.

**sensor** any device that records the level of a substance of interest or under investigation, using physical parameters (heat, conductivity) or chemical methods. Sensors are often applied to continuous monitoring in flow systems; biosensors utilize the reactions of enzymes immobilized on a probe and often coupled with a second substrate that yields a coloured or fluorescent product.

**sensory transducer** any component of bacterial systems involved in signal transduction. An example is the *ntrBlntrC* system, which occurs in several bacteria (the following examples are from *Escherichia coli*). Under nitrogen limitation the product of the *ntrB* gene, NtrB (EC 2.7.1.-), activates NtrC – the *ntrC* gene product – by phosphorylating it; in nitrogen excess it reverses this. Examples: NtrB, database code NTRB\_ECOLI, 349 amino acids (38.51 kDa); NtrC, database code NTRC\_ECOLI, 469 amino acids (52.19 kDa); NtrC contains an ATP-binding domain that interacts with sigma factor  $\sigma^{54}$ . Another instance of a sensory transducer is sensory rhodopsin I transducer from archaeabacteria. Example from *Halobacterium halobium*: database code HTRI\_HALHA, 536 amino acids (56.61 kDa); this is a typical seven-transmembrane-domain opsins-type protein used for sensing light. See also ehe.

**separation** (in genetics) the break-up of a cointegrate into two or more replicons of similar sizes. Compare excision.

**Sephacel** proprietary name for a gel-filtration medium based on cellulose cross-linked using epichlorohydrin so that a mesh results, the size of the apertures in the mesh being determined by the extent of cross-linking.

**Sephacryl** proprietary name for a gel-filtration medium prepared from allyldextran covalently cross-linked using *N,N*-methylene bisacrylamide, to yield a mesh; the size of the apertures in the mesh depend on the degree of cross-linking.

**Sephadex** proprietary name for a gel-filtration medium based on dextran cross-linked using epichlorohydrin so that a mesh results, the size of the apertures in the mesh being determined by the extent of cross-linking.

**Sephadex**

**Sephadex** proprietary name for a gel-filtration medium based on agarose cross-linked using epichlorohydrin so that a mesh results, the size of the apertures in the mesh being determined by the extent of cross-linking.

**septanose** the form of any monosaccharide, or monosaccharide derivative, in which the molecule contains a ring consisting of six carbon atoms and one oxygen atom. In monosaccharide symbolism the septanose form may be indicated by the suffix *s*; e.g. *Glc*s symbolizes glucoseptanose. Compare furanose, heptose, pyranose.

**septate** divided by, or involving, a septum or septa.

**septation** the process of forming the septum that cuts a cell into two at the end of the cell cycle in bacteria.

**septum I** (*in anatomy*) a wall of tissue, sheet of cells, or other membrane-like structure that partitions two compartments. 2 a disk of silicone rubber, PTFE, or similar material used in any apparatus to seal an injection port. The needle of a syringe can be punched through the septum for the purpose of injection, and on withdrawal of the needle the elasticity of the septum ensures that the hole reseals.

**Sequenase** proprietary name for a chemically modified T7 DNA polymerase with high processivity. It is the usual choice for DNA sequencing by the chain-termination method.

**sequenator** an apparatus for determining the sequence of monomeric residues (e.g. amino acids) in an ordered linear polymer (e.g. an oligopeptide) by repeating a chemical process.

**sequence 1** the ordinal arrangement of the constituent parts of a biopolymer, e.g. the order of amino-acid residues in a polypeptide chain or of the nucleotide residues in a polynucleotide chain; the known arrangement of such units in any biopolymer or fragment. 2 any particular segment, occurring in or derived from a biopolymer, having a known order of its constituent parts; a synthetic polymer composed of parts equivalent to those occurring naturally and present in a particular known order. 3 to determine the order of residues in a biopolymer or fragment. -sequential *adj.*

**sequence compression** see band compression.

**sequence homology** similarity (often to an indicated degree) of sequences of residues in encoded macromolecules or specified segments of them. The term is often used synonymously with conservation (when used of primary structure) if the sequences occur in corresponding locations in specimens of any particular macromolecule obtained from genetically differing sources. Homology is discussed more fully in Appendix E.

**sequence hypothesis** the hypothesis, formulated by F. H. C. Crick in 1958, that 'the specificity of a piece of nucleic acid is expressed solely by the sequence of its bases, and that this sequence is a (simple) code for the amino-acid sequence of a particular protein.'

**sequence ladder** the ladder-like bands of separated components occurring in the chromatographic gel that result from DNA sequencing experiments.

**sequencer** an apparatus for automatically determining the sequence of monomeric residues in an ordered linear polymer.

**sequence rule or Cahn-Ingold-Prelog rule or R/S convention (of configuration specification)** a system for specifying the absolute molecular chirality of a chemical compound. This system considers the sequence of the proton numbers of the atoms directly attached to a chiral centre (see chirality); if two or more of these atoms have the same proton number, their substituents are then taken into account, the group with substituents of highest proton number taking precedence. When a multiple bond to a substituent is present, the substituent is arbitrarily considered to occur twice, or thrice; an isotope of higher nucleon number takes precedence over one of lower number. The priorities of some common ligands are tabulated in Appendix G. For a tetrahedral centre (e.g. a carbon atom) the substituent with the lowest priority is placed away from the observer (behind the chiral atom) with the other three projecting towards the observer; if these three substituents lie in a clockwise (right-handed) array of decreasing priority, then the

serial dilution

chiral centre is designated with the stereochemical descriptor *R*, denoting Latin *rectus*, right; if the substituents lie in an anti-clockwise (left-handed) array of decreasing priority, then the chiral centre is designated with the stereochemical descriptor *S*, denoting Latin *sinister*, left. For the name of a compound consisting of molecules with a single chiral centre the descriptor *R* or *S*, with a preceding locant if needed, is formed into a prefix by placing it in parentheses and adding a linking hyphen; a racemate with a single chiral centre in its molecules is labelled with the prefix (RS)-. When a molecule contains more than one chiral centre the prefix to the name is composed of multiple descriptors, each preceded by an appropriate locant; e.g. (2R,3R)-2,3-dihydroxybutanedioic acid (= L-glyceraldehyde). If only the relative, but not the absolute, configurations of two or more chiral centres in a molecule are known, these centres may be designated with the descriptors *R*\* and *S*\* (spoken as *R* star, *S* star), preceded when necessary by appropriate locants, on the arbitrary assumption that the chiral centre first cited (which usually is the one with the lowest locant) has an *R* configuration; for examples, compare the systematic names of allothreonine and threonine. See also *oL* convention. Extensions of the sequence rule are the *E/Z* convention, the pro-*E*/pro-*Z* convention, the pro-*R*/pro-*S* convention and the *ReIS*; convention. [After Robert Sidney Cahn (1899-1981), British natural-products chemist, editor, and scientific semanticist, (Sir) Christopher Kelk Ingold (1893-1970), British physical organic chemist, and Vladimir Prelog, who jointly developed the system and described it in a series of three papers published in 1951, 1956, and 1966.]

**sequence-tagged site abbr.: STS** a short, single-copy DNA sequence that characterizes a mapping landmark on the genome. Such sequences provide unambiguous identification of DNA markers generated by the Human Genome Project (see HUGO). STSs are short segments of DNA of known (and unique) sequence which bind to VACs. If two YACs contain the same STS they must overlap. The YACs can be built up into an overlapping series of clones (a contig) covering an entire gene. sequencing the act or process of determining the sequence (def. 1) of proteins or nucleic acids. See chain-termination method, chemical cleavage method, solid-phase technique.

**sequencing by hybridization** see SBH.

**sequencing gel** a polyacrylamide gel run to resolve oligonucleotides produced in a DNA sequencing procedure. See chain-termination method, chemical cleavage method.

**sequential analysis** the analysis of a protein or nucleic-acid sequence (def. 1).

**sequential mechanism** an enzyme reaction involving two or more substrates in such a way that all the substrates must be bound to the enzyme to form the central complex before any products can be released. A sequential mechanism may be an ordered mechanism or a random mechanism.

**sequestering agent** see chelating agent.

**sequestration** 1 the process of removal or separation. 2 (*in chemistry*) the effective removal of ions from solution by co-ordination with another kind of ion or molecule to form a firm complex molecule with different properties from the original ion. Compare chelation. 3 (*in cell biology*) the intracellular enclosing of material in an organelle. -sequester *vb.*

**Ser** symbol for a residue of the *a*-amino acid L-serine (alternative to S).

**SER abbr.** for smooth endoplasmic reticulum (see endoplasmic reticulum).

**sera** a plural of serum.

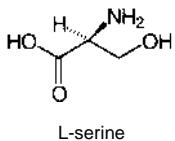

**SERCA abbr.** for sarcoplasmic/endoplasmic reticulum calcium-transporting ATPase, EC 3.6.1.38; any of a family of  $\text{Ca}^{2+}$  pump integral membrane protein isoforms of sarcoplasmic or endoplasmic reticulum. They catalyse the hydrolysis of ATP coupled with  $\text{Ca}^{2+}$  transport. Example from *Drosophila melanogaster*: database code ATCB\_DROME, 1002 amino acids (109.47 kDa).

**serial dilution** a method of achieving dilution of a liquid by se-

quentially transferring a sample of predetermined volume into another, empty, vessel (usually a tube), which is then made up with diluent to the same total volume as the first. The overall dilution achieved is  $(vls)X$ -fold, where  $v$  is the chosen total volume in each tube,  $s$  is the size of the sample, and  $x$  is the number of times the procedure is repeated.

**serinate** 1 serine anion; the anion, HO-CH<sub>2</sub>-CH(NH<sub>2</sub>)-COO<sup>-</sup>, derived from serine. 2 any salt containing serine anion. 3 any ester of serine.

**serine** *the trivial name for* α-amino-p-hydroxypropionic acid; 2-amino-3-hydroxypropanoic acid; HO-CH<sub>2</sub>-CH(NH<sub>2</sub>)-COOH; a chiral α-amino acid. L-Serine (*symbol*: S or Ser), (S)-2-amino-3-hydroxypropanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: AGC or AGU; UCA, UCC, UCG, or UCU. In mammals it is a nonessential dietary amino acid and is glucogenic. D-Serine (*symbol*: D-Ser or DSer), (R)-2-amino-3-hydroxypropanoic acid, in both free and combined forms occurs in silkworms and earthworms; residues of D-serine occur in certain peptide antibiotics, e.g. polymyxins D<sub>1</sub> and D<sub>2</sub>. [*Note*: The absolute configuration of D-serine (and hence that at the α-carbon atom of other α-amino acids of the D series) is identical with that of D-glyceraldehyde (and hence with that at the reference carbon atom of other monosaccharides of the D series).]

L-serine

**L-serine dehydratase** EC 4.2.1.13; *systematic name*: L-serine hydro-lyase (deaminating); *other names*: serine deaminase; L-hydroxyaminoacid dehydratase. An enzyme that catalyses a reaction between L-serine and water to form pyruvate and ammonium ion. It is a pyridoxal-phosphate enzyme. The enzyme for gluconeogenesis from serine in *Escherichia coli* is a 4Fe-4S protein; database code SDHL\_ECOLI, 454 amino acids (48.85 kDa).

**serine hydroxymethyl transferase** *see* glycine hydroxymethyltransferase.

**serine-like carboxypeptidase** *see* serine endopeptidase.

**serine C-palmitoyltransferase** EC 2.3.1.50; an enzyme of the pathway for the biosynthesis of sphingoid bases. It catalyses the formation of 3-dehydro-D-sphinganine from palmitoyl-CoA and L-serine, releasing CoA and CO<sub>2</sub>. Pyridoxal-phosphate is a coenzyme. Example from yeast (long-chain-base biosynthesis protein), two forms: database code LCBL\_YEAST, 558 amino acids (62.16 kDa); and database code LCB2\_YEAST, 561 amino acids (63.04 kDa).

**serine peptidase** any enzyme characterized by having a residue of serine (and one of histidine) at the active centre and by being irreversibly inhibited by organic fluorophosphates (which phosphorylate the serine's hydroxyl group). Serine peptidases are of two types: (1) serine-type carboxypeptidases, and (2) serine endopeptidases, sub-subclass EC 3.4.21. During catalysis by serine peptidases an acyl-enzyme intermediate is formed by esterification of the hydroxyl group of the reactive serine with the carbonyl group of a sensitive peptide bond of the substrate. The serine endopeptidase group includes chymotrypsin, most elastases, kallikrein, thrombin, trypsin, and a number of microbial proteinases. *See also* serine-type carboxypeptidase.

**serinelthreonine kinase** a protein kinase that phosphorylates serines or threonines on its target protein.

**serinelthreonine-specific protein phosphatase** EC 3.1.3.16; *recommended name*: phosphoprotein phosphatase; *other names*: protein phosphatase-I; protein phosphatase-2A; protein phosphatase-2B; protein phosphatase-2C. This name

includes a group of enzymes that hydrolyse the serine- or threonine-bound phosphate group from many phosphoproteins. Examples from yeast: PP2a-1 catalytic subunit: database code P2AI\_YEAST, 369 amino acids (41.89 kDa); PP2a-2 catalytic subunit: database code P2A2\_YEAST, 377 amino acids (43.00 kDa).

**serine transhydroxymethylase** *see* glycine hydroxymethyltransferase.

**serine-type carboxypeptidase** EC 3.4.16.1; this name includes many enzymes that hydrolyse protein with release of a C-terminal amino acid; they have a broad specificity. Examples (3-D structures) from wheat (chains a and b, respectively); database codes NRL\_IWHSA, 255 amino acids (28.38 kDa), and NRL\_IWHSB, 153 amino acids (17.28 kDa).

**serinium** serine cation; the cation, HO-CH<sub>2</sub>-CH(NH<sub>3</sub><sup>+</sup>)-COOH, derived from serine.

**serino+** prefix denoting the group, HO-CH<sub>2</sub>-CH(NH<sub>2</sub>)-COOH,

derived from serine by loss of hydrogen from the amino group.

**sero+** comb. form denoting a connection within or origin in serum.

**serological** pertaining to, or originating in, serum; connected with the study of serum.

**serology** the study of serum; in particular, the immunological phenomena involving circulating antibody that may be observed *in vitro*.

**serosa** a serous membrane, especially the peritoneal covering. -  
serosal adj.

**serotonergic** 1 describing a nerve that is activated by serotonin. 2 describing a nerve that acts by the release of serotonin from the nerve endings. *Compare* adrenergic, aminergic, cholinergic, peptidergic, purinergic.

**serotonin** 5-hydroxytryptamine (*abbr.*: 5-HT); a monoamine neurotransmitter occurring in the peripheral and central nervous systems, also having hormonal properties; it is also found in mast cells, platelets, brain, and the enterochromaffin cells of the gastrointestinal tract, and is capable of causing vasoconstriction, increased vascular permeability, and contraction of smooth muscle. It is formed from tryptophan, after hydroxylation to 5-hydroxytryptophan, by tryptophan 5-monooxygenase (EC 1.14.16.4) followed by decarboxylation by aromatic-L-amino-acid decarboxylase (EC 4.1.1.28). It is a substrate for monoamine oxidase.

**serotonin receptor** *see* 5-hydroxytryptamine receptor.

**serotransferrin** *see* transferrin.

**serous** 1 relating to or resembling serum (or similar watery fluid). 2 producing a fluid resembling serum.

**serous membrane** or serosa a thin connective-tissue membrane lining certain closed body cavities and reflected over the viscera. The peritoneum of the abdomen, pleura of the chest, and pericardium of the heart are all serous membranes. Each consists of a parietal layer, lining the walls of the cavity, and a visceral layer covering the organs. The two are continuous, forming a closed sac. *Compare* mucous membrane.

**serpentine domain** any sequence of transmembrane segments of a single polypeptide chain of a membrane protein that traverses the membrane several times, as, e.g., in seven-transmembrane-domain proteins.

**serpin** any of a superfamily of proteins, many of which inhibit serine proteinases and exhibit a high degree of homology with classical serine proteinase inhibitors such as α1-antitrypsin or antithrombin. The superfamily is now considered to extend beyond compounds that are known to be proteinase inhibitors and, based on homology, includes proteins such as ovalbumin and angiotensinogen, which have no inhibitory function. [From serine proteinase inhibitorL]

**Sertoli cell** or sustentacular cell a supporting cell of the mammalian testis that surrounds and nourishes developing sperm cells. [After Enrico Sertoli (1842-1910), Italian histologist.]

**serum** (*pl.* sera or (*esp.* US) serums) the liquid extruded after blood has clotted and the clot has retracted (syneresis (def. 2)). *Compare* plasma.

## serum albumin

serum albumin or plasma albumin the smallest and most abundant of the plasma proteins;  $M_r$  65 000–68 000 for the bovine form, 69 000 for the human. It is involved in the regulation of osmotic pressure and in the transport of sparingly soluble metabolites. The serum albumins belong to a multigene family of proteins that includes IX-fetoprotein and vitamin D-binding protein. Human serum albumin has three homologous domains which assemble to form a heart-shaped molecule. It consists of 28 helices, ranging from five to 31 amino-acid residues each, formed into six subdomains; two each of these subdomains form one of the major domains. There is no beta structure. Bovine (serum) albumin (abbr.: BSA) and human (serum) albumin (abbr.: HSA) are widely used as standards in protein estimations. These include fatty acids, amino acids (such as tryptophan), steroids, metals (e.g. calcium, copper, and zinc), and hydrophobic drugs. *See also* albumin.

serum amyloid P-component abbr.: SAP; a precursor of amyloid component P. Amyloid component P is found in basement membranes and is associated with amyloid deposits.

serum converting enzyme *a former name for* angiotensin converting enzyme.

serum globulin any serum protein that is also a globulin. An early classification of globulins was according to their mobility on electrophoresis. Serum albumin moves the fastest; behind albumin on paper electrophoresis or cellulose acetate strips are two bands known as the  $\alpha_1$ - and  $\alpha_2$ -globulin bands, followed by a  $\beta$ -globulin band with the  $\gamma$ -globulins forming a diffuse band near the origin. The  $\alpha_1$ -globulins include thyroxine-binding protein, transcortin,  $\alpha_1$ -glycoprotein, a-lipoprotein, and antitrypsin. The  $\alpha_2$ -globulins include haptoglobin,  $\alpha_2$ -glycoprotein, macroglobulin and ceruloplasmin. The  $\beta$ -globulins include transferrin,  $\beta$ -lipoprotein and  $\beta$ -glycoprotein. The  $\gamma$ -globulins comprise the immunoglobulins.

serum protein any protein contained in serum; the term is usually applied to those proteins present in high quantities. The most prominent of these is albumin, which is present in the normal serum of human adults in the range 34–48 g L<sup>-1</sup>. *See also* serum globulin.

serum response element abbr.: SRE; a stretch of DNA that regulates promoters for a group of genes that are activated by addition of serum to cell cultures. Such elements have the consensus sequence CCATATTAGG.

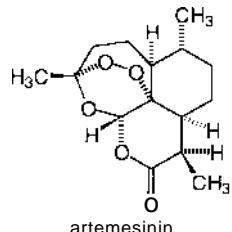

serum spreading factor *see* vitronectin.

seryl the acyl group, HO-CH<sub>2</sub>-CH(NH<sub>2</sub>)-CO-, derived from serine.

sesqui+ comb. form 1 denoting one-and-a-half times; in a ratio of three parts to two. 2 (in chemistry) indicating a compound having one-and-a-half molecular proportions of the specified element group, or unit, either in relation to a second component, as in sesquioxide (e.g. chromium sesquioxide, Cr<sub>2</sub>O<sub>3</sub>), or in relation to a reference compound, as in sesquiterpene; it also sometimes denotes a compound intermediate in constitution between two others, as in sesquicarbonate (e.g. sodium sesquicarbonate, Na<sub>2</sub>CO<sub>3</sub>·NaHC<sub>2</sub>O<sub>3</sub>·2H<sub>2</sub>O).

sesquiterpene any terpene formed from three isoprene units, i.e. having 15 carbon atoms per molecule as compared with a monoterpene which has 10 carbon atoms per molecule and is formed from two isoprene units.

sesquiterpene lactone any sesquiterpene (15 carbon atoms) containing a lactone structure. Several are derived from

## sex factor

*Artemisia* spp., including artemesinin (qinghaosu) from *A. annua* (qing hao). Qing hao has been used for almost 2000 years as an antimalarial; its mechanism of action is unknown. sester+ comb. form 1 denoting two-and-a-half times; in a ratio of five parts to two or 10 parts to 4. 2 (in chemistry) indicating a compound having two-and-a-half molecular proportions of the specified group or unit in relation to a reference compound, as in sesterterpene.

sesterterpene any terpene formed from five isoprene units, i.e. having 25 carbon atoms per molecule as compared with a monoterpene, which has 10 carbon atoms per molecule and is formed from two isoprene units. An ophiobolin is an example.

**sev** symbol for sevenless gene; *see* Sevenless protein.

Sevag method a method for removing proteins from nucleic acids during purification of the latter. The proteins are precipitated after repeated denaturation by shaking with a solution of octanol in chloroform.

Sevenless protein abbr.: Sev; a protein, encoded by the *sevenless* (sev) gene, that is part of a system for differentiation of R7 photoreceptors in *Drosophila*. Sev is a receptor for an extracellular signal; it has tyrosine kinase activity and belongs to the family of insulin receptors. Sev has a ligand, Boss, the product of the *bride of sevenless* (boss) gene; it is expressed by R8 photoreceptor cells and internalized (as a transmembrane protein) in a Sev-dependent manner. Examples, Sev: database code 7LES-DROME, 2554 amino acids (286.79 kDa); Boss: database code BOSS\_DROME, 896 amino acids (99.81 kDa).

seven-minute phosphate *see* labile phosphate.

seven-transmembrane-domain protein or seven-transmembrane-segment protein or seven-transmembrane-helix protein a type of receptor protein that contains, in a single polypeptide chain, seven hydrophobic domains that traverse the lipid bilayer. This structural characteristic is typically used to describe the structures of receptors that couple to effector systems through G-proteins. These are also sometimes referred to as serpentine receptors. The structures of only a few membrane proteins have been determined at high resolution, and this structural characteristic has been attributed to other proteins mainly on the basis of sequence comparison. Thus, for the majority of proteins, the name 'seven-transmembrane-domain protein' is a tentative one. The suggestion that the transmembrane domains are helical is even more tentative.

seven-up a receptor required for photoreceptor cells during eye development. It is a zinc-finger DNA-binding protein with two forms (I and 2) generated by alternative splicing. Example (type I) from *Drosophila melanogaster*: database code 7UPL DROME, 543 amino acids (57.92 kDa).

sex chromatin a condensed mass of chromatin that represents an inactivated X chromosome. In mammalian nuclei, each X chromosome apart from the activated one forms a sex chromatin body or Barr body.

sex chromosome a chromosome involved in sex determination. In many species, these are the Xchromosome and Ychromosome. They are distinguished from the autosomes i.e. all the other chromosomes of that species. In some species, however, e.g. fish of the genus *Xiphophorus*, sex determinants are spread over a number of chromosomes.

sex determination the specification of the sex of an individual organism by genes. In many animal species, these genes are located on the Xchromosome and the Ychromosome. Their effects are manifested as a result of secretion of androgens and estrogens.

sex factor or fertility factor or F factor or F agent an episomal genetic element (*see* episome) in bacteria that enables the cell to act as a genetic donor. Cells of such donor strains are able to form stable unions with cells devoid of such factors and to transfer to them extrachromosomal material, including the sex factor, and sometimes segments of bacterial chromosomes (*see* conjugation (def. 4)). The Fplasmid is the prototypical sex factor, responsible for conjugation in certain strains of *Escherichia coli*.

## sex hormone

**sex hormone** any steroid hormone that is responsible for controlling sexual characteristics and reproductive function. Estrogens and progesterone are the female sex hormones, while androgens are the male sex hormones. They are produced mainly by the ovaries or testes, with contributions from the adrenals and placenta.

**sex linkage** a special type of gene linkage occurring when a gene producing a certain phenotype (often unrelated to primary or secondary sexual characters) is located on a sex chromosome. Such a gene, or the character it determines, is said to be sex linked. One consequence of a mutation of genes on the X chromosome is that they may often be apparent only in male offspring, which have only one X chromosome. The mutation may be masked in the female because of the presence of a second, unaffected X chromosome.

**sexual conjugation** see conjugation (def. 4).

**S-form abbr.** for smooth form; describing bacterial colonies with a smooth appearance. Compare Rform (def. 2).

**SGF abbr.** for skeletal growth factor.

**SGOT abbr.** for serum glutamic-oxaloacetic transaminase (name not now recommended; see aspartate transaminase).

**SGPT abbr.** for serum glutamic-pyruvic transaminase (name not now recommended; see alanine transaminase).

**shadow casting** a procedure used in the preparation of specimens for electron microscopic examination. The specimen is placed in a vacuum and a heavy metal is applied by evaporation – the metal is evaporated with an electrically heated tungsten filament. In high vacuum the metal atoms travel in straight lines and so, if evaporation is from an acute angle, metal will condense on only one side of the features of the specimen leading to variations in electron-density over the specimen, creating a 'shadow' effect.

**sham operated** describing a control procedure in which all the operations employed in a surgical technique are imitated with the exception of the experimental lesion that is the subject of study.

**Shardinger enzyme** see xanthine oxidase.

**shark's tooth comb** a plastic device for creating wells in an electrophoretic gel. It is shaped like a comb with the teeth coming to a point.

**Sharp, Phillip Allen (1944- )**, US molecular biologist; Nobel Laureate in Physiology or Medicine (1993) jointly with R. J. Roberts 'for their discovery of split genes'.

**Sharples super centrifuge** a, now superseded, efficient centrifuge with a flow-through rotor in which the sedimentation path was short. It is used for harvesting bacteria, blood cells, etc. The version powered with an electric motor turned at 21 000–23000 rpm while the air-turbine-driven version turned at 50 000 rpm. The instruments of this type have been superseded by others that can operate continuous flow rotors.

**She** a gene family that was identified by screening eDNA libraries for genes encoding SH2-containing proteins (see SH domain). The mammalian gene encodes two overlapping, widely expressed proteins with a C-terminal SH2 domain that binds activated growth factor receptors, and which are phosphorylated on tyrosine in growth factor activated cells. These She proteins are transforming when overexpressed in fibroblasts. Phosphorylated She forms a complex with Grb2, and may form a link between certain tyrosine kinases and the Grb2/Ras signalling pathway. Example of gene product from human: database code SHC\_HUMAN, 473 amino acids (51.61 kDa).

**SH domain abbr.** for Src homology domain; the SH2 domain is a protein module consisting of about 100 residues found in many proteins involved in signal transduction. Apart from Src, which contains the prototype SH2 domain (see src), these include among many others phospholipase C, products of proto-oncogenes such as *ASL*, *FYN*, and *FGR*, GTPase-activating protein, and protein tyrosine phosphatases. The SH2 domain has also been found in structural proteins such as fodrin. One function of the domain is to bind to the autophosphorylated site of growth factor receptors, e.g. PDGF and EGF recep-

## shikimate pathway

tors. Proteins with SH2 domains are frequently found also to have SH3 domains. The SH3 domain is composed of approximately 50 amino acids and was originally identified in Src, but has since been found within a number of other proteins. SH3 domains mediate protein-protein interactions through their ability to recognize and bind proteins containing specific amino-acid sequences rich in proline and hydrophobic residues. To date, there are known to be at least two general classes of ligand to which SH3 domains can bind: class I, which comprises proteins containing the consensus sequence PXLPPZP; and class II, with the sequence XPPLPX<sub>n</sub>Z (where X is any amino acid and Z appears to be a residue specific to the type of SH3 domain involved). Given the nature of the proteins possessing SH3 domains and SH3-binding domains, it is clear that the protein interactions mediated by these motifs are important to the operation and maintenance of cytoskeletal architecture and intracellular signalling pathways.

**shear** 1 to disrupt or fracture (an entity) using forces acting parallel to a plane, rather than perpendicularly, as with tensile or compressive forces. For example, shear forces can be used to disrupt DNA or other macromolecules by enclosing the molecules between two closely applied plane surfaces moving rapidly in opposite directions. Homogenization techniques depend on shear forces. 2 the deformation or fracture produced by such forces.

**shear gradient** see viscosity.

**shear rate** see viscosity.

**shear stress** see viscosity.

**shikalkin** the racemic mixture of alkannin and its (+)(R) enantiomer, shikonin.

**shikimate** the anion of shikimic acid; [−]3a,4a,5p-trihydroxy-1-cyclohexene-1-carboxylic acid; (3R,4S,5R)-trihydroxy-1-cyclohexenecarboxylic acid; an important intermediate, in microorganisms and plants, in the pathway for the synthesis of phenylalanine, tyrosine, tryptophan, and many other substances (e.g. tocopherol, vitamin K, folic acid, ubiquinone, enterobactin, and some antibiotics); this is known as the shikimate pathway. The enzyme 3-phosphoshikimate 1-carboxyvinyltransferase (EPSP synthase) in higher plants is specifically inhibited by the compound glyphosate, which inhibits growth and can thus be used as an effective and readily degraded broad-spectrum herbicide. Shikimic acid was first isolated from the plant *Illicium religiosum* (star anise) in 1885. The name is derived from the Japanese name for this plant, *shikimi-no-ki*. See also shikimate kinase.

**shikimate 5-dehydrogenase** EC 1.1.1.25; systematic name: shikimate: NADP+ 5-oxidoreductase; an enzyme of the shikimate pathway that catalyses the reduction by NADPH of 3-dehydroshikimate to shikimate with formation of NADP+. The description of the enzyme as a 5-dehydrogenase derives from the older numbering system for shikimate. With the now-accepted chemical numbering, it is in fact a 3-dehydrogenase. See also pentafunctional arom polypeptide.

**shikimate kinase** EC 2.7.1.71; systematic name: ATP:shikimate 3-phosphotransferase; an enzyme of the shikimate pathway that catalyses the phosphorylation by ATP of shikimate to shikimate 3-phosphate with formation of ADP. The product, shikimate 3-phosphate, is the precursor of 5-enolpyruvylshikimate 3-phosphate (5-(0-(1-carboxyvinyl)-3-phosphoshikimate) from which chorismate is formed. Example, shikimate kinase I from *Escherichia coli*: database code AROK\_ECOLI, 172 amino acids (19.39 kDa). See pentafunctional arom polypeptide for another example. See also shikimate.

**shikimate pathway** the 'classical' shikimate pathway in plants and microorganisms led to the production of the aromatic amino acids (phenylalanine, tyrosine, tryptophan) from carbohydrate precursors, with a requirement for chorismate as well as shikimate. Chorismate was regarded as a (single) branch point, being converted to phenylalanine and tyrosine via prephenate (see also arogenate) and to tryptophan via anthranilate. Chorismate can also be converted to ubiquinones,

## shikonin

plastoquinones, and tocopherols. Moreover, on isomerization it yields isochorismate, from which are derived many naphthoquinones (including the vitamins K), 3-carboxy aromatic amino acids, salicylate, and dihydroxybenzoate (for enterobactin formation). Certain non-aromatic cyclohexane compounds are produced from shikimate itself. The pathway is now recognized to contain multiple branch points at many (possibly all) of the pathway intermediates, and has been termed a 'metabolic tree with many branches'. The carbohydrate precursors are *phosphoenolpyruvate* and *o*-erythrose 4-phosphate; they yield 2-dehydro-3-deoxy-D-arabino-heptonate 7-phosphate (I, more commonly termed 3-deoxy-D-arabinoheptulosonate 7-phosphate, abbr.: DAHP) by action of EC 4.1.2.15, 2-dehydro-3-deoxyphosphoheptonate aldolase (DAHP synthase). I is converted to 3-dehydroquinate (II) by 3-dehydroquinate synthase, EC 4.6.1.3, and II is then converted to 3-dehydroshikimate (III) by 3-dehydroshikimate dehydratase, EC 4.2.1.10. Shikimate is then formed from III by shikimate 5-dehydrogenase, EC 1.1.1.25, and converted to shikimate 3-phosphate (IV) by shikimate kinase, EC 2.7.1.71. Phosphoenolpyruvate is used again to convert IV to 5-enolpyruvylshikimate 3-phosphate (V, abbr.: EPSP) by 3-phosphoshikimate I-carboxyvinyltransferase, EC 2.5.1.19, and V yields chorismate (VI) by action of chorismate synthase, EC 4.6.1.4. Chorismate leads to prephenate by action of chorismate mutase, EC 5.4.99.5, and in another branching undergoes isomerization by isochorismate synthase, EC 5.4.99.6, to form isochorismate. Organization of the various enzymatic activities varies considerably in plants, bacteria, yeasts, and other fungi. In yeasts and other fungi, and also in *Euglena gracilis*, the conversion of DAHP to EPSP requires a complex pentafunctional polypeptide specified by the *arom* gene cluster (see pertafunctional *I*arom polypeptide).

shikonin the (+)-(*R*) enantiomer of alkannin.

**Shine-Dalgarno sequence** a sequence for the formation of the correct preinitiation complex between a 30S ribosomal subunit and a messenger RNA (mRNA) molecule. It is suggested that a seven-nucleotide, pyrimidine-rich sequence near the 3' terminus of 16S (prokaryotic) or ISS eukaryote ribosomal RNA, found in many organisms, can form base pairs with a complementary three- to seven-nucleotide, purine-rich sequence (the Shine-Dalgarno sequence) preceding the initiation codon in many mRNA molecules, thereby allowing the initiating ribosomal subunit to bind the mRNA so as to discriminate between many AUG or GUG (i.e. initiation) triplets and to select only the one at the beginning of a cistron. [After John Shine (1946- ) and Lynn Dalgarno (1935- ).]

**shockate** the preparation that is obtained when (bacterial) cells are suspended in an osmotically stabilizing medium and lysed by osmotic shocking through the sudden addition of water, followed by immediate centrifugation.

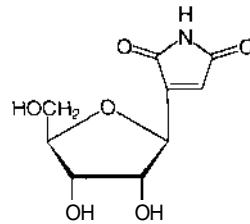

**short-chain** describing an aliphatic compound of any type with a chain length of less than 10 carbons.

**short-patch repair** a type of excision repair of DNA in which the average size of excised DNA is about 20 nucleotides. It contrasts with very-short-patch repair, which deals with mismatches between specific bases, and long-patch repair, in which relatively long stretches of DNA are involved, mostly about 1500 nucleotides long, but in some cases up to 9000 nucleotides or more. See also DNA repair enzyme, *uvr*.

**shotgun cloning** a method, first used for cloning an entire genome, in which the DNA is randomly broken into fragments of approximately the average size of genes. The fragments are then cloned into suitable vectors, to give a genome library.

**shotgun collection** see genomic library.

**showdomycin** 2-(fJ-o-ribofuranosyl)-maleimide; an antibiotic produced by *Streptomyces showdoensis* and active against a number of Gram-positive bacteria. It is sometimes used in biochemical studies as a thiol-reactive agent. Compare N-ethylmaleimide.

**shuttle** (sometimes) an intracellular metabolic cycle concerned in the transfer of, e.g., reducing equivalents or carbon chains across membranes. Different carriers operate each way across the membrane. Examples include the 3-hydroxybutyrate cycle, the glycerol-3-phosphate cycle, and the malate-aspartate cycle.

**shuttle vector** a DNA molecule, e.g. a plasmid, that is able to replicate in two different host organisms and can therefore be used to 'shuttle' or convey genes from one to the other.

**shuttle vesicle** an endocytotic vesicle that transfers proteins across an epithelial cell from one face to another e.g. from the sinusoidal to the bile-canicular face of a hepatocyte.

**sI symbol** for a residue of the ribonucleoside thioinosine; mercaptopurine ribonucleoside (alternative to Sno).

**Si symbol** for silicon.

**Si-** stereochemical descriptor denoting *sinister* (i.e. counter-clockwise, or 'left-handed') configuration of face of a trigonal atom. See *RelSi* convention.

**SI abbr.** for Système International (d'Unités); International System (of Units); a rationalized coherent system of metric units, in which the magnitude of any physical quantity may be expressed, that is recommended for use by scientists throughout the world. The system is founded on seven SI base units: ampere, candela, kelvin, kilogram, metre, mole, and second. There are also 21 SI derived units, which are expressed in terms of the base units, and two SI supplementary units, radian and steradian, which are now regarded as dimensionless derived units. A series of prefixes signify decimal multiples and submultiples of any SI unit.

**Sia symbol** for the sialoyl group.

**sial+** a variant of sialo+ (before a vowel).

**sialagogue** or sialagogue any agent that stimulates the flow of saliva. -sialagogic or sialogic ad.

**sialate** the anion of sialic acid.

**sialic of,** or relating to, saliva or a salivary gland.

**sialic acid** any of the N- or O-substituted derivatives of neuraminic acid found as components of complex carbohydrates, e.g. N-acetyleneuraminic acid (5-(acetylamo)-3,5-dideoxy-D-glycero-D-galacto-non-2-ulosonic acid, (abbr.: Neu5Ac; see also NeuNAc). Linkage of sialic acids is through C-2 to monosaccharides at the ends of glycosylation chains of glycolipids and glycoproteins. Neu5Ac can also be linked at its C-S and C-9 hydroxyl groups to another Neu5Ac residue, often forming multiple repeats as in mammalian NCAM. Hydroxyl groups at C-4, -7, -8, and -9 can be O-acylated (see also NeuOAc). Other common derivatives are N-glycoloyleneuraminic acid (in mammals, but not normally in humans; abbr.: NeuGe), and N-ketodeoxyoctanoyleneuraminic acid (e.g. in bacteria).

**sialidase** EC 3.2.1.18; recommended name: exo-a-sialidase; former name: neuraminidase; a glycosidase enzyme that hydrolyses 2,3-, 2,6-, and 2,8-glucosidic linkages joining terminal nonreducing N- or O-acyleneuraminyl residues to galactose, N-acetylhexosamine, or N- or O-acylated neuraminyl residues in oligosaccharides, glycoproteins, or glycolipids. Example from *Clostridium perfringens*: database code NANH\_CLOPE, 3S2 amino acids (42.81 kDa).

**sialidosis** another name/or mucolipidosis I.

**sialo-** or (be/ore a vowel) sial+ comb. form I of, or relating to, saliva or a salivary gland; sialic. 2 denoting the presence in a

## sialoadhesin

compound of one or more residues of sialic acid. Compare *asialo-*.

**sialoadhesin** a macrophage-restricted sialic-acid-dependent glycoprotein receptor of several forms. It contains 17 immunoglobulin-like domains. It is an adhesion molecule that recognizes oligosaccharides terminating in NeuAc(a2-3)Gal in N-linked and O-linked glycans. Example, 16-domain form from the mouse: database code MMSIAL1, 1598 amino acids (172.68 kDa).

**sialogogue** a variant spelling of *sialagogue*.

**slatosyl** the glycosyl group derived by removal of the exomeric hydroxyl group from sialic acid or sialate.

**sialoyl** the acyl group derived from sialic acid by removing the hydroxyl group from its carboxyl group.

**sickle cell** an abnormal red blood cell obtained from an individual exhibiting sickle-cell anemia. At low oxygen tensions such cells adopt a crescent shape reminiscent of the blade of a sickle. The defect originates in a mutation leading to replacement of Glu by Val at position 6 in the hemoglobin  $\beta$  chain. In its deoxygenated state the hemoglobin forms long rodlike helical fibres, which cause the deformation of the red cells because the  $\beta$ 6 Val can pack into a pocket at the EF corner (between helices E and F) of another  $\beta$  chain, a pocket which is lost in conformational changes resulting from oxygenation. Sickling can also result from  $\beta$ 121 Glu  $\rightarrow$  Lys replacement, a site that lies close to  $\beta$ 6.

**sickle-cell anemia** an inherited disease of humans arising in individuals homozygous for a mutation resulting in replacement of Glu by Val at position 6 of the hemoglobin  $\beta$  chain. It is particularly common in populations indigenous to or originating from subtropical areas, including the Mediterranean region, parts of Saudi Arabia and India, and in those of African origin. The resultant abnormal red blood cells, called sickle cells, are removed from the circulation, leading to anemia. There is no satisfactory treatment, and early death often results. Less serious consequences occur in heterozygotes i.e. individuals with sickle-cell trait; these survive longer and benefit from greater resistance against the malaria parasite, which is adversely affected by sickle-cell trait during the red-cell phase of its life cycle. This results from the fact that, when the heterozygous sickle cells pass through capillaries, they sickle, causing them to lose K<sup>+</sup> and killing the malaria parasite, which needs high levels of K<sup>+</sup>. See also glucose-&phosphate dehydrogenase.

**side-by-side model abbr.:** SBS model or SBS; a model of duplex DNA consisting of an alternating arrangement of right-handed and left-handed segments of duplex DNA, or other double-stranded polynucleotide, with five base pairs per segment. This produces a structure similar to the Watson-Crick model of DNA except that the two antiparallel strands are side by side rather than intertwined in a double helix.

**side chain** 1 any part of an organic molecule based on an aliphatic carbon chain that can be regarded as branching from a main chain. 2 the part of an amino acid that extends from the a-carbon atom and is unique for that amino acid.

**sideramine** one of the two main categories of siderochrome. See also sideromycin.

**siderochromes or siderophore or ironophore** any of various low-molecular-mass Fe(m)-chelating substances elaborated by aerobic or facultatively anaerobic microorganisms, especially when growing in iron-deficient media. Fe<sup>3+</sup>-siderochrome complexes have very high stability constants ( $10^{30}$ – $10^{50}$  dm<sup>3</sup> mol<sup>-1</sup>). They are taken up by specific transport systems in the microorganisms; subsequent intracellular release of iron requires enzymic action. A siderochrome is thus an iron ionophore. Siderochromes are of two main categories, one or both of which may be formed by any particular organism: (1) catechol derivatives, e.g. enterobectin; and (2) hydroxamic acid derivatives (or sideramines), e.g. mycobactin (see also ferrichrome). It is curious that the transport systems for ferrichrome or ferric enterobactin in certain strains of bacteria

## sigmoid kinetics

appear to be identical with the membrane receptors for colicin M or B respectively (see colicin), and in the former case for the antibiotic albomycin and various phages as well.

**aideromycin** any of a class of iron-containing antibiotic substances elaborated by certain actinomycetes. They are structurally related to sideramines (see siderochrome), by which their antibiotic action can be antagonized.

**siderophage** an alternative name for siderophore D.

**siderophilin** an alternative name for serotransferrin, serum transferrin.

**siderophore** 1 or siderophage a macrophage containing granules of hemosiderin. 2 an alternative name for siderochrome.

**aiderosom**, a membrane-bound organelle found in spleen macrophages and containing aggregates of hemosiderin. Siderosomes may be derived from lysosome•.

**siemens symbol:** S; the SI derived unit of electric conductance, defined as the electric conductance between two points on an electric conductor when an electric potential difference of one volt causes an electric current of one ampere to flow; i.e. I S =  $1 \Omega^{-1}$ . It was formerly called the mho or the reciprocal ohm. [After (Ernst) Werner von Siemens (1816-92), German electrical engineer, industrialist, inventor, and metrologist.]

**sievert symbol:** Sv; 1 the SI derived unit of (radiation) dose equivalent, equal to one joule per kilogram of living tissue; i.e. 1 Sv = 1 J kg<sup>-1</sup>. Also, 1 Sv = 100 rem. Compare gray. 2 or intensity millicurie an obsolete non-SI unit of intensity of gamma radiation, numerically equal to 8.4 roentgens per hour. [After Rolf Maximilian Sievert (1896-1966), Swedish radiation physicist.]

**sievorpitive chromatography** a form of chromatography in which absorption chromatography and molecular-sieve chromatography are combined within a single separative system.

**Si-face** (of an atom or molecule) see ReIS; convention.

**SIF cell abbr.** for small intensely fluorescent cell.

**sigma symbol:**  $\sigma$  (lower case) or  $\Sigma$  (upper case); the eighteenth letter of the Greek alphabet. For uses see Appendix A.

**sigma bond** see orbital.

**sigma factor** an RNA polymerase initiation factor occurring in bacteria; a protein that promotes attachment of the RNA polymerase, of which it is a subunit, to specific initiation sites and is then released. The main sigma factor of *Escherichia coli* is  $\sigma^70$ ; database code RP70\_ECOLI, 613 amino acids (70.18 kDa). An unrelated family is  $\sigma^{54}$  (four motifs), with associated regulatory proteins; members of this are specific to certain operons; example from *E. coli*: database code RP54\_ECOLI, 477 amino acids (53.93 kDa). Other sigma factors are involved in response to heat shock and respiratory stress; examples (*E. coli*),  $\sigma^E$ ; database code RI'OE\_ECOLI, 191 amino acids (21.67 kDa); and  $\sigma^{32}$ ; database code RP32\_ECOLI, 284 amino acids (32.43 kDa). Major switches in transcriptional control in bacteria, e.g. sporulation in bacilli, and transcriptional control in certain phages, involve modification to or replacement of sigma factors.

**sigma orbital** see orbital.

**sigma receptor** any of a class of receptors formerly regarded as opioid receptors but now generally regarded as nonopioid receptors because morphine has a very low affinity for them, and naloxone, the classical opioid antagonist, does not block the action of morphine. They are noted for their activation by powerful psychotomimetic drugs, e.g. phencyclidine. These receptors appear to mediate disorientated and depersonalized feelings.

**sigma subunit** a component of bacterial RNA polymerase; see sigma factor.

**sigmoid or sigmoidal** S-shaped; especially as in a sigmoid flexure (e.g. of the large intestine); or a sigmoid plot, i.e. one similar to a skewed letter S, that is with slope increasing initially slowly, progressively increasing more rapidly, and then decreasing towards a plateau. -sigmoidicity n.

**sigmoid kinetics** (in enzymology) a type of kinetics of en-

**signal**

zyme-catalysed reactions characterized by a sigmoid plot of rate versus substrate concentration. Such kinetics are characteristic of allosteric enzymes, in that progressive activation occurs with increasing substrate concentration due to cooperativity in binding of substrate. The presence of allosteric modifiers will alter the inflection of the curve, activators shifting it towards that found in Michaelis-Menten kinetics (*see* Michaelis kinetics).

**signal** 1 any variable property or parameter that serves to convey information. 2 the message potentially to be transmitted by any agonist interacting with a cell membrane receptor. 3 a signal peptide.

**signalase** *see* signal peptidase.

**signal averaging** a method used to improve signal-to-noise ratios, particularly in spectroscopy, by summing repeated scans of the information. The signals are thereby reinforced while the background noise tends to average out.

**signal hypothesis** a model proposed for the synthesis of secretory proteins on ribosomes bound to the rough endoplasmic reticulum. In 1971 the US cytologist Gunter Blobel (1936-) and the US cell biologist David Domingo Sabatini (1931-) suggested that secretory proteins would have a common sequence of amino-acid residues near the N terminus of the nascent chains and that the peptide, or a modification of it, would then be recognized by a factor mediating the binding to the membrane. César Milstein and coworkers in 1972 proposed from experiments in which immunoglobulin light chain mRNA was translated in a reticulocyte lysate system, that light chains are initially synthesized as a precursor of slightly higher molecular weight, which is subsequently converted into the authentic product. From these experiments they proposed, independently of Blobel and Sabatini, that a short peptide at the N terminus of a precursor protein would be a simple way to provide a signal to ensure that secretory proteins were synthesized on membrane-bound ribosomes. This hypothesis has been largely substantiated (*see* signal peptidase, signal peptide, signal recognition particle).

**signalling molecule** any extracellular or intracellular molecule, e.g. hormone, cytokine, or second messenger, that cues the response of a cell to the behaviour of other cells or objects in its environment.

**signal peptidase** any of a group of endopeptidases that remove the signal peptide after insertion of membrane proteins into the membrane. In prokaryotes there are two types: 1 signal peptidase I, EC 3.4.99.36; *recommended name*: leader peptidase; *other name*: prelipoprotein signal peptidase; an endopeptidase that cleaves N-terminal signal peptides from secreted proteins and periplasmic membrane proteins. It is a protein of the inner membrane with a single transmembrane domain. Example from *Salmonella typhimurium*: database code LEP\_SALTY, 324 amino acids (35.78 kDa). 2 signal peptidase II, EC 3.4.99.35; *recommended name*: premurein-leader peptidase; an endopeptidase that selectively cleaves the signal peptide from bacterial membrane lipoproteins, hydrolysing the protein on the N-terminal side of a specific Cys residue. Example from *Haemophilus influenzae*: LSPA\_HAEIN, 171 amino acids (19.36 kDa). In eukaryotes, signal peptidases, EC 3.4.-, are endoplasmic integral membrane proteins with five subunits, numbered according to the approximate  $M_r$ , SPC25, SPC22/23, SPC21, SPC18 and SPC12. Example, SPC21 from *Canis familiaris*: database code SPC3\_CANFA, 191 amino acids (21.47 kDa).

**signal peptidase**" *see* premurein-leader peptidase.

**signal peptide** or **leader peptide** any sequence of amino-acid residues which when linked to a newly synthesized protein directs the protein to a location among the organelles of a eukaryotic cell and from the cytoplasm to the periplasmic space of prokaryotic cells. The term was originally applied to the N-terminal linked peptide that is responsible for the attachment of ribosomes which translate the mRNA for secretory proteins to the endoplasmic reticulum. Such peptides usually comprise

**significant**

20–30 amino-acid residues and are characterized by a central region of hydrophobic amino acids preceded by one or more basic amino-acid residues. An interesting feature is that at the junction of the signal peptide and the mature protein there is no consensus sequence of amino-acid residues, so the basis for the specificity of the protease at this position remains unclear (*see* signal peptidase). The term signal peptide is now more generally applied to any peptide that is responsible for the location of a newly synthesized protein within the organelles of eukaryotic cells (*see* protein kinesis). Thus it applies to the mitochondrial proteins synthesized in the cytoplasm, nuclear proteins and luminal proteins that are retained within the cisternae of the endoplasmic reticulum. In addition to the signal peptides described, which may be located either at the N terminus or C terminus of the nascent protein and which are subsequently cleaved, single-spanning membrane proteins also contain a signal sequence within the protein known as a stop-transfer sequence. This serves to anchor the protein within the membrane. The orientation of the protein within the membrane may be either type I or type II depending on whether the N terminus of the resulting protein is extracytoplasmic (type I) or cytoplasmic (type II). *See also* signal recognition particle.

**signal recognition particle** *abbr.*: SRP; a ribonucleoprotein particle of 325 kDa composed of a 7S (300 nucleotide) RNA molecule and a complex of six different polypeptides. This binds both to the N-terminal signal peptide for proteins destined for the endoplasmic reticulum as they emerge from the large ribosomal subunit and also to the ribosome. This binding arrests further translation thereby preventing the proteins from being released into the cytosol. The SRP-ribosome complex then diffuses to the endoplasmic reticulum where it is bound to the signal recognition particle receptor, which allows resumption of protein synthesis and facilitates the passage of the growing polypeptide chain through the translocon. Through a process involving GTP hydrolysis, the SRP-SRP receptor complex dissociates and SRP returns to the cytosol. Of the six polypeptides of SRP the 54 kDa subunit (SRP54) is the central player. It contains an N-terminal GTPase domain and a C-terminal domain that binds directly to the signal peptide and the SRP RNA.

**signal recognition particle receptor** *abbr.*: SRP receptor; a transmembrane heterodimeric protein ( $\alpha$  subunit, 69 kDa;  $\beta$  subunit, 30 kDa), also known as docking protein, located in the membrane of the rough endoplasmic reticulum. Both subunits contain GTPase domains with which signal recognition particle interacts. In the presence of GTP and SRP receptor, SRP is released from the ribosome-nascent chain complex. Example,  $\alpha$  subunit (dog): database code SSRA\_CANFA, 286 amino acids (31.94 kDa). The  $\alpha$  subunits have an unusual charge distribution with a highly negatively charged N-terminus and a highly positively charged but phosphorylated cytoplasmic tail (C terminus). *See also* signal peptide, signal recognition particle.

**signal-to-noise ratio** the proportional difference between the average level of values observed for a specific property under investigation (signal) measured against the average of nonspecific values (noise) in any record. *See also* signal averaging.

**signal transduction** the transfer of a signal from the outside to the inside of a cell by means other than the introduction of the signal molecule itself into the cell. Typically, interaction of the extracellular signal - a hormone, growth factor, or other agonist - with a specific membrane receptor leads to synthesis within the cell of one or more second messengers, or to activation of other downstream cascades, e.g. by phosphorylation of proteins.

**signature** *an alternative term for motif* (in protein sequences); the word is used in the PRINTS database. *See* Appendix E.

**significant** (*in statistics*) reaching a degree of probability that experimental values lie on a distribution different from that of control values, such that the investigator will conclude that experimental and control samples differ, using tests such as Student's *t*-test or the chi-square test. The degree of probabil-

ity that will be accepted as indicating a significant difference depends on the type of investigation being conducted. If the tests indicate that the probability that the results are due to chance is  $\geq 5\%$  (for biological or medical studies) or  $\leq 1\%$  or, in some cases,  $\leq 0.1\%$  (for biochemical studies), differences are considered significant. -significance *n*.

**silane** 1 monosilane; silicon tetrahydride;  $\text{SiH}_4$ ; the silicon-containing analogue of methane. 2 any of a class of saturated silicon hydrides. Such compounds are silicon-containing analogues of alkanes or cycloalkanes; linear or branched silanes are of general formula  $\text{SiH}_{ln+1}$ , and cyclic silanes, termed cyclosilanes, are of general formula  $[\text{SiH}_2]^n$  ( $n > 2$ ). The value of  $n$ , when  $> 1$ , may be indicated by a specific or general numerical prefix; e.g. disilane, cyclohexasilane, oligosilane, polysilane. Silane and disilane are gases with a repulsive odour; higher silanes are liquids or solids. Silanes are spontaneously flammable in oxygen or air. 3 a term often loosely applied to any hydrocarbyl or other derivative of a silane.

**silanization** treatment of a hydrophilic surface with a reactive silane (def. 3) such as dimethyldichlorosilane, trimethylchlorosilane, octyltrichlorosilane, or an octadecyltrialkoxysilane in order to render it more hydrophobic. Such a treatment is useful in particular for converting hydrophilic silanol (def. 4) groups on the surfaces of glassware or dried silica-gel particles into lipophilic alkylsiloxane moieties. When applied to glass, it reduces adsorption of polar compounds and minimizes the activation of lymphocytes, platelets, or other cells that can occur when untreated glass vessels are used; other benefits include promotion of drainage of aqueous liquids and minimization of electrical leakage (see also siliconize). Silanization has been applied to particles of dried silica gel for use in reversed-phase adsorption chromatography (see also end capping) and to diatomaceous earth used as the support for the stationary phase in reversed-phase liquid-liquid partition chromatography or in some variants of gas-liquid (partition) chromatography. Compare silvlation.-silanize *vb.*; silanized *ad.*

**silanol** 1 silyl hydroxide;  $\text{H}_3\text{SiOH}$ ; the silicon-containing analogue of methanol. 2 any monohydroxy derivative of a silane (def. 2); such compounds are silicon-containing analogues of alkanols and are of general formula  $\text{SiH}_{ln+1}\text{OH}$ . 3 a commonly used term for any Si-hydrocarbyl derivative of silanol, silanediol, or silanetriol; such derivatives are respectively of general formula  $\text{R}_3\text{SiOH}$ ,  $\text{R}_2\text{Si}(\text{OH})_2$ , or  $\text{RSi}(\text{OH})_3$ . 4 the trivalent group  $\text{Si}-\text{OH}$  occurring in hydrated silica (so-called silicic acid). Such groups occur also on the surfaces of dried silica-gel particles and of silica-based glasses under normal conditions (i.e. in equilibrium with undried air).

**sildenafil** see Viagra.

**silent mutation** or synonymous mutation or same-sense mutation a mutation in a codon of a DNA sequence that does not cause an amino-acid change in the translation product. The term 'silent' is also applied to a protein gene product arising from such a mutation, e.g. silent hemoglobin. Other names: silent site mutation; silent nucleotide change.

**silica** silicon(IV) oxide; silicon dioxide;  $\text{SiO}_2$ ; a colourless or white solid used as the basis of many chromatographic procedures; silicic acid contains silanol (def. 4) groups to some of which water is bound. For chromatographic use, it is heated to  $100^\circ\text{C}$  to drive out this water. Heating above  $170^\circ\text{C}$  causes formation of oxide linkages ( $\text{Si}-\text{O}-\text{Si}$ ), and when heated to very high temperatures ( $800$ - $1000^\circ\text{C}$ ) it forms glass. Silicic acid is prepared for different uses in a variety of particle sizes. For chromatography, these range from  $10$  to  $500\ \mu\text{m}$ , the larger sizes being used for column chromatography at normal pressures, the smaller sizes for thin layer chromatography and high-pressure liquid chromatography. Silicic acid precipitated as granules, about  $3\ \text{mm}$  diameter, is known as silica gel; in its dry state it takes up water and can be used as a drying agent, which can be re-used after heating to drive out water. A powder of very fine silica particles,  $0.007$ - $0.014\ \mu\text{m}$ , known as fumed silica, has thixotropic properties and was formerly em-

ployed to create a gel in organic solvents, e.g. in scintillation cocktails to maintain hydrophilic materials in suspension during counting (this use is now superseded by cocktails that themselves form a gel with water). Silica is found in certain algae, notably in the hard shell, or test, of diatoms; it also serves to reinforce the stems of the primitive vascular plants known as horsetails.

**siliceous** or silicious of, pertaining to, or containing silica.

**silicone** the common name for any oligomeric or polymeric siloxane containing the repeating structural unit  $-\text{O}-\text{SiR}_3$ , where R is a hydrocarbyl (e.g. methyl or phenyl) group. The molecules of an individual silicone are usually linear, but sometimes branched, crosslinked, or cyclic. Silicones are odourless and generally colourless, and are characterized by high hydrophobicity and by remarkably high chemical and thermal stability. Depending on their molecular size and configuration and on the nature of their R groups, silicones may be oils, greases, gums, elastomers, or resins. By virtue of their unusual and varied properties they have acquired a correspondingly wide range of clinical, electrical, engineering, industrial, and laboratory applications. In commercial usage, the term may be extended to include organosilicon compounds used for silanization and silvation.

**siliconize** to render (filter-paper, glassware, textiles, etc.) water-repellent by application of a coating of an appropriate silicone. See also silanization.-siliconized *ad.*; siliconizing *n.*

**siloxane** any saturated silicon-oxygen hydride with unbranched or branched chains of alternating silicon and oxygen atoms in the molecule. Unbranched siloxanes are of general formula  $\text{H}_3\text{Si}-[\text{O}-\text{SiH}]_{n-1}-\text{SiH}_3$ ; each is named after its respective parent silane (def. 2), e.g. disiloxane ( $n = 0$ ), tetrasiloxane ( $n = 2$ ). By extension, hydrocarbyl derivatives are commonly included. See also silicone.

**silyl** 1 strictly,  $\text{H}_3\text{Si}-$ , the group derived from silane (def. 1) by loss of a hydrogen atom. 2 a commonly used term for any hydrocarbyl derivative,  $\text{R}_3\text{Si}-$ , of the silVI (def. 1) group.

**silylation** the process of converting organic compounds in general into their silyl (def. 2) derivatives by attachment of trimethylsilyl (or similar organosilicon) groups, or an instance of this process applied to a particular compound or mixture of compounds. Reagents frequently used for the purpose are trimethylchlorosilane and 1-(trimethylsilyl)imidazole, although a number of others have particular applications. The classes of reactive compounds include those possessing amino, carboxyl, hydroxyl, or thiol groups, for which silylation is a means of selective protection in the course of synthetic work (see protecting group). Silylation is widely used also for conversion of mixtures of related compounds of such classes into derivatives capable of separation and analysis by gas chromatography/mass spectrometry. Compare silanization.-silylate *vb.*; silylator *n.*; silylated, silylating, *adj.*

**simian** characteristic of, resembling, or belonging to the apes.

**simian immunodeficiency virus** abbr.: SIY; a retrovirus, one of the lentiviruses, common in the sooty mangabey (a type of monkey) and many African green monkeys. SIYSM, a virus of the sooty mangabey, is closely related to - and probably gave rise to - HIY-2 (see HIV). HIY-1 is closely related to SIY from chimpanzees. Infection of sooty mangabeys and African green monkeys does not cause disease, but SIY infection has been found in macaques in captivity and is pathogenic.

**simian virus 40** abbr.: SY40; an icosahedral virus containing circular duplex DNA of about  $5.2\ \text{kb}$  associated with four histones (H4, H2A, H2B, H3) in a minichromosome. It infects monkeys and apes and is capable of inducing tumours in other species or their cells, its DNA being integrated into the host genome. It can enter two types of life cycle: in permissive cells (usually monkey permanent cell lines) replication occurs in normal infection; in nonpermissive cells there is no lytic infection, but growth transformation can occur. The virus is useful as an expression vector in recombinant DNA technology, having good promoter properties: it can be used either as a virion

## simple diffusion

or as a construct maintained transiently in host cells at high copy number in unintegrated plasmid-like DNA molecules. *See also* small T-antigen.

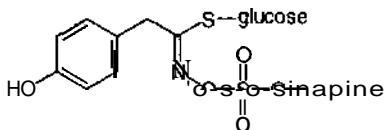

**simple diffusion** or passive diffusion a type of diffusion (def. 2) across a membrane in the absence of any specific transporting agent or carrier. *Compare* facilitated diffusion, active transport.

**simple radial immunodiffusion** *see* single radial immunodiffusion.

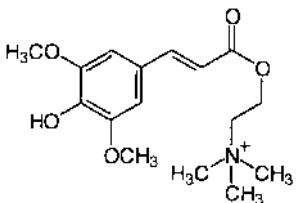

**SIMS** abbr. for secondary ion mass spectrometer.

**sin** abbr. for sine.

**sinalbin** a glucoside found in white or yellow mustard. *See also* sinapine.

**sinapine** 2[[3-(4-hydroxy-3,5-dimethoxyphenyl)-1-oxo-2-propenyl]oxy]-N,N,N-trimethylethanaminium; a component of sinalbin; it is also found in black mustard and other seeds.

**sinaptobrevin** a variant spelling of synaptobrevin.

**sine** abbr.: sin; a trigonometric function, being the ratio of the side of a right-angled triangle opposite a given angle to the hypotenuse; the sine of an obtuse angle is numerically equal to that of its supplement.

**SINE** abbr. for short interspersed element; a highly repeated sequence of DNA occurring interspersed in a mammalian genome; it is similar to a LINE but is shorter - typically less than 500 bp long - and is generated by RNA polymerase III. A family of closely related SINES has of the order of  $10^5$  members, consisting of DNA segments that are similar if not identical in length and sequence. The function of SINES is unknown. They appear to be processed pseudogenes derived from genes that encode small cytoplasmic RNAs including tRNAs. Thus the sequences of SINES are often homologous to the sequences of such RNAs.

**Singer-Nicholson model** an alternative name for fluid-mosaic model.

**single-cell protein** abbr.: SCP; a protein-rich material produced by the culture of bacteria, yeasts, other fungi, or algae and extracted for use as a protein supplement in animal or human foods.

**single-copy plasmid** a plasmid that replicates at the same pace as the bacterial chromosome, and thus maintains equality in numbers with the chromosome.

**single nucleotide polymorphism** abbr.: SNP; the occurrence of single-base variations in the genetic code that occur about once every 1000 bases along the human genome.

**single radial immunodiffusion** or Mancini method an immunodiffusion technique in which holes (wells) are cut in a sheet of antibody-containing agar in a glass dish or on a slide. The wells are filled with antigen solution, which is then left to diffuse radially outwards; in doing so, it reacts with antibody to form a ring of precipitate. The diameter of the circle of precipitate is proportional to the concentration of antigen.

## sinigrin

**single-spanning** describing an integral membrane protein anchored in the membrane by means of a single hydrophobic sequence embedded in the membrane lipid bilayer.

**single-strand binding protein** abbr.: SSB protein; any of a group of proteins found in bacteria and mitochondria that have a greater affinity for single-stranded DNA than for double-stranded species. They are essential for replication, recombination, and repair. They bind tightly and cooperatively and do not catalyse associated activities such as the DNA-dependent ATPase activities of helicases and topoisomerases. They have been called 'unwinding', 'melting', and 'helix-destabilizing' proteins, but each of these names is somewhat misleading since these proteins have multiple functions. Example from *Escherichia coli*: database code SSB\_ECOLI, 177 amino acids (18.82 kDa).

**single-strand conformation polymorphism analysis** abbr.: SSCP analysis; a method for comparing mutations by the rate at which DNA migrates on denaturing gels, under conditions in which the conformation adopted by the DNA is critical. The technique involves amplification of a DNA sequence of interest using the polymerase chain reaction (PCR); the rate of migration of this DNA is then compared with that of a known mutation on gels of differing composition, such that DNA conformation (and thus rate of migration) will depend on the gel conditions (e.g. varying glycerol concentration, ionic strength). If the DNA of unknown composition migrates the same as the known DNA under all conditions, it is an indication that a mutation of a similar character to the known mutation may have occurred.

**single-stranded DNA** abbr.: ssDNA; a form of DNA consisting of a single chain of deoxyribonucleotides instead of the normal two chains. Single-stranded DNA occurs naturally in certain circumstances: (1) transiently, during replication (*see* replicate), when the duplex helical molecule of double-stranded DNA is unwound in the replication fork, initiated by helicase; (2) during replication of circular DNA, when in some circumstances only one strand is replicated, yielding a single-stranded product; as replication proceeds, the synthesized DNA unwinds as a single-stranded 'tail'. Replication may proceed around the unbroken circular DNA strand for more than one cycle, giving rise to the term rolling circle; (3) in certain filamentous coliphages, such as M13, f1, and fd, which contain a single-stranded circular DNA molecule.

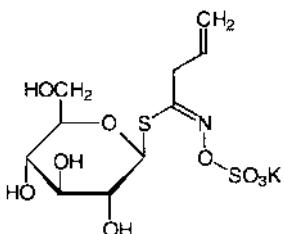

**singlet oxygen** a dioxygen molecule in which two 2p electrons have similar spin. It is more highly reactive than the form in which these electrons are of opposite spin. Singlet oxygen is produced in chloroplasts that, due to mutation, lack carotenoids; excited triplet chlorophyll reacts with oxygen to yield singlet oxygen, which is normally quenched by carotenoids. In the absence of carotenoids, lethal photodynamic damage occurs.

**single-turnover kinetics** the study of the kinetics of an enzyme-catalysed reaction in conditions under which formation of the enzyme-substrate complex can be measured. Such conditions are required for the detection and analysis of transient enzyme-substrate and enzyme-intermediate forms in the investigation of the pre-steady state (*see* pre-steady state kinetics), and contrast with measurement of the multiple recycling of the enzyme in the steady state. Although the enzyme reaction is proceeding normally, only the first part of the reaction is studied, leading to the expression 'single-turnover conditions'. In this kind of study, a substrate is chosen such that the enzyme-substrate complex can be distinguished from substrate alone, e.g. in having a different absorption spectrum. The rate of formation of the complex can then be determined, often by stopped-flow methods.

**singly labelled** describing a specifically labelled compound containing only one isotopically modified atom in a uniquely specified position, e.g.  $\text{CH}_3\text{-CH}[2\text{H}]\text{-OH}$ .

**sinigrin** I-thio-P-D-glucopyranose 1-[N-(sulfo-oxy)-3-butene-imidate] monopotassium salt; a P-D-thioglucoside occurring in

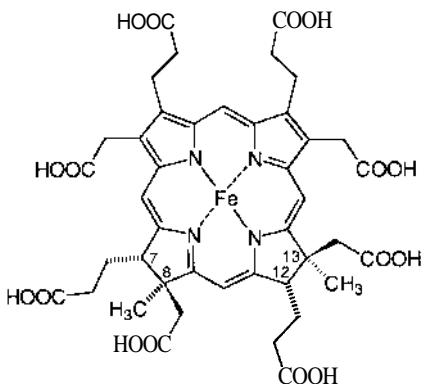

mustard seeds and horseradish roots; it is used as a substrate for thioglucosidase.

**sinister** Latin left; used to describe the left, or counterclockwise, configuration of one of the two faces of a compound containing a trigonal carbon atom. It is designated by the prefix *Si-*. Compare *rectus*. See also *Re/Si* convention.

sintered glass or (rit small particles of glass that have been heated so that they just fuse but without extensive melting. The resultant material is porous, and is often used in glass filtration apparatus or as a support to retain packing materials in chromatographic columns.

siroheme or (esp. Brit.) sirohaem a heme molecule discovered in bacterial sulfite reductase, EC 1.8.99.1. It is a tetrahydroporphyrin, having adjacent, reduced pyrrole rings. It is also a component of nitrite reductase (EC 1.6.6.4) from *Nitrobacter*.

siroheme synthase or (esp. Brit.) sirohaem synthase a multifunctional bacterial enzyme that contains uroporphyrin-III C-methyltransferase, ferrochelatase and precorrin-2 oxidase. The latter activity results in the conversion of precorrin-2 into siroheme by oxidation and Fe<sup>2+</sup> chelation. Example from *Escherichia coli*: database code CYSG\_ECOLI, 457 amino acids (49.90 kDa).

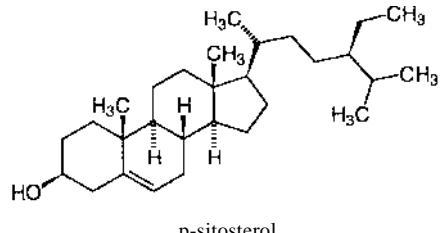

sirup a variant spelling (esp. US) of syrup.

**sis** an oncogene (*v-sis*) from simian osteosarcoma virus that is also expressed in human disease. The related protooncogene, *c-sis*, encodes the B chain of platelet-derived growth factor (PDGF), and *v-sis* encodes a protein almost identical to the B chain, differing only in the amino acids at its N and C termini. Cells are transformed by *v-sis* and produce the PDGF-related molecules, which stimulate the PDGF receptor in an autocrine fashion. Example, PDGF-related transforming protein *p28<sup>sis</sup>* of simian sarcoma virus: database code TSIS\_SMSAV, 226 amino acids (25.42 kDa).

site-directed mutagenesis or site-specific mutagenesis the use of cDNA technology to generate a point mutation at a predetermined position in a genome. It may be achieved by stepwise synthesis of a strand of genomic nucleic acid with substitution of a mutagenic analogue of the base naturally pre-

sent (e.g. guanine for adenine) at a specific position in the nucleotide sequence. After purification this is replicated *in vitro* to allow the generation of base substitutions at the corresponding site in the complementary strand.

site-specific DNA methyltransferase see DNA methylase. sitosterol 22,23-dihydrostigmastanol; a widely distributed plant sterol related to stigmastanol.

p-sitosterol

SI units see 51.

SIV abbr. for simian immunodeficiency virus.

sizing column a gel-filtration column that is used to provide information about the *M<sub>r</sub>* (size) of proteins.

sizing gel a gel-filtration medium, especially one used in a sizing column.

sizukacillin see peptaibophol.

S2 kallikrein see tonin.

SKALP abbr. for skin-derived antileukoproteinase; other name elafin; an inhibitor of serine proteinases; it probably inhibits elastase-mediated tissue proteolysis. Example, human protein sequence (precursor): database code ELAF\_HUMAN, 117 amino acids (12.26 kDa).

skatole 3-methylindole; a bacterial metabolic product of indoleacetic acid that contributes to the odour of feces.

skeletal growth factor a protein that stimulates bone growth. Skeletal growth factor from human bone (hSGF) stimulates growth in human bone cells and embryonic chick bones in culture. The activity comprises insulin-like growth factors (IGFs) in association with IGF-binding proteins (IGFBPs). Example, precursor of human IGFBP-5: database code !BPS\_HUMAN, 272 amino acids (30.53 kDa).

skeleton (formerly) an alternative name for desmin.

skeleton 1 (in zoology) any structure that provides support and protection for the soft tissues and organs of the body. An exoskeleton, such as the cuticle in arthropods, lies external to the body tissues, while an endoskeleton, such as the bony or cartilaginous skeleton of vertebrates, lies within the body.

2 (in chemistry) the carbon chain of a molecule, including any noncarbon elements that necessarily link carbon moieties of the chain. -skeletal ad.

skew 1 asymmetric, biased, distorted. 2 oblique, slanting. 3 (of a statistical distribution) not symmetrical about the mean. 4 to become or make skew; to distort. See also skew conformation. -skewness *n*.

skew conformation 1 any conformation of a six-membered ring form of a monosaccharide or monosaccharide derivative when three adjacent ring atoms and the remaining nonadjacent ring atom are coplanar. Such compounds may be designated by the conformational descriptor -S added to the name. The reference plane is so chosen that the lowest-numbered carbon atom in the ring, or failing that the atom numbered next above it, is exoplanar. Skew conformation is the median conformation through which one boat conformation passes during conversion to another boat conformation in the cycle of flexible forms; it is similar to twist conformation (def. 1). See also conformation. 2 a less common alternative term for synclinal conformation; see conformation.

SKI a gene encoding a protein of unknown function but related to v-ski, the oncogene of Sloan-Kettering viruses; it has no marked homology with other oncogenes.

## slab gel

**slab gel** a gel, usually polyacrylamide or starch, that is formed as a sheet rather than a rod.

**slaty** a coat colour mutation in mice allelic for the *tyrp-2* gene. The mice have a defect in melanin formation that causes dark-grey (slate-coloured) melanin to be formed. The enzyme affected is dopachrome A-isomerase.

**sleep peptide** any peptide that brings about sleep when infused into the cerebrospinal fluid (CSF) of animals. Delta-sleep-inducing peptide, isolated from CSF, has the structure Trp-Ala-Gly-Gly-Asp-Ala-Ser-Gly-Glu. A large number of endogenous substances isolated from the brain can likewise induce sleep, but it is not known if this is their physiological function.

**sliding filament model** a model of muscle contraction that envisages contraction occurring as a result of thin filaments sliding past thick filaments. The mechanism of activation involves enhanced binding of  $\text{Ca}^{2+}$  by troponin C (see troponin), one of the three troponin peptide components of the thin filament. In the resting state, troponins I and T inhibit the actin-tropomyosin complex of the thin filament from binding to myosin; increase in  $\text{Ca}^{2+}$  concentration causes troponin C (each molecule of which binds up to four  $\text{Ca}^{2+}$  ions) to release this inhibition, allowing the myosin headgroups to bind actin. Then, in the presence of ATP, the thin filaments slide over the thick filament myosin molecules to cause contraction. The myosin heads contain an active ATPase that hydrolyses the ATP; the latter must be continuously resynthesized for contraction to continue.

**sliding (of repressor)** the mode of action of *lac* repressor in *Escherichia coli*. It first binds at a non-operator site, then slides along the DNA until it finds the target site, i.e. the operator.

**slime mould or (US) slime mold** any of a group of organisms that exhibit features of both fungi and protozoa. Characteristically they exist as slimy masses on decaying wood or in damp soil, and have the ability to switch from an amoeboid single-celled phase, called a myxamoeba, to an aggregated or multicellular phase from which fruiting bodies may arise. In the so-called true slime moulds, the myxamoebae form an acellular mass called a plasmodium, whereas in the cellular slime moulds the myxamoebae aggregate to form a multicellular pseudoplasmodium, or 'slug'. A well-known example of a cellular slime mould is *Dictyostelium discoideum*; when the food supply is exhausted, its myxamoebae aggregate to form a small (1-2 mm) slug, containing up to  $10^5$  cells, which migrates to seek an area of food abundance. When nutritional conditions are favourable the slug undergoes differentiation to form fruiting bodies, from which spores are released. Germination of a spore leads to the formation of a myxamoeba. *D. discoideum* has a relatively small genome (about 10 times larger than that of a bacterium) and is popular with geneticists, providing insights into the nature of the inducible behaviour leading to aggregation, and the rapid cell division and differentiation that precede the formation of a fruiting body.

**slip** a term used in regard to situations in which the mitochondrial enzyme, cytochrome *c* oxidase, may carry out its redox reaction without pumping protons into the intermembrane space.

**slope  $\delta y/\delta x$** , where results are expressed graphically as a continuous line, the ordinate (vertical axis) representing *y*, the abscissa (horizontal axis) representing *x*.

**slow-cycling rhodopsin** a retinal-containing energy-transducing pigment present in small amounts in some of the strains of *Halobacterium halobium* in which purple membranes occur. It is distinct from bacteriorhodopsin and halorhodopsin and is believed to play a role in the characteristic variation in the phototactic response of such organisms at different wavelengths. Illumination with yellow light or with blue or near-ultraviolet light results respectively in accumulation of forms with absorption maxima at 375 nm and 590 nm.

**slow reacting substance (of anaphylaxis) or slow reacting substance A abbr.: SRS or SRS-A;** one of a number of sub-

## Smith

stances that mediate anaphylaxis; it was identified as a polar, lipid-like compound not normally present in mammalian tissues but synthesized in them as a consequence of the combination of antibody with antigen. It increases vascular permeability and induces contraction of some types of smooth muscle, especially bronchial muscle. It is slow in action relative to histamine - hence its name - and is not antagonized by antihistamines. Leukotrienes C<sub>4</sub>, D<sub>4</sub> and E<sub>4</sub> are now known to be the active components.

**slurry** a fluid suspension of particles having the consistency of cream.

**Sm symbol for samarium.**

**small cytoplasmic ribonucleoprotein abbr.: scRNP** (hence often colloquially termed 'scyrp'); any of various particulate complexes of proteins with molecules of small cytoplasmic RNA, found in the cytoplasm. Their function is unknown.

**small cytoplasmic RNA abbr.: scRNA**; any of various low-molecular mass (100-300 nucleotides) RNA molecules found in the cytoplasm as components of small cytoplasmic ribonucleoprotein.

**small intensely fluorescent cell abbr.: srF cell**; a cell found in autonomic ganglia and containing dopamine. The name derives from the appearance of such cells after formaldehyde condensation in fluorescence microscopy.

**small nuclear ribonucleoprotein abbr.: snRNP** (hence often colloquially termed 'snurp'); any of various particulate complexes of proteins with molecules of small nuclear RNA (snRNA), found in the eukaryotic nucleus; the particles are  $\approx 250$  kDa. They are named according to the snRNAs they contain: the V4/V6 snRNP, e.g., contains V4 and V6 snRNA. They are involved in RNA splicing (see spliceosome). Patients with systemic lupus erythematosus make antibodies directed against one or more snRNPs.

**small nuclear RNA abbr.: snRNA**; any of various low-molecular-mass (100-300 nucleotides) RNA molecules, designated VI, V2, ... V12 RNA, found in the eukaryotic nucleus as components of small nuclear ribonucleoprotein. See also spliceosome.

**small nucleolar ribonucleoprotein abbr.: snoRNP** (hence often colloquially termed 'snorp'); any of various particulate complexes of proteins with molecules of small nucleolar RNA, found in the eukaryotic nucleolus. They are possibly the same as processosomes.

**small nucleolar RNA abbr.: snoRNA**; any of a class of small RNAs that are associated with the eukaryotic nucleus as a component of small nucleolar ribonucleoproteins and participate in the processing of ribosomal RNA. They contain a long stretch of sequence complementarity to conserved sequences in mature mRNA. Six have been identified in metazoan cells (87-280 bases) and 12 in yeast (125-605 bases). They exist as ribonucleoprotein (RNP) particles, which appear to assemble with a large multi-RNA RNP complex.

**small T-antigen** see T-antigen (def. I).

**51 mapping or 51 nuclease mapping** a commonly used technique depending on the property of S<sub>1</sub> nuclease to remove single-stranded DNA or RNA from double-stranded hybrids of DNA and RNA. It may be used to detect the coding region of genomic DNA that contains introns by a procedure in which either cDNA for a particular mRNA or the mRNA itself is hybridized to the genomic DNA, and the single-stranded DNA removed by the S<sub>1</sub> nuclease leaving the hybridized coding DNA (the exons). The enzyme can also be used in a similar way to identify the 5' end of a mRNA.

**smectic** (of a substance) being or having a mesomorphic state in which the molecules are arranged in parallel layers. The molecules in any layer can move in the plane of that layer but not into adjacent layers. Compare nematic. See also liquid crystal.

**Smith 1** Hamilton Othanel (1931- ), VS molecular biologist; Nobel Laureate in Physiology or Medicine (1978) jointly with W. Arber and D. Nathans 'for the discovery of restriction enzymes and their application to problems of molecular genet-

ics'. 2 Michael (1932– ), British-born Canadian biochemist; Nobel Laureate in Chemistry (1993) 'for his fundamental contributions to the establishment of oligonucleotide-based, site-directed mutagenesis and its development for protein studies' [prize (awarded 'for contributions to the developments of methods within DNA-based chemistry') shared with K. B. Mullis].

**smooth** describing a bacterial strain having shiny (smooth) colonies. *See* smooth-rough variation.

**smooth endoplasmic reticulum abbr.:** SER; *see* endoplasmic reticulum.

**smooth muscle** or involuntary muscle muscle that lacks striations, hence giving a 'smooth' appearance under the microscope; it produces slower, longer lasting contractions than striated muscle and is responsible for the contractile function of visceral organs such as stomach, bladder, intestine, and uterus, and the walls of arteries. The cells are mononucleate, and contain both thick filaments and thin filaments although these are not arranged in the pattern that leads to striations in skeletal muscle and cardiac muscle. The thin filaments are composed mainly of actin, polymerized into a double-helical strand, and associated with tropomyosin arranged along the length of the actin filament. The thick filaments are composed of aggregated myosin molecules. The thick and thin filaments comprise the contractile elements and are thought to function in an analogous manner to their striated muscle counterparts (*see* sliding filament model). Muscle contraction is regulated by the sarcoplasmic (cytosolic) free  $\text{Ca}^{2+}$  concentration, which increases from resting levels of 120–270 nM to 500–700 nM in response to stimuli such as membrane depolarization, or the action of a-adrenergic or muscarinic agonists.  $\text{Ca}^{2+}$  then binds to calmodulin, which activates myosin-light-chain kinase, which phosphorylates myosin at Ser<sup>19</sup> of each of the two 20 kDa light chains. This causes cycling of myosin cross-bridges along actin filaments and the development of force. Calponin, caldesmon, and protein kinase C are also thought to play a role in fine-tuning the contractile state.

**smooth-rough variation** or S→R variation any of a number of types of cell-surface compositional variation that occur in bacteria, usually giving rise to changes in the appearance of colonies from that of the original strain. In the Enterobacteriaceae the colonies are typically shiny (smooth) and change to matt (rough), an S→R variation that may be accompanied by loss of surface antigens, reduction or loss of virulence, and changes in susceptibility to certain bacteriophages.

**sn-** prefix (*in chemical nomenclature*) signifying stereospecifically numbered; it is used in designating the configuration of derivatives of certain classes of prochiral compounds (especially glycerol and its derivatives) to ensure differentiation from conventional numbering. Thus sn-1 denotes Col of the glycerol moiety of a phospholipid under the stereospecific numbering system. C-2 and C-3 are similarly denoted sn-2 and sn-3 under the same system.

**Sn symbol** for tin.

**SNAP abbr.** for 1 S-nitroso-N-acetylpenicillamine. 2 synaptosome-associated protein; a number of these exist. The nomenclature has become somewhat confusing, since SNAPS exist with different but closely related roles. Thus SNAP-25 functions as a SNAP receptor, or SNARE, while other SNAP proteins such as α-SNAP (*see* def. 3) function to bind NSF proteins (*see* N-ethylmaleimide) to SNAREs such as SNAP-25. Example, SNAP-25 from chicken and mouse neurons: database code SN25\_MOUSE, 206 amino acids (23.29 kDa). 3 soluble NSF attachment proteins, such as α-SNAP, β-SNAP, etc. These are cytoplasmic proteins that mediate binding of N-ethylmaleimide-sensitive fusion protein to membranes. *See also* SNARE. SNARE hypothesis.

**SNARE abbr.** for SNAP receptor; syntaxin, synaptobrevin, and SNAP-25 (*see* SNAP (def. 2)) act as SNAREs; they bind in an ATP-dependent manner to NSF-SNAP complexes (SNAP in this case being the NSF attachment protein (*see* N-ethyl-

maleimide)). Syntaxin, synaptobrevin, and SNAP-25 form a complex that is much more effective than the single proteins acting alone, leading to the concept of a core complex that bridges the synaptic vesicle and plasma membranes, and which may function in the docking and fusion process. *See also* SNARE hypothesis.

**SNARE hypothesis** a suggested model of vesicular fusion, in which two types of SNARE are involved; v-SNAREs are found on vesicles and t-SNAREs are found on the target membranes, each transport vesicle having its own v-SNARE which recognizes a cognate t-SNARE on a target membrane and mediates docking; fusion is then mediated by N-ethylmaleimide-sensitive fusion protein and an attachment protein (SNAP (def. 3)).

**Snell, George Davis** (1903–96), US geneticist; Nobel Laureate in Physiology or Medicine (1980) (jointly with B. Benacerraf and Jean Dausset 'for their discoveries concerning genetically determined structures on the cell surface that regulate immunological reactions').

**Snell's law** *see* refraction.

**Sno symbol** for a residue of the ribonucleoside thioinosine; mercaptopurine ribonucleoside; alternative to sl.

**snoRNA abbr.** for small nucleolar RNA.

**snoRNP abbr.** for small nucleolar ribonucleoprotein.

**snorp colloquialism** for snoRNP, i.e. small nucleolar ribonucleoprotein.

**snRNA abbr.** for small nuclear RNA.

**snRNP abbr.** for small nuclear ribonucleoprotein.

**S1 nuclease** EC 3.1.30.1; *recommended name:* *Aspergillus* nuclease S1; a single-strand endonuclease, purified from *Aspergillus oryzae*, that degrades single-stranded RNA or DNA to 5' mononucleotides; it has no apparent base specificity. It is useful for the removal of unpaired regions in hybridization technology (*see also* SI mapping). The enzyme is a monomer, and contains three zinc atoms. Database code NUS1\_ASPO, 267 amino acids (29.02 kDa). Similar enzymes occur in *Penicillium* spp. and barley.

**snurp colloquialism** for snRNP, i.e. small nuclear ribonucleoprotein.

**snurposome** any of at least three (A, B, and C) morphologically and biochemically distinct granules in the amphibian oocyte nucleus that contain one or more types of small nuclear ribonucleoproteins (snRNP).

**soap** any salt formed between a hydroxide of a metal (usually an alkali or alkaline earth) and a higher fatty acid; such compounds are useful as detergents (def. 2). The meaning is sometimes extended to include the salt of any ionized lipid amphipath, e.g. of a long-chain amine or sulfate or of a sterol carboxylate. The common soaps of commerce were traditionally the mixed sodium salts (giving hard soaps) or the mixed potassium salts (giving soft soaps) of oleic, palmitic, and stearic acids, prepared by saponification of animal or vegetable fats or oils with sodium or potassium hydroxide respectively. Modern soap compositions are more complex, with solid or liquid soaps containing various additional detergents.

**soapstone** *see* talc.

**SOD abbr.** for superoxide dismutase.

**soda** any of various compounds of sodium, especially sodium hydroxide (NaOH; caustic soda), sodium hydrogen carbonate (sodium bicarbonate, NaHCO<sub>3</sub>; baking soda), or sodium carbonate decahydrate (Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O; washing soda). The term may also indicate sodium monoxide (Na<sub>20</sub>).

**soda glass** common glass, made from a mixture of silica, sodium oxide (soda), and lime, in approximate proportions SiO<sub>2</sub> 70%, Na<sub>2</sub>O 15%, CaO 10%. Its low melting point led to the production of more heat-resistant glasses, e.g. Pyrex. *See also* borosilicate (glass).

**Soddy, Frederick** (1877–1956), British inorganic and physical chemist; Nobel Laureate in Chemistry (1921) 'for his contributions to our knowledge of the chemistry of radioactive substances, and his investigations into the origin and nature of isotopes'.

**sodium symbol:** Na; a soft, silvery-white, highly reactive alkali metal of group I of the (IUPAC) periodic table; atomic number II; relative atomic mass 22.997. Sodium is widely distributed and is one of the most abundant elements of the Earth's crust; it exists in great quantity as sodium chloride (salt), especially in sea water. Apart from the nonradioactive, and most abundant, isotope, sodium-23, there are two radioactive isotopes, sodium-22 and sodium-24. In biochemistry, sodium ( $\text{Na}^+$ ) is the principal extracellular cation, and the one that largely determines the extracellular fluid volume. In humans the normal range for plasma sodium is 135–145 mmol L<sup>-1</sup>. Sodium ions are actively pumped out of cells by sodium/potassium ATPase. Their concentration in the blood is regulated by the mineralocorticoid hormone aldosterone, which increases sodium reabsorption in the kidney distal tubule. In scientific and medical literature sodium was formerly given the Latin name 'natrium', hence the symbol Na and the term natriuretic.

**sodium-22** a radioactive nuclide of sodium,  $^{22}\text{Na}$ . It emits a  $\beta^+$  particle (1.83 MeV) and gamma radiation (1.275 MeV). Its half-life is 2.605 years.

**sodium-24** a radioactive nuclide of sodium,  $^{24}\text{Na}$ . It emits an electron ( $\beta^-$  particle, 1.39 MeV) and gamma radiation (2.75 MeV). Its half-life is 15.02 h.

**sodium-alanine symporter** see sodium/neutral amino acid co-transporter.

**sodium-ealcium ion exchanger** a plasma membrane protein antiporter of muscle and nerve cells that promotes the exchange diffusion of sodium and calcium ions. Influx of  $\text{Na}^+$  to the cytosol drives the efflux of  $\text{Ca}^{2+}$  from the cell. The affinity for  $\text{Ca}^{2+}$  is low, so that it only functions at high intracellular  $\text{Ca}^{2+}$  concentrations, transporting  $\text{Ca}^{2+}$ , e.g., during excitation-contraction coupling. Example from human cardiac sarcolemma, type III membrane glycoprotein (precursor): database code NACA\_HUMAN, 973 amino acids (108.42 kDa).

**sodium channel** any of several types of structure that permit controlled (gated) passage of sodium ions through membranes. Two important types of gated sodium-ion channels are the voltage-gated channel and the transmitter-gated channel. Voltage-gated channels are involved in conduction and transmission of nerve impulses, whereas transmitter-gated channels respond only to neurotransmitters; a well-studied example of the latter type of channel is the acetylcholine receptor. Voltage-gated sodium-ion channels consist of integral proteins in the plasma membranes of excitable cells. The proteins sense the membrane electric field, opening channels to permit an inward flux of sodium ions, thereby causing the membrane depolarization that is essential for the propagation of the action potential. Primary sequence data for the *Electrophorus* electroplax protein indicate that this channel consists of a single polypeptide chain of about 2000 amino-acid residues and contains four homologous repeats (domains I, II, III, and IV), each of which has six putative transmembrane segments (designated S1 to S6) with extensive nonmembrane cytosolic and extracellular loops. This sequence shares significant homology to other ion channels, particularly the  $\alpha 1$  subunit of the  $\text{Ca}^{2+}$  channel, segment S4 showing strong structural similarity to sequences in the  $\text{Ca}^{2+}$  and  $\text{K}^+$  channels. The cytoplasmic loop between repeats III and IV has been implicated in the rate of inactivation of the channel. As normally expressed the protein bears about 500 sugar residues (mostly N-acetylglycosamine and sialic acid) and 50 fatty-acyl chains (palmitoyl and stearoyl). Structural data are also available for enzymes of *Drosophila* and mammalian skeletal muscle and brain. The mammalian channels are heterooligomeric, consisting of a large a subunit similar to the *Electrophorus* protein, and several other smaller peptides; most of the functional properties reside in the a subunit. Example from rat brain (large subunit): database code CINI\_RAT, 2009 amino acids (228.51 kDa); seven motifs. The a subunit is the target for polypeptide neurotoxins, e.g. from scorpions; other sodium-channel blockers include saxitoxin, tetrodotoxin, and veratridine.

**sodium dodecyl sulfate or (esp. Brit.) sodium dodecyl sulphate abbr.: SDS; sodium lauryl sulfate;  $\text{CH}_3(\text{CH}_2\text{OCH}_2\text{S}(\text{O})\text{Na}^+$**  the sodium salt of the I-dodecanol half-ester of sulfuric acid (I-dodecanol was formerly known as lauryl alcohol). It is an anionic detergent and wetting agent; aggregation number 62 (0–0.1 M  $\text{Na}^+$ ), 101 (>0.1 M  $\text{Na}^+$ ); CMC 7–10 mM (0–0.05 M  $\text{Na}^+$ ), 1–2 mM (0.1–0.2 M  $\text{Na}^+$ ). The amphipathic dodecylsulfate anion is a powerful hydrophobic-bond breaker, hence it is much used in protein chemistry as, e.g. a denaturant, a dissociant of oligomers, and a solubilizer of membrane components. See also SOS-polyacrylamide gel electrophoresis.

**sodium-hydrogen ion exchanger** a plasma membrane protein that functions as a  $\text{Na}^+/\text{H}^+$  antiporter. Influx of  $\text{Na}^+$  drives the efflux of  $\text{H}^+$ . It functions to maintain intracellular pH, to which it is sensitive, its activity increasing as pH falls. Example from the gills of the crab, *Carcinus maenas*: database code CMU09274, 672 amino acids (75.89 kDa).

**sodium-ion channel** see sodium channel.

**sodium/neurotransmitter transporter** any of a family of integral membrane glycoproteins, having eight motifs and 12 putative transmembrane helices, that are involved in sodium-dependent transport of neurotransmitters. Examples (precursors) include sodium-dependent choline transporter from rat: database code NTCH\_RAT, 635 amino acids (70.55 kDa); sodium- and chloride-dependent GABA transporter 1 from human: database code NTGLHUMAN, 599 amino acids (66.94 kDa). This latter protein is the target for cocaine and other psychomotor stimulants.

**sodium/neutral amino-acid cotransporter** an integral membrane protein responsible for the  $\text{Na}^+$ -dependent uptake of the neutral amino acids alanine, serine, glycine, cysteine, and proline. Example from pig: database code NAAA\_PIG, 660 amino acids (72.66 kDa). Transporters with specificities for different types of amino acid are system A, system L, and system N.

**sodiUm/potassium ATPase EC 3.6.1.37; recommended name:  $\text{Na}^+/\text{K}^+$ -exchanging ATPase; systematic name: ATP phosphohydrolase ( $\text{Na}^+/\text{K}^+$ -transporting); other names: sodium pump;  $\text{Na}^+,\text{K}^+$ -ATPase.** An integral membrane protein that catalyses the hydrolysis of ATP to ADP and orthophosphate.  $\text{Na}^+,\text{K}^+$ -ATPases are integral (cell membrane) proteins, and pump out approximately 3  $\text{Na}^+$  ions for every 2  $\text{K}^+$  ions that enter, with hydrolysis of 1 ATP. They are tetrameric proteins, consisting of two large  $\alpha$  subunits and two smaller  $\beta$  subunits. The  $\alpha$  subunits bear the active site and penetrate the membrane, while the  $\beta$  subunits carry oligosaccharide groups and face the cell exterior only. Ouebain is a specific inhibitor. Examples from rat:  $\alpha$ -I chain: database code ATNLRAT, 1023 amino acids (112.92 kDa);  $\beta$  chain: database code ATNB\_RAT, 304 amino acids (35.16 kDa);  $\gamma$  chain: database code ATNG\_RAT, 58 amino acids (6.49 kDa).

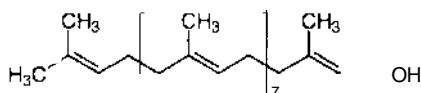

**sodium pump** any of various transporters that transport sodium ions across membranes, especially enzymes of the  $\text{Na}^+,\text{K}^+$ -ATPase type (see sodiUm/potassium ATPase). The  $\text{Na}^+/\text{K}^+$  ratio across the plasma membrane of eukaryotic cells (outside:  $\text{Na}^+$  140 mM,  $\text{K}^+$  10 mM; inside:  $\text{Na}^+$  10 mM,  $\text{K}^+$  100 mM) requires that sodium ions be continually pumped out of the cell in exchange for potassium ions if the gradient is to be maintained; this is an energy-requiring process. See also active transport.

**software (in computing)** programs used by computer hardware to execute commands keyed or otherwise supplied by the computer operator to bring about the completion of desired tasks. Most software is not permanently resident in the computer but is accessed from disks as instructed by the operator, operating systems, or other software.

**sol** any fluid colloidal system composed of two or more components. The dispersed phase may be either particles of solid or droplets of liquid, and the continuous phase either a liquid or a gas (see aerosol).

## solanesol

solanesol a 45-carbon polypropenol present in tobacco leaves.

solation the (usually reversible) act or process of forming a sol from a gel. *Compare* gelation. -solate *vb.*

solid a physical state of matter in which the constituent atoms, ions, or molecules have no translatory motion though they vibrate about fixed positions. In crystalline solids the constituents are arranged in a definite array, whereas in amorphous solids they are not. Solids, especially crystalline solids, commonly have characteristic melting temperatures at which they change to liquids.

**solid-phase peptide synthesis** see peptide synthesis.

**solid-phase technique** any technique in which reagents are immobilized on a support or in some other way insolubilized. In radioimmunoassay the insolubility or binding properties of an antigen-antibody complex are commonly exploited to remove labelled antigen. Enzymes immobilized on columns (immobilized enzymes) have many applications. In peptide synthesis, the growing peptide chain may be immobilized on a column. So-called solid-phase extraction systems are in effect extractions using batch column chromatography techniques, in which the material to be extracted is bound to a column, then removed by batch elution. In peptide sequencing a peptide immobilized on a column may be degraded residue by residue, facilitating recovery of the undegraded remaining peptide at each cycle.

**solid scintillation fluorography** a technique for visualizing radioactive materials in a specimen (e.g. a chromatogram) by covering the specimen with a solid fluor and allowing the ejected photons to darken an applied photographic emulsion. *Compare* fluorography (def. 2).

**solid-state** (in *electronics*) describing any system in which current flow takes place entirely through solid materials, such as semiconductors and transistors, rather than through vacuum devices such as thermionic valves.

**solubility** 1 the attribute of being soluble, of being able to dissolve. 2 the amount of a substance (solute) that can dissolve in a given amount of another substance (solvent) at a given temperature and pressure.

**solubility product symbol:**  $K_{sp}$ ; for a solute  $A_xB_y$  that ionizes in a stated solvent according to the equilibrium  $A_xB_y \rightleftharpoons xA + yB$ , at a given temperature and pressure,  $K_{sp} = [aAl][aBl]$ , where  $[aAl]$  and  $[aBl]$  are the activities of the two ions when the solution is saturated by the solute. In unsaturated solutions the product  $[aA]^x[aB]^y$  can have any value less than  $K_{sp}$ , but if further amounts of either ion are added from whatever source, such that  $K_{sp}$  is exceeded, precipitation from solution will occur to the extent that the relationship  $[aA]^x[aB]^y = K_{sp}$  is restored. In dilute solutions the concentrations  $C_A$  and  $C_B$  of A and B may be used as a good approximation.

**solubilize** or **solubilise** to bring into solution any material, especially complexes that normally exist in the cell as part of membrane structures. Such materials usually have hydrophobic domains, and solubilization depends on masking these with detergents or similar substances, to bring the material into micellar suspension.

**soluble** 1 capable of being dissolved in or as if in a fluid. 2 (of, e.g., a problem or mathematical equation) capable of being solved.

**soluble collagen** see tropocollagen.

**soluble RNA** abbr.: S-RNA or srRNA; *an old term for* transfer RNA (a 'soluble' RNA fraction from disrupted liver cells that did not sediment after centrifuging at 100000 g for several hours led to the discovery of transfer RNA).

**solute** a dissolved substance, particularly a component of a solution that is present in a smaller amount than the solvent.

## somatostatin

**solution** 1 a homogeneous molecular mixture of two or more substances, usually of dissimilar molecular structures, i.e. of a solid in a liquid. 2 the action or process of solving a problem. 3 the result of solving a problem, equation, etc.

**solvation** the (loose) combination of solvent with molecules or ions of the solute.

**solvation effect** the effect of solvent molecules on the behaviour of (especially) macromolecules in solution, especially during centrifugation.

**solvent** 1 a substance or mixture, usually a liquid, that is able to dissolve other substances to form a solution. Typically it has the same physical state as the solution itself, and is the component of greatest extent in the solution. 2 (in *chromatography*) the liquid used to pass through a chromatography column, paper, or other support to 'develop' the chromatogram.

**solvent-perturbation method** a technique in which some physical property of a macromolecule is measured in a polar and in a nonpolar solvent. For example, it can be determined whether an amino-acid residue in a protein is internal or external by measuring the absorption spectra of the protein in the two types of solvents. Difference spectroscopy is conveniently applied in such instances.

**soma** (*pl. somata or somas*) 1 the whole of any plant or animal organism but excluding the germ cells. 2 the body, as opposed to the mind. *See also* somatic cell. -somatic *adj.*

**somat+** *a variant form of somato+* (before a vowel).

**somatic cell** any cell of an organism other than a germ cell.

**somatic cell genetic disorder** a category of genetic disorders in which defects are restricted to specific somatic cells, e.g. cancer cells. This contrasts with the other types of genetic disorder - single gene, multifactorial, and chromosome - in which the abnormality is present in all cells, including the germ cells.

**somatic cell hybrid** a hybrid cell formed from the fusion of different cells, usually from different species. Somatic cell hybrids obtained by the fusion of human and rodent cells are frequently used for gene mapping. *See* cell fusion.

**somatic crossing over** *an alternative name for* mitotic recombination.

**somato+** *or* (before a vowel) **somat+** *comb. for* denoting the body, or soma.

**somatotropin** *another name for* growth hormone releasing hormone (GHRH).

**somatogenic** 1 originating in the soma (def. 1), or body tissues. 2 of organic, rather than mental, origin.

**somatotropin** *the recommended name for* growth hormone releasing hormone (GHRH).

**somatotropin** human chorionic somatomammotropin; *see* choriomammotropin.

**somatomedin** *generic name for* insulin-like growth factors (abbr.: IGF); in the human they comprise IGF-IA, IGF-IB, and IGF-II. Somatomedins were isolated on the basis of several properties: (a) activity on cartilage (incorporation of sulfate and thymidine), (b) insulin-like activity in adipose and muscle, and (c) mitogenic activity in cell culture. Somatomedin A is IGF-II, and somatomedin C is IGF-I (A and B). The term somatomedin should be used only when a generic term is needed, IGF-I (A or B) and IGF-II being used for the specific peptides. Somatomedin B is released from vitronectin, is a serum factor of unknown function, is increased in response to somatotropin, and has proteinase-inhibitory activity.

**somatostatin** or **somatotropin-release inhibiting factor** (abbr.: SRIF) or (formerly) growth hormone-release inhibiting hormone (abbr.: GH-RIH) a hypothalamic cyclic 14-residue peptide discovered as an inhibitor of the release of the pituitary growth hormone somatotropin and of the release of glucagon and insulin from the pancreas of fasted mammals; it also inhibits the release of gastrointestinal hormones and other secretory proteins. It has the sequence Ala-Gly-Cys-Lys-Asn-Phe-Phe-Trp-Lys-Thr-Phe-Thr-Ser-Cys, with a disulfide link

**somatostatin receptor**

between cysteines 3 and 14; this is called **somatostatin 14**. There also exists a bioactive 28-residue peptide - **somatostatin 28** - in which the 14-residue peptide is extended from the N terminus (the N-terminal residues are SANSNPALAPRE-RKAG-). Both forms are derived from the 92 amino-acid precursor, **prosomatostatin**, by tissue-specific proteolytic processing. Somatostatin is widely distributed, occurring not only in the central nervous system, but also in peripheral tissues such as stomach, intestine, and pancreas. It has diverse effects that are tissue specific, and can function as a neurotransmitter. Example (precursor) from human and *Macaca fascicularis* (a crab-eating monkey); database code SMS1\_HUMAN, 116 amino acids (12.72 kDa). See also **somatostatin receptor**.

**somatostatin receptor** any of several membrane proteins that bind different forms of **somatostatin** and mediate its effects. Pharmacological studies indicate that there are at least two subtypes of receptor. In appropriate systems somatostatin suppresses receptor-induced stimulation of adenylyl cyclase by activating the inhibitory **G-protein** G<sub>i</sub>; it can decrease intracellular Ca<sup>2+</sup> concentrations and inhibit the voltage-dependent current, *I<sub>Ca</sub>*, by a G-protein-dependent cyclic AMP-independent mechanism. Somatostatin 14 enhances and somatostatin 28 reduces potassium current, *I<sub>K</sub>*, also by G-protein-dependent cyclic AMP-independent mechanisms. There are several different types of somatostatin receptor; all are G-protein-coupled seven-transmembrane-domain proteins. The examples below are all from *Rattus norvegicus*. Type 1 has higher affinity for somatostatin 14 than 28 and is coupled to phosphotyrosine phosphatase and sodium-hydrogen-ion exchanger; example, database code SSRLRAT, 391 amino acids (42.75 kDa). Types 2 and 3 are receptors for somatostatins 14 and 28 and inhibit adenylyl cyclase; examples, database code SSR2\_RAT, 369 amino acids (41.20 kDa) and database code SSR3\_RAT, 428 amino acids (47.15 kDa). Type 4 is a receptor for somatostatin 14 and inhibits adenylyl cyclase; example, database code SSR4\_RAT, 384 amino acids (42.09 kDa). Type 5 is a receptor for somatostatin 28 and inhibits adenylyl cyclase; example, database code SSR5\_RAT, 363 amino acids (39.97 kDa). Hybridization studies indicate these are members of a larger family of somatostatin receptors; they are G-protein-coupled adenylyl cyclase activators.

**somatotrope or somatotroph** a type of cell found in the lateral wings of the anterior pituitary and comprising about 50% of the hormone-producing cells of that part of the gland. Somatotropes are responsible for the production of **somatotropin**. Somatotrope adenomas cause **acromegaly**.

**somatotroph** see **somatotrope**.

**somatotropic** 1 stimulating and maintaining the growth and development of any cell or tissue. 2 (sometimes) of or pertaining to **somatotropin**.

**somatotropic** 1 of, or relating to, **somatotropin**. 2 stimulating the mechanisms connected with growth or development of a cell or tissue. Compare **somatotropic**.

**somatotropic hormone** see **somatotropin**.

**somatotropin or growth hormone** (abbr.: GH); also called **somatotropic hormone** (abbr.: STH); a hormone secreted by the anterior pituitary whose main effect is to stimulate growth. The human hormone (hGH) is mostly synthesized as the precursor of a single-chain, 191-residue protein, *M<sub>r</sub>* 22 000, but 5-10% is a form of *M<sub>r</sub>* 20 000 resulting from alternative splicing that deletes codons for amino acids 32-46 from the mRNA. Genes encoding hGH, **prolactin**, and **choriomyamotropin** form a family with high nucleotide homology with five coding exons. Somatotropin secretion is pulsatile, especially during fasting, when cycles of about four hours' duration occur; it is stimulated by fasting or hypoglycemia, and hormonally by glucagon, GHRH, estrogens, and arginine vasoressin, and during the first phase of sleep; secretion is inhibited by hyperglycemia, somatostatin, the insulin-like growth factor IGF-I, and glucocorticoids. It is secreted from

storage granules. *In vivo*, somatotropin tends to promote synthesis of protein, and lipolysis or reduced fat deposition, and growth and mitosis of cartilage. Deficiency leads to pituitary dwarfism types I and IV. Its actions *in vitro* include stimulation of amino-acid uptake in muscle, and lipolysis in adipose tissue, but many of its actions *in vivo* may depend on its action in stimulating synthesis and secretion of **somatomedins**. hGH has 85% homology with human choriomyamotropin and 35% homology with human prolactin. Example (precursor) from human: database code SOMA\_HUMAN, 217 amino acids (24.82 kDa). See also **GHRH**, **GHRH receptor**, **hypopituitarism**.

**somatotropin-release inhibiting factor** abbr.: SRIF; an alternative name for **somatostatin**.

**somatrem** methionyl human **somatotropin** (growth hormone); somatotropin with an additional N-terminal methionine. It results from the production of somatotropin using cDNA technology in bacterial clones; methionine is involved in the initiation of bacterial protein synthesis.

**+some** comb. form denoting body, esp. intracellular particle.

**somite** any of a series of paired blocks of mesoderm that form during early development in vertebrate embryos and lie on either side of the notochord. -**somital** or **somic** adj.

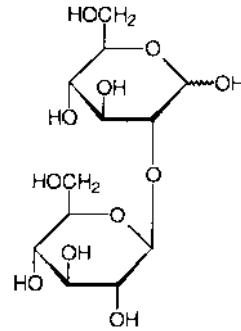

**sonicate** to expose any material or sample to ultrasonic pressure waves (at or around 20 kHz). The immersion of vessels in a water bath and their exposure to ultrasound is used as a means of cleaning (see **sonication bath**). The insertion of a **sonicator** probe into a vessel containing a suspension of membranes or other large assemblies causes their dispersion to smaller aggregates or assemblies.

**sonication bath** a water bath that is equipped with an oscillator, sited beneath the bowl, to produce ultrasound waves that permeate the water. It may be used for cleaning glass or other vessels or for degassing solvents.

**sonicator** a device that produces **ultrasonic** pressure waves. It usually consists of a stainless-steel rod, of diameter from 1-2 mm to about 2 cm, that is activated by an oscillator to produce ultrasound waves and is inserted into a vessel to **sonicate** a sample. See also **sonication bath**.

**sonic hedgehog proteins** analogues of **hedgehog protein** found in **zebrafish** and chickens and involved (in the latter case) in limb-bud pattern formation. The hedgehog proteins thus appear to be vital to pattern formation in several metazoan groups. The name sonic hedgehog is an allusion to a children's animated cartoon character.

**sophorose** the disaccharide 2-O-p-O-glucopyranosyl-O-glucose; it occurs in a glycoside of *Sophora japonica*.

**sorbin** a heat-stable peptide isolated from porcine intestine that increases water and sodium absorption in the intestine and gall-bladder. Example, database code SORB\_PIG, 153 amino acids (17.46 kDa).

**sorbitol** a nonsystematic name for o-glucitol, one of the ten stereoisomeric hexitols. It can be derived from glucose chemically or metabolically (by NADPH-requiring aldehyde reductase; other name: aldose reductase, EC 1.1.1.21) by reduction of the aldehyde group, and is converted to o-fructose by L-idi-

tol 2-dehydrogenase (EC 1.1.1.14). It is widely distributed in algae and higher plants, and was first discovered (1872) in the juice of berries from mountain ash (*Sorbus aucuparia*). It has a sweetening power about half that of sucrose, and is often used in sweeteners in conjunction with saccharin. Industrially it is of great importance in the food, pharmaceutical, paper, and textile industries. Its formation from excessive glucose concentrations in diabetics has been regarded as having pathological implications in lens tissue, which cannot convert it to fructose.

sorbose trivial name for the ketohexose xylo-2-hexulose; the enantiomer, L-sorbose, is present in fermented juice of mountain-ash berries, being formed by the bacterial oxidation of sorbitol. It is produced commercially by fermentation and used as an intermediate in the manufacture of ascorbic acid.

**sorcina** a protein, encoded in multidrug-resistant cells (see MDB), that binds calcium with high affinity. Example from human: database code SORC\_HUMAN, 198 amino acids (21.68 kDa). See also grancalcin.

**Soret band** an absorption band at about 400 nm, characteristic of porphyrins. See also cytochrome absorption bands. [After Louis Soret (1827-90), Swiss physician.]

**sorocarp** see *Oicystostelium discoideum*.

**sos** symbol for son of sevenless, a gene encoding a guanine-nucleotide releasing protein involved in neuronal development in *Drosophila*. When coupled to the activated Sev receptor (see Sevenless protein) the sos product, Sos, mediates activation of ras by stimulating release of GDP, thereby promoting uptake of GTP. Database code SOS\_DROME, 1595 amino acids (177.64 kDa).

**SOS repair** or error-prone repair a metabolic alarm system, occurring in bacteria, that helps the cell to save itself in the presence of potentially lethal stresses such as UV irradiation, thymine starvation, or the inactivation of genes essential for replication. Responses include mutagenesis, filamentation (cell elongation in the absence of division), activated excision repair, and activation of latent phage genomes. Mutagenesis occurs because under SOS conditions the gaps formed opposite thymine dimers can be filled by replication rather than by daughter-strand transfer. Replication of the dimer template is extremely inaccurate. The proteins involved include RecA protein (see recA) and the products of two other RecA-inducible genes; expression is regulated by the *lexA* gene product.

**Southern blotting** a procedure for transferring denatured DNA from an agarose gel to a solid support membrane such as nitrocellulose or nylon. The procedure takes advantage of the property of nitrocellulose that it tenaciously binds single-stranded but not duplex DNA. The gel is soaked in 0.5 M NaOH, which converts the DNA to the single-stranded form. The gel is then overlaid with a sheet of nitrocellulose paper, which in turn is covered by a thick layer of paper towels and the entire assembly is compressed by a heavy weight. The liquid in the gel is forced (blotted) through the nitrocellulose so that the single-stranded DNA binds to it at the same position it had in the gel. The transfer to nitrocellulose can alternatively be accomplished by electrophoretic transfer. Nylon is now usually used in preference to nitrocellulose. DNA bands may be located using a radioactive or otherwise labelled probe. The name led to a nomenclature for other types of blotting (see also Northern blotting, South-western blotting, Western blotting). [After E. M. Southern (1938- ), British molecular biologist.]

**South-western blotting** a technique in recombinant DNA technology for detecting plaques expressing fusion proteins where the foreign sequence encodes a DNA-binding protein that binds specifically to a particular DNA sequence. After treatment of the plaques to ensure release of the protein, plaque-lift is carried out onto a nitrocellulose (or other) transfer membrane, which is then incubated with a radiolabelled duplex DNA oligonucleotide that binds to the protein, which can then be detected by autoradiography. The term was derived by extension through the cardinal points from Southern blotting.

**Soviet gramicidin** an alternative name for gramicidin S.

**Soxhlet extractor** an apparatus for exhaustive extraction of soluble components from a sample of solid material by recycling a solvent through it, whereby solvent vapour from a boiler is continually condensed and the condensate allowed to percolate through the sample in a solvent-permeable thimble, from which it is returned, usually periodically via a siphon, to the boiler, where the eluted substances accumulate. [After Franz Soxhlet (1848-1926), Belgian chemist, who devised it.]

**soybean or (esp. Brit.) soya bean** a leguminous plant, *Glycine max*, originating in China (known from at least 2500 BC) and now cultivated widely in Asia, Europe, and America for forage and for its seeds. The bean has an oil content of 18-22%, and is also rich in protein — soybean protein is used as a human food and is the basis of tofu. See also soybean oil, soybean trypsin inhibitor.

**soybean oil** an edible oil obtained from the seeds of the soybean plant and valued for its high content of linoleic acid. The composition is typically as follows: 18:2 ω6, 44-62%; 18:3 ω3, 4-11%; 18:1 ω9, 19-30%; 16:0, 7-14%.

**soybean trypsin inhibitor abbr.:** STI; either of two different types of trypsin inhibitor, the Bowman-Birk and the Kunitz inhibitors. Both have given their names to a class of proteinase inhibitor. The two soybean inhibitors differ markedly from each other in size, structure, and properties. The Bowman-Birk inhibitor is a 71 amino-acid, 7.873 kDa protein: database code IBBLSOYBN. It has seven disulfide bridges. There are two active sites, one specific for trypsin and the other for chymotrypsin. Bowman-Birk type inhibitors are found in many cereals and legumes, and ancestrally may represent storage proteins. The soybean Kunitz inhibitors comprise three allelic proteins, A, B, and C, together with two Kunitz-type trypsin inhibitors, named KT1l and KT12. The A, B, and C proteins have 181 amino acids (20 kDa): database code (of A and C) ITRA\_SOYBN. They have two disulfide bonds. They are heat-stable and resistant to proteases, and form a 1:I stoichiometric complex with trypsin, that is highly stable ( $K_a$  5 x 10<sup>9</sup>). They inhibit chymotrypsin to a much smaller degree and are inactive against other endopeptidases, but modification of Arg<sup>63</sup> to Trp converts them to strong chymotrypsin inhibitors with little action on trypsin. The Kunitz family of inhibitors embraces trypsin, chymotrypsin, cathepsin D, and subtilisin inhibitors (see Kunitz inhibitor).

**sp abbr.** for synperiplanar; see conformation.

**sp. (pl. spp.) abbr.** for species (singular).

**Sp abbr.** for isomer of a thionucleotide.

**SP abbr.** for 1 secretory piece. 2 substance P.

**SP-1 abbr.** for secretory protein I.

**[S]pA symbol** for adenosine 5'-thiophosphate (alternative to AdoP[S]).

**space** or volume of distribution (in tracer kinetics) an apparent volume obtained as the amount of radioactivity retained divided by the concentration of the tracer in the plasma. The concept of space has the limitations discussed under apparent exchangeable mass. See also compartment.

**spacer 1** (in molecular biology) a sequence of bases of unknown function occurring in a DNA molecule and lying between sequences of transcribed DNA; spacer DNA is not usually transcribed. The term has also been used to refer to some stretches of primary transcript, e.g. a region in the mammalian primary transcript for rRNA, lying between 18S RNA and 28S RNA, that is not found in mature rRNA. 2 (in chromatography) an alternative term for spacer arm.

**spacer arm** or spacer the (usually) hydrocarbon chain interposed, by covalent linkages, between the specific ligand and the supporting matrix in affinity chromatography.

**spacer gel** (in electrophoresis) a small section of gel, polymerized above a polyacrylamide (or other) resolving gel, that lacks resolving power and serves to concentrate the material being electrophoresed as a tight band at the top of the resolving gel.

**SPARe abbr.** for secreted protein acidic and rich in cysteine; also called osteonectin; a protein expressed in cells of tissues

undergoing morphogenesis or wound repair and secreted into the basement membrane, where it interacts with other proteins, e.g. collagen and thrombospondin, and appears to have a role in regulating cell growth. It contains an EF-hand that binds one calcium ion and an acidic region that binds other calcium ions more loosely. Example from human (precursor): database code SPRC\_HUMAN, 303 amino acids (34.63 kDa). spare receptors receptors that are in excess of those required to evoke a given response to a drug, hormone, or other agonist. For a given agonist, the size of the population of spare receptors (receptor reserve) can vary with the tissue and with the magnitude of the response being measured. For different drugs, the receptor reserve varies with drug efficacy.

aparglng the bubbling of gas into a liquid medium. This technique may be applied to fermenters to introduce air directly into a culture, or it may be used to replace one dissolved gas by another, e.g. in displacing oxygen with an inert gas in liquid chromatography solvents.

spatula a (usually) small, flattened, sometimes curved, utensil made of metal (often stainless steel), bone, or wood and used to dispense crystalline or powdered material.

Spd abbr. for sphingoid.

species (pl. species) abbr.: sp. (sing.) or spp. (pl.); a fundamental taxonomic category ranking below a genus and consisting of a group of closely related individuals that can interbreed freely to produce fertile offspring.

species-specific confined to the one or several species referred to.

specific 1 relating to a particular or specified thing. 2 (as a modifier of certain quantitative terms) indicating a relationship of the quantity to mass and dimension in terms of standard (now normally SI) units; e.g. specific catalytic activity, specific enzyme activity, specific optical rotation. 3 of, or relating to, a species. See also specificity.

specific acid **catalysis** a homogeneous catalysis in which the catalysts are free hydrons, H<sup>+</sup> (or hydronium ions, H<sub>3</sub>O<sup>+</sup>). The catalysis is not affected by other acidic species present. Compare general acid-catalysis.

specific activity the activity (def. I, 2) of, e.g., a radionuclide or an enzyme, expressed as a function of mass.

specifically labelled describing an isotopically labelled compound in which both the position of labelling and the number of labelling nuclides at that position are known. Such a molecule is designated by a convention exemplified by CH[2H<sub>2</sub>]-CH<sub>2</sub>-O-[<sup>2</sup>H].

specific base catalysis a homogeneous catalysis in which the catalysts are hydroxide ions, OH<sup>-</sup>. The catalysis is not affected by other basic species present. Compare general base-catalysis.

specific catalytic activity the catalytic activity of an enzyme under specified conditions divided by the mass of an enzyme or enzyme preparation. It is a quantity useful for denoting the extent of purification of an enzyme; it may be expressed in katal per kilogram.

specific dynamic action the increase in heat production above the basal level that occurs in animals after the ingestion of food, particularly of protein.

specific enzymic activity the phenomenological coefficient that relates enzymic activity under specified conditions to the mass of an enzyme or enzyme preparation. It may be expressed in katal per kilogram of protein. Now obsolete, it has been superseded by specific catalytic activity. Compare molar enzymic activity.

specific gravity *a former name for* relative density.

specific heat capacity symbol: c<sub>p</sub> (at constant pressure) or c<sub>v</sub> (at constant volume); the quantity of heat required to raise the temperature of unit mass of a substance by one degree. It is expressed (usually) in J K<sup>-1</sup> kg<sup>-1</sup>.

specificity an index of the degree to which an association between two molecular units or assemblies may be considered unique; in many applications it is judged by the magnitude of an effect (enzyme-substrate, ligand-receptor interaction, or

drug action). It is quantified in suitable units under defined conditions, in relation to the magnitude of effect of other substances with similar action, amplified by studies made when the substance under consideration is in a direct competitive interaction with other such substances. The success of other substances in competing with the subject of study is normally quantified by kinetic analysis (*see* competitive inhibition). The problem of quantifying specificity may be examined by referring to specificity constant.

**specificity** constant the ratio of the catalytic constant, k<sub>cat</sub>, to the Michaelis constant, K<sub>m</sub>. It can aid in comparing the activity of an enzyme in its action on different substrates. From Michaelis kinetics, using the Michaelis-Menten equation,

$$v = (k_{cat}K_m)/[E]_0[S]$$

when [S] is very small (since then, little enzyme has bound substrate, so [E]<sub>0</sub> ≈ [E]<sub>t</sub> and [S] can be neglected in relation to K<sub>m</sub>). Thus for substrate A,

$$v_A = (k_{cat}K_m)A/[E]_0[A],$$

and for substrate B,

$$v_B = (k_{cat}K_m)B/[E]_0[B].$$

So

$$ValVb = \{(keatKm)AX[A]/\{(keatKm)BX[B]\},$$

and, at the same substrate concentrations, the activity of the enzyme against the different substrates reduces to a comparison of the respective specificity constants (k<sub>cat</sub>/K<sub>m</sub>); K<sub>m</sub> is not of itself a sufficient index of specificity.

specific optical rotation symbol  $[\alpha]_D^\theta$ ; the optical rotation of light of a specified wavelength (or frequency) achieved by a solution at a specified temperature. It is given by the relation  $[\alpha]_D^\theta = a/lp$  where a is the observed rotation in degrees, l is the length of the sample tube (in dm), p is the density of the liquid (in g mL<sup>-1</sup>),  $\lambda$  is the wavelength of the light (or other electromagnetic radiation) used, and  $\theta$  is the Celsius temperature. For a solution of concentration c (in g solute per 100 mL solution),  $[\alpha]_D^\theta = allc$  in degrees dm<sup>2</sup> g<sup>-1</sup> Compare molecular optical rotation. specific refractivity see reactivity.

specific viscosity symbol: Η<sub>sp</sub>; the fractional change in viscosity produced by adding a solute to a solvent. It is given by the equation:

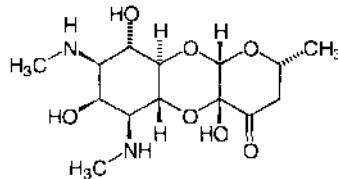

$$\eta_{sp} = (\eta/\eta_0) - 1 = Avc + Bv^2c^2 + Cv^3c^3 + \dots$$

where  $\eta_0$  is the viscosity of the solvent,  $\eta$  is the intrinsic viscosity of the solution, A, B, and C are shape-dependent constants, c is the concentration of the solute, and v is the specific volume of one solute molecule.

specific volume symbol: v; for a pure substance, the volume, V, of a sample, divided by the mass, m, of the sample;  $v = V/m = lip$ , where p is the mass density of the substance. The SI unit is m<sup>3</sup> kg<sup>-1</sup>. See also partial specific volume.

'specifier' protein a protein that, when it combines with an enzyme or enzyme-substrate, modifies the catalytic specificity of the system. An example is a-lactalbumin, which modifies the substrate (acceptor) specificity of N-acetyllactosamine synthase (EC 2.4.1.90; other name: UDPgalactose:N-acetylglucosamine p-O-galactosyltransferase) from N-acetylglucosamine to glucose.

spectinomycin an aminocyclitol antibiotic found in the growth medium of *Streptomyces spectabilis*. It has a wide

## spectra

range of activity against Gram-negative bacteria, with a more selective activity against Gram-positive bacteria. It is highly active against *Neisseria gonorrhoeae*. It inhibits protein synthesis by binding to the bacterial 30S ribosomal subunit.

spectra the plural of spectrum.

**spectrin** a protein that is the major constituent of the erythrocyte cytoskeletal network. It associates with band 4.1 (see band protein) and actin to form the cytoskeletal superstructure of the erythrocyte plasma membrane. It is composed of nonhomologous chains,  $\alpha$  and  $\beta$ , which aggregate side-to-side in an antiparallel fashion to form dimers, tetramers, and higher polymers. Anchorage to the cytoplasmic face of the plasma membrane is mediated by another protein, ankyrin, which links  $\beta$  spectrin to transmembrane protein band 3, and by the binding of band 4.1 to glycophorin. Interaction between spectrin and other proteins is thought to be responsible for the maintenance of the biconcave shape of human erythrocytes, for the regulation of plasma membrane components, and for the maintenance of the lipid asymmetry of the plasma membrane. Spectrin-like proteins have five domains. Example from human,  $\alpha$  chain: database code SPCA\_HUMAN, 2429 amino acids (280.74 kDa);  $\beta$  chain: database code SPCB\_HUMAN, 2137 amino acids (246.04 kDa).

**spectrofluorometer** an instrument used for measuring the fluorescence emitted by compounds excited by incident radiation produced within the instrument. The excitation radiation is produced by a lamp, and filters or diffraction grating monochromators are employed to isolate both the incident and emitted radiation to narrow wavebands. The emitted radiation is detected by photomultipliers.

**spectrogram** a photographic record of a spectrum produced by a spectrograph.

**spectrograph** a spectrometer or spectroscope with a facility for producing a photographic record of the spectrum under consideration. Compare spectroscope. -spectrographic adj.; spectrographically adv.; spectrography n.

**spectrometer** any instrument used to produce and examine a spectrum, such as a spectrophotometer or a spectroscope. -spectrometric adj.; spectrometry n.

**spectrophotometer** an apparatus to measure the proportion of the incident light (or other electromagnetic radiation) absorbed (or transmitted) by a substance or solution at each wavelength of the spectrum. -spectrophotometric adj.; spectrophotometry n.

**spectroscope** an instrument for studying spectra, either qualitatively or quantitatively. -spectroscopic or spectroscopical adj.; spectroscopically adv.

**spectroscopy** the investigation of the chemical composition, molecular structure, or atomic structure of a substance or solution by observation of its interaction with electromagnetic radiation using a spectroscope.

**spectrum** (*pl. spectra*) (*in physics*) an arrangement of the components of a complex electromagnetic radiation (light, etc.) or sound in order of frequency or energy, thereby showing a distribution of energy among the components. -spectral adj.

**Spemann's organizer** an embryonic signalling centre located in the dorsal lip of the blastopore. It plays a crucial role in the organization of the formation of the main body axis of a developing embryo. [After Hans Spemann (1869-1941), German zoologist and embryologist.]

**spermaceti** or *cetaceum* a white, translucent, waxy solid, m.p. 42-50 °C, consisting mainly of the ester cetyl palmitate and obtained from oil in the head of the sperm whale (*Physeter catodon*) and related cetaceans. It is used in the manufacture of cosmetics, ointments, soaps, etc.

**spermadhesin** or *AQNI* a secretory protein of male accessory glands that is found on the sperm surface and mediates sperm binding to the zona pellucida. Example from *Sus scrofa*: database code AQNLPIG, III amino acids (11.88 kDa).

**spermatogenesis** the formation of spermatozoa in the male reproductive system. The sperms are formed from male germ

## sphingolipid

cells, spermatogonia, which line the inner wall of the seminiferous tubules in the testis. A single spermatogonium divides by mitosis to form primary spermatocytes, each of which undergoes the initial division of meiosis to form two secondary spermatocytes. Each of these then undergoes the second meiotic division to form two spermatids, which mature into spermatozoa without further cell division by a process called spermiogenesis. All these cell types are nourished and supported by neighbouring Sertoli cells. Spermatogenesis also requires the presence of testosterone-secreting Leydig cells.

**spermidine** N-(3-aminopropyl)-1,4-diaminobutane; NH<sub>2</sub>(CH<sub>2</sub>NH(CH<sub>2</sub>)<sub>4</sub>NH<sub>2</sub>): one of the polyamines.

**spermidine synthase** EC 2.5.1.16; other names: putrescine aminopropyltransferase; aminopropyl-transferase; an enzyme that catalyses the formation of spermidine from S-adenosylmethionine and putrescine with formation of 5'-methylthioadenosine. Example from human: database code SPEE\_HUMAN, 302 amino acids (33.79 kDa).

**spermine** N,N-bis(3-aminopropyl)-1,4-diaminobutane; NH<sub>2</sub>(CH<sub>2</sub>NH(CH<sub>2</sub>)<sub>4</sub>NH<sub>2</sub>(CH<sub>2</sub>NH<sub>2</sub>): one of the polyamines.

**spermine synthase** EC 2.5.1.22; other name: spermidine aminopropyltransferase; an enzyme that catalyses the formation of spermine from S-adenosylmethionine and spermidine with formation of 5'-methylthioadenosine.

**sperm tail** see cilium.

**SPF abbr.** for specific-pathogen-free.

**Sph symbol** for sphingosine.

**S phase** the phase of the eukaryotic cell cycle in which DNA is synthesized. See cell-division cycle.

**spherocyte** a rounded red blood cell that has lost its normal biconcave shape owing to damage to the surface membrane or to some disorder of metabolism. Spherocytes appear smaller and darker than normal red cells.

**spherocytosis** the condition of having spherocytes in the blood.

**spheroid** 1 a solid figure that is similar to but not identical with a sphere. 2 an ellipsoid of rotation, especially one in which the major axis of its parent ellipse is only slightly longer than its minor axis. -spheroidal adj.

**spheroplast** the globular form of a bacterial cell in which the cell-wall structure has been modified (e.g. by growth in the presence of penicillin) rather than totally removed. The term also denotes a form of yeast cell obtained by partial hydrolysis of the cell wall. A prefix may be used to indicate the method of induction, e.g. penicillin-spheroplast. Compare protoplast.

**spherosome** an organelle, generally spherical or oblate and 0.4-3  $\mu\text{m}$  in diameter, that occurs in lipid-storage tissues in plants, e.g. endosperm of castor-bean seeds. The nature of the surrounding membrane is still in doubt.

**sphinganine** D-erythro-2-amino-1,3-octadecanediol; D-erythro-dihydrosphingosine; the metabolic precursor of sphingosine. It is formed from palmitoyl-CoA and serine by, first, the action of serine C-palmitoyltransferase, which forms 3-dehydro-D-sphinganine, which is then reduced to sphinganine by 3-dehydrosphinganine reductase, EC 1.1.1.102. See also sphingolipids, sphingoid.

**sphingoid** or **sphingoid base** symbol: Spd; any of a class of compounds comprising sphinganine and its homologues and stereoisomers, and derivatives of these compounds.

**sphingolipid** any of a class of lipids containing the long-chain amino diol, sphingosine, or a closely related base (i.e. a sphingoid). A fatty acid is bound in an amide linkage to the amino group and the terminal hydroxyl may be linked to a number of residues such as a phosphate ester or a carbohydrate. The predominant base in animals is sphingosine while in plants it is phytosphingosine. The main classes are: (1) phosphosphingolipids (also known as sphingophospholipids), of which the main representative is sphingomyelin; and (2) glycosphingolipids, which contain at least one monosaccharide and a sphingoid, and include the cerebrosides and gangliosides. Sphingolipids play an important structural role in cell membranes, and may be involved in the regulation of protein kinase C.

sphingolipid activator proteins *see* saposins.

**sphingolipidosis** (*pl.* sphingolipidoses) any of several inherited pathological conditions in humans in which one or more sphingolipids accumulate in the tissues because of a deficiency of the corresponding degradative enzyme. They include ceramidase deficiency, Fabry's disease, galactosylceramide lipidoses,  $G_{MI}$  and  $G_{MZ}$  gangliosidoses, Gaucher's disease, metachromatic leukodystrophy, and sphingomyelin lipidoses.

**sphingomyelin** N-acyl-4-sphingenyl-1-O-phosphorylcholine; any of a class of phospholipids in which the amino group of sphingosine is in amide linkage with one of several fatty acids, mostly  $C_{18}$  or higher and either saturated or monounsaturated, while the terminal hydroxyl group of sphingosine is esterified to phosphorylcholine. Sphingomyelins are found in large amounts in brain and other nervous tissue. They do not occur in plants.

**sphingomyelin lipidosis or Niemann-Pick disease** a genetic disease of humans in which sphingomyelin accumulates in the tissues due to a deficiency of the enzyme sphingomyelin phosphodiesterase. It is associated with mental retardation.

**sphingomyelin phosphodiesterase** EC 3.1.4.12; *other names:* acid sphingomyelinase; neutral sphingomyelinase; a lysosomal enzyme that catalyses the hydrolysis of sphingomyelin to N-acylsphingosine and choline phosphate. Deficiency of the enzyme is the cause of Niemann-Pick disease (sphingomyelin lipidosis), in which there is an accumulation of sphingomyelin. Example (precursor) from human: database code ASM\_HUMAN, 629 amino acids (69.78 kDa).

**sphingophospholipid** *see* sphingolipid.

**sphingosine symbol:** Sph; *trans-D-erythro-2-amino-4-octadecene-1,3-diol;*  $CH_3(CH_2)_2CH=CH-CHOH-CHNH_2-CH_2OH$ ; a long-chain amino diol sphingoid base that occurs in most sphingolipids of animal tissues. *See also* phytosphingosine.

**sphingosine N-acyltransferase** EC 2.3.1.24; an enzyme of the pathway for synthesis of sphingolipids that catalyses the acylation of sphingosine by acyl-CoA to form N-acylsphingosine (ceramide) and CoA.

**spicule** a roughly cone-shaped structure or tissue element, such as that projecting from the membrane of a red blood cell. Calcareous or siliceous spicules are found in the skeletons of sponges and corals.

**spin (in physics)** 1 the quantized angular momentum of an elementary particle, in the absence of orbital motion. 2 the quantized angular momentum of an atomic nucleus, including contributions from the orbital motions of nucleons. 3 the quantized angular momentum of an electron that adds to the orbital angular momentum, thus producing fine structure in line spectra.

**spinal cord** the part of the central nervous system that is enclosed in the vertebral column. Its function is to connect the innervation of most parts of the body via the spinal nerves to the brain.

**spinal nerves** the pairs of nerves that arise from the spinal cord and are distributed to various peripheral parts of the body. In humans there are 31 pairs.

**spin coupling or spin-spin coupling (in nuclear magnetic resonance spectroscopy)** the influence of one nucleus on another, such that the nuclear spin of one nucleus is coupled via the bonding electrons to the coupled nucleus, which experiences two different microenvironments and thus resonates at two slightly different frequencies. This results in the splitting of the resonance line into two lines (a doublet).

**spin density** the fraction of unpaired electron spin that is in the vicinity of a given atomic nucleus in a molecule.

**spindle** the array of microtubules and associated molecules that forms between the opposite poles of a eukaryotic cell during mitosis or meiosis and serves to move the duplicated chromosomes apart. During mitosis the spindle starts to form outside the nucleus while the chromosomes are condensing during prophase. At the start of M phase, the two centrosomes

that have been formed move to opposite sides of the nucleus, and form the two poles of the mitotic spindle. Microtubules grow away from the centrosomes towards the chromosomes, the minus ends being attached to the centrosome, and the plus ends growing towards the kinetochore. These microtubules eventually bind to kinetochores and are thus known as kinetochore microtubules. Other microtubules, known as polar microtubules, grow towards the chromosomal region, but eventually bind directly to other polar microtubules growing from the opposite centrosome. These push the poles of the spindle apart. Each centrosome eventually becomes attached through the kinetochore microtubules to one of the sister chromatids of each chromosome, and pulls these away to effect the chromatid separation that occurs at anaphase. A similar series of events occurs at the corresponding phases of meiosis.

**spin hamiltonian** a formulation in quantum mechanics used in the determination of the energy levels of the spin of an electron or a nucleus in electron spin resonance spectroscopy or, less commonly, in nuclear magnetic resonance spectroscopy. *See also* Hamiltonian operator.

**spin immunoassay or free-radical assay technique (of immunoassay) (abbr.: FRAT)** a technique in which a spin label is attached to a specimen of the substance to be assayed and an antibody is raised against the substance. On mixing the antibody with the labelled substance there is a change in the electron spin resonance (ESR) spectrum because of the inhibition of tumbling caused by the antibody 'immobilizing' the labelled substance. On adding some of the unlabelled substance there is competition for the antibody, and the changes in the ESR spectrum are partially reversed to an extent dependent on the concentration of the added, unlabelled, substance.

**spin label** 1 a synthetic paramagnetic organic free radical, usually having a molecular structure and/or chemical reactivity that facilitates its attachment or incorporation at some particular target site in a macromolecule, or assemblage of macromolecules. 2 spin-label to effect labelling of a substance or structure with a spin label (def. 1).

**spin-lattice relaxation time or longitudinal relaxation time (in nuclear magnetic resonance spectroscopy) symbol:**  $T_1$ ; the time taken for the upper electron spin state to dissipate its excess energy. Its reciprocal is the spin-lattice relaxation rate (*see* correlation time).

**spinner culture** the culture of cells in bottles or tubes that are continuously rotated.

**spin polarization or spin polarisation** a phenomenon in which the unpaired electron spin on one atom or part of a molecule is transferred to another atom, brought about by interaction between the unpaired electron on the first atom and the paired electrons on the second atom (which lacks unpaired electrons) causing one of the paired electrons to have a lower energy than the other. *See also* chemically induced dynamic nuclear polarization.

**spin-spin broadening** an increase in line width in electron spin resonance spectroscopy, caused by interactions between neighbouring dipoles.

**spin-spin coupling** *see* spin coupling.

**spin-spin coupling constant (in nuclear magnetic resonance spectroscopy)** a measure of the specific interaction of one nucleus with another that gives rise to a splitting of the resonance bands produced by each nucleus.

**spin-spin splitting** splitting in the lines of a nuclear magnetic resonance spectrum brought about by the interaction of the magnetic moment of the nucleus of a given atom in a molecule with those of neighbouring nuclei. It is used in the assignment of particular nuclear resonances and in the determination of molecular conformations. *See also* hyperfine splitting.

**spin state** the orientation, in a strong magnetic field, of an unpaired electron or nuclear spin, e.g. parallel or antiparallel to the field direction.

**spin trapping** a technique in which a reactive free radical is

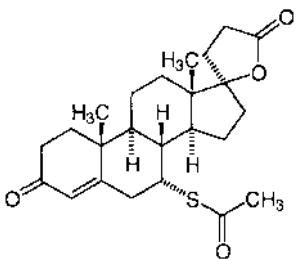

## spiro compound

## squalamine

trapped by an addition reaction to produce a more stable radical, detectable by electron spin resonance spectroscopy, whose hyperfine coupling parameters permit identification of the initial radical trapped.

**spiro compound** any compound containing two rings joined by one common atom, designated the spiro atom, as in the case of the  $\gamma$ -lactone ring of spironolactone.

**spironolactone** 7-(acetylthio)-17-hydroxy-3-oxo-pregn-4-ene-21-carboxylic acid  $\gamma$ -lactone; a synthetic steroid lactone that is used as a diuretic. It is structurally similar to aldosterone, and competitively inhibits the renal tubular action of this hormone. It is metabolized to canrenone, the active compound, by removal of the acetylthio group and insertion of a 6,7 double bond.

**spleen exonuclease** see phosphodiesterase II.

**splenin** seethymopoietin.

**splenopentin** a synthetic peptide that corresponds to residues 32–36 of splenin (see thymopoietin).

**spliceosome** a ribonucleoprotein complex, containing RNA and small nuclear ribonucleoproteins (snRNPs) that is assembled during the splicing of the messenger RNA primary transcript to excise an intron. snRNPs designated U1, U2, U4, U5, and U6 are variously involved; U1 may bind the GU consensus sequence of the 5' splice site and U5 with U41U6 probably binds to the 3' splice site consensus sequence, AG. U2 may be part of a component binding the UACUA[AjC] consensus sequence ([Aj is invariant) at a site slightly upstream from the 3' splice site, known as the branch site. The mechanism appears to involve cutting at the 5' side of the GU consensus sequence, which curls back to form a G5'-2'A bond with the invariant A of UACUA[AjC]. This linkage generates the loop of the so-called lariat. Cutting out the 3' splice site follows on the 3' side of AG to release the complete intron (in the form of the lariat), and the cut ends of the exons are then ligated.

**splice site** the sequence of bases at each end of an intron that determines the point of splicing. The 5' splice site (site at the 5' end of the intron) is termed the donor site, consensus sequence GU, while the 3' splice site is termed the acceptor, consensus sequence AG.

**splicing** 1 (of DNA) the covalent linkage, by the action of a DNA ligase (EC 6.5.1.1, requires ATP, or EC 6.5.1.2, requires NAD<sup>+</sup>), of two fragments of duplex DNA at complementary single-stranded terminations. 2 (of RNA) the enzymic process in eukaryotic cells by which introns are excised from heterogeneous nuclear RNA (hnRNA) following its transcription from DNA, and the cut ends are rejoined to form messenger RNA (mRNA), in which the message is continuous, before its translation into polypeptide. In yeast, the splicing of transfer RNA involves cutting at the splicing junctions by an endonuclease followed by a process involving ATP whereby the two exon sequences are joined. Group I mitochondrial RNA is spliced by an autocatalytic mechanism, the RNA itself having the ability to catalyse its own splicing; nuclear mRNA precursor - the primary transcript - is spliced by a complex assembly incorporating snRNP and called a spliceosome; it involves the formation of a lariat. Splicing of group II mitochondrial RNA also involves the formation of a lariat but without formation

of a spliceosome. Splicing in which the cut ends are joined directly within the same RNA molecule is called *cis*-splicing; *trans-splicing* refers to situations in which the cut end from the splicing site rejoins to a splicing site on another RNA molecule. 3 (of protein) a post-translational modification of protein that includes two concerted proteolytic cleavages and one ligation that results in excision of an inner sequence of the original polypeptide chain to form one protein, and ligation of the two outer sequences to form a second protein. It is thought to be an autocatalytic process. The excised inner sequence is known as an *intein*, the ligated outer sequences as an *extein*. See also gene splicing.

**splicing factor 2 abbr.**: SF2; a protein, present in nuclear extracts, that functions in an early step in splicing pre-mRNA. It is resistant to mild heat treatment, but inactivated by N-ethylmaleimide. It consists of two peptides, P32 and P33, and is involved in ensuring accuracy of splicing. Example, P32 from human: database code SP32\_HUMAN, 282 amino acids (31.36 kDa). See also pre-mRNA processing protein.

**split gene** a gene that is not represented by a continuous DNA sequence; an interrupted gene.

**spoke protein** a protein associated with the filamentous structure of kinetochore microtubules in the mitotic spindle. Soluble and cytoplasmically localized during interphase, it becomes primarily associated with the mitotic spindle in mitosis. Example, spoke protein 4 (of five different ones) from *Chlamydomonas reinhardtii*: database code RSP4\_CHLRE, 465 amino acids (49.74 kDa).

**spongiform encephalopathy** any of a group of diseases of human and other animals characterized by the presence of many vacuoles in brain tissue, giving it a spongy appearance. The group includes bovine spongiform encephalopathy, scrapie in sheep, and Creutzfeldt-Jakob disease, Gerstmann-Straussler syndrome, and kuru in humans. See also prion, prion protein.

**spontaneous generation** see abiogenesis.

**spontaneous hypoglycemia** see glycemia.

**spore** a small, often microscopic, reproductive unit consisting of one or several cells. Spores are produced by fungi, bacteria, certain plants, and protozoa. They may variously serve as a means of rapid vegetative propagation, or as a dormant stage in the organism's life cycle. Spores have very low metabolic activity and give rise to a vegetative cell upon germination; they are usually more heat resistant than vegetative cells and are adapted for dispersal. Spores may be sexual or asexual. Sporulation the formation of spores.

**spot 1 (in chemistry)** or spot test to test for a substance by applying a small amount of detection reagent to a surface. 2 (in molecular biology) to detect, using radioactive oligonucleotide probes, oligonucleotides applied in spots onto hybridization filters (spot blots).

**spotT** a gene in *Escherichia coli* for the enzyme guanosine-3',5'-bis(diphosphate) 3'-pyrophosphohydrolase; EC 3.1.7.2; other name: (ppGpp)ase; it catalyses the hydrolysis of guanosine 3',5'-bis(diphosphate) to guanosine 5'-diphosphate and pyrophosphate. The SpoT protein cycles ppGpp formed as a part of the stringent response. The name is jocular, ppGpp and pppGpp originally having been referred to as 'magic spot nucleotides'. Example from *E. coli*: SPOT\_ECOLI, 702 amino acids (79.34 kDa). See also reA, stringent factor.

**spp. abbr.** for species (plural).

**SPP-1** see osteopontin.

[S]ppA symbol for adenosine 5'-P-thiodiphosphate (alternative to AdoPP[S]).

[S]ppppA symbol for adenosine 5'- $\gamma$ -thiotriphosphate (alternative to AdoPPP[S]).

**spreading factor** see hyaluronidase.

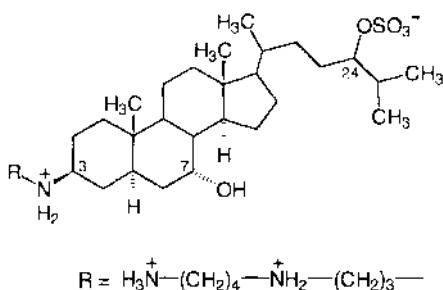

**SaOG** abbr. for sulfoquinovosyldiacylglycerol (see sulfonolipid).

**sal** abbr. for symbolic query language; a query language used with related databases, e.g. SYBASE. It is often pronounced 'sequel'.

**squalamine** a water-soluble aminosterol isolated from the

**squalene**

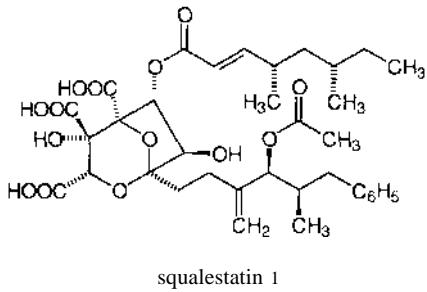

dogfish shark, *Squalus acanthias*. It has antibiotic properties against Gram-negative and Gram-positive bacteria and protozoa. It is an adduct of **spennidine** and a sulfate bile salt.

**squalene** 2,6,10,15,19,23-hexamethyl-2,6,10,14,18,22-tetra-cosa-hexaene; the linear triterpene precursor of all cyclic triterpenoids and the sterols. Although first isolated from shark-liver oils and later found in many other fish-liver and plant oils, squalene is widely distributed in plant and animal cells as a metabolic intermediate. It is formed from acetyl-CoA, via a pathway whose intermediates include **mevaloate**, **isopeoteoyl diphosphate**, **geranyl diphosphate**, and farnesyl diphosphate. The latter is converted to presqualene diphosphate, which is then reduced to squalene by NADPH with loss of pyrophosphate; both steps are catalysed by **farnesyltransferase**. [From Latin *squalus*, marine fish, later specifically used to mean shark.]

**squalestatin** a fermentation product of *Coelomycete* spp. that is a potent selective inhibitor of squalene synthase, and lowers serum cholesterol *in vivo*.

**sr** symbol for steradian.

**Sr** symbol for strontium.

**SR** abbr. for sarcoplasmic reticulum.

**src** an oncogene (*v-src*), originally discovered in the Rous sarcoma virus, the product of which is pp60<sup>v-src</sup>, a 60 kDa protein that undergoes phosphorylation/dephosphorylation. A normal cellular gene (or **protooncogene**), *c-src*, codes for a related protein; both proteins have **tyrosine kinase** activity. The viral oncogene product and its normal counterpart differ in amino-acid residues, especially at the C terminus where the last 19 residues of pp60<sup>c-src</sup> are replaced by 12 other residues in

**stability constant**

pp60<sup>v-src</sup>. The Src family of tyrosine kinases is the largest of the nonreceptor tyrosine kinase families and is formed from a group of proteins that all share a high homology with the oncoprotein, v-Src, and the cellular counterpart, c-Src. Members of the Src family include Src, Yes, Fyn (see **FYN**), Lck (see **LCK**), Lyn (see **lyn**), Blk (see **blk**), Hck, Fgr (see **FGR**), and Yrk, which range in size from 53 to 64 kDa. They all share a number of features including an N-terminal myristylation site (a mechanism for promoting their association with membranes), a unique domain, two conserved segments known as Src homology 2 domain (SH2 domain) and Src homology 3 domain (SH3 domain) (see **SH domain**), a tyrosine kinase domain, and a C-terminal regulatory domain. In vertebrates, the kinase activity of Src family members is normally inhibited by the phosphorylation of a tyrosine residue within the kinase domain. In *v-src* the region of the gene encoding the negative regulatory C-terminal tyrosine has been deleted, leading to v-Src having a higher constitutive tyrosine kinase activity than c-Src. Other mutations associated with oncogenic activation map to the SH2 and SH3 domains, supporting the proposal that in the resting cell Src is kept in an inactive state by the binding of its SH2 domain to the phosphotyrosine residue in its negative regulatory domain so keeping the kinase in an inactive conformation. SH3 domains may participate in this repression, possibly by binding proline-rich regions in the kinase domain. Activation of Src family members occurs by two potential mechanisms: (1) the co-presence of another protein containing a specific phosphotyrosine residue that has a higher affinity for the SH2 domain than the negative regulatory phosphotyrosine within the Src member; or (2) the dephosphorylation of the negative regulatory phosphotyrosine by a specific protein tyrosine phosphatase. Example from human: database code KSRC\_HUMAN, 536 amino acids (59.77 kDa).

**Src homology domain** see **SH domain**.

**Srd** symbol for a residue of the ribonucleoside thiouridine (when the position of the thiol group in its thiouracil moiety is unknown or unspecified; alternative to S or sU).

**SRE** abbr. for serum response element.

**SRF** abbr. for serum response factor; a nuclear, dimeric transcription factor. It forms a complex with **E1K**\* that is constitutively bound to the **serum response element**. Example from human: database code SRF\_HUMAN, 508 amino acids (51.54 kDa).

**SRIF** abbr. for somatotropin release-inhibiting factor (i.e. somatostatin).

**sRNA** or **S-RNA** abbr. for soluble RNA (an early name for transfer RNA).

**SRP** abbr. for signal recognition particle.

**SR protein** any protein belonging to a family of pre-messenger RNA splicing factors possessing highly related primary amino-acid sequences. They share an N-terminal RNA recognition motif and a C-terminal domain that varies in length and consists almost exclusively of alternating serine (S) and arginine (R) residues, from which the proteins are named. Many animal cells possess a series of SR proteins of similar molecular mass: 20, 30, 40, 55, and 70–75 kDa; as yet these have undetermined specificities.

**SRS** or **SRS-A** abbr. for slow reacting substance (of anaphylaxis).

**S—■ variation** see **smooth-rough variation**.

**SSB protein** abbr. for single-strand binding protein.

**SSCP analysis** abbr. for single-strand conformation polymorphism analysis.

**ssDNA** see **DNA**.

**St** symbol for stokes (a cgs unit of kinematic viscosity).

**Sta** symbol for statine.

**stability constant** symbol: *K*; an equilibrium constant for the reversible formation of a complex chemical compound from two or more simpler entities; the reciprocal of the **dissociation constant**. In some cases, an **apparent stability constant** (symbol:

## stable factor

$K'_s$ ), constrained with respect to certain variables (e.g. pH) is determined (for the distinction see equilibrium constant). The stability constant is also known as the  $\alpha$ "ociation constant (*symbol*:  $K_{ass}$ ) in cases where ions associate into a substance, e.g. for the reaction  $A^+ + B^- = AB$ , the (concentration) stability or association constant is given by:

$$K_s = [AB]/[A^+][B^-] = K_{ass}.$$

stable factor *an alternative name for* factor VII; *see* blood coagulation.

stable isotope an isotope that is not radioactive.

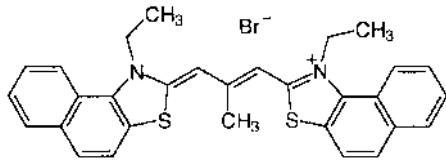

stachyose *or* luopeose the tetrasaccharide, O-a-D-galactopyranosyl-(I → 6)-O-a-D-galactopyranosyl-(I → 6)-O-a-D-glucopyranosyl-p-D-fructofuranoside. It is widely distributed, usually associated with raffinose (*see* that entry for synthesis) and sucrose; it is isolated from *Stachys tuberifera* rhizomes.

stacking gel *an alternative name for* spacer gel.

Staden, R. US molecular biologist; the author of a much used suite of computer programs for sequence analysis of nucleic acids and proteins, available for both VMS and UNIX.

staggered conformation *see* conformation.

stainless steel steel that is resistant to corrosion due to its high content of chromium and, often, nickel. It is highly resistant to all organic acids and weak mineral acids but is slowly attacked by concentrated mineral acids. It does not rust. Stains-all *a proprietary name for* 1-ethyl-2-[3-(3-ethylnaphtho[1,2-d]thiazolin-2-ylidene)-2-methylpropenyl]naphtho[1,2-d]thiazolium bromide; a cationic carbocyanine metachromatic dye used as a semiselective stain for locating nucleic acids, proteins, and polysaccharides. RNA stains bluish-purple, DNA blue, protein red, and phosphoprotein blue.

stamp collecting according to Lord Rutherford (1871-1937), one of the two branches of science (the other being physics).

standard (*in analytical chemistry*) 1 primary standard a chemical that can be obtained in an unvarying state (e.g. of purity and/or stability) and used as an approved example against which other examples of the same chemical can be compared. 2 secondary standard a chemical that can be used for comparative purposes following calibration against a primary standard. Although its properties are less stringent than a primary standard, its ready availability makes for convenience of use. *See also* standard atmosphere, standard state, standard temperature and pressure.

standard atmosphere an internationally established reference for pressure, defined as 101 325 pascals. The atmosphere (def. 3) (*symbol*: atm), equal to 101 325 pascals, was formerly used as a unit of pressure; its use is now discouraged. *See also* standard temperature and pressure.

standard curve a plot of any appropriate parameter against known amounts (or concentrations) of detectable substance. Such a curve can be used to determine the amount (or concentration) of the same substance in an unknown solution given a reading for the parameter in the unknown solution.

standard deviation *abbr.*: SD; *symbol*:  $s$  (for a sample) *or*  $\sigma$  (for a distribution); the common measure of dispersion of a series of observations of  $x$  that is normally distributed. It is the root-mean-square average of the deviations of the observations from their mean and is in the same units as those of the observations. The standard deviation,  $s_x$ , is given by:

$$s_x = \sqrt{\left[ \frac{1}{n} \sum_{i=0}^n (x_i - \bar{x})^2 \right]}$$

## starch synthase

Where  $\bar{x}$  is the arithmetic average of  $x$  and  $n$  is the number of observations;  $s_x^2$  is called the variance of the sample of observations of  $x$ . Some authorities prefer the definition:

$$s_x = \sqrt{\left[ \frac{1}{n-1} \sum_{i=0}^n (x_i - \bar{x})^2 \right]}$$

so that  $s_x^2$  is then the best estimate of the variance,  $a^2$ , of the population from which the sample of observations of  $\bar{x}$  was made. *See also* degrees of freedom, standard error of estimate of the mean.

standard error of estimate of the mean *or* standard error of the mean *abbr.*: SEM; a measure of the reliability of an estimate of the mean of a population. It is equal to the standard deviation,  $s_x'$  of the observations divided by the square root of the number of observations,  $n$ ; i.e.  $SEM = s_x'/\sqrt{n}$ .

standard free energy *see* Gibbs energy.

standardize *or* standardise to relate any instrument, vessel, or reaction to an absolute standard. -standardization *or* standardisation  $n$ .

standard pressure *symbol*:  $p$ ; an established reference for pressure. Since 1982 the recommended standard pressure for reporting thermodynamic data has been set at  $10^5$  pascals (1 bar). Before 1982 it was taken to be 101 325 pascals (1 atmosphere).

standard state a set of conditions, established by convention, under which a standard reference is determined or calculated. *See* chemical potential, enthalpy, entropy, Gibbs energy, hydrogen electrode, standard pressure, standard temperature and pressure.

standard temperature and pressure *abbr.*: stp *or* s.t.p. *or* STP; the standard conditions for the comparison of properties of gases. Standard temperature is now 298.15 K (formerly 273.15 K, i.e. 0 °C) and standard pressure is  $10^5$  pascals. *Former name*: normal temperature and pressure (*abbr.*: ntp *or* n.t.p. *or* NTP).

Stanley, Wendell Meredith (1904-71), US biochemist; Nobel Laureate in Chemistry (1946) jointly with J. H. Northrop 'for their preparation of enzymes and virus proteins in a pure form' [prize shared with J. B. Sumner].

*Staphylococcus* a genus of Gram-positive bacteria, commonly associated with wounds and generally causing localized infections. *Staphylococcus aureus* forms yellow or orange pigments and yields plasmids that are useful in recombinant DNA experimentation: *S. aureus* plasmids coding for resistance to various antibiotics can be transfected into *Escherichia coli* or into *Bacillus subtilis* where they are stable, replicate, and express antibiotic resistance. They have provided the basis from which improved vectors have been developed.

starch the most important reserve polysaccharide found in plants. It is a glucan consisting of two components: amylose, which is a homopolymer of glucose units linked only by  $\alpha(1 \rightarrow 4)$  bonds; and amylopectin, also a glucose homopolymer (branched) that contains  $\alpha(1 \rightarrow 6)$  bonds as well as  $\alpha(1 \rightarrow 4)$  bonds. Starch is synthesized as a temporary storage form of fixed carbon in chloroplasts during active periods of photosynthesis, accumulating as starch grains. The starch is subsequently converted to sucrose and translocated to storage organs, such as seeds and tubers, where it is re-formed. *Compare* glycogen.

starch (bacterial glycogen) synthase EC 2.4.1.21; *recommended name*: starch synthase; *systematic name*: ADP-glucose: 1,4-a-D-glucan 4-a-D-glucosyltransferase; *other name*: ADPglucose-starch glucosyltransferase. An enzyme that catalyses a reaction between ADPglucose and (1,4-a-D-glucosyl)n to form (1,4-a-D-glucosyl)n+1 and ADP. It uses ADPglucose instead of the UDPglucose of glycogen synthase. Example from *Escherichia coli*: database code GLGA\_ECOLI, 477 amino acids (52.48 kDa).

starch phosphorylase *see*  $\alpha$ -glucan phosphorylase.

starch synthase EC 2.4.1.11; *recommended name (example)*: glycogen (starch) synthase (the nature of the synthetic product should be included in the name); *systematic name*: UDP-glucose:glycogen 4-a-D-glucosyltransferase; *other name*:

## starch syrup

UDPglucose-glycogen glucosyltransferase. An enzyme that catalyses a reaction between UDPglucose and (1,4-a-D-glucosyl)n to form (1,4-a-D-glucosyl)n+ and UDP. Example (precursor) from maize chloroplasts: database code UGST\_MAIZE, 605 amino acids (65.89 kDa). *See also* glycogen synthase. *Compare* starch (bacterial glycogen) synthase.

starch syrup *an alternative name for* corn syrup.

Start an important checkpoint in the G<sub>j</sub> phase of the eukaryotic cell-division cycle. Passage through Start commits the cell to enter S phase.

start codon the trinucleotide codon AUG that codes for N-formylmethionine, the first amino-acid residue in the synthesis of all prokaryotic and mitochondrial proteins.

start kinase a complex of Cdc2 (*see cdc gene*) and a G<sub>i</sub> cyclin that functions as a serine/threonine protein kinase; its activation is necessary for the cell to pass Start. The G<sub>i</sub> cyclin that interacts with Cdc2 is thought to be any of several. The identity of the G<sub>i</sub> cyclin modifies the specificity of the complex.

start point the base pair in DNA at which the first nucleotide is incorporated into an RNA transcript. It is most often a purine, and in many cases is the central base of the sequence CAT. It is sited at the downstream end of the promoter. *Compare* start codon.

start protein any protein that is involved uniquely at the start of the cell cycle. Example, protein Cdc10 from *Schizosaccharomyces pombe*: database code CCIO\_SCHPO, 767 amino acids (85.42 kDa). This protein (which has a close homologue in *Saccharomyces cerevisiae*) is probably a transcriptional regulator for *cdc10* and also for *cdc2*, which encodes a component of start kinase.

starve to deprive of nutrients. In animal experiments a minimum of 24 h deprivation is generally understood. Cultures may be starved of specified single nutrients.

stasis arrest or stagnation of flow.

+stasis *comb. form* denoting lack of movement; cessation of flow. *-+static adj.*

STAT *abbr. for* signal transducer and activator of transcription; a family of eukaryotic transcription factors that mediate the response to many cytokines and growth factors. Upon receptor activation, STAT proteins dimerize, translocate to the nucleus, and bind to specific promoter sequences on target genes. Seven different genes have been so far identified in mammals. Example: STALHUMAN, 750 amino acids (87.33 kDa).

+stat *comb. form* indicating a device for maintaining a particular property at a constant value, e.g. cryostat, thermostat. *-+static adj.*

stathmin *other names:* phosphoprotein p19; oncoprotein p18; prosolin; an ubiquitous phylogenetically conserved cytoplasmic protein that serves as a phosphorylated intermediate in diverse second-messenger pathways. Stathmin undergoes phosphorylation; both phosphorylation and expression of the protein are regulated throughout development, in response to extracellular signals that control cell proliferation and differentiation. It is a major phosphorylation substrate in neurons. Example (precursor) from *Rattus norvegicus*: database code STHM\_RAT, 148 amino acids (17.14 kDa).

+static *see +stasis, +stat.*

statics *functioning as sing.* the branch of applied mathematics dealing with the interaction of forces in nonmoving systems.

statin 1 a phosphoprotein present specifically in the nuclei of nonproliferating cells. It forms a complex with a 45 kDa serine/threonine protein kinase, and has structural similarity to the elongation factor EF-1<sub>u</sub>. Example from rat: database code STTN\_RAT, 463 amino acids (50.28 kDa). 2 a variant spelling of statine.

+statin *word ending (in hormone nomenclature)* denoting a hypothalamic release-inhibiting factor (or hormone). *Compare* +liberin.

statine or statin *symbol:* Sta; [3S,4S]-4-amino-3-hydroxy-6-methylheptanoic acid; a novel amino acid contained in positions 3 and 5 of pepstatin A.

## stearate

stationary phase 1 (*in chromatography*) the immobile phase to which the analyte adsorbs or partitions from the mobile phase. 2 (*in fermentation*) the phase of an *in vitro* culture of microorganisms or eukaryotic cells that follows the exponential growth phase and in which there is little or no growth. statistically significant *see* significant.

statistical mechanics the theoretical analysis of molecular properties based on quantum theory.

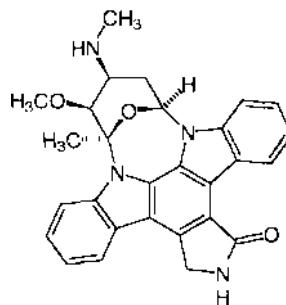

statistical sample a finite selection of items from a population of which the measurement of a variable will give a close approximation to the distribution of that variable in the whole population. *See also* random sample, sample.

statistics 1 *functioning as sing.* the science of collecting, analysing, interpreting, and presenting quantities of numerical data. 2 *functioning as pl.* a collection of quantitative data. — statistical adj.

statyl the acyl group derived from statina.

Staudinger, Hermann (1881-1965), German chemist; Nobel Laureate in Chemistry (1953) 'for his discoveries in the field of macromolecular chemistry'. He was particularly distinguished for his work on polymers such as polystyrene.

staurosporine an antibiotic from *Streptomyces* spp., M<sub>r</sub> 466.2, best known as a potent inhibitor of protein kinase C.

Ste *symbol for* the stearoyl group, CH<sub>3</sub>-[CHzh6-CO-].

steady state a condition in which the properties of any part of a system are constant during a process or reaction; Le. where the rate of formation or increase of a particular quantity is balanced by its rate of removal or decrease.

steady-state fluorescence anisotropy a method in which a sample containing a fluorescent compound is irradiated with plane-polarized light, the emitted fluorescence being analysed to determine its degree of polarization both in the plane of the excitation radiation and in a plane at right angles to this. Only molecules of the fluorescent compound that are aligned in the plane of the incident radiation can absorb radiation and be excited to emit fluorescence. If, in the interval between absorption of the radiation and the emission of fluorescence, the molecule moves out of the plane of polarization of the incident radiation, the emitted radiation will lose polarization (be depolarized) to a degree that depends on the extent to which the molecule had moved. The technique is used to measure the degree to which fluorescent probes are tumbling in a sample. If the probes are held in a relatively rigid position, the extent of depolarization will be small, if tumbling freely it will be high.

steady-state kinetics the analysis of an enzyme reaction in the steady state, Le. after the pre-steady state and when the intermediates have reached a steady concentration. The duration of the steady state is relatively short, and this state is in any case an approximation since the accumulation of products and the depletion of substrate occur continuously from the start of the reaction. *See* Michaelis kinetics.

steapsin *an old term for* pancreatic lipase.

stearate 1 a trivial name for octadecanoate, CH<sub>3</sub>-[CH2]6-COO-, the anion derived from stearic acid, or octadecanoic acid, a saturated straight-chain higher fatty acid. 2 any

## stearin

mixture of free stearic acid and its anion. 3 any salt or ester of stearic acid. *See also* stearoyl.

**stearin** 1 *an old name* for any of the glyceryl esters of stearic acid, especially the triester, tristearin (tristearoylglycerol). 2 *a commercial name* for a grade of stearic acid containing other fatty acids, especially palmitic acid.

**stearoyl symbol:** Ste; *numerical symbol* 18:0; *a trivial name* for octadecanoyl, CH<sub>3</sub>-[CH<sub>2</sub>h<sub>6</sub>-CO-], the acyl group derived from stearic acid (*see* stearate). It is one of the major fatty-acid components of plant and animal lipids; tallow and other hard animal fats contain up to 35%. Together with palmitate it represents a high proportion of the saturated fatty-acid content of dietary and other lipids. It is synthesized from palmitoyl-CoA by a microsomal chain-elongation enzyme. It was formerly and sometimes still is (incorrectly) referred to as stearyl.

**stearoyl-CoA desaturase** EC 1.14.99.5; *systematic name:* stearoyl-CoA,hydrogen donor:oxygen oxidoreductase; *other names:* acyl-CoA desaturase; fatty-acid desaturase; Δ<sup>9</sup>-desaturase. An enzyme that catalyses a reaction between dioxygen, an electron donor and stearoyl-CoA to form oleoyl-CoA. It is an iron protein with a short half-life, and is the only inducible component of the endoplasmic reticulum fatty acyl-CoA desaturase system. It utilizes electrons from reduced cytochrome b<sub>5</sub>. Example from rat: database code ACOD\_RAT, 358 amino acids (41.44 kDa).

**stearyl** 1 *a common name* for octadecyl, CH<sub>3</sub>-[CH<sub>2</sub>h<sub>16</sub>-CH<sub>2</sub>]- the alkyl group derived from octadecane; octadecyl is recommended. 2 *an old trivial name* for octadecanoyl; stearoyl now used instead.

**steatite** *see* talc.

**steato+** *comb. form* indicating presence or relation to fatty substances.

**steatorrhoea** the presence of abnormally large amounts of fat in the feces.

**steatosis** fatty degeneration of tissue.

**steel factor** *see* stem cell factor.

**steel factor receptor** *see* KIT.

**stefin** *see* cystatin.

**Stein**, William Howard (1911-80), US protein chemist; Nobel Laureate in Chemistry jointly with S. Moore (1972) 'for their contribution to the understanding of the connection between chemical structure and catalytic activity of the active centre of the ribonuclease molecule' [prize shared with C. B. Anfinsen]. In addition to this he, together with Moore, was responsible for devising the means for automatic analysis of the amino-acid constituents of protein hydrolysates, and free amino acids in body fluids, separated by ion-exchange chromatography.

**Stelazine** *see* trifluoperazine.

**stellacyanin** a blue copper-containing mucoprotein of low molecular weight obtained from the Japanese lacquer tree, *Rhus vernicifera*. It functions as an electron-transfer protein, accepting electrons from the cytochrome b<sub>6</sub>-f complex and donating them to photosystem I, and has been much studied for the structure of the copper-binding site.

**STEM** *abbr. for* scanning transmission electron microscope.

**stem cell** any member of the various groups of reserve cells whose role is to replace cells that are destroyed during the normal life of the animal, e.g. blood cells, epithelial cells, spermatogonia, and skin cells. Stem cells can divide without limit; after division, the stem cell may remain as a stem cell or proceed to terminal differentiation. Although appearing morphologically unspecialized, the stem cell may be considered as having reached a state of differentiation where the possibilities for further differentiation are very limited.

**stem cell factor** (*abbr.:* SCF) or mast cell growth factor or steel factor a cytokine that stimulates the proliferation of mast cells. It is produced by endothelial cells, fibroblasts, bone marrow cells, and Sertoli cells. A homodimer glycoprotein with type I membrane and soluble forms, it is able to augment the proliferation of both myeloid and lymphoid hemopoietic progenitors. It acts as a ligand for the product of the protooncogene

## stereobase unit

**c-kit** (*see* KIT). Example from human precursor: database code SCF\_HUMAN, 273 amino acids (30.86 kDa).

**stem name** any generic name of a category of similar compounds, enzymes, organisms, etc. that is used also as an affix in forming the specific names of individual members of such a category.

**steno+** or (*before a vowel*) sten+ *comb. form* indicating narrowness.

**stenohaline** describing an organism that is unable to tolerate wide variations in environmental osmotic pressure.

**stenothermous** describing an organism that is unable to tolerate wide variations in environmental temperature.

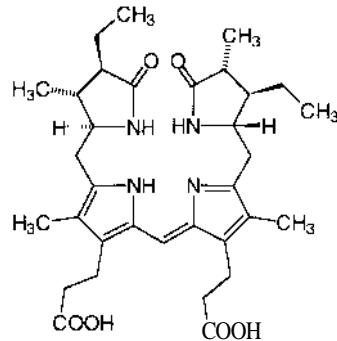

**step gradient** a discontinuous gradient, formed in a tube by layering solutions of different densities carefully one on the other. In column chromatography the same effect is achieved by pumping buffers of different composition sequentially through the column. *See* gradient.

**steradian symbol:** sr; the SI supplementary unit of solid angle.

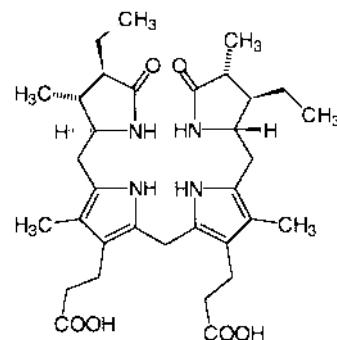

It is equal to the angle subtended at the centre of a sphere by an area of surface equal to the square of the sphere's radius.

The surface of a sphere subtends an angle of 4π sr at its centre.

**stercobilin** or **stercobilin IXα** a linear tetrapyrrole formed in heme catabolism with a red brown colour. Structurally it is an oxidation product of stercobilinogen, comparable to the urobilinogen→urobilin conversion. Metabolically, it is a major product formed from urobilinogen by intestinal bacteria and is the major pigment of feces.

**stercobilinogen** *an alternative name* for 1O,23-dihydrostercobilin; *former name*, stercobilinogen IXa. A product of heme catabolism; it is a linear tetrapyrrole and structurally is a urobilinogen molecule in which the double bonds between the methyl and ethyl substituents on the two end rings have been reduced.

**sterculic acid** *see* cyclic fatty acid.

**stereo+** *comb. form* denoting solid or three-dimensional.

**stereobase unit** the smallest set of one, two, or more succes-

## stereochemistry

sive configurational base units that prescribes repetition in a polymer molecule.

stereochemistry the branch of chemistry dealing with the three-dimensional properties of molecules; the study of the properties of stereoisomers. See *cis-trans* isomerism, *RelSi* convention, sequence rule, stereospecific numbering.

steroheterotopic a term describing chemically-like ligands (or faces of double bonds) whose separate replacement with an achiral ligand (or for faces, addition of an achiral reagent) gives rise to two stereoisomers. If the stereoisomeric products are enantiomers, the ligands (faces) are enantiotopic; if they are diastereoisomers, the ligands (faces) are diastereotopic. For more extensive descriptions, see diastereotopic, enantiotopic.

stereoisomer any of two or more isomers that have the same molecular constitution and differ only in the three-dimensional arrangement of their atomic groupings in space. Stereoisomers may be diastereoisomers or enantiomers. Compare constitutional isomer. -stereoisomeric *adj.*; stereoisomerism *n.*

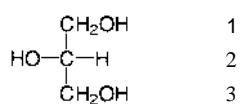

stereology the body of mathematical methods dealing with the interpretation of the structure and dimensions of three-dimensional objects from information contained in two-dimensional representations, such as photomicrographs of tissue sections.

stereoregular polymer a regular polymer composed of molecules having a regular repetition of identical stereobase units at all stereoisomeric sites of the main chain.

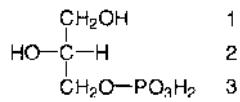

stereoselective polymerization the formation of a polymer from a mixture of stereoisomeric monomer molecules by preferential incorporation of one species into a growing polymer chain.

stereospecific (of an enzymatic or other reaction system) acting on or producing a particular stereoisomer; stereochemically specific. -stereospecificity *n.*

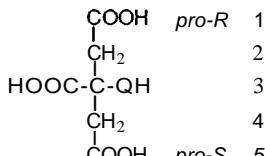

stereospecific numbering a numbering system finding most application for prochiral compounds, *Caabe*, with two chemically-like atoms, or groups of atoms, *a*. It provides identifying numbers for the prochiral *a* groups and, by extension, a numbering system for their chiral derivatives. A stereospecifically numbered compound is designated by the prefix *sn*- to differentiate it from a conventionally numbered compound. Two systems have been described. That of Hirschmann was

(1) glycerol

(2) sn-glycerol-3-phosphate

(3) citric acid

## steroid-hormone receptor

devised particularly so that the 14C-labelled glycerol giving rise to [3,4-14C]glucose (in rats) could be termed [*l*-14C] glycerol and thus be related, biosynthetically and by nomenclature, to [*l*-14C]lactate. It uses the basic *RIS* system (see sequence rule) to set up a model, which is viewed away from the group with the lowest sequence priority. If this is *e* in *Caabe*, a counterclockwise ordering is examined for the remaining three groups, *baa*, starting with *b*. The first *a* group to be encountered receives the lower number. The numbering for glycerol is shown in structure 1. By extension, the naturally occurring glycerol phosphate formed by the action of glycerol kinase becomes *sn*-glycerol 3-phosphate (structure 2). This structure has also been described as D-glycerol 3-phosphate, L-glycerol 3-phosphate, and L-a-glycerophosphate. The Hirschmann nomenclature has found wide acceptance in the lipid field. The other method, the Hanson and Hirschmann system, expands the *RIS* system in a logical fashion (rather than using the arbitrary counterclockwise ordering described for glycerol). The two chemically-like groups, *a*, of *Caabe* are first given *pro-R* and *pro-S* assignments. Then, following the established 'R precedes S rule', *pro-R* precedes *pro-S*, and the *pro-R* group is assigned the lower number. This system has been applied to citric acid as shown in structure 3. Application of this system to glycerol unfortunately leads to the product of glycerol kinase being *sn*-glycerol 1-phosphate. Although this system has a logical basis in terms of established nomenclature, it seems unlikely that the *sn* system for glycerol and derivatives will be brought into line.

stereospecific polymerization a polymerization in which a tactic polymer is formed.

steric relating to effects involving arrangements of atoms in space.

steric hindrance 1 prevention of the free rotation of an atom or group in a molecular entity with respect to a connected one due to the relative sizes and/or spatial disposition of the atoms or groups in question. 2 restriction or prevention of the reaction of a molecular entity with another due to the relative sizes and/or spatial disposition of atoms or groups in either or both of the reactants.

sterile 1 (of inanimate objects) free from microbiological or other life forms. 2 (of a living organism) incapable of sexual reproduction.

sterilize or sterilise 1 to treat in such a way as to kill undesired microorganisms without damaging the material under treatment. Compare disinfection. 2 to render incapable of sexual reproduction. -sterilization or sterilisation *n.*

Stern-Volmer equation an expression relating fluorescence quenching to the concentration of the quenching substance, *e*, and the fluorescence lifetime,  $\tau$ . It is:  $F_0/F = 1 + kef$ , where  $F_0$  is the fluorescence intensity when no quencher is present,  $F$  is the fluorescence intensity in the presence of quencher, and *k* is a constant that depends on the system; the concentration of the absorbing molecule must be the same in both quenched and unquenched systems. The Stern-Volmer plot is a plot of  $F_0/F$  against concentration of quenching substance, from the slope of which, if the fluorescence lifetime is known, the quenching constant can be obtained. [After Otto Stern (1888-1969) and M. Volmer].

steroid any of a large group of substances that have in common a ring system based on 1,2-cyclopentanoperhydrophenanthrene. The group includes such natural products as bile acids, corticosteroids, sex hormones, sterols, and various plant steroids. See also vitamin D.

steroid diabetes a condition involving decreased glucose tolerance, fasting hyperglycemia, and glucosuria, found in patients exposed to excessive quantities of glucocorticoids. It may thus accompany Cushing's syndrome.

steroid-hormone receptor any member of a family of intracellular receptors that bind steroid hormones and mediate their effects; the family also includes receptors for thyroid

**steroid  $\Delta$ -isomerase**

hormones, retinoids, and vitamin D. After binding steroid that has entered the cell, the steroid-receptor complex is translocated to the nucleus and binds to a specific DNA sequence, a **response element**. The receptors are composed of three domains: a modulating N-terminal domain, a DNA-binding domain, and a C-terminal steroid-binding domain. Their zinc fingers are characteristic (four motifs). Examples (human), steroid-hormone receptor ERRI: database code ERR1\_HUMAN, 521 amino acids (55.68 kDa); estrogen receptor: database code ESTR\_HUMAN, 595 amino acids (66.18 kDa). **steroid  $\Delta$ -isomerase** EC 5.3.3.1; systematic name: 3-oxo-steroid j5-j4-isomerase; other name:  $\Delta^5$ - $\Delta^4$ -ketosteroid isomerase. An enzyme (dimer) involved in microbial transformation of steroids; it catalyses the reaction:

Example from *Comamonas testosterone* (*Pseudomonas testosterone*): database code SDIS\_COMTE, 125 amino acids (13.38 kDa).

**steroid 21-monoxygenase** EC 1.14.99.10; other names: steroid 21-hydroxylase; cytochrome P450 21AI; an enzyme that catalyses a reaction between dioxygen, an electron donor, and a steroid to form a 21-hydroxysteroid. It is a heme-thiolate protein. A deficiency underlies congenital adrenal hyperplasia: there is a failure to synthesize cortisol, and this results in overproduction of **corticotropin**, as well as of 17-hydroxyprogesterone and androstenedione. Example from human: database code CPSLHUMAN, 494 amino acids (55.82 kDa).

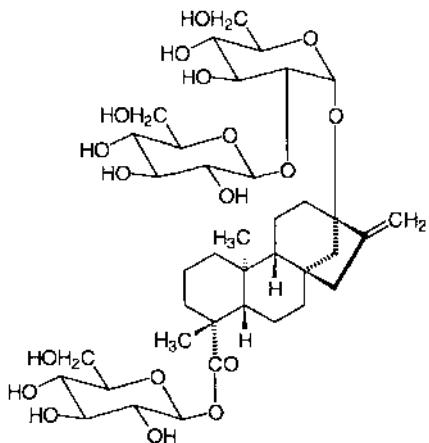

**steroidogenesis** the biosynthesis of steroids, but often referring to the genesis of other steroids from cholesterol.

**sterol** any of a group of **steroids** characterized by the presence of one or more hydroxyl groups and a hydrocarbon side-chain in the molecule.

**sterol D-acyltransferase** EC 2.3.1.26; other names: cholesterol acyltransferase; sterol-ester synthase; an intracellular enzyme that catalyses the formation of cholesterol ester from acyl-CoA and cholesterol. It is involved in the storage of cholesterol esters in phagocytic cells, a process that plays a part in producing lipid-laden cells in arterial walls. Example from human: database code ACAT\_HUMAN, 550 amino acids (64.77 kDa).

**steryl-sulfatase** EC 3.1.6.2; other names: steroid sulfatase (sulfatase); steryl-sulfate sulfohydrolase; arylsulfatase C; an enzyme that catalyses the hydrolysis of 3-p-hydroxyandrost-5-en-17-one 3-sulfate to 3-p-hydroxyandrost-5-en-17-one and sulfate. Example (precursor) from human: database code STS\_HUMAN, 583 amino acids (65.42 kDa).

**stevioside** 13-[2-(*O*-*p*-*o*-glucopyranosyl)- $\alpha$ -*o*-glucopyranosyloxy]kaur-16-en-18-oic acid *p*-*o*-glucopyranosyl ester; a glycoside extracted from the leaves of *Stevia rebaudiana* (yerba dulce). It is used as a sweetening agent, being about 300 times as sweet as sucrose.

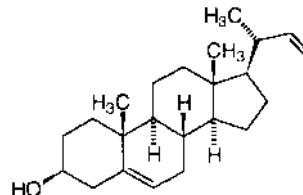

**STH** abbr. for somatotropic hormone; see **somatotropin**.

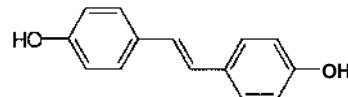

**STI** abbr. for soybean trypsin inhibitor.

**sticky end** see **cohesive end**.

**stigmasterol** 3p-hydroxy-24-ethyl-L1<sup>5</sup>,22-cholestadiene; a **phytosterol** structurally related to p-sitosterol (see **sitosterol**) and found in plant oils.

**stilbestrol** or (esp. Brit.) **stilboestrol** 4,4'-dihydroxystilbene; a synthetic nonsteroid compound, first prepared in 1938, that proved to be the mother substance of a range of compounds with estrogenic activity, of which *a,p*-diethylstilbene (see **diethylstilbestrol**) is the most active. Stilbestrol was formerly used as a growth promoter in farm animals but is now banned in most countries. However, it is still sometimes used to treat hormonal disorders in small animals. It was formerly used to treat prostatic cancer but there is some evidence for its carcinogenicity.

*trans*-stHbestrol

**still** an apparatus for the distillation of liquids, including the preparation of distilled water. It consists of a heated vessel, a condenser, and a receiver. A continuous apparatus incorporates an automatic feed for the liquid in question, a heating element, and a thermoregulator.

**stimulate** (in physiology) to provide a **stimulus** to any tissue or cell leading to its excitation or to initiation of a sequence of events with some defined endpoint, involving an electrical event, activation of a metabolic pathway, or initiation of cell division or growth. **-stimulation** *n.*; **stimulative** *adj.*

**stimulus** (in physiology) any event or phenomenon, such as radiation, electrical potential, or addition of molecules that leads to excitation of a tissue or cell.

**stimulus-response coupling** a molecular mechanism, often involving **signal transduction**, that transmits a stimulus from the exterior of a cell's plasma membrane, in many cases through **second messenger** pathways, to effector systems that bring about a response. For example, in **stimulus-secretion coupling** the effector system brings about a secretion event such as degranulation of mast cells or release of hormone (e.g. insulin) from storage granules to the cell exterior.

**stimulus-secretion coupling** see **stimulus-response coupling**.

**stochastic** arrived at by skilful conjecture; e.g. a stochastic model, a stochastic process.

**stock solution** a solution of a reagent, at a stable or convenient concentration, from which appropriate dilutions can be made at the time of use.

**Stock system** (in *inorganic nomenclature*) a system of designating the **oxidation number** of an element by placing a Roman numeral in parentheses immediately following the name of the element or, where symbols are used, in superscript to the right of the symbol; e.g. manganese(IV) oxide, MnIVO<sub>2</sub>'

**stoichiometry** or (rarely) **stoicheiometry** the quantitative relationship of the reactants and products of a chemical reaction

**stokes**

in the proportions that they appear in the chemical equation describing the reaction. -stoichiometric or stoicheiometric *adj.*

**stokes symbol:** St; the cgs unit of **kinematic viscosity**; its use is now discouraged. In SI units, kinematic viscosity is measured in square metres per second;  $1 \text{ St} = 10^{-4} \text{ m}^2 \text{ s}^{-1}$ . [After (Sir) George Gabriel Stokes (1819-1903), British mathematician.]

**Stokes' law of fluorescence** a law stating that the wavelength of the emitted fluorescent light,  $\lambda_{\text{em}}$ , is greater than that of the light exciting the fluorescence,  $\lambda_{\text{ex}}$ . This relationship is true for most fluorescent materials; those for which it does not hold are termed anti-Stokes.

**Stokes' law of viscosity** a law stating that the frictional coefficient,  $f$ , of a spherical particle of radius  $r$ , moving through a liquid of viscosity  $\eta$ , is given by  $f = 6\pi\eta r$ .

**Stokes' loss** the loss of excitation energy available for fluorescence due to collision of molecules in the first excited state,  $S_1$ , with their neighbours, which results in a lower vibration level of St.

**Stokes' shift** the difference in wavelength between the excitation and emission maxima for a particular fluorescent substance. In quantitative form, Stokes' shift is  $10^7(1/\lambda_{\text{ex}} - 1/\lambda_{\text{em}})$ , where  $\lambda_{\text{ex}}$  and  $\lambda_{\text{em}}$  are the corrected maximum wavelengths for excitation and emission expressed in nanometres.

**stoma** (*pl.* stomata) any of the pores occurring in the epidermis of plants, particularly in leaves, through which gaseous exchange takes place.

**stop codon** any of the trinucleotide **codons**, UGA, UAG, and UAA, that signal the termination of translation of a messenger RNA molecule and the release of the nascent polypeptide chain. *See also termination codon.*

**stopped-flow technique** a method in which two solutions are caused to flow into a mixing chamber and then into an observation chamber, after which the flow is caused to stop abruptly and the time course of the chemical reaction can be followed, usually spectroscopically, as the mixture in the observation chamber ages. Critical features include the quality of mixing, the speed with which the mixed solution fills the observation volume, and the geometry of the observation volume in relation to the sensitivity of observation. *See also rapid-reaction kinetics.*

**STOP protein** *abbr.* for stable tubule only polypeptide; a protein that blocks the endwise dissociation of microtubules.

**stop-transfer protein** *see* **signal peptide**.

**storage granule** any small **organelle**, bounded by a membrane having a single lipid bilayer, that contains stored material. For example, mast-cell storage granules contain histamine, while those of pancreatic B cells contain insulin; in both cases the stored material is destined for secretion. This involves a stimulus applied to the cell that causes fusion of the granule membrane with the plasma membrane, followed by release of the granule contents by **exocytosis**.

**storage polysaccharide** any polysaccharide that serves as a form of stored energy in living organisms. Storage polysaccharides include starch, phytoglycogen (e.g. in maize), and fructosans (e.g. inulin) in plants, and glycogen in animals.

**stp or s.t.p. or STP** *abbr.* for standard temperature and pressure.

**straight-chain** describing any chain of carbon atoms in which none of the carbon atoms is directly bonded to more than two other carbon atoms.

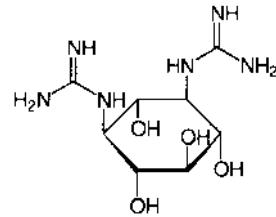

**strain 1** a group of related individuals having certain characters that distinguish the members from other such groups within the same species or variety; a race. 2 a line of organisms descended or derived from a particular ancestral individual. 3 (*in physics*) the temporary or permanent deformation of a body resulting from an applied stress.

**streptavidin** a tetrameric biotin-binding protein (subunit M<sub>r</sub> 14 500) produced by *Streptomyces avidinii*, capable of binding up to four molecules of **biotin** per molecule. It is useful in techniques such as enzyme-linked immunosorbent assay (ELISA), radioimmunoassay, immunocytochemistry, and protein blotting. It is also used with DNA probes as a detection reagent,

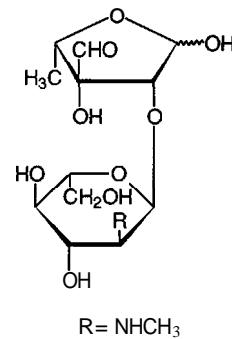

**streptolydigin**

where biotin can be incorporated into the molecule under study; streptavidin can then be used to bind to the biotin. The streptavidin may be labelled with **file**, gold, peroxidase, or another agent directly as a detection reagent. Alternatively, a biotin-labelled detection system (such as alkaline phosphatase) can be bound to streptavidin through another of its biotin-binding sites. Streptavidin has the advantage over **avidin** (also used in such techniques) of having a near-neutral isoelectric point (7.25-7.45); consequently its use results in less nonspecific binding. *See also biotinylation.*

**streptidine** 1,3-diguanido-2,4,5,6-cyclohexanetetrol; the non-carbohydrate component of **streptomycin**.

**streptobiosamine** 5-deoxy-2-O-[2-deoxy-2-(methylamino)-*α*-L-glucopyranosyl]-3-C-formyl-L-Iyxose; a disaccharide component of **streptomycin**, containing **streptose** and N-methylglucosamine.

R = NHCH<sub>3</sub>

**Streptococcus** a genus of Gram-positive, facultatively or obligately anaerobic cocci or coccoid bacteria, of biochemical significance for their production of **streptokinase**, **streptolysin**, and **streptodornase**.

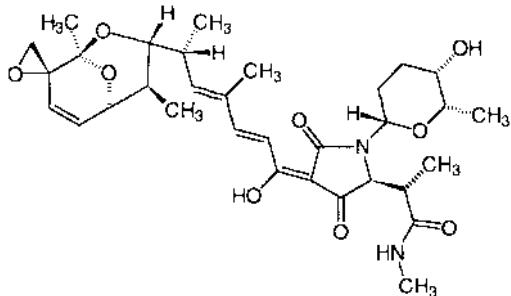

**streptodornase** any of the extracellular deoxyribonucleases produced by streptococci. At least four such serologically distinct nucleases are known. Some or all have the characteristics of **deoxyribonuclease I** (EC 3.1.21.1), bringing about endonucleolytic cleavage of DNA to 5'-phosphodinucleotide and 5'-phosphooligonucleotide end-products. [From streptococcal deoxyribonuclease.]

**streptokinase** any of a number of extracellular proteins produced by certain streptococci; they exhibit no enzymic activity, despite the name. In human blood streptokinase forms a tight 1:1 complex with plasminogen that catalyses the activation of plasminogen to plasmin, and this in turn lyses fibrin clots. It has been used therapeutically after heart attacks and strokes. It is assumed that streptokinase assists the invasiveness of pathogenic streptococci. Example, streptokinase A precursor from *Streptococcus pyogenes*: database code STRP-STRPY, 440 amino acids (49.84 kDa); residues 1-26 are the signal, 27-440 the protein.

**streptolydigin** an antibiotic, derived from *Streptomyces lydicus*, that possesses potent antibacterial action, particularly against anaerobes and some Gram-positive aerobes. This is probably due to its inhibitory activity against bacterial RNA

## streptolysin

polymerase; it reduces the rate of transcription, slowing the rate of phosphodiester bond formation without affecting the fidelity of transcription. This contrasts with rifampicin, which inhibits initiation. *Compare* rifamycin.

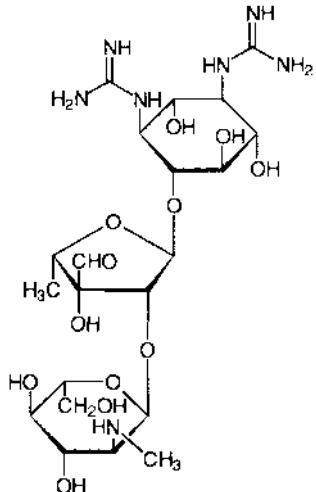

streptolysin either of two dissimilar hemolysins produced by certain streptococci (particularly of group A). Streptolysin-O (oxygen-sensitive) is produced by culture in serum-free medium. Its hemolytic activity is destroyed by oxygen (but restored by certain mild reducing agents, e.g. 2-mercaptoethanol) and inhibited by free cholesterol. It is immunogenic, the level of circulating antibody (antistreptolysin-O, ASO) being useful clinically in the diagnosis of streptococcal infections. Hemolysis by streptolysin-O is not complement-dependent. Streptolysin-O can also lyse lysosomes. Biochemically and serologically it resembles O-toxin of *Clostridium perfringens*. It can be used as an agent to permeabilize cells. Streptolysin-S (serum-dependent) is oxygen-insensitive and its production is promoted by serum proteins. Its hemolytic activity is inhibited by certain phosphatides, e.g. phosphatidyl ethanolamine, at low concentration. It is nonimmunogenic, and is also toxic to leukocytes.

*Streptomyces* a genus of filamentous, spore-forming, Gram-positive bacteria that are largely responsible for the 'earthy' smell of soil but are chiefly remarkable for the diversity of secondary metabolites that they produce, including clinically useful antibiotics, e.g. streptomycin. They are amenable to genetic manipulation with many plasmid and phage vectors; this provides a unique opportunity for overexpression and for the design and synthesis of novel and 'hybrid' antibiotics. *See also* streptomycete.

streptomycete strictly, any member of the bacterial genus *Streptomyces*. However, the term may sometimes be extended to include certain related types, including *Streptoverticillium* spp.

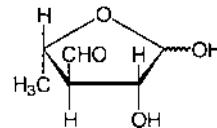

streptomycin an aminoglycoside antibiotic produced by the soil

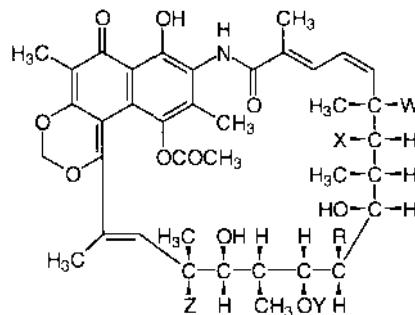

## striated muscle

bacterium *Streptomyces griseus*, having a relatively broad spectrum of activity against bacteria; it is particularly active against mycobacteria (especially against *Mycobacterium tuberculosis*), enterobacteria, and staphylococci. It acts at the 30S ribosomal subunit and distorts the A site (aminoacyl site), thereby causing miscoding or prevention of binding of aminoacyl-tRNA. The components of streptomycin are streptidine, streptose, and N-methyl-L-glucosamine.

streptose L-streptose; 5-deoxy-3-C-formyl-L-lyxose; a component of streptomycin and streptobiosamine.

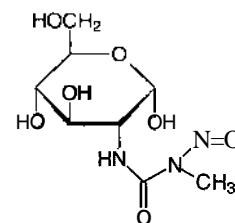

streptovaricin anyone of a group of ansamycin antibiotics obtained from *Streptomyces spectabilis*. *Compare* rifamycin.

Streptovaricin	W	X	y	Z	R
A	OH	OH	Ae	OH	COOCH <sub>3</sub>
B	H	OH	Ae	OH	COOCH <sub>3</sub>
C	H	OH	H	OH	COOCH <sub>3</sub>
D	H	OH	H	H	COOCH <sub>3</sub>
E	H	O=	H	OH	COOCH <sub>3</sub>
G	OH	OH	H	OH	COOCH <sub>3</sub>
J	H	OAE	H	OH	COOCH <sub>3</sub>
K	OH	OAE	H	OH	COOCH <sub>3</sub>

streptozocin 2-deoxy-2-(3-methyl-3-nitrosoureido)-D-glucopyranose; a broad-spectrum antibiotic, antineoplastic, and diabetogenic substance isolated from *Streptomyces achromogenes*. It has a rapid and specific cytotoxic effect on the B cells in pancreatic islets, and is used to induce experimental diabetes in animals and for chemotherapy of insulinoma or other islet-cell neoplasms in humans. It acts as a methylating agent for DNA.

α-D-streptozocin

striated muscle muscle in which the thick filaments and thin fila-

strict aerobe

sub+

ments are arranged in microscopically visible bands producing a striped appearance. Such an arrangement is typical of skeletal muscle and cardiac muscle. *Compare* smooth muscle. *See also* sarcomere.

strict aerobe *see* aerobe.strict anaerobe *see* anaerobe.

**stringency** (*in molecular biology*) the rigour with which the ability of complementary DNA sequences to recognize each other (and thus to hybridize) is tested. As temperature is increased it becomes less likely that more distantly related sequences will hybridize; hence, high stringency is associated with high temperature.

**stringent** very rigorous. *See also* stringency, stringent control, stringent plasmid, stringent response.

**stringent control** a mechanism of control of plasmid replication whereby the plasmid is replicated only once for each time the chromosome is replicated, thus regulating the plasmid copy number.

**stringent factor** a protein associated with ribosomes, and encoded by the gene *felA*, that is associated with the stringent response. The stringent factor is associated with enzyme activity that donates a pyrophosphate group to 3' of either 5'-GTP or GDP for the production of pppGpp and ppGpp, which probably act as allosteric modulators mediating the stringent response. *See also* relaxed mutant, *spoT*.

**stringent plasmid** a plasmid that has a limited number of copies per cell.

**stringent response** a response by bacteria to poor growth conditions (e.g. lack of amino acids) in which the cell shuts down protein synthesis and other metabolic activity. *See also* relaxed mutant, stringent factor.

**strip** 1 to remove adherent, admixed, or combined substances or material from a fundamental, underlying, or required substance or structure. 2 (*in molecular biology*) a to remove polysomes from rough endoplasmic reticulum *in vitro* to produce stripped membranes (*see* degranulation (def. 2»). b to remove ribosomal proteins from a ribosome to produce a core particle. c to remove the amino acid from an aminoacyl-transfer RNA molecule to produce stripped transfer RNA. d to remove hybridized probe (deL 3) from a transfer membrane prior to reprobeing. 3 (*in biochemistry*) to remove endogenous 2,3-bisphosphoglycerate from a hemoglobin solution to produce stripped hemoglobin. 4 to remove liquid components from a gaseous mixture.

**stripped hemoglobin** a hemoglobin solution from which endogenous 2,3-bisphosphoglycerate has been removed, e.g. by gel filtration or dialysis at high NaCl concentrations.

**stripped membrane** rough endoplasmic reticulum from which polysomes have been removed *in vitro*. This technique has been applied mainly to membranes from dog pancreas, which lack ribonuclease; the ribosomes are removed by treatment with EDTA.

**stripped transfer RNA** a molecule of aminoacyl-transfer RNA from which the amino acid has been hydrolytically removed.

**stroma** (*pl.* stromata) 1 fibrous connective tissue or other intercellular material that forms the structural framework of an organ, as opposed to the functional tissue (parenchyma). 2 the spongy framework of protein strands within a red blood cell in which the hemoglobin is packed. 3 (*in botany*) the space enclosed by the double membrane of a chloroplast but excluding the thylakoid space. It contains DNA, ribosomes, and some temporary products of photosynthesis. 4 (*in mycology*) a mass of interwoven hyphae in which fruiting bodies (perithecia) develop. *-stromal adj.*

**stromelysin** EC 3.4.24.17; *other names*: matrix metalloproteinase-3 (*abbr.*: MMP-3); transin-I; an enzyme that catalyses the degradation of fibronectin, laminin, and some (but not all) gelatins and collagens. Zn<sup>2+</sup> and Ca<sup>2+</sup> are cofactors. It is a glycoprotein of the extracellular matrix. Example, stromelysin I precursor from human: database code COG3\_HUMAN, 477 amino acids (53.92 kDa).

**strong acid** an acid that remains ionized at all except the lowest pH values, i.e. one that has a large acid dissociation constant.

**strong base** a base that remains ionized at all except the highest pH values, i.e. one that has a large basic dissociation constant.

**strophantdin** a highly toxic glycoside mixture produced by *Strophanthus kombe*, with actions similar to those of digoxin and ouabain.

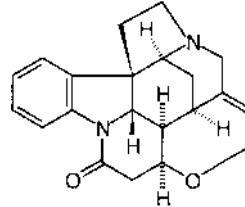

**structural gene** any gene that carries the genetic information determining the structure, and therefore the specificity of function, of a protein. One or more structural genes may be contained in an operon. *Compare* regulator gene.

**structural polysaccharide** any of several components of a plant cell wall that perform a structural function. They can be divided into three solubility classes: pectins, extractable with dilute acid; hemicelluloses, extractable with aqueous alkali; and microfibrillar polysaccharides.

**structure factor** a parameter describing the scattering of electromagnetic radiation (e.g. X-rays) by an electron. It is the ratio of the radiation scattered by any real sample to that scattered by a single electron at the origin.

**Strutt, John William, Lord Rayleigh** (1842-1919), British mathematician and physicist noted *inter alia* for his contributions to the theory of sound, for his investigations of physical optics, e.g. Rayleigh scattering, and for his discovery (with W. Ramsay) of argon; Nobel Laureate in Physics (1904) 'for his investigations of the densities of the most important gases and for his discovery of argon in connection with these studies'.

**strychnine** a bitter alkaloid obtained from seeds of the Indian tree *Strychnos nux-vomica*. It is highly toxic, and is sometimes used to poison moles, rodents, and other vermin. Its lethal convulsant action is a result of antagonism of the inhibitory transmitter, glycine, in the spinal cord (*see* glycine receptor). *See also* brucine.

**STS** *abbr.* for sequence-tagged site.

**Stuart factor** or **Stuart-Prower factor** *an alternative name for* factor X; *see* blood coagulation. [After a Mr Stuart, in whom the deficiency was first described.]

**Student's t test** a statistical test, based on a distribution due to William Sealy Gosset (1876-1937) writing in 1908 under the pseudonym 'Student', that can be applied to small samples of data, *x*. In this distribution *t* depends only on the sample size, *N*, and not on the variance of the population; as *N* increases, the distribution curve of *t* approaches a normal distribution curve more closely.

**STX** *abbr.* for saxitoxin.

**SU symbol** *for* a residue of the ribonucleoside thiouridine (when the position of the thiol group in its thiouracil moiety is unspecified or unknown; alternative to S or Srd).

**S2U symbol** *for* a residue of the ribonucleoside 2-thiouridine (alternative to 2S).

**S4U symbol** *for* a residue of the ribonucleoside 4-thiouridine (alternative to 4S).

**subjargon term** *for* subculture (def. I).

**sub+** *prefix* 1 beneath, under, at the bottom (of). 2 immediately below in order, rank, or status; secondary. 3 less than, partial(lly), imperfect(lly). 4 in place of. 5 denoting a subordinate part or subdivision of a whole. 6 (*in chemical nomenclature*) designating a compound that contains less than the usual pro-

**subcellular**

portion of a specified element; e.g. carbon suboxide,  $C_2O_3$ . *Compare* infra+, super+.

**subcellular** describing organelles, functional units, or other components that are found within cells or derived from cells.

**subcellular organelle** a pleonasm that is commonly used to describe organelles (which by definition are subcellular).

**subclone** to clone into a new vector a subfragment of part of a larger cloned DNA, after excising the required fragment using restriction endonucleases.

**subculture** 1 to prepare a fresh culture from a small sample of an existing culture. 2 a culture prepared in such a way.

**subcutaneous** abbr.: s.c.; below the skin.

**suberin** the polymeric substance that covers the epidermal cell layer in the underground parts of plants (e.g. roots and tubers). It is a polyester containing w-hydroxy fatty acids and aromatic fatty acids, e.g. ferulic acid.

**sublime** to vaporize from the solid without passing through a liquid phase. -sublimation *n*.

**submaxillary protease** an endopeptidase isolated from the submaxillary gland of mice. It acts specifically at Arg-j-Xaa bonds.

**submaxillary** relating to the region beneath the upper jaw (maxilla).

**submaximal** below the maximal.

**submitochondrial particle** any particle derived by disruption of mitochondria. *See* W-transferring ATPase, complex I, II, III, IV.

**submolecular** describing any chemical or chemical component that exists or functions at a lower level of complexity than that of intact individual molecules. The term may be used in reference to electrons, ions, free radicals, or other molecular fragments. *Compare* supramolecular.

**subnatant** 1 lying under. 2 a liquid lying under a supernatant or under solid material. *Compare* infranatant.

**suboptimal** below or failing to reach the optimal condition.

**subsite** a site, e.g. on a protein, that has a specific function within the overall function of a larger site.

**substance K** see neurokinin A.

**substance K receptor** or neurokinin A receptor or NK-2 receptor a membrane protein that binds substance K and mediates its intracellular effects. It is a G-protein-coupled, seven-transmembrane-domain protein that activates the phosphatidylinositol cycle. Example from *Bos taurus*: database code NK2R\_BOVIN, 384 amino acids (43.07 kDa).

**substance P** abbr.: SP; an II-residue amide,

H-Arg-Pro-Lys-Pro-Gln-Gln-Phe-Phe-Gly-Leu-Met-NH<sub>2</sub>, found in most tissues of the mammalian body but at highest concentrations in nervous tissue (both central and peripheral) and in gut tissues. It also occurs in the central nervous system of many other vertebrates. Derived from protachykinin  $\beta$  precursor, it is a tachykinin; its main pharmacological actions are to cause hypotension and vasodilatation, and to stimulate contraction of the intestine and secretion of saliva. However, its physiological function remains to be fully determined. *See also* tachykinin receptor.

**substituent group** or substituent (*in organic-chemical nomenclature*) any atom or group (def. I) that has replaced or can be considered to have replaced (i.e. been substituted for) a hydrogen atom in a parent molecular entity, which may be either real or hypothetical; in the special cases of bivalent or trivalent groups there are corresponding replacements of two or three hydrogen atoms.

**substituted mechanism** a mechanism of an enzyme reaction in which the first substrate reacts with the original enzyme to produce a modified enzyme and one product. The modified enzyme then reacts with the second substrate to produce the second product and regenerate the original enzyme, e.g.

then

**subtrahend**

where E is the enzyme, E\* the modified enzyme, S<sub>1</sub> and S<sub>2</sub> the substrates, and P<sub>1</sub> and P<sub>2</sub> the products.

**substitution reaction** the replacement of a substituent (normally hydrogen), usually at a carbon atom, by any other group.

**substrate** 1 a substance that is acted upon, especially by an enzyme; a molecule or structure whose transformation is catalysed by an enzyme. 2 *or substratum* a the base upon which an organism grows or lives, e.g. soil or rock. b the material upon which a microorganism grows or is placed to grow.

**substrate activation** the increase of an enzyme's activity by its substrate by an allosteric mechanism. *Compare* substrate inhibition.

**substrate cycle** interconversion of reactant and product by two enzymes, one of which (A) catalyses the reaction in one direction while the second enzyme (B) catalyses the reaction in the opposite direction, e.g.

As flux (def. 3) (i.e. the rate of reaction catalysed by A minus rate of reaction catalysed by B) through a system varies, the rate of each enzyme reaction may vary independently with concomitant changes in cycling rate. The existence of a substrate cycle increases sensitivity of control, since even if rates of forward and reverse reaction are high, changes in one or both may make relatively larger changes to flux; e.g. if rate of A = 9 and rate of B = 8, then flux = 1; if rate of A doubles to 18 and rate of B remains 8, then flux = 10 (i.e. increases tenfold).

**substrate dissociation constant** or (formerly) substrate constant symbol  $K_s$ ; the parameter of an enzymatic reaction that is the equilibrium (dissociation) constant for the reaction ES = E + S; i.e.  $K_s = [E][S]/[ES]$ .

**substrate inhibition** the inhibition of an enzyme's activity by its substrate by an allosteric mechanism. *Compare* substrate activation.

**substrate-level phosphorylation** the formation of ATP (or GTP) in a coupled reaction that is not linked to an electron transport system, e.g. coupled to the deacylation of succinyl coenzyme A or the conversion of 3-phosphoglycerol phosphate to 3-phosphoglycerate.

**substrate-site hypothesis** a hypothesis for the control of insulin release from pancreatic islet B cells by glucose. It postulates that the glucoreceptor is either a carrier transporting glucose into the cell or an enzyme phosphorylating glucose, and the signal for insulin release is a metabolite in the pathway of metabolism of glucose in the B cell. *Compare* regulator-site hypothesis.

**substratum** (*pl.* substrata) 1 any layer (stratum) or structure that lies beneath another, or that forms a base or underlying support for something else. 2 *an alternative term for substrate* (def. 2).

**subtiligase** one of several engineered derivatives of subtilisin that efficiently ligate peptides. The two mutations converting the peptidase, subtilisin, to a ligase involve Ser<sup>221</sup> to Cys and Pro<sup>225</sup> to Ala.

**subtilin** or subtilin C an antibiotic produced by *Bacillus subtilis* and active against Gram-positive bacteria, *Neisseria* spp. (*N. catarrhalis*, *N. gonorrhoeae*), and some pathogenic fungi.

**subtilisin** EC 3.4.21.62; a bacterial endopeptidase enzyme isolated from *Bacillus subtilis* and other *Bacillus* spp. (e.g. commercially from *B. licheniformis*). It is a serine endopeptidase that catalyses the hydrolysis of proteins with broad specificity for peptide bonds, with preference for a large uncharged residue at P1 (see peptidase P-sites) and low activity for glutamyl residues; it hydrolyses peptide amides. Example from *B. subtilis*: database code NRL\_ISBC, 274 amino acids (27.26 kDa); 3-D structure is known; the enzyme has similar active-site geometry to the trypsin family but otherwise no homology. *See also* Nagarse proteinase.

**subtrahend** (*in mathematics*) the number to be subtracted from another number (the minuend).

## subunit

**subunit** any polypeptide component within a protein or other distinct biochemical entity, whether identical to or different from any other components, that is separable from such other components without rupture of covalent bonds. The term is sometimes used in a more restricted sense as referring to any chemically or physically identifiable submolecular entity within a protein, whether identical to, or different from, other components.

**subunit-exchange chromatography** a form of chromatography in which protein subunits are immobilized on a solid matrix and allowed to interact with protein subunits in solution. Quantification of subunit exchange between the matrix and solution may be used in analysing the association-dissociation properties of the protein system. The method also provides a powerful, specific purification method.

**Suc-** symbol for succinyl (def. 1).

**-Suc-** or **Suc<** symbol for succinyl (def. 2).

**succinamic acid** a trivial name for 3-carbamoylpropanoic acid, the monoamide of succinic acid.

**succinamide** a trivial name for butanediamide, the diamide of succinic acid.

**succinate** 1 a trivial name for butanedioate; ethanedicarboxylate; the dianion of succinic acid. It is an important intermediate in metabolism and a component of the tricarboxylic-acid cycle. 2 any mixture of free succinic acid and its mono- and di-anions. 3 any salt or ester of succinic acid.

**succinate-CoA ligase (GOP-forming)** EC 6.2.1.4; other name: succinyl-CoA synthetase (GDP-forming); an enzyme of the tricarboxylic-acid cycle that catalyses the formation of succinyl-CoA from GTP, succinate, and CoA with release of GDP and orthophosphate. Examples:  $\alpha$ -chain precursor from rat: database code SUCA\_RAT, 333 amino acids (34.99 kDa);  $\beta$  chain (from pig): database code A44529, 417 amino acids (45.10 kDa).

**succinate dehydrogenase** EC 1.3.99.1; systematic name: succinate:(acceptor) oxidoreductase; other names: fumarate reductase/dehydrogenase; fumaric hydrogenase. A bacterial enzyme, or a degraded entity from succinate dehydrogenase (ubiquinone), a major component of mitochondrial complex II (see respiratory complex). It catalyses the oxidation of succinate by an acceptor to form fumarate and a reduced acceptor; it does not react with ubiquinone. It is a flavoprotein (FAD) and plays an important role during anaerobic growth. Example from *Escherichia coli*; there are four subunits: (1) cytochrome  $b_{56}$ ; (2) an iron-sulfur protein: database code DHSB\_ECOLI, 238 amino acids (26.74 kDa); (3) a flavoprotein related to succinate dehydrogenase (ubiquinone): database code DHSA\_ECOLI, 588 amino acids (64.33 kDa); and (4) a hydrophobic anchor protein.

**succinate dehydrogenase (ubiquinone)** EC 1.3.5.1; systematic name: succinate:ubiquinone oxidoreductase; other name: succinic dehydrogenase. An enzyme that catalyses the oxidation of succinate by ubiquinone to form fumarate and ubiquinol. It is an iron-sulfur flavoprotein (FAD), containing at least four different subunits: a flavoprotein, an iron-sulfur protein, and two hydrophobic anchor proteins. It is located in the mitochondrial inner membrane, where it is a major component of complex II (see complex I, II, III, IV) of the respiratory chain. Example, FAD, subunit (precursor) from bovine: database code DHSA\_BOVIN, 664 amino acids (73.63 kDa). Two other examples (subunits, precursors, from yeast): flavoprotein subunit: database code DHSA\_YEAST 640 amino acids (70.15 kDa); iron-sulfur protein subunit: database code DHSB\_YEAST 266 amino acids (30.20 kDa).

**succinate-semialdehyde dehydrogenase** EC 1.2.1.24; an enzyme that catalyses the reaction:

Succinate semialdehyde can undergo transamination to form  $\gamma$ -aminobutyric acid. However, the transaminase primarily

## sucrase

functions to convert  $\gamma$ -aminobutyrate to succinate-semialdehyde, which is then converted to succinate by succinate-semialdehyde dehydrogenase in the catabolism of  $\gamma$ -aminobutyrate. See also 4-aminobutyrate transaminase.

**succinic dehydrogenase** see succinate dehydrogenase (ubiquinone).

**succinimide** a trivial name for butanimide; 2,5-pyrrolidine-dione; the imide of succinic acid. For structure see +imide.

**succinoglycan** an acidic exopolysaccharide needed for symbiosis between *Rhizobium meliloti* and alfalfa. Also synthesized by other bacteria, it is a polymer of octasaccharide subunits (one galactose and seven glucose residues) with acetyl, succinyl, and pyruvyl modifications.

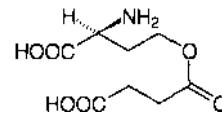

**succinyl** 1 (in biochemistry) symbol: Suc-; the univalent acyl group 3-carboxypropanoyl, HOOC-[CH<sub>2</sub>-CO-], derived from succinic acid by loss of one hydroxyl group. 2 (in chemistry) symbol: -Suc- or Suc<; the bivalent acyl group butanediolyl, -CO-[CH<sub>2</sub>-CO-], derived from succinic acid by loss of both hydroxyl groups.

**succinylation** the introduction of one or more succinyl (def. 1) groups into a substance by acylation, either chemically, e.g. with succinic anhydride, or enzymically, e.g. with succinyl-coenzyme A. Succinylation of a protein with succinic anhydride is used to acylate its free lysine (and other) amino groups in order to change their charge at neutral pH from positive to negative and to render adjacent peptide bonds resistant to hydrolysis by trypsin; it can also lead to disaggregation of a multimeric protein. The reaction occurs readily at pH 7-10 (at 0-25 °C), but it is irreversible, unlike the otherwise similar processes of citraconylation and maleylation, and so is of limited usefulness in protein sequence work.

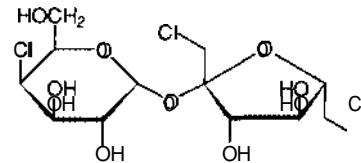

**succinylcholine chloride** see suxamethonium.

**succinyl-CoA synthetase (GOP-forming)** see succinate-eoA ligase (GOP-forming).

**$\alpha$ -succinylhomoserine** an intermediate in methionine biosynthesis in plants and bacteria. It is formed by succinylation (utilizing succinyl-CoA) of homoserine. It reacts with cysteine with loss of succinate to form cystathione.

**sucralose** 4,1',6'-trichloro-4,1',6'-trideoxy-galacto-sucrose; a chlorinated sucrose, tasting sweeter than sucrose itself.

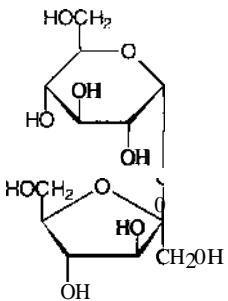

**sucrase** 1 recommended name: sucrose a-glucosidase; EC 3.2.1.48; systematic name: sucrose a-D-glucohydrolase; an  $\alpha$ -D-glucosidase-type enzyme from intestinal mucosa that hydrolyses sucrose and maltose. It is also known as sucrase-isomaltase by virtue of its activity as an oligo-1,6-glucosidase, EC 3.2.1.10, displayed towards isomaltose. 2 a former alternative trivial name for invertase. 3 any of several bacterial or plant enzymes within sub-subclass EC 2.4.1 (hexosyltransferases) that synthesize various homopolysaccharides from sucrose by transfer of either its fructose moiety or its glucose moiety respectively to a fructan or to a glucan, with release of the opposing moiety as free D-glucose or D-fructose. The recommended names are formed by adding 'sucrase' to a prefix

## sucrase-isomaltase

indicating the polysaccharide product. These enzymes include: (1) amylosucrase; EC 2.4.1.4; *other name*: sucrose-glucan glucosyltransferase; *systematic name*: sucrose: I,4-a-D-glucan 4-a-D-glucosyltransferase; it synthesizes amylose; (2) dextran-sucrase; (3) inulosucrase; EC 2.4.1.9; *other name*: sucrose 1-fructosyltransferase; *systematic name*: sucrose:2,I-p-D-fructan I-p-D-fructosyltransferase; it synthesizes inulin; and (4) levansucrase; EC 2.4.1.10; *other name*: sucrose 6-fructosyltransferase; *systematic name*: sucrose:2,6-p-D-fructan 6-P-D-fructosyltransferase; it synthesizes levan.

sucrase-isomaltase *see* oligo-1,6-glucosidase.

sucrose or saccharose *the trivial name for* O-p-D-fructofuranosyl-(2→1)-a-D-glucopyranoside; a sweet-tasting, non-reducing disaccharide. The sugar of commerce, it is usually isolated industrially in crystalline form from sugar cane, *Saccharum officinarum*, or from sugar beet, *Beta vulgaris*.

sucrose gradient a density gradient made by mixing different concentrations of sucrose and layering them in a centrifuge tube. It is commonly used to separate molecules or particles on the basis of their sedimentation coefficients. *See also* isopycnic centrifugation.

sucrose-phosphate synthase EC 2.4.1.14; *systematic name*: UDPglucose:D-fructose-6-phosphate 2a-D-glucosyltransferase; *other names*: UDPglucose-fructose-phosphate glucosyltransferase; sucrocephosphate-UDP glucosyltransferase. An enzyme that catalyses a reaction between UDPglucose and D-fructose 6-phosphate to form sucrose 6-phosphate and UDP. Example from *Zea mays* (maize): database code SPS\_MAIZE, 1068 amino acids (118.44 kDa).

sucrose phosphorylase EC 2.4.1.7; *systematic name*: sucrose:orthophosphate a-D-glucosyltransferase; *other name*: sucrose glucosyltransferase. An enzyme that catalyses the phosphorylation of sucrose to D-fructose and a-D-glucose 1-phosphate. Example from *Leuconostoc mesenteroides*: database code LEUSUCP, 490 amino acids (55.68 kDa).

sucrose synthase EC 2.4.1.13; *systematic name*: UDP glucose:D-fructose 2a-D-glucosyltransferase; *other names*: UDPglucose-fructose glucosyltransferase; sucrose-UDP glucosyltransferase. An enzyme that catalyses a reaction between UDPglucose and D-fructose to form sucrose and UDP. Example, sucrose synthase I from *Hordeum vulgare* (barley): database code SUSI\_HORVU, 807 amino acids (92.11 kDa).

Sudan the family name of a group of dyes that are soluble in organic solvents and are used for staining lipids. Sudan Red is the 2,2'-demethyl analogue of Oil Red O. Sudan Black B is used for staining chromosomes, Golgi apparatus, and leukocyte granules.

sugar *a general and imprecise name used for* any, usually sweet, soluble disaccharide or small oligosaccharide carbohydrate. More specifically it is applied to sucrose, the sugar of commerce. The name is also sometimes used as a synonym for carbohydrate. *See also* beet sugar, blood sugar, cana sugar, corn sugar, fruit sugar, grape sugar, malt sugar, milk sugar, mushroom sugar, reducing sugar.

sugar acid any aldaric acid, aldonic acid, or uronic acid.

sugar alcohol *an old name for* alditol.

## sulfite reductase

sugar beet the plant *Beta vulgaris*, which has a large root with a high sugar content, for which it is extensively cultivated.

sugar transporter any of various transmembrane proteins responsible for sugar transport into cells. There are several mechanisms, and different superfamilies of proteins are involved, characteristically with five motifs. For example, 6TR1 causes facilitated diffusion of glucose, whereas XylE protein in *Escherichia coli* acts as an H<sup>+</sup>-xylose symporter (*see* xylE). Both belong to the 12-transmembrane domain superfamily. Other types include the ABC transporter type and PTS type. *See* glucose transporter.

suicide enzyme *see* suicide repair (of DNA).

suicide inhibitor a type of enzyme inhibitor that is distinguished from a classical active-site-directed enzyme inhibitor in two key respects: (1) the inhibitor itself is relatively unreactive and becomes reactive only after interaction with the enzyme's active site; and (2) conversion to the active form depends on the specific catalytic capabilities of the active site, i.e. some part of the enzyme's normal catalytic capability is required. *See also* photosuicide inhibitor.

suicide repair (of DNA) a response in both bacteria and mammalian cells to a situation in which exposure to a nontoxic alkylation dose causes the rapid induction of enzymes that counter the mutagenic effect by removal of 06-methylguanine formed by the alkylating agent. In the course of this repair reaction the methyl group is transferred to the enzyme, which is thereby inactivated (i.e. it is a suicide enzyme).

suicide substrate 1 a substrate that, in undergoing conversion by an enzyme, causes the enzyme to be modified in a way that permanently inactivates it. Hence the enzyme, by acting on the substrate, 'commits suicide'. 2 a compound that is converted by a metabolic pathway into an inhibitor of the pathway, as with the conversion of fluoroacetate to fluorocitrate. If the pathway is of sufficient importance, the cell thereby 'commits suicide'. *See also* lethal synthesis.

sulfa drug any member of a group of sulfonamide compounds that are clinically useful in the treatment of bacterial infections. sulfamethoxazole 4-amino-N-(5-methyl-3-isoxalolyl)benzenesulfonamide; a sulfonamide antibacterial agent. As a mixture with trimethoprim it has the name co-trimoxazole (*proprietary names*: Bactrim; Septrim).

sulfane a chain of divalent sulfur atoms, as in hydrogen per sulfide (HSSH) or polysulfanes (H<sub>2</sub>S<sub>x</sub>; e.g. H<sub>2</sub>S<sub>8</sub> is pentasulfane).

sulfanilamide p-aminobenzenesulfonamide; *see* sulfonamide.

sulfatase *see* arylsulfatase.

sulfate or (*esp. Brit.*) sulphate the anion SO<sub>4</sub><sup>2-</sup>.

sulfate adenylyltransferase EC 2.7.7.4; *other names*: sulfate adenylate transferase; ATP-sulfurylase; sulfurylase; an enzyme that catalyses the formation of adenosine 5'-phosphosulfate (adenylylsulfate) from ATP and sulfate with release of pyrophosphate. Example from *Escherichia coli*, two subunits: database code CYSD\_ECOLI, 302 amino acids (35.16 kDa); database code CYSN\_ECOLI, 475 amino acids (52.50 kDa).

sulfatide a galactosyl cerebroside with a sulfate radical esterified at the 3' position of the galactose moiety. Sulfatides are formed by galactosylceramide sulfotransferase.

sulfatide lipidosis *an alternative name for* metachromatic leukodystrophy.

sulfation factor a factor originally identified as promoting sulfate uptake by cartilage *in vitro*; it is now known as somatomedin.

sulfhemoglobin any of a group of poorly characterized derivatives of hemoglobin, often formed *in vivo* together with ferrihemoglobin. They are incapable of carrying oxygen and cannot be converted back to hemoglobin.

sulphydryl or thiol the chemical group -SH; it is found in the amino acid cysteine and in other molecules. Two sulphydryls can be oxidized to a disulfide bond, -S-S-.

sulfite or (*esp. Brit.*) sulphite the anion SO<sub>3</sub><sup>2-</sup>.

sulfite reductase 1 sulfite reductase (NADPH) EC 1.8.1.2;

**sulfmethemoglobin**

*systematic name:* hydrogen sulfide:NADP<sup>+</sup> oxidoreductase; the enzyme responsible for interconversion of hydrogen sulfide and sulfite in plants and most bacteria. It catalyses the reduction of sulfite, e.g. released from 3'-phosphoadenosine 5'-phosphosulfate by thioredoxin. The reaction is:

cofactors are FAD, FMN, and siroheme. In plants and most microorganisms the H<sub>2</sub>S reacts with O-acetylserine to form cysteine and acetate. The enzyme also oxidizes H<sub>2</sub>S to sulfite. Example from *Thiocapsa roseopersicina*, two subunits: database code S34190, 522 amino acids (57.72 kDa); database code S34191, 561 amino acids (62.38 kDa). **2** sulfite reductase EC 1.8.99.1; *systematic name:* hydrogen-sulfide:(acceptor) oxidoreductase. An iron-protein enzyme that catalyses the reaction:

Example from *Archaeoglobus fulgidus*, two subunits: database code S27478, 418 amino acids (47.47 kDa); database code S27479, 366 amino acids (41.52 kDa).

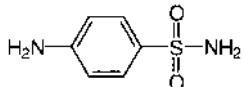

**sulfmethemoglobin** the complex formed by combination of sulfide with the ferric ion of ferrihemoglobin in poisoning by sulfide.

**sulf(o)+** or (*esp. Brit.*) sulph(o)+ of, or pertaining to, or containing a sulfur atom or group.

**sulfokinase** or aryl sulfotransferase EC 2.8.2.1; *other name:* phenol sulfotransferase; an enzyme that catalyses transfer of a sulfate radical from 3'-phosphoadenylylsulfate to a phenol to form an aryl sulfate.

**sulfolipid** any lipid containing sulfur, especially a sulfatide. *See also* sulfonolipid.

**sulfonamide** the amide of a sulfonic acid; the sulfonamide group is -SO<sub>2</sub>-NH<sub>2</sub>. In biology and medicine the name is used especially for any member of a large group of antibacterial substances - also known as sulfa drugs - derived from sulfanilamide (p-aminobenzenesulfonamide), many of which also have a substituent on the amide nitrogen.

sulfanilamide

**sulfone** the oxidation product that results when one oxygen atom is added to sulfur bonded to two alkyl chains.

**sulfonolipid** or plant sulfolipid 1,2-diacyl-3-(6-sulfo-a-D-quinosyl)-sn-glycerol; sulfoquinovosyldiacylglycerol (*abbr.:* SQDG); the only sulfolipid present in higher plants and the only lipid with a sulfonic-acid linkage reported so far; the predominant fatty acid is a-linolenic acid. Sulfonolipid is localized in the chloroplasts, mainly in the membrane of the thylakoid system.

**sulfoxide** the oxidation product that results when two oxygen atoms are added to sulfur bonded to two alkyl chains.

**sulfur** or (*esp. Brit.*) sulphur symbol: S; a yellow nonmetallic element of group 16 of the IUPAC periodic table; atomic number 16; relative atomic mass 32.066. Its main oxidation states are -2, +4, and +6. Sulfur exists in a number of forms including crystalline (rhombic, monoclinic, rhombohedral) and amorphous forms. The relative abundance of stable isotopes is: sulfur-32 (mass 31.972) 95.02%; sulfur-33 (mass 32.971) 0.75%; sulfur-34 (mass 33.968) 4.21%. There are two radioactive isotopes, sulfur-35 and sulfur-38. Sulfur is important as a constituent of the amino acids methionine and cysteine, and as a constituent of glutathione. It also occurs in sulfolipids. Sulfate is the terminal electron acceptor for anaerobic respiratory metabolism in certain bacteria e.g. *Desulfovibrio* spp.

sulfur-35 the radioactive nuclide,  $^{35}\text{S}$ , with a mass of 34.969. It

**supercritical fluid chromatography**

emits an electron ( $\beta^-$  particle, 0.167 MeV), no gamma radiation, and has a half-life of 87.4 days.

**sulfur-38** the radioactive nuclide,  $^{38}\text{S}$ , with a mass of 37.971. It emits an electron ( $\beta^-$  particle, 3.0 MeV) and gamma radiation (1.94 MeV), and has a half-life of 2.87 h.

**sulfurylase** *see* sulfate adenylyltransferase.

**sulph(o)+** *a variant spelling (esp. Brit.) of sulf(ol+).*

**sum** 1 the total value of a set of individual values. 2 to determine a sum.

**sumatriptan** 3-[(2-dimethylamino)ethyl]-N-methyl-IH-indole-5-methanesulfonamide; a preferential agonist for 5-HT<sub>1B</sub> receptors (*see* 5-hydroxytryptamine receptor). It causes constriction of cerebral blood vessels, and is used in the treatment of migraine and cluster headaches. *Proprietary name:* Imigran (succinate).

**summation** the determination of the sum (def. 1) of a series.

**Sumner, James Batcheller** (1887-1995), US biochemist; Nobel Laureate in Chemistry (1946) 'for his discovery that enzymes can be crystallized' [prize shared with J. H. Northrop and W. M. Stanley].

**SUMT** *abbr. for* S-adenosyl-L-methionine:uroporphyrin-III C-methyltransferase (*see* uroporphyrin-III C-methyltransferase).

**super+** prefix 1 above, over, at the top (of). 2 of greater size or extent, or of higher quality. 3 beyond the usual or normal standard; exceeding. 4 (*in chemical nomenclature*) designating a compound that contains more than the usual proportion of a specified element. *Compare* sub+, supraf.

**superantigen** an antigen with the ability to activate a large proportion (up to 20%) of T lymphocytes in a given individual through interaction with the variable domain of the  $\beta$  chain of the lymphocyte's antigen receptor. This contrasts with conventional foreign antigens the peptides of which, attached to the major histocompatibility complex (MHC), have to be specifically recognized by the T-cell receptor. With superantigens the specificity resides in the  $\beta$  chain of the receptor not the MHC peptides. This accounts for the fact that many more than usual T lymphocytes are activated. Superantigens are present in a number of bacteria and viruses; the best example is the *Staphylococcus* enterotoxin. Superantigens have been implicated in autoimmunity.

**supercoil** or **superhellix** or coiled coil the form of DNA that can be envisaged as resulting if a duplex were turned through a hairpin bend and the two duplex rails twisted one around the other. DNA *in vivo* generally is supercoiled, and as it has a closed structure, a supercoil may be envisaged as a rubber band twisted to a helical shape. In negative supercoiling the DNA twists around its axis in the opposite direction from the clockwise turns of the right-handed double helix; this allows relief of torsional pressure, and the DNA is said to be underwound. Twisting in the other direction (positive supercoiling) increases torsional pressure, winding the double helix more highly; the DNA is said to be overwound. Superhelix density,  $\omega$ , is defined as the number of turns of the superhelix,  $\tau$ , per turn of the duplex,  $f_1$ ; i.e.  $\omega = r/f_1$  ( $f_1$  represents about 10 base pairs). Linking number is the number of times the duplex strands cross over each other (in projection onto a plane surface). The number of superhelical turns is called the writhing number (W). **supercritical fluid**'!uomatography a technique that can be regarded as an extension of gas-liquid (partition) chromatography in which the mobile phase is a relatively dense gas such as CO<sub>2</sub> (or SF<sub>6</sub>, NH<sub>3</sub>, or Xc). The gas must be pumped (at pressures up to 6000 psi) through a capillary column that is coated with stationary phases similar to those used in gas chromatography. The system depends on the partition of the compounds being separated between the stationary and mobile phases and has the advantage that compounds with high boiling points partition appreciably into the gas phase at temperatures well below their boiling points so that such compounds can be separated at lower temperatures than with less dense gases.

## superfamily

superfamily any group of genes and their cognate proteins that can be held to be related by sequence homology. The main criterion determining homology is conservation of residues that can be matched, if necessary, by alignment of the sequence. Normally, similarity of function is an additional criterion, but proteins apparently not related in function may be included if the degree of sequence homology is high. *See also Appendix E.*

superfolding (of proteins) the formation of small domains, beyond the level of simple secondary structures, that are energetically stable and contribute as units to the full tertiary structure of a protein. They may consist of alpha **helices** or beta **sheets** or both. Nine such protein folds have been identified in proteins having neither sequence nor functional similarities. In the folding of a protein, they may be formed initially before the protein fully folds. Beta barrels represent an example.

superfusion 1 the pouring of a liquid onto or over something. 2 (in physiology and medicine) a technique in which blood, plasma, or other fluid is allowed to drip onto, or flow over, the surface of an organ or piece of tissue.

supergene a group of linked genes (see linkage (def. I») that are usually inherited as a unit.

superhelix *an alternative name/or supercoil.*

superhelix density *see supercoil.*

superinfection the proliferation of one or more pathogenic microorganisms arising from the disturbance of a mixed population of microorganisms normally sustained at non-pathogenic levels by secretion of endogenous antibiotics. Such disturbance can be induced by administration of exogenous antibiotic agents.

superinfection inhibition interference with the entry or establishment of an entering plasmid by a resident plasmid.

supernatant 1 floating on the surface of a liquid or lying over something. 2 (or supernate) a liquid lying above another liquid, a sediment, or a settled precipitate. b the fluid phase that remains after removal of solid material by centrifugation. A cell supernatant is the fluid phase that remains after centrifugation of a cell homogenate at high speed (characteristically at 100 000g for 30 min). *Compare infranatant.*

supernate *an alternative name for supernatant (def. 2).*

superoxide 1 the anion, O<sub>2</sub><sup>-</sup>, formed by addition of one electron to dioxygen. 2 any compound containing the superoxide anion.

superoxide dismutase abbr.: SOD; Ee 1.15.1.1; systematic name: superoxide:superoxide oxidoreductase; other names: cytocuprein; erythrocuprein; hemocuprein. Any of a group of metal-containing enzymes that bring about the dismutation of superoxide radicals to form dioxygen and hydrogen peroxide as follows:

It is important in removing the highly toxic superoxide radical. Some (e.g. those from *Neurospora*, yeast, erythrocytes, heart, peas) contain copper and zinc; others (e.g. those from *Escherichia coli*, *Streptomyces mutans*) contain manganese or iron. Eukaryotic cells have copper-zinc types in cytoplasm and manganese types in mitochondria. The copper-zinc types comprise a well-conserved family with four motifs. Examples: (1) copper-zinc type (bovine): database code NRL\_2S0DO, 151 amino acids (15.53 kDa); 3-D structure known; (2) manganese type (heterodimer) from human; chain A: database code NRL\_IMSDA, 198 amino acids (22.18 kDa); 3-D structure known; chain B: database code NRL\_1 MSDB, 198 amino acids (22.18 kDa); 3-D structure known; (3) iron type (heterodimer) from *Pseudomonas putida*; chain A: database code NRL\_3SDPA, 186 amino acids (20.47 kDa); 3-D structure known; chain B: database code NRL\_3SDPB, 186 amino acids (20.47 kDa); 3-D structure known.

supported reagent any reagent linked to a support medium.

support medium any (usually solid or insoluble) medium to which a cell, reagent, or functional group can be attached.

## surface tension

suppression 1 (*in molecular biology*) the cancellation, or reversal of the effects, of one mutation by another mutation, except where the second mutation causes a single base change at the same point as an earlier point mutation (in which case the term reversion is used). In intergenic suppression, the effects of a mutation in one gene are reversed by a mutation in another gene, usually because the second gene codes for a mutant tRNA (see frameshift suppressor). In intragenic suppression a mutation is cancelled by a second mutation close to the first in the same gene, normally within the same triplet, giving rise to a codon that is compatible with translation to a functional protein product. As an example, if the first mutation changed AGT (leading to the RNA codon for Ser) to ATT (giving a nonsense codon), a suppressor mutation might change the triplet to ATA (giving the RNA codon for Tyr); if the change Ser to Tyr led to a functional protein, suppression would be achieved. *See also amber suppressor, ochre suppressor, opal suppressor.* 2 (*in immunology*) any attenuation of an immune response. The existence of a subpopulation of T cells, suppressor cells, is held to be responsible for attenuation of the effect of helper cells. A different mechanism is probably responsible for the reduction in antibody production arising from injection of antibody prior to administration of antigen. Allotype suppression refers to suppression of the production of one allotype (e.g. expression of the allotype inherited from the mother, and suppression of the allotype of the father).

suppressor cell or suppressor T cell or T-suppressor cell any of a subset of T lymphocytes that exert a negative regulatory effect (*see suppression (def. 2»)* on the stimulation of the immune response by helper cells. Classically they belong to the CD8<sup>+</sup> subset in the human. Induction of the suppressor function may derive from helper cells.

suppressor gene a gene that by its presence can reverse the effect of a specific type of mutation in another gene. *See suppression (def. 1).*

suppressor mutation a secondary mutation that totally or partially restores a function lost due to a primary mutation at another locus. *See suppression (def. 1).*

suppressor tRNA any species of transfer RNA (tRNA) that recognizes a termination codon in messenger RNA. It adds an amino-acid residue to what is normally the C terminus of a nascent polypeptide chain; hence termination of synthesis of the peptide is suppressed and a readthrough protein is consequently formed. Suppressor tRNA may occur naturally or be produced by mutagenesis.

supra+ *prefix above, over, greater than. Compare infra+, super+.*

supramolecular describing any chemical system or component thereof that exists and functions at a higher level of complexity than intact individual molecules. In biochemistry the term may refer to multienzymes, microtubules, organelles, biological membranes, viral envelopes, cell walls, ribosomes, or other cellular elements; hence, e.g., supramolecular assembly, supramolecular complex, supramolecular structure. *Compare submolecular.*

Suprarenal gland *an obsolete term/or adrenal gland.*

suprarenin *a former name for adrenaline (i.e. epinephrine).*

Sur symbol for a residue of the thiopyrimidine base thiouracil.

surface-active agent *an alternative term/or surfactant.*

surface concentration *see concentration (def. 1).*

surface-stress theory a theory that considers the problem of mechanical stress in relation to enlargement of the bacterial cell wall during growth. The cell wall withstands stress from hydrostatic pressure by a stress-bearing, two-dimensionally linked peptidoglycan sacculus that surrounds the cell. During enlargement, enzymes that enlarge the wall must at the same time maintain the hydrostatic integrity of the cell by withstanding stress.

surface tension symbol:  $\gamma$  or  $\sigma$  or  $\gamma$ ; the property that makes a liquid behave as if it had an elastic skin on its surface - at an interface with a gas or an immiscible liquid - as a result of intermolecular forces tending to pull the molecules in the sur-

## surfactant

face into the interior of the liquid. It is defined as the force acting tangential to the surface on one side of a line of unit length in the surface, and is expressed in newtons per metre. It can also be defined as the work required to produce unit increase in surface area, expressed in joules per square metre.

**surfactant** or surface-active agent any substance, such as a detergent or an emulsifier, that can bring about a reduction of the surface tension of a liquid, allowing it to foam, to penetrate porous solids more easily, and to wet surfaces of nonporous solids or of immiscible liquids.

**surfactin** a surface-active antibiotic and nonimmunogenic hemolysin produced extracellularly by *Bacillus subtilis*. It consists of a nonapeptide (containing *inter alia* two residues each of L- and D-Ieucine) in cyclic depsipeptide linkage with  $\beta$ -hydroxy- $\omega$ -methylmyristic acid.

**surrogate genetics** a branch of molecular genetics in which DNA is modified *in vitro* and then reintroduced into a genetic system - the 'surrogate' system - e.g. by injection into *Xenopus* oocytes, by transfection of cells, or by the creation of transgenic animals. The effect of the modification on the expression of the gene provides insights into the role in the genetic system of particular base sequences.

**surveyor substrate** one of a system of fluorescent substrates designed to measure distances within the active centre of an enzyme and also to survey other aspects of the topography of the active centre during the catalytic event.

**survivin** a protein expressed in the G<sub>2</sub>/M phase of the cell-division cycle that associates with microtubules of the mitotic spindle. It inhibits apoptosis.

**Sushi domain** a polypeptide domain of approximately 60 amino acids that contains disulfide bonds between the first and third and second and fourth cysteines, as found in  $\beta_2$  glycoprotein-I of plasma, in complement proteins, and in blood coagulation factor XIII.

**suspension culture** the culture of cells in medium without adherence to a stationary substrate. Relatively few animal cell types are amenable to suspension culture (classically HeLa cells can be so grown). An intermediate situation utilizes beads to which the cells adhere; the beads can be maintained in suspension and collected by sedimentation

**Sutherland**, Earl Wilbur Jr (1915-74), US biochemist; Nobel Laureate in Physiology or Medicine (1971) 'for his discoveries concerning the mechanisms of the action of hormones'; these included the discovery of cyclic AMP.

**suxamethonium** succinylcholine chloride, 2,2'-[(1,4-dioxo-1,4-butanediyl)bis(oxy)]bis[N,N,N-trimethylethanaminium] dichloride; a nicotinic receptor ligand that causes sustained activation of the receptors leading to blockade of synaptic transmission ('depolarizing block'). It is used as a neuromuscular blocking agent in surgery. It acts by mimicking acetylcholine at the neuromuscular junction, but disengagement from the receptor site and subsequent breakdown are slower than for acetylcholine. It is hydrolysed by serum cholinesterase and recovery is spontaneous. Decamethonium was the first drug of this type to be developed. Both of these compounds depend for their action on the N+–N+ distance of 1.1 nm. Compare curare, tubocurarine.

**Sv** symbol for 1 sievert. 2 svedberg (alternative to S).

**SV40 abbr.** for simian virus 40.

**svedberg** or Svedberg unit symbol: S or Sv; a coherent non-SI unit used as a measure of sedimentation coefficient; 1 S = 10<sup>-13</sup> s. Svedberg, Theodor (1884-1971), Swedish colloid chemist noted for his invention (in 1923) of the ultracentrifuge; Nobel Laureate in Chemistry (1926) 'for his work on disperse systems'.

**Svedberg centrifuge** a centrifuge, designed and built by Svedberg in 1923, that was the forerunner of the ultracentrifuge.

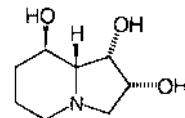

**Svedberg equation** an equation relating the relative molecular mass,  $M_r$ , of a solute to its sedimentation velocity in an applied centrifugal field. If  $s$  is the sedimentation coefficient,  $D$  is the diffusion coefficient,  $\bar{v}$  is the partial specific volume of

## symmetry

the solute,  $p$  is the density of the solution,  $R$  is the gas constant, and  $T$  is the thermodynamic temperature, then

$$M_r = sRTID(I - \bar{v}p),$$

**swainsonine** 8a,p-indolizidine-1a,2a,Sp-triol; an inhibitor of a number of a-mannosidases, particularly Golgi mannosidase II (*see* Goigi mannosidase), an important enzyme in the synthesis of the core oligosaccharide of a number of membrane glycoproteins. It inhibits the growth of tumours and prevents metastases in mice. [After its source, *Swainsona canescens*.]

**swaposin** a form of protein homology in which domains, characteristically found in one protein, are found arranged in other proteins in a different order. The phenomenon was first commented on in relation to certain plant aspartic peptidases, which contain saposin-like domains swapped into a different order to that found in saposins (hence the name). In another example some pleckstrin homology domains are found to be interrupted by inserts of SH domains.

**sweetener** any compound intended as a substitute for sucrose in sweetening food or drink, and aimed at avoiding the possible harmful effects of sucrose. Such compounds therefore should be nonnutritive but with a taste and aftertaste similar to those of sucrose; they should also be nonharmful. They include aspartame, lactitol, mannitol, monellin, saccharin, stevia, sucralose, and volemitol. Sodium cyclamate was used as a sweetener until it was banned in the USA in 1970 because of its carcinogenicity.

**sweetness** one modality of the sense of taste, characterized by the effect of certain sugars such as sucrose and fructose.

**swinging-bucket rotor** a type of centrifuge head in which the centrifuge tubes are placed in buckets that swivel on trunnions so that at speed the tube is oriented with its axis parallel to the centrifugal force (i.e. horizontal). Such a head is essential for zonal centrifugation through density gradients as angled tubes induce mixing. *Compare* angle head.

**SwissProt** a protein sequence database maintained by the University of Geneva. It contains sequences of many proteins and references to articles in which the sequences were reported, together with a limited amount of general information and the name of the gene that encodes the protein.

**switch peptide** the flexible covalent connection between the variable region and constant region of an immunoglobulin molecule.

**switch recombinase** *see* homothallic switching endonuclease.

**swivelase** *see* DNA swivelase.

**SYBASE** a relational database used, e.g., for HUGO.

**sym+** a variant form of fsyn+ (before b, m, or p).

**sym- prefix** (*in chemical nomenclature*) denoting symmetric; e.g. sym-trinitrobenzene.

**symbiont** an organism that lives as a partner in a symbiosis.

**symbiosis** (*pl.* symbioses) a long-term association between individuals belonging to two different species. The term is often used in a restricted sense to denote associations that are beneficial to one or both partners, although strictly it refers equally to neutral or harmful associations. *-symbiotic ad.*

**symmetry** precise correspondence between two halves with respect to both size and shape. A molecule has an  $n$ -fold axis of symmetry if rotation around this axis through an angle of 360°/ $n$  produces an arrangement indistinguishable from the original ( $n$  being a small integer). For example, water has a twofold ( $n$  = 2) axis of symmetry. A plane of symmetry is a plane drawn through a molecule such that a mirror placed in

**sympathectomy**

this plane forms an image of one half of the molecule that is superimposable on the other half. For example, a plane of symmetry is present in *meso-tartaric acid*. An alternating axis of symmetry or rotation-reflection axis is an axis such as is present in a molecule when rotation around the axis through an angle of  $360^\circ$  followed by reflection in a plane perpendicular to the axis produces a molecule superimposable on the original molecule. For example, a compound with such a twofold ( $n = 2$ ) axis is fumaric acid. A centre of symmetry is a position (point) such that if a straight line is drawn from every atom to the point, and is continued beyond the point, an equivalent atom is found at a distance equal to that between the point and the original atom. A molecule with such a centre has a twofold alternating axis of symmetry. An example of a molecule with a centre of symmetry is fumaric acid.

**sympathectomy** the surgical section of sympathetic nerve fibres.

**sympathetic nervous system** one of the two divisions of the autonomic nervous system the other being the parasympathetic nervous system. Most, but not all, sympathetic nerves release norepinephrine as a neurotransmitter.

**sympatheticomimetic** *an alternative term for sympathomimetic.*

**sympathomimetic** or **sympatheticomimetic** 1 describing a substance or action that stimulates the sympathetic nervous system; adrenergic. 2 a sympathomimetic agent, especially a sympathomimetic amine.

**symport** or **cotransport** the process of solute translocation in which two solutes equilibrate across an osmotic barrier, and the translocation of one solute is coupled to the translocation of the other in the same direction. *Compare antiport.*

**symporter** any substance or structural feature that promotes the exchange diffusion of two specific substances across a membrane by symport.

**syn-** abbr. for synclinal (def. 1); *see also* conformation.

**syn+ comb. form** signifying similarity, association, or concerted action.

**Synacthen** *see* tetracosactide.

**synaeresis** *a variant spelling of* syneresis.

**synapse** or (rare) **synapsis** the junction between a nerve fibre of one neuron and another neuron; the site of interneuronal communication. As the nerve fibre approaches the synapse it enlarges into a specialized structure, the presynaptic nerve ending, which contains mitochondria and synaptic vesicles. At the tip of the nerve ending is the presynaptic membrane; facing it, and separated from it by a minute cleft - the synaptic cleft - is a specialized area of membrane on the receiving cell, known as the postsynaptic membrane. In response to the arrival of nerve impulses, the presynaptic nerve ending secretes molecules of neurotransmitters into the synaptic cleft. These diffuse across the cleft and transmit the signal to the postsynaptic membrane. *See also* neuromuscular junction. *-synaptic adj.*

**synapsin I** a major neuron-specific protein present in virtually all synaptic vesicles. Phosphorylated at multiple sites by  $\text{Ca}^{2+}$ -calmodulin-dependent and cyclic AMP-dependent protein kinases, it coats synaptic vesicles and binds to the cytoskeleton. Example, precursor for human synapsin IA: database code SYNLHUMAN, 705 amino acids (73.92 kDa); synapsin IB is derived by alternative splicing; synapsins II are related.

**synapsis** 1 the pairing of chromosomes during meiosis. 2 *a less common word for* synapse.

**synaptic cleft** the extracellular space, typically some 20 nm across, that separates the outer membrane of the presynaptic nerve ending from the postsynaptic membrane of the receiving neuron (or other target cell) in a synapse. Chemical mediation of nerve transmission occurs across the synaptic cleft.

**synaptic vesicle** a vesicle, 20–65 nm in diameter, occurring within the cytoplasm of the presynaptic nerve ending and often closely related to the presynaptic membrane (*see synapse*). Synaptic vesicles store neurotransmitters and release them by fusing with the presynaptic membrane.

**syncytium**

**synaptic vesicle-associated membrane protein** *another name for* synaptobrevin.

**synaptobrevin** or **sinaptobrevin** or **synaptic vesicle-associated membrane protein** (abbr.: VAMP) a SNAP receptor involved in the docking and fusion complex (*see SNARE*) of synaptic vesicles and playing a central role in neural exocytosis. Synaptobrevin isoforms I and 2 (VAMP-1 and VAMP-2) are known. Both are expressed in all the main rat tissues, but differential expression is found, e.g. VAMP-I is restricted to exocrine pancreas and kidney tubular cells, VAMP-2 predominates in islets of Langerhans and kidney glomerular cells. Example from *Drosophila melanogaster* (similar to fish and mammalian proteins): database code SYB\_DROME, 152 amino acids (16.69 kDa).

**synaptotjanin** a protein found in brain in nerve terminals, that has inositol 5-phosphatase activity and binds to the SH3 domain of amphiphysin, colocalizing with that protein in double immunofluorescence micrographs. It appears to participate with dynamin in synaptic vesicle recycling. It has homology with the yeast protein Sac1, which is genetically implicated in phospholipid metabolism and the function of the actin cytoskeleton. mRNA sequence from *Rattus norvegicus*: database code RNU45479.

**synaptonemal complex** a structure that holds paired chromosomes together during prophase I of meiosis and that promotes genetic recombination.

**synaptophysin** an integral membrane glycoprotein that occurs in presynaptic vesicles of neurons and in similar vesicles of the adrenal medulla. A marker protein for neuroendocrine cells and neoplasms, it has the attributes of a vesicular channel protein. Example from rat: database code SYNP\_RAT, 265 amino acids (29.03 kDa).

**synaptosome** any of the discrete particles (nerve-ending particles) formed from the clublike presynaptic nerve endings that resist disruption and are snapped or torn off their attachments when brain tissue is homogenized in media isosmotic to plasma. In synaptosomes the main structural features of the nerve endings are preserved.

**synaptosome-associated protein** *see* SNAP (def. 2).

**synaptotagmin** an abundant integral membrane protein of synaptic vesicles and chromaffin granules with a proposed role in membrane interactions during trafficking of synaptic vesicles at the active zone of the synapse. The primary structure contains two copies of a repeat that is homologous to the regulatory domain of protein kinase C. Example, homotetramer, human synaptotagmin I (*other name:* p65): database code SYTLHUMAN, 422 amino acids (47.52 kDa).

**synarchic regulation** *see* synarchy.

**synarchy** cooperation between two intracellular messengers (e.g. cyclic AMP and  $\text{Ca}^{2+}$ ) that act in concert to activate intracellular pathways.

**syncatalytic** synchronous with the catalytic process.

**synchrotron** an apparatus used in nuclear physics that accelerates particles of atomic size through an electric field. The particles are initially charged by an ion source, and their path may be linear (linear accelerator) or of spiral form (cyclotron). The acceleration imparts a high kinetic energy to the particles, which can lead to structural changes in the particles. One use of a synchrotron, therefore, is the production of radioactive or other nuclides for use in biology or medicine. A synchrotron radiation source is a circular storage ring in which electrons are accelerated in a magnetic field.

**synclinal** 1 abbr.: *syn-*; describing one of the two possible conformations of the base and sugar ring in a nucleotide, the other being the anticlinal conformation. *See* conformation. 2 or (sometimes) **gauche** or **skew** abbr.: *sc-*; describing a particular staggered conformation of a molecule in which the torsion angle is within  $\pm 60^\circ$  of  $0^\circ$ . *See* conformation.

**syncytium** (*pl.* syncytia) a mass of cytoplasm containing several nuclei enclosed within a single plasma membrane. Syncytia are normally derived from single cells that fuse or fail to

complete cell division. Examples are muscle fibres, formed by fusion of myoblasts, and residual bodies formed during spermatogenesis.

**SYND2** abbr. for syndecan-2. See syndecan.

**syndecan** a type I integral membrane proteoglycan that links the cytoskeleton to the interstitial matrix. It bears heparan sulfate and chondroitin sulfate and binds to bFGF (see fibroblast growth factor) with high affinity, and also to components of the extracellular matrix. Its intracellular domain binds to the actin cytoskeleton. Examples (precursors) from human, syndecan-1: database code SDC1\_HUMAN, 310 amino acids (32.44 kDa); syndecan-2 (abbr.: SYND2); (other names: fibroglycan; heparan sulfate proteoglycan core protein; (abbr.: HSPG); database code SDC2\_HUMAN, 201 amino acids (22.15 kDa).

**syndein** an alternative name for ankyrin.

**syndesine** a di(a-amino acid) isolated from hydrolysates of certain collagens, in which it forms covalent cross-links between adjacent polypeptide strands. It is formed by aldol condensation between the side chains of a residue of allysine and one of hydroxyallysine; two isomers are possible.

**syndiotactic** having or relating to a regular alternation of differences in stereochemical structure in the repeating units of a polymer. Compare isotactic.

**syndiotactic polymer** a regular polymer composed of molecules having a regular repetition of alternating enantiomeric configurational base units at least at one main-chain chiral or prochiral atom in the configurational base unit.

**syndrome** a set of concurrent symptoms characteristic of a particular pathological state.

**synemin** a protein, M<sub>r</sub> 230000, that is found in the Z disk of skeletal and cardiac muscle cells and in intermediate filaments of some nonmuscle cells. It binds tightly to desmin.

**synenkephalin** or **proenkephalin 1-70** a derivative of proenkephalin secreted as an intact molecule or as a part of precursors in the adult brain and adrenal medulla. It has the immunoreactivity of proenkephalin but does not contain the enkephalin sequence.

**syneresis** or **synaeresis** 1 (in chemistry) the separation of liquid from a gel caused by contraction of the gel structure. 2 (in pathology) the gradual contraction of a blood clot that occurs after its formation, leading to a more solid mass that seals the ruptured blood vessel.

**synergism** 1 the phenomenon whereby the effect of two or more agonists together is greater than the sum of their effects when used individually. 2 the concerted action of two muscles to enhance their combined effects. Compare antagonism. -synergistic or synergistic adj.

**synergist** 1 an agent that increases the effectiveness of another agent. 2 a muscle that acts in concert with another muscle to increase its effect. Compare antagonist.

**synexin** or **annexin VII** a cytosolic Ca<sup>2+</sup>-dependent lipid-binding protein belonging to the annexin family. Originally isolated from adrenal medullary cells, isoforms have since been found in skeletal muscle, brain, and liver, and also in *Dictyostelium discoideum*. Adrenal medulla and liver have isoforms of 47 kDa and 51 kDa, while skeletal muscle has only the 51 kDa isoform. Synexin promotes membrane fusion, aggregates isolated chromaffin granules, and forms voltage-dependent calcium channels in artificial and natural membranes.

**syngamy** the union of the nuclei of two gametes to form the single nucleus of the zygote during fertilization; sexual reproduction. -syngamic or syngamous adj.

**Synge**, Richard Laurence Millington (1914-94), British biochemist and peptide chemist; Nobel Laureate in Chemistry (1952) jointly with A. J. P. Martin 'for their invention of partition chromatography'.

**syngeneic** of or pertaining to cell types in an experimental mammalian chimera that are antigenetically similar. Compare allogeneic.

**synonym codon** a synonym triplet in messenger RNA.

**synonymous mutation** an alternative name for silent mutation.

**synonym triplet** any of the two or more sequences of three purine and/or pyrimidine bases in nucleic acids that may specify the same amino acid. In messenger RNA the term is synonymous with synonym codon.

**synovia** or **synovial fluid** the fluid surrounding a joint or filling a tendon sheath.

**synovial membrane** or **synovium** the membrane of mesothelial cells and connective tissue that surrounds a joint; it secretes the synovia.

**synovium** an alternative name for synovial membrane.

**synperiplanar** see conformation.

**syntaxin** a SNAP receptor (SNARE) involved in docking of synaptic vesicles at the presynaptic zone of a synapse. Example, syntaxin A from rat: database code SYNA\_RAT, 288 amino acids (33.03 kDa).

**syntenic genes** gene loci or genes that lie on the same chromosome.

**synthase** a generic name that may be added to the name of a substance to designate an enzyme catalysing a reaction in which the named substance is synthesized. The synthases are distributed amongst various systematic classes of enzymes – e.g. glycogen synthase is in class EC 2 and malate synthase is in class EC 4 – although until 1984 no enzyme of class EC 6 (ligases) could be so named. Now the term is used also to form the recommended names of a few enzymes where the reaction is complex and there is a common name for the product (e.g. E<sub>6</sub> 6.3.2.11, carnosine synthase). The majority of enzymes in the EC 6 class now have recommended names ending in ligase, e.g. EC 6.5.1.3, RNA ligase (ATP), which has also been termed polyribonucleotide synthase (ATP). In the past, the term synthase was frequently used interchangeably with synthetase.

**synthase-phosphorylase kinase** EC 2.7.1.37; recommended name: protein kinase; other names: phosphorylase b kinase kinase; glycogen synthase a kinase; hydroxyalkyl-protein kinase; serine(threonine) protein kinase. A serine/threonine protein kinase that catalyses phosphorylation of several proteins as indicated by the names above; it is activated by phosphorylation by cyclic AMP-dependent protein kinase. In addition to regulating the glycogen phosphorylase/synthase enzymes, it can activate the ATP,Mg<sup>2+</sup>-dependent (AMD) protein phosphatase and other proteins. Example, GSK-3 (rat), a serine protein kinase implicated in the hormonal control of several regulatory proteins including glycogen synthase, Myb protein, and the transcription factor product of *c-jun*; monomer: database code KG3B\_RAT, 420 amino acids (46.69 kDa). See also phosphorylase kinase.

**synthesis** (in chemistry) the production of a more complex molecule from simpler reagents by one or a series of reactions.

-synthesize or synthesise vb.

**synthesizer** or **synthesiser** an instrument that automates a chemical synthesis, especially of peptides or oligonucleotides.

**synthetase** 1 an old class name, still widely used but no longer recommended, for any enzyme of class EC 6; these enzymes are now classified under the systematic class name ligase. 2 a generic name that may be added to the name of a substance to form the common name of any ligase-class enzyme that catalyses a reaction producing the named substance with concomitant breaking of a diphosphate linkage in a nucleoside triphosphate; e.g. acetyl-CoA synthetase (EC 6.2.1.1, acetate-CoA ligase), glutamine synthetase (EC 6.3.1.2, glutamate-ammonia ligase is recommended). Until 1984 names so formed were often the recommended names of such enzymes; now, the generic names ligase or synthase are used to form the recommended names, although common names formed from synthetase are still acceptable. In the past, the term synthetase was frequently used interchangeably with synthase.

**synthetic** 1 of, or pertaining to, synthesis. 2 (of a substance or material) chemically synthesized as opposed to prepared from recognizable natural materials. Such a product is identical chemically to that isolated from the natural source.

**synxenic**

**synuclein** a brain presynaptic protein that is expressed also in other tissues, but at very low levels. It is highly conserved, rodent and zebrafish  $\alpha$  synucleins being 95% and 86% identical to human. Some mutations are linked to familial Parkinson's disease. Example: SYUA\_HUMAN, 140 amino acids (14.46 kDa).

**synxenic** pertaining to the growth of organisms of a single species in the presence of one or more other species. A culture in which one other species is involved is described as monoxenic; with two other species it is dixenic; and with three it is trixenic. Cultures with more than three additional species are described as polyxenic. Compare axenic. -synxenite *n.*; -synxenite or synxenise *vb.*

**synxenite** the principal organism being studied in a synxenic culture.

**syrup** or **sirup** 1 a thick, sticky, viscous liquid consisting of a concentrated aqueous solution of sucrose. 2 the concentrated juice of a fruit or plant, especially of sugar cane. 3 any solution that is thick, sticky, and viscous.

**system A** one of the transport systems responsible for the uptake of neutral amino acids by animal cells. It is most reactive with amino acids having short, polar or linear side chains, including the nonmetabolizable 2-aminoisobutyric acid. Transport is sodium ion-dependent and is reduced by lowered extracellular pH. System ASC, prominent in erythrocytes, is distinguished from system A on the basis of pH insensitivity and higher stereospecificity. See also sodium/neutral amino acid cotransporter, system L, system N.

system ASC see system A.

**systematic name** 1 (*in organic-chemical nomenclature*) a name of a molecular entity that is composed wholly of specially coined or selected syllables, with or without numerical affixes and locants; e.g. oxazole, pentane, cyclohex-2-en-1-ol. Such a name unequivocally specifies the complete chemical structure of a particular molecular entity. Compare semisystematic name, trivial name. 2 (*in enzyme nomenclature*) a name of an enzyme that describes its catalytic action as exactly as possible, thus identifying the enzyme precisely. Such names are formed in accordance with definite rules, which provide the basis for classifying enzymes according to the type of reaction catalysed and for assigning code numbers to them. One important consequence of this method of classifying is that, with certain exceptions, all proteins having the same catalytic property share the same systematic name and code number irrespective of their source and structure. To simplify classification, the direction of the reaction catalysed is chosen to be the same for all enzymes in a given class, even if only the reverse reaction has been actually demonstrated experimentally for a particular enzyme. A systematic enzyme name consists of two parts: the first contains the name of the substrate or, in the case of a bimolecular reaction, of the two substrates separated by a colon (with small and equal spaces before and after the

**Szent-Gyorgyi**

colon); and the second, ending in '+ase', indicates the nature of the catalysed reaction.

**systematics** functioning as sing. 1 the study of systems, especially the principles of classification. 2 (*in biology*) the discipline that deals with classification and nomenclature.

**Système International** abbr.: SI; Système International d'Unités; a system of units based on the metric system. See 51 units.

**systemic** concerning the whole body of an animal or a whole plant rather than an individual part.

**systemic circulation** the blood vessels supplying all parts of the body except the lungs.

**systemin** an 18-residue polypeptide, isolated from tomato leaves, that acts as a potent activator of plant proteinase inhibitor genes. It induces synthesis of two proteinase inhibitors in tomato and potato leaves. It is the only plant polypeptide hormone-like signalling molecule presently known. It has the sequence

and is proteolytically processed from a 200-residue precursor, prosystemin. Example: database code SYST\_LYCES, 200 amino acids (23.00 kDa). Plant proteinase inhibitors are induced by wounding, e.g. by insects or pathogens, and may be part of the plant defence mechanisms.

**system L** one of the transport systems responsible for the uptake of neutral amino acids by animal cells. It is most reactive with branched-chain and aromatic amino acids such as leucine, isoleucine, valine, phenylalanine, and the nonmetabolizable analogue 2-aminobicyclo-[2,2,1]-heptane-2-carboxylic acid (BCH). The transport mechanism is sodium-ion-independent and may be stimulated by lowered extracellular pH. System L has been described in a wide variety of animal cell types, including avian and mammalian. Example from *Pseudomonas aeruginosa*: database code BRAZ\_PSEAE, 437 amino acids (45.27 kDa). See also sodium/neutral amino-acid cotransporter, system A, system N.

**system N** one of the transport systems responsible for the uptake of amino acids by animal cells. It is a sodium-ion-dependent system specific to asparagine, glutamine, and histidine. See also sodium/neutral amino acid cotransporter, system A, system L.

**systole** a rhythmical repeated contraction, as of the chambers of the heart or of a pulsating vacuole. Compare diastole. -systolic adj.

**Szent-Gyorgyi** Albert Szent-Gyorgyi von Nagyrapolt (1893-1986), Hungarian-born US biochemist distinguished for his work in a variety of fields, including the isolation of ascorbic acid, the role of dicarboxylic acids in oxidative metabolism, and the biochemistry of muscle contraction; identified adenylic acid; Nobel Laureate in Physiology or Medicine (1937) 'for his discoveries in connection with the biological combustion processes, with special reference to Vitamin C and the catalysis of fumaric acid'.

# Tt

**t** 1 symbol for a tert+ (i.e. tertiary) in a chemical name (alternative to *t*). 2 triton (def. 2). 2 abbr. for terminator sequence.

**t** symbol for 1 time. 2 Celsius temperature (alternative to *B*). 3 transference number.

- abbr. for 1 *tert*-, 2 *trans*-.

**$T_{1/2}$**  symbol for half-life. See also  $T_{1/2}$ .

**T** symb()! for 1 tera+ (SI prefix denoting  $10^{12}$  times). 2 tritium. 3 tesla. 4 a residue of the a-amino acid L-threonine (alternative to Thr). 5 a residue of the base thymine in a nucleic-acid sequence. 6 a residue of the ribonucleoside ribosylthymine (*not* thymidine, i.e. deoxyribosylthymine; alternative to Thd). 7 twist number.

**T** symbol for 1 thermodynamic temperature. 2 transmittance. 3 period. 4 kinetic energy (alternative to  $E_K$  or *K*).

**T** conformational descriptor designating the twist conformation (def. 2) of a five-membered ring form of a monosaccharide or monosaccharide derivative. Locants of ring atoms that lie on the side of the structure's reference plane from which the numbering appears clockwise are indicated by left superscripts and those that lie on the other side of the reference plane are indicated by right subscripts; e.g. 1,2-O-isopropylidene-p-L-ido-furanose-<sup>3</sup>*T*<sub>2</sub>. See also conformation.

**$T_{1/2}$**  symbol for half-life of a radionuclide (alternative to  $t_{1/2}$ ).

**T<sub>1</sub>**, symbol for spin-lattice relaxation time, longitudinal relaxation time.

**T<sub>2</sub>**, symbol for spin-lattice relaxation time, transverse relaxation time.

**T<sub>m</sub>** or  $t_m$  or  **$\Theta_m$**  symbol for melting temperature.

**T<sub>t</sub>** symbol for transition temperature.

**T1** abbr. for bacteriophage T1, a T-odd phage.

**T2** 1 or **T<sub>2</sub>** symbol for L-diiodothyronine. 2 abbr. for bacteriophage T2, a T-even phage.

**T3** 1 or **T<sub>3</sub>** symbol for L-triiodothyronine. 2 abbr. for bacteriophage **N**, a T-odd phage.

**T4** *or* **T<sub>4</sub>** symbol for L-thyroxine. 2 abbr. for bacteriophage T4, a T-even phage.

**T6** abbr. for bacteriophage T6, a T-even phage.

**T7** abbr. for bacteriophage T7, a T-odd phage.

**TA** symbol for N<sup>6</sup>-(threonylcarbamoyl)adenosine; see hypermodified base.

**Ta** symbol for tantalum.

**tachometer** an instrument that measures the speed at which any object is rotating. -tachometric *ad.*; tachometry *n*.

**tachy+** comb. form denoting fast or rapid.

**tachykinin** any of a group of closely related vasoactive peptides characterized by a rapid stimulant effect on vascular (and extravascular) smooth muscle, producing hypotension (compare bradykinin). They also directly effect nervous tissue and stimulate salivary and lachrymal secretion. Naturally occurring tachykinins are oligopeptide amides containing 10-12 amino-acid residues and terminating in the common sequence -Phe-Xaa-Gly-Leu-Met-NH<sub>2</sub> (where Xaa = Phe, Tyr, ile, or Val). Mammalian tachykinins include neuromedin K, neurokinin A (formerly substance K), and substance P; others (e.g. eledoisin, physalaemin) occur in amphibians and octopods. Substance P and neurokinin A are generated from a prepro-tachykinin protein precursor (see protachykinin  $\beta$  precursor). The primary mRNA transcript is differentially processed into three mature mRNAs:  $\alpha$ ,  $\beta$ , and  $\gamma$ ; the  $\beta$  and  $\gamma$  prepro-tachykinin mRNAs are predominant in the rat, each encoding substance P and neurokinin A. Example, human (precursor): database code TKNB\_HUMAN, 129 amino acids (15.00 kDa).

**tachykinin receptor** any of a number of membrane proteins that bind tachykinins and mediate their transmembrane action. They fall according to the relative potency of agonists into three classes: (1) NK<sub>1</sub> (407 amino acids, human), agonist po-

tency: substance P (SP) > neurokinin A (NKA) > neurokinin B (NKB); (2) NK<sub>2</sub> (398 amino acids, human), agonist potency: NKA > NKB > SP; and (3) NK<sub>3</sub> (452 amino acids, rat), agonist potency: NKB > NKA > SP. All are of the seven-transmembrane-domain type and share significant sequence similarity with G-protein-coupled receptors. The effector pathway in all cases is by activation of phosphoinositide-specific phospholipase C. Example of putative receptor from human: database code TXKR\_HUMAN, 440 amino acids (49.43 kDa).

**tachyphylaxis** a decline in the response to repeated applications of doses of agonists. See also desensitization, fade.

**tachyplesin** any of a group of arthropodous peptide antibiotics, 17 or 18 amino acids long and with a C-terminal arginine a-amide. They are abundant in acid extracts of hemocyte debris of horseshoe crabs (*Tachypleus* spp.). They strongly inhibit the growth of Gram-positive and Gram-negative bacteria, and of fungi such as *Candida albicans*. Example from *Tachypleus gigas*: database code TAC3\_TACG1, 17 amino acids (2.24 kDa).

**tae promoter** a hybrid promoter, constructed *in vitro*, that contains the -35 sequence of the *trp* promoter and the -10 sequence of the *lacZ* promoter. See minus 10 region.

**Tacrolimus** see FK506.

**tactic polymer** a regular polymer in whose molecules there is an ordered structure with respect to the configurations around at least one main-chain site of stereoisomerism per constitutional base unit.

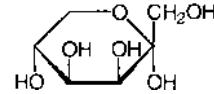

**tactile** capable of exciting the sense of touch; relating to the sense of touch (as a sense organ).

**tactoid** a paracrystal-like aggregate; the term may be applied to the rodlike filaments of hemoglobin that form in sickle cells, or to assemblies of virus particles (e.g. of tobacco mosaic virus).

**tag** 1 to identify by a marker; for example, a cell may be tagged by attachment of a (fluorescent or radiolabelled) antibody. 2 an identifier used in tagging.

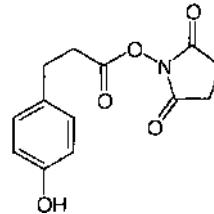

**Tagamet** see cimetidine.

**D-tagatose** a nonsystematic name for *o*-lyxo-2-hexulose, a hydrolysis product of some plant gums.

a-*o*-pyranose form

**Tagit** a proprietary name for N-succinimidyl 3-(4-hydroxyphenyl) propionate; a substance used in the preparation of Bolton and Hunter reagent for tagging peptides and proteins with radioiodine.

**tail** 1 an extension growing or appending from a point of origin

## tailing

or attachment. For example, the fatty-acyl groups of a phospholipid and the glycerol to which they are bonded are referred to as the tail. Compare headgroup. 2 (in chromatography) a region of more slowly moving or decomposed material extending back from a band towards the origin. See also poly(A) tail, tailing.

tailing 1 the addition of a stretch of identical nucleotides to the ends of a restriction fragment using terminal deoxynucleotidyl transferase. 2 the spreading out of a band or spot in a chromatographic process.

Tal symbol for a residue, or sometimes a molecule, of talose. talaric acid one of the hexanic acids; see also aldaric acid.

talc a soft mineral composed of hydrated magnesium silicate,  $Mg_3Si_4O_{10}(OH)_2$ , with small quantities of metal impurities. In its powdered form it is known as talcum powder, or French chalk, and in granular form as soapstone (steatite). Powdered talc is used as a lubricant, as a filler in paper and other products, and in cosmetics, etc.

talcum powder powdered talc.

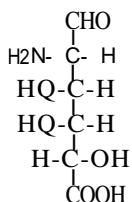

talin a protein involved in connections between the cytoskeleton and the plasma membrane. A phosphoprotein, it binds strongly to vinculin, and less strongly to integrins. It is a founder member of the TERM family. Example from mouse: database code TALI\_MOUSE, 2541 amino acids (269.53 kDa).

talo+ or (before a vowel) tal08+ comb. form of 18lose.

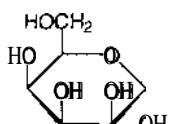

**talo-** prefix (in chemical nomenclature) indicating a particular configuration, a set of (usually four) contiguous CHOH groups as in the acyclic form of D- or L-talose. See also monosaccharide.

talopeptin  $N$ -(6-deoxy-a-L-talopyranosyl-oxyphospho)-L-leucyl-L-tryptophan; an inhibitor of several metallopeptidases, including thermolysin. Compare phosphoramidon.

talosaminouronic acid a component of the peptidoglycan of Archaea.

**talose** symbol: Tal; the trivial name for the aldohexose talo-hexose, which differs from glucose in the configuration of the groups at C-2 and C-4; there are two enantiomers.

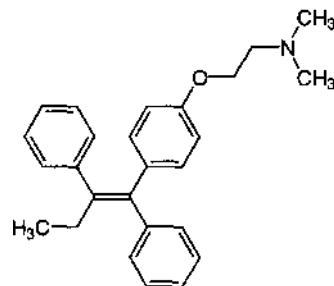

a- $\alpha$ -talose

Tamm, Igor Yevgenyevich (1885-1971), Russian-born Soviet physicist; Nobel Laureate in Physics (1958) jointly with P. A. Cherenkov and I. M. Frank 'for the discovery and the interpretation of the Cherenkov effect'.

Tamm-Horsfall glycoprotein or uTomodulin the principal glycoprotein of human urine. It occurs in other species, e.g. the cow and rat. The molecule is filamentous with an  $M_r$  of several million and is composed of subunits of  $M_r \approx 80\ 000$ ; it contains about 25% carbohydrate and a small amount of lipid. An abnormally high  $M_r$  is observed in cystic fibrosis. Example from human (precursor): database code UROM\_HUMAN,

640 amino acids (69.76 kDa). See also proteinuria. [After Igor Tamm (1922-71), US virologist and Frank Lappin Horsfall (1906-71).]

**Tamoxifen** [Zl-2-[4-(1,2-diphenyl-1-butene)-phenoxy]-N,N-dimethylethanolamine; the proprietary name of an estrogen antagonist, used in the treatment of breast cancer and suggested for use as a prophylactic drug in women with a family history of breast cancer. The drug has complex pharmacological properties and can behave as a pure estrogen agonist, a partial agonist, or an antagonist, depending on the species of animal, the target organ examined, and the endpoint measured. It is a genotoxic carcinogen in the rat.

**tan** abbr. for tangent (def. I).

**tandem-crossed immunoelectrophoresis** see crossed immunoelectrophoresis.

**tandem repeat** 1 (of DNA sequences) an arrangement in which two or more copies of a particular base sequence are situated immediately one after the other. Tandem repeats are commonly found in telomeres, the repeated sequence being characteristic of species and source of DNA, and of relatively short length (up to about 10 bases). They also occur in highly repetitive DNA. 2 (of genes) a cluster of adjacent multiple copies of the same gene. The genes for ribosomal RNA (rRNA) are characteristically contained in tandem clusters, sometimes referred to as ribosomal DNA (rDNA). See also concatemer.

**Tanford-Kirkwood theory** a theory of protein titration curves based on a model in which the charges are taken to be discrete unit charges located at fixed positions on the protein molecule. [After Charles Tanford (1921- ) and John Gamble Kirkwood (1907-59).]

**tangent** 1 abbr.: tan; a function of an angle, being, in a right-angled triangle, the ratio of the side opposite the given angle (if acute) to that of the side opposite the other acute angle. The tangent of an obtuse angle is numerically equal to that of its supplement but of opposite sign. 2 a straight line that touches, but does not cut, a curve or a curved surface.

**tangential-flow filtration** a convenient and rapid method of concentrating cells, cell organelles, or other particulate material, or for eliminating such material from solutions. Using a special apparatus, the suspension containing the material is caused to flow over ('tangential flow') a semipermeable membrane; only material smaller than the membrane pores will pass through the membrane, forming the filtrate, leaving larger matter to be collected (retentate).

**Tangier disease** a rare autosomal recessive condition in humans in which there is a deficiency or complete absence of high-density lipoprotein. Homozygotes have very low levels of apolipoprotein A-I. There is accumulation of cholesterol esters in cells of the mononuclear phagocyte system. The condition is relatively benign as organ function is not affected. [After Tangier Island, Chesapeake Bay; the disease was first found in inhabitants of this island.]

**tannic acid** or **tannin** or **gallotannin** or **gallotannic acid** an imprecise term used for a mixture of hydrolysable tannins (def. I).

## tannin

## tanning

can be used to tan animal skins to produce leather. The term was introduced in 1796. Tannins are divided into hydrolysable tannins (the larger group) and condensed tannins. The former consist of a core of a polyhydric alcohol, usually glucose, esterified with either gallic acid or hexahydroxydiphenic acid. Condensed tannins are polymers of flavans and never contain sugar residues; they are often termed flavolans. Tannins form insoluble protein tannates with proteins, which, when the protein is a skin protein, forms the basis of tanning (def. 1). The liberation of tannins during the extraction of plant enzymes can cause difficulties because they tan enzymes, i.e. form insoluble tannates. The addition of polyvinylpyrrolidone may help to avoid this problem. Good tanning agents should have an  $M_r$  of between 500 and 3000 and contain sufficient phenolic hydroxyl groups (1-2% of  $M_r$ ) to form effective cross-links with protein. 2 a common name for tannic acid.

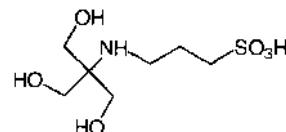

**tanning** 1 a technique of considerable antiquity, being known by the Egyptians around 3000 BC, for producing leather from animal skins by the use of tannin (def. 1). Modern methods using chrome salts are faster, taking a few hours rather than weeks. 2 the treating of red blood cells with tannic acid. Such cells are used in a test for anti-thyroglobulin antibodies, after they have been treated with thyroglobulin. The tanning enhances sensitivity.

**T antigen** 1 any of the several early gene products of a genetic locus of certain transforming DNA viruses, including adenovirus, simian virus 40 (SV40), and polyoma virus. The substance originally detected in nuclei of transformed cells by Immunofluorescence (hence the name antigen; the 'T' indicates tumour or transformation) led to the identification of several products, the genes of this locus encoding a number of essential early proteins that are needed for replication. Two products are formed by SV40, known as large T antigen (*or* T antigen) and small t antigen (*or* t antigen). Polyoma virus expresses three products from this locus, large T antigen, middle T antigen, and small t antigen. Large T antigen of SV40 alone is sufficient to immortalize primary rodent cells and transform established rodent cell lines. It is a multifunctional protein that is a potent transcriptional activator which promiscuously activates simple promoters containing a TATA box or initiator element and at least one upstream transcription-factor-binding site. Examples, large T antigen from SV40: database code TALA\_SV40, 708 amino acids (81.58 kDa); large T antigen from polyoma virus: database code TALA\_POVMK, 648 amino acids (74.71 kDa). Middle T antigen of polyoma virus is essential for polyoma-virus-mediated tumorigenesis and cell transformation. It associates with and activates cellular tyrosine kinases, including c-Src, c-Yes, and Fyn, and also binds phosphatidylinositol 3-kinase and protein phosphatase 2A. Example, middle T antigen of polyoma virus: database code TAMI\_POVMA, 442 amino acids (48.62 kDa). Small t antigen of SV40 exercises a helper effect in SV40 transformation. It forms complexes with protein phosphatase 2A and regulates the phosphorylation and transcriptional transactivation of CREB protein. It stabilizes p53 in a manner that correlates with enhanced transformation efficiency of SV40. Example, small t antigen from polyoma virus: database code TASPM\_POVMA 195 amino acids (22.81 kDa). 2 an antigen found on normal human erythrocytes that is unreactive unless the cells are first treated with neuraminidase. 3 one of the principal protein antigens in the cell wall of *Streptococcus* spp. 4 abbr. for transplantation antigen (i.e. a class I MHC antigen); see major histocompatibility complex.

**tapeworm** any parasitic flatworm (phylum Platyhelminthes) belonging to the class Cestoda.

**Taps** or **TAPS** abbr. for N-tris(hydroxymethyl)methyl-3-amino-propanesulfonic acid; 3-[2-hydroxy-1,1-bis(hydroxymethyl)-ethyl]-amino propanesulfonic acid; a Good buffer substance,  $pK_a$  (20°C) = 8.4.

## TATA-binding protein

Taps

**TBq DNA polymerase** a heat-stable DNA polymerase from *Thermus aquaticus*, a thermophilic bacterium. It is used in the polymerase chain reaction.

**tare** 1 to compensate for the weight of a container, etc. when weighing, by adjusting the balance to zero with the empty container in place before adding the material to be weighed. 2 the weight of the tared vessel or material.

**target** the object at which an action or process is directed. For example, a target cell is the cell under attack by a cytolytic or killer cell or other cytolytic agent, and a target tissue is the tissue that is acted on by any hormone, growth factor, or other agonist.

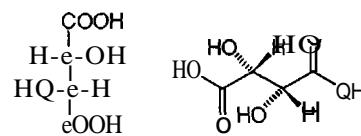

**targeting subunits** protein subunits that specify the location and catalytic and regulatory properties of protein phosphatases and kinases.

**target repeat** see transposon.

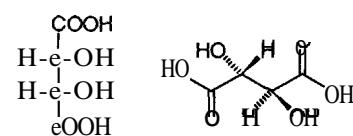

**target site** the site at which a restriction endonuclease cleaves a DNA molecule; usually the same as the recognition site (def. 2).

**target theory** (*in radiation chemistry*) a theory stating that all single hits on biologically active macromolecules by particles or quanta of ionizing radiation result in damaged and inactive molecules, that no partially active molecules are formed, and that all unhit molecules retain full activity.

**tartaric acid** 2,3-dihydroxybutanedioic acid; 2,3-dihydroxy-succinic acid; one of the aldaric acids formed by oxidation of a tetrose at C1 and C-4. The L<sub>(+)</sub> (see OIL convention), or 2R,3R, enantiomer occurs widely in plants, especially grape juice, and in fungi and bacteria; the D<sub>(-)</sub> (or 2S,3S) enantiomer and meso form have limited distribution in plants. The racemic mixture, DL-tartaric acid, sometimes occurs during wine manufacture; it was originally known as paratartaric acid. The first determination of an absolute configuration by anomalous dispersion of X-rays was made on sodium rubidium L(+)-tartrate in 1951. The property of optical activity of some substances was first described by Pasteur in experiments with crystals of sodium ammonium tartrate.

L-form

meso-form

**TATA-binding protein** abbr.: TBP; a component of transcription factor IID (*see* TFII). See also RNA polymerase.

## TATAbox

**TATA box or Hogness box** a base-sequence element common in eukaryotic promoters, characterized by the consensus TATAAAA. It binds a general transcription factor and hence specifies the position where transcription is initiated.

Tatum, Edward Lawrie (1909-75), US microbiologist; Nobel Laureate in Physiology or Medicine (1958) jointly with G. W. Beadle 'for their discovery that genes act by regulating definite chemical events' [prize shared with J. Lederberg].

**tau 1 symbol:**  $\tau$  (lower case) or T (upper case); the nineteenth letter of the Greek alphabet. For uses see Appendix A. 2 *an alternative name for transcription factor TFIIIC; see TFIII.*

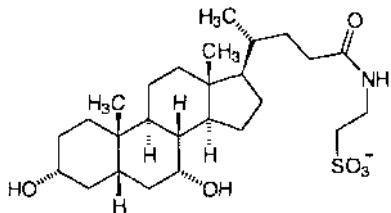

**tau protein** a microtubule-associated protein that promotes microtubule assembly and stabilizes microtubules. It constitutes at least a part of the paired helical filament (PHF) core found in Alzheimer's disease. Example from human: database code TAULHUMAN, 383 amino acids (39.96 kDa).

**tau-protein kinase EC 2.7.1.135;** an enzyme that catalyses the phosphorylation by ATP of -protein to O-phospho-t-protein. Example bovine (fragment): database code S43683, 209 amino acids (23.14 kDa). *See also tau protein.*

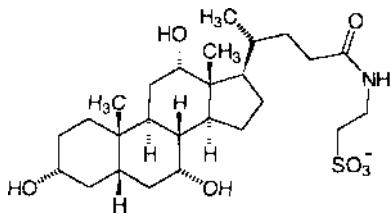

**taurine** 2-aminoethanesulfonic acid; a compound that is derived metabolically from cysteine by oxidation of the sulphydryl group to sulfoxide followed by decarboxylation of the resulting cysteic acid. N-conjugated with cholic acid, it forms the bile salts taurochenodeoxycholate, taurocholate, and taurodeoxycholate.

**taurochenodeoxycholate** the anionic form of the amido conjugate of taurine and chenodeoxycholate. It is a major bile acid.

**taurocholate** the anionic form of taurocholic acid, N-cholyltaurine, a major bile salt of humans and other mammals. It is useful as an anionic bile-salt detergent (aggregation number 4; CMC 3-11 mM). The anions of similar taurine conjugates of other bile acids are known, e.g. taurochenodeoxycholate and taurodeoxycholate.

**taurocyamine** N-(aminoimil\omethyl) taurine; a compound found in marine polychaete worms. The guanidine group can undergo phosphorylation, to form phosphotaurocyamine, which acts as a phosphagen.

**taurodeoxycholate** the anionic form of taurodeoxycholic

## Tay-Sachs disease

acid, N-(7-deoxy)cholytaurine. It is useful as an anionic bile-salt detergent (aggregation number 6; CMC 1-4 mM).

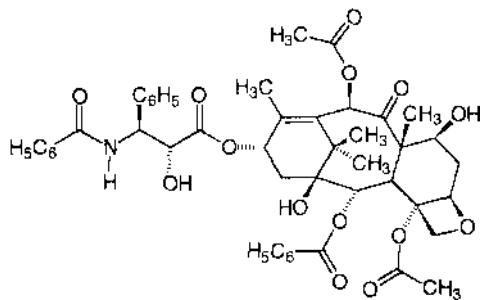

**taurolipid** any of a class of lipids consisting of a non-hydroxy fatty acid esterified with a hydroxy group of trio-, tetra-, or pentahydroxystearic acid in amide linkage with taurine. They are characteristic lipids of the protozoan *Tetrahymena*. **tauryl** the acyl group,  $\text{H}_2\text{N}-\text{CH}_2-\text{CH}_2-\text{SO}_2-$ , derived from taurine.

**taut form abbr.:** T form; *see* tense form, Monod-Wyman-Changeux model for allosteric interaction.

**tautomer** anyone of the possible alternative structures that may exist as a result of tautomerism.

**tautomerism** a form of constitutional isomerism in which a structure may exist in two or more constitutional arrangements, particularly with respect to the position of hydrogens bonded to oxygen. The isomers, or tautomers, are readily interconvertible and exist in equilibrium. The best-known example is **keto-enol** tautomerism, in which the structures  $\text{X}-\text{C}(=\text{O})-\text{CH}\text{X}$  (keto) and  $\text{X}-\text{C}(\text{OH})=\text{CH}-\text{X}$  (enol) exist, in proportions determined by the equilibrium position for the conditions pertaining (normally strongly favouring the keto form). Other examples include quinone-quinol and amino-imino tautomerism. *-tautomeric adj.*

**taxol** an antitumour and antileukemic agent isolated from the bark of the Pacific yew, *Taxus brevifolia*. It is used clinically to treat refractory ovarian cancer. Its anticancer activity results from its ability to inhibit mitosis and block the cell cycle in its G or M phases through enhancement of the polymerization of tubulin and the consequent stabilization of the microtubules. In view of the endangered status of *T. brevifolia*, taxol is manufactured semisynthetically from a material present in *T. baccata*. A total chemical synthesis has also been achieved. After the discovery of taxol, a compound with similar properties was isolated from the myxobacterium *Sporangium celulosum*. This compound, epothilone, is more water-soluble than taxol and has the advantage that it can be produced in quantity by fermentation. Taxol and its analogues are known as taxanes. One proprietary name is Paclitaxel. A proprietary name of a semisynthetic analogue is Docetaxel.

**taxon (pl. taxa)** a named taxonomic group of any rank; a particular taxon comprises organisms having certain genetic characters in common. Strictly, the term should be used to denote only named groups, e.g. Chordata, Homidae, etc., not as a generic term for the ranks themselves, e.g. phylum, family, etc.

**Tay-Sachs disease or GM<sub>2</sub> gangliosidosis** an inherited neurological metabolic disorder resulting from deficiency of the lysosomal enzyme, hexosaminidase (form A, deficiency in  $\alpha$  chain). This leads to the accumulation of its substrate, ganglioside GM<sub>2</sub> (*see* ganglioside), in the brain. The disease is relatively common (1 in 2500 live births) among Ashkenazy Jews. There is motor and mental deterioration with an exaggerated startle response to sound; by 18 months of age, most patients are blind, deaf, and spastic; they die by the age of 3 years. *See also saposin.* [After Warren Tay (1843-1927), British physician, and Bernard Sachs (1858-1944), US neurologist.]

**Tb** symbol for terbium.

**TBP** abbr. for TATA-binding protein (*see* TFII, RNA polymerase).

**tBu** abbr. for tertiary butyl (alternative to But).

**TBW** abbr. for total body water; *see* body water.

**Tc** symbol for technetium.

**TCA** abbr. for 1 tricarboxylic acid, 2 trichloroacetic acid.

**TTC** arm the base-paired segment of the clover-leaf model of transfer RNA to which the loop containing the base sequence  $\Psi\text{C}$  is attached ( $\Psi$  = pseudouridine).

**T cell** an alternative name for T lymphocyte.

**T<sub>H</sub>** cell abbr. for helper cell.

**T-cell growth factor** abbr.: TCGF; an alternative name for interleukin 2.

**T-cell receptor** a heterodimer glycoprotein of the immunoglobulin superfamily located in the plasma membrane of T cells (T lymphocytes). T-cell receptors have structural similarities with class II MHC antigens (*see* major histocompatibility complex) but the  $\alpha$  and  $\beta$  chains are disulfide bonded. They are responsible for recognition of target antigen in combination with MHC. After binding to antigen/MHC (class I or class II depending on the type of antigen presentation), the T-cell receptor transduces the signal into the T cell, probably through mediation by associated CD3 molecules (see CD marker), and brings about T-cell activation. One constant region and one variable region (*see* immunoglobulin) are located in each subunit ( $\alpha$  and  $\beta$ ); the subunits are related to one another. As with immunoglobulins, the variable regions are designed for specificity of recognition (but they are not products of the immunoglobulin genes). A small number of adult T-cell receptors have  $\gamma$  and  $\delta$  chains. This class of receptor appears first in ontogeny. Examples from human leukemic cell line, constant regions:  $\alpha$  subunit: database code TCA\_HUMAN, 142 amino acids (15.91 kDa);  $\beta$  subunit: database code TCB\_HUMAN, 177 amino acids (19.88 kDa).

**T-cell-replacing factor** abbr.: TRF; a term formerly used for some interleukins. *See* interleukin 1, interleukin 5.

**TCGF** abbr. for T-cell growth factor (i.e. interleukin 2).

**T chain** an alternative name for secretory piece.

**TCP-1** abbr. for T-complex protein I; a molecular chaperone that forms two stacked rings, 12–16 nm in diameter and is associated with other proteins in a 850–900 kDa complex. It is similar in function to Hsp60 (a heat-shock protein) in mitochondria and the *groEL* product in bacteria (*see also* chaperonin). Example from human: database code TCPI\_HUMAN, 556 amino acids (60.27 kDa).

**T-DNA** abbr. for transfer DNA; that part of the *Agrobacterium* Ti plasmid that is incorporated into the genome of infected plant cells. It is approximately 23 kb long and codes for an opine, usually nopaline or octopine, which the transformed cells produce and the bacteria then use. At each end of the T-DNA in the Ti plasmid there is a 25 bp sequence; the right hand one of these almost identical sequences is essential for the transfer process.

**TDP** abbr. for 1 ribosylthymine diphosphate or ribothymidine diphosphate, the common names for ribosylthymine 5'-diphosphate, ribothymidine 5'-diphosphate, 5'-ribothymidyl phosphate, thymine riboside 5'-diphosphate. 2 (sometimes) thymidine diphosphate (dTDP is recommended).

**Tdr** or **TdR** or **TDR** abbr. for thymine deoxyriboside (i.e. thymidine). Use deprecated; the symbol dThd is recommended.

**TdT** abbr. for terminal deoxynucleotidyltransferase.

**Te** symbol for tellurium.

**TEA** abbr. for 1 triethanolamine;  $N(CH_2CH_2OH)_3$ ; a base used in the preparation of buffers,  $pK_a$  ( $25^\circ C$ ) 7.90. 2 tetraethylammonium; used to block sympathetic and parasympathetic ganglionic transmission; normally used as the chloride.

**TEAE** abbr. for the triethylaminoethyl group,  $(C_2H_5)_3NCH_2CH_2-$ . It may be used as a substituent in hydroxylated chromatographic support matrices, e.g. cellulose, Sephadex, to form anion-exchange columns.

**teichoate** the anionic form of teichoic acid.

**teichoic acid** any polymer occurring in the cell wall, membrane, or capsule of Gram-positive bacteria and containing chains of glycerol phosphate or ribitol phosphate residues. Additionally, carbohydrates are linked to glycerol or ribitol, and some -OH groups are esterified with D-alanine.

**tektins** a family of similar proteins that are adapted to the assembly of a variety of eukaryotic cell structures. Tektins have common features that adapt them to sensitive and specific associations with molecules of their own kind; they have similar amino-acid compositions. They include actin, actin-like proteins, some microtubule proteins, mitochondrial structural protein, and erythrocyte membrane proteins.

**tele** a designator of the position of one of the nitrogens of the histidine imidazole ring, indicating the nitrogen furthest from the side chain. It is often symbolized by r, as in NT. Compare pros.

**teleology** the doctrine or study of ends or final causes, especially as related to the evidences of design or purpose in nature; the use of design, purpose, or utility as an explanation of any natural phenomenon. An example of a teleological concept in biology is that organs are made to react for the good of the organism as a whole.

**teleonomy** the idea that the existence of a structure or a function in an organism must have conferred an evolutionary advantage upon that organism.

**teleost** any member of the infraclass Teleostei, comprising fishes with rayed fins and a swim bladder; it includes most of the extant bony fishes.

**telestability** the transmission of three-dimensional stability from a stable part of a macromolecule to an inherently less stable part.

**telokin** the C-terminal sequence of smooth muscle myosin-light-chain kinase expressed as an independent protein. It binds calmodulin. Example from rabbit: database code TELO\_RABIT, 155 amino acids (17.18 kDa).

**telolysosome** a lysosome that has accumulated so much indigestible residue that it is unable to accumulate further material to be digested. The structure still contains enzymes but these are no longer renewed. Compare residual body.

**telomerase** EC 2.7.7.-; a DNA polymerase enzyme involved in telomere formation, and in telomere elongation to maintain the telomere sequences during replication. The enzyme recognizes the G-rich strand of an existing telomere repeat sequence, elongating it in the 5' to 3' direction. *Tetrahymena* telomerase is a large ribonucleoprotein, a specialized example of a reverse transcriptase. The RNA component includes a template for synthesizing the G-rich repeating sequence. The ESN gene product is a probable example.

**telomere** the structure that seals the end of a chromosome. In order to counteract the tendency of the chromosome otherwise to shorten with each round of replication, the telomeric DNA consists of simple tandemly repeated sequences specific for each species. Typically one strand is G-rich and the other C-rich. The G-rich strand forms a 3'-terminal overhang about 15 residues long. These are the sequences added to the 3' terminus of chromosomal DNAs by telomerase. The elongation allows a primer to bind and initiate synthesis on the other strand, maintaining the length of the chromosome and preventing the loss of coding sequences. -telomeric adj.

**telopeptide** any of the peptides that protrude from the triple-helical body of tropocollagen and have a composition different from the triple-helical portions. They are removed by proteases, with concomitant breakage of intramolecular inter-chain bonds. They are thought to occupy near-terminal positions. The antigenic response to injected heterologous tropocollagen is directed against these telopeptide appendages external to the triple helix.

**telophase** the final stage of mitosis or meiosis in which the nuclei form in the daughter cells, which then revert to the resting state.

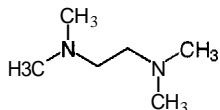

**TEM** or **T.E.M.** abbr. for 1 transmission electron microscope;

## TEMED

tenside

*see* electron microscope. 2 Tris-EDTA-mercaptopoethanol (buffer).

TEMED *abbr.* for N,N,N',N'-tetramethylethylenediamine; N,N,N',N'-tetramethyl-1,2-diaminoethane; a substance used as a polymerizing agent in the preparation of polyacrylamide gels. It acts to stabilize free radicals produced by ammonium persulfate.

Temin, Howard Martin (1934-94), US virologist; Nobel Laureate in Physiology or Medicine (1975) jointly with D. Baltimore and R. Dulbecco 'for their discoveries concerning the interaction between tumour viruses and the genetic material of the cell'.

temperate phage a bacteriophage that, following infection of its host bacterium, may either enter the lytic cycle, like a virulent phage, or establish a kind of symbiotic relationship with the host cell that results in its subsequent perpetuation in all the descendants of the bacterium. Bacteria carrying temperate phage are said to be lysogenic, while the form of the carried phage is known as a prophage.

temperature *abbr.*: temp.; a fundamental physical quantity of a body, region, or system that determines the direction of net heat flow between it and its surroundings. If two systems have the same temperature they are in thermal equilibrium and there is no net heat flow between them. If they have different temperatures they are not in thermal equilibrium and heat flows from the system of higher temperature to that of lower temperature. Essentially there are two different methods of measuring temperature. One is to use a scale of values set up between arbitrary fixed points based on reproducible temperature-dependent events. For example, the Celsius temperature scale uses a freezing point and boiling point of water as fixed points, to which are assigned the values 0 and 100, respectively; the scale between them is divided into 100 degrees. Although widely used for many practical purposes, it lacks a theoretical basis and is unsuitable in many scientific contexts. Instead, the concept of thermodynamic temperature is used. This is defined in terms of the second law of thermodynamics (*see* thermodynamics) and is independent of any particular substance. However, in practice thermodynamic temperatures cannot be measured directly. Consequently, a practical realization of the thermodynamic temperature scale is used, called the International Practical Temperature Scale (IPTS). This is based on a number of fixed points, and is measured in kelvins; it defines temperature down to 13.81 kelvins, the triple point of equilibrium hydrogen.

temperature coefficient of a reaction *symbol*:  $Q_{10}$ ; the factor by which the velocity of a chemical reaction is increased by raising the temperature,  $t$ , by  $10^\circ\text{C}$ . Usually it is the ratio of the rate of reaction at  $(t + 10^\circ)$  to that at  $t$ , denoted by  $Q_{10} = k_{t+10}/k_t$  where  $k_{t+10}$  and  $k_t$  are the rate constants at the respective temperatures. The  $Q_{10}$  value of homogeneous chemical reactions is generally in the range 2-3; many enzyme-catalysed reactions and physiological processes exhibit, over a limited range of temperatures, a  $Q_{10}$  value of  $\approx 2$ . *See also* Arrhenius equation.

temperature jump a technique used in relaxation kinetics for the study of enzyme mechanisms in which the temperature is raised rapidly (e.g. over about  $1\mu\text{s}$ ), the reaction being monitored during this and the subsequent (very short) period during which the system relaxes to a new equilibrium.

temperature-sensitive mutation a mutation that is manifest in only a limited range of temperature. The mutant carrying such a mutation behaves normally at the lower, permissive

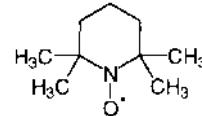

temperature, but when grown at the lower or higher, restrictive temperature, it shows the mutant phenotype.

template a macromolecule whose structure serves as a pattern for the synthesis of another macromolecule. The term applies particularly to a nucleic acid on which another nucleic acid of complementary base sequence is synthesized, as in genetic transcription, or in the case of messenger RNA, on which a polypeptide is synthesized (genetic translation).

template RNA *an alternative name for* messenger RNA.

template strand *see* noncoding strand.

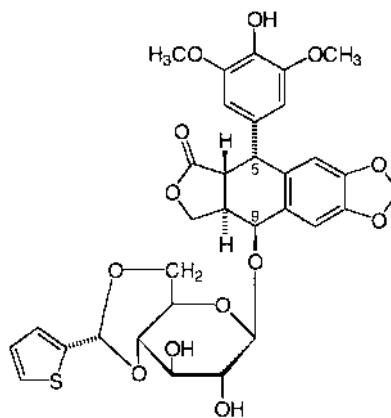

TEMPO *abbr.* for 2,2,6,6-tetramethylpiperidinoxyl; 2,2,6,6-tetramethylpiperidine 1-oxyl; a stable free radical used as a spin label in electron spin-resonance spectroscopy.

temporal gene any gene that 'programs' a system in time, determining the activation of structural, architectural, and regulatory genes controlling different developmental stages in various cell types.

tenascin a substrate-adhesion molecule of the extracellular matrix that appears to inhibit cell migration and may play a role in supporting the growth of epithelial tumours. It is a hexameric protein; a homotrimer may be formed in the triple coiled-coil region and may be stabilized by disulfide rings at both ends; two such half-hexabronchions (*see* hexabronchions) may be disulfide linked within the central globule. Alternative splicing leads to four variants from a single gene in a tissue- and time-specific manner during development. It has EGF-like repeats (*see* epidermal growth factor) and fibronectin domains. Example from human: database code TENA\_HUMAN, 2199 amino acids (240.45 kDa). Other names: hexabronchion; cytactin; neuronectin; gmem; ji; miotendinous antigen; glioma-associated extracellular matrix antigen; gp150-225.

Teniposide a semisynthetic lignan derivative prepared from podophyllotoxin. It is similar in action to Etoposide, but more potent as a cytotoxic agent *in vitro*.

ten-minute phosphate *see* labile phosphate.

tense form *or* taut form *abbr.*: T form; the form of an allosteric protein that has a lower affinity for a ligand than the R form (relaxed form). *See* Monod-Wyman-Changeux model (for allosteric interaction).

tenside any of the group of surface-active compounds widely

## tension

known as detergents. The name derives from their effects on surface tension.

**tension** 1 the concentration of a gas expressed as the partial pressure of the gas. 2 the force exerted by stretching any material. 3 voltage, electromagnetic force, or potential difference, as in high tension, low tension.

**tensor** 1 (*in mathematics*) a quantity expressing the ratio in which the length of a vector is increased. *Compare* scalar. 2 (*in anatomy*) a muscle that stretches or tightens some part while not altering the direction of the part.

**tentoxin** cyclo[L-leucyl-N-methyl-(Z)-dehydrophenylalanyl-glycyl-N-methyl-L-alanyl]; a cyclic tetrapeptide, originally isolated as a metabolite of *Alternaria alternata*. It selectively induces chlorosis in some plant species when applied to the germinating seedling.

**Ter** *see* reactivity of enzymes.

**tera+** symbol: T; SI prefix denoting  $10^{12}$  times.

**terato+** or (*before a vowel*) terat+ *comb. form* denoting congenital abnormality.

**teratocarcinoma** a teratoma that includes carcinomatous cells.

**teratogen** a substance that produces malformations in embryos. -teratogenic *adj.*

**teratoma** a tumour composed of disorganized tissues that are foreign embryologically to the tissue normally found at the site. Teratomas most frequently occur in testis or ovary, and may be derived from remnants of multipotential embryological cells that can differentiate into many cell types.

**TERM** a family of F-actin binding proteins, named from talin and the related proteins ezrin, radixin, and moesin.

**terminal amino acid** the amino-acid residue at the end of a peptide or polypeptide chain. The C-terminal amino acid is the end amino acid that has a free α-carboxyl group (*see* Cterminus); the N-terminal amino acid is the end amino acid that has a free α-amino group (*see* Nterminus).

**terminal deletion** *see* deletion.

**terminal deoxynucleotidyltransferase** abbr. TdT; EC 2.7.7.31; *recommended name*: DNA nucleotidyltransferase; *systematic name*: nucleoside-triphosphate:DNA deoxy-nucleotidyltransferase; *other names*: terminal addition enzyme; terminal transferase; terminal deoxyribonucleotidyl-transferase. An enzyme, commonly isolated from calf thymus, that catalyses the successive transfer of deoxynucleotide residues from the corresponding nucleoside triphosphates to the 3' end of an oligo- or polydeoxynucleotide. It is a template-independent,  $Mg^{2+}$ -dependent DNA polymerase. Example (bovine; enzyme used in molecular biology): database code TDT\_BOVIN, 520 amino acids (59.60 kDa).

**terminal transferase** *see* terminal deoxynucleotidyltransferase.

**terminal web** the network of filaments forming the part of the cytoskeleton that lies close under the plasma membrane. It is a specialized cortex, to which actin filament bundles may be attached, especially, e.g., at the base of microvilli of intestinal epithelial cells. It contains a dense network of spectrin molecules that connect the inner intermediate filaments to the actin filaments that are connected to the plasma membrane.

**termination codon** or **terminator codon** any codon that signals the termination of a growing polypeptide chain. *See also* amber codon, ochre codon, stop codon.

**termination factor** any protein that participates in the termination of either transcription (*see* rho protein) or translation (*see* release factor).

**terminator** (*of transcription*) a DNA sequence lying just downstream of the coding segment of a gene that is recognized by RNA polymerase as a signal to stop synthesizing messenger RNA during transcription.

**termolecular reaction** *see* molecularity.

**ternary** consisting of three parts.

**ternary complex** any complex formed between three chemical entities, e.g. a complex formed between an enzyme and two substrate molecules.

**terpene** any member of a class of hydrocarbons occurring par-

## testosterone

ticularly in most essential oils but represented throughout the biological world. Terpenes are composed essentially of multiples of isoprene ( $C_5H_{10}$ ) units, and may be acyclic, cyclic, or multicyclic, saturated or unsaturated, and can be substituted by various functional groups, e.g. OR. Terpenes containing 10, 15, 20, 30, 40, or a large number, of carbon atoms per molecule are known as mono-, sesqui-, di-, trio-, tetra-, or poly-terpenes respectively. The class is often taken to include alcohol, aldehyde, and carboxylic acid derivatives of terpene hydrocarbons. Isoprene is the only naturally occurring hemiterpene, i.e. having five carbons, but the phosphorylated compounds  $A^{2-}$  and  $Li^+$ -isopentenyl diphosphates are key intermediates in terpene biosynthesis. *See also* polypropenyl.

**terpenoid** 1 resembling a terpene in chemical structure. 2 any member of a class of compounds characterized by an isoprenoid chemical structure (as in a terpene) and often including their oxygenated and hydrogenated derivatives.

**Terramycin** a proprietary name for oxytetracycline.

**tert-** abbr.: t; *prefix* (*in chemical nomenclature*) signifying tertiary (def. I).

**tertiary** (*in chemistry*) 1 a prefix: tert- (abbr.: t-); describing an alkyl compound (e.g. an alkanol) in which the functional group (e.g. a hydroxyl group) is attached to a carbon atom linked to three others. b describing the carbon atom bearing the functional group in such a compound. 2 describing an amide or an amine in which three appropriate groups are attached to a nitrogen atom. 3 describing a salt formed by replacing all three of the ionizable hydrogen atoms of a tri-basic acid by one, two, or three other cations of appropriate valency. *Compare* primary, secondary.

**tertiary structure** the level of protein structure at which an entire polypeptide chain has folded into a three-dimensional structure. The tertiary structure results from interactions between amino-acid residues, that may be widely separated in the primary structure, but may be brought into proximity by the folding of the polypeptide chain. The forces of interaction between residues include hydrogen bonds and electrostatic attraction. The structure is stabilized in some proteins by disulfide bonds. In multichain proteins, the term tertiary structure applies to individual chains. *Compare* primary structure, secondary structure, quaternary structure.

**Tes** or **TES** abbr. for N-tris(hydroxymethyl)methyl-2-aminoethanesulfonic acid; 2-[{[2-hydroxy-1,1-bis(hydroxymethyl)ethyl]amino}ethanesulfonic acid; a Good buffer substance;  $pK_a$  (20°C) = 7.5.

**tesla** symbol: T; the SI derived unit of magnetic flux density. It is equal to one weber of magnetic flux per square metre; i.e. 1 T = 1 Wb m<sup>-2</sup>. [After Nikola Tesla (1856-1943), Croatian-born US physicist.]

**testicular** of, or relating to, the testis.

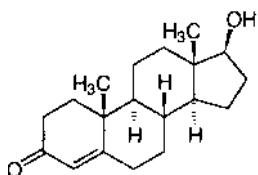

**testicular feminization** or **testicular feminisation** an inherited X-linked condition in which genetic males have developmental abnormalities ranging from a complete external female phenotype to partially masculinized ambiguous genitalia. The primary defect is an unresponsiveness to dihydrotestosterone; defects in an X-linked gene coding for a dihydrotestosterone receptor may be responsible.

**testis** (*pl.* testes) the male gonad; in vertebrates there is typically a pair of testes, producing spermatozoa and synthesizing androgens.

**testosterone** 4-androsten-17β-ol-3-one; the principal and most potent androgen. It is formed from androstenedione by 3α(17β)-hydroxysteroid dehydrogenase (NAD<sup>+</sup>) (EC 1.1.1.239), in Leydig cells of the testis. Testosterone is responsible during embryonic development for virilization, and promotes and maintains male secondary sex characteristics throughout life. It is also synthesized in the ovary from which some is secreted into the blood, but most is converted to estradiol. Its actions are in large part mediated by dihydrotesto-

## tetanus

sterone, to which it is converted in target cells. *See also* androgen receptor.

**tetanus** 1 a disease resulting from infection with the bacterium *Clostridium tetani*. *See also* tetanus toxin. 2 or tetany a sustained contraction of a muscle. -tetanal or tetanoid adj.

**tetanus toxin** the protein toxin of *Clostridium tetani*, the causative agent of tetanus. It is a heterodimer of light and heavy chains. It blocks neural exocytosis and thus norepinephrine release, possibly as a result of a Zn<sup>2+</sup>-dependent proteolysis of synaptobrevin by the light chain, but also by inhibition of a neuronal transglutaminase (protein-glutamine γ-glutamyltransferase, EC 2.3.2.13). The protein is synthesized as a precursor; database code TETX\_CLOTE, 1314 amino acids (150.55 kDa); this is cleaved to yield the light chain (residues 1-456) and heavy chain (residues 457-1314).

**tetanus toxoid** the toxoid prepared from *Clostridium tetani* toxin and included in anti-tetanus immunogens.

**tetany** an alternative term for tetanus (def. 2).

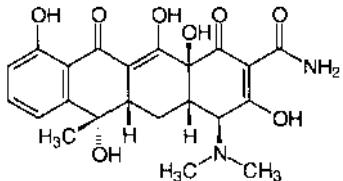

**tetra+** or (before a vowel) **tetr+** comb. form 1 denoting four, fourfold, every fourth; *see also* tetrakis+ (def. 1).2 (in chemical nomenclature) (distinguish from **tetrakis+** (def. 2)) a indicating the presence in a molecular entity of four identical specified unsubstituted groups; e.g. tetrachloroethylene, tetramethylammonium chloride. b indicating the presence in a molecular entity of four identical inorganic oxoacid residues in linear anhydride linkage; e.g. sodium tetraborate.

**tetracosa+** or (before a vowel) **tetracos+** comb. form indicating twenty-four.

**tetracosactide** or **tetracosactrin** or **cosyntropin** generic names for p1-24-corticotropin, a synthetic polypeptide identical to the N-terminal 24 residues of corticotropin, and having all of its hormonal activity. It is sometimes known as 1-24 ACTH. Proprietary names include Synacthen.

**tetracosapeptide** a 24-residue peptide.

**tetracycline** 1 any of a group of broad-spectrum antibiotics which are also effective against rickettsial organisms, mycoplasmas, and certain protozoa. The bacteriostatic activity of the tetracyclines depends on their direct inhibition of protein synthesis. They are active against protein synthesis on both bacterial 70S and eukaryotic 80S ribosomes although 70S ribosomes are rather more sensitive. The tetracyclines are much more effective against protein synthesis in intact bacteria than against that in eukaryotic cells because of selective absorption by bacterial cells. The tetracyclines inhibit the binding of aminoacyl-tRNA to the acceptor site on the ribosome. 2 any of a group of antibiotics based on the tetracycline nucleus. They include aureomycin (7-chlortetracycline); terramycin (5-oxytetracycline); declomycin (6-demethyl-7-chlorotetracycline); doxycycline (6-deoxy-5-oxytetracycline). *See also* tetracycline resistant.

## tetrahydrofuran

tetracycline resistant abbr.: TC'; resistant to the effects of the antibiotic tetracycline. The most commonly encountered mode of resistance depends on a diminished cellular accumulation of these compounds. In enteric bacteria two transposons, Tn1721 and TnLO, commonly carry the genes for tetracycline resistance. TnLO encodes two proteins: a membrane-located protein (M<sub>r</sub> 36 000) that appears to mediate resistance and a repressor protein associated with the inducibility of tetracycline resistance. In Gram-positive bacteria the induction mechanism does not appear to involve a repressor protein but depends upon a translational attenuation mechanism. The membrane protein is responsible for a pump that specifically pumps the tetracycline out of the cells against a concentration gradient. Foreign DNA may be fused to the tetracycline-resistance gene in a cloning vector thereby enabling bacterial clones containing the foreign DNA to be selected from those lacking resistance to the antibiotic. The plasmid pBR322 contains genes for resistance to both tetracycline and ampicillin. Insertion of a foreign DNA at certain sites inactivates either or both genes.

**tetracycline sensitive** abbr.: TCs; sensitive to the effects of tetracycline.

**tetradeca+** or (before a vowel) **tetradec+** comb. form indicating fourteen.

**tetradecadienoic acid** any 14-carbon straight-chain fatty acid having two double bonds. Tetradeca-3E,5Z-dienoic acid (megatonic acid) and the (3Z,5Z)-isomer are sex attractants for *Attagenus megatoma* and for *A. elongatus* respectively.

**tetradecapeptide** a 14-residue peptide.

**tetradecenoic acid** any 14-carbon monounsaturated fatty acid. Tetradec-9Z-enoic acid (myristoleic acid) is the most common naturally occurring form, but the 4Z-isomer occurs in tohoku oil and the 5Z-isomer (physeteric acid) in sperm-whale oil.

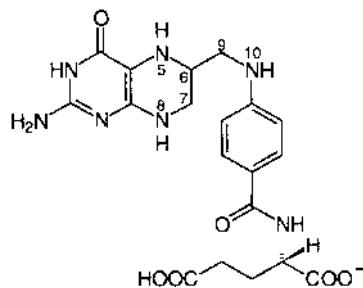

**tetraenoic** describing an acid having four double bonds. In long-chain fatty acids of the n-6 or n-3 families (*see* fatty acid), these will be methylene-interrupted double bonds.

**tetragonal symmetry** an arrangement, e.g. of a crystal or of ligands around a metal ion in solution, having a single four-fold axis of symmetry.

**tetrahydro-** or **tetrahydro-** comb. form (in chemical nomenclature) indicating the presence of four hydrogen atoms at positions of specific interest (in relation to the parent compound, or as specified by a locant).

**tetrahydrobiopterin** *see* biopterin.

**tetrahydrofolate** abbr.: H<sub>4</sub>folate or (not recommended) THF; N-[4- {[(2-amino-3,4,5,6,7,8-hexahydro-4-oxo-pteridin-6-yl)-methyl]amino} benzoyl]-L-glutamate; folate bearing additional hydrogens at positions 5, 6, 7, and 8 of the pterin moiety. It is formed as the reduction product of the action of dihydrofolate reductase on dihydrofolate with NADPH as co-substrate.

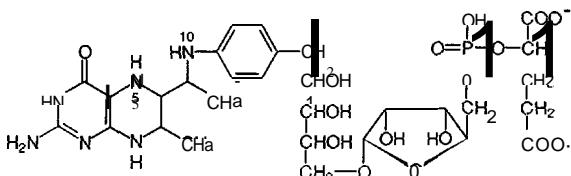

**tetrahydrofuran** abbr.: THF; tetramethene oxide; an organic solvent that is useful for bringing into aqueous solution com-

## tetrahydromethanopterin

pounds that are otherwise sparingly soluble in water. It is a cyclic ether that is moderately soluble in water.

## Q

**tetrahydromethanopterin abbr.: H<sub>4</sub>MPT**; a derivative of 7-methylpterin (2-amino-4-hydroxy-7-methylpteridine) that participates in the pathway of methane formation in methanogenic bacteria. It undergoes a series of interconversions involving NS and N/O, analogous to those of the folate coenzymes, with formation of formyl-H<sub>4</sub>MPT, methenyl-H<sub>4</sub>MPT, methylene-H<sub>4</sub>MPT, and methyl-H<sub>4</sub>MPT.

**Tetrahymena** a genus of ciliated protozoans, members of which are used in studies of ciliary axonemes, self-splicing RNA, and telomere reproduction.

**tetrakis+** prefix 1 denoting four times, quadrupled; *see also* **tetra+** (def. I). 2 (*in chemical nomenclature*) (distinguish from **tetra+** (def. 2)) a indicating the presence in a molecular entity of four identical specified groups each substituted in the same way; e.g. tetrakis(2-hydroxyethyl)ammonium chloride. b indicating the presence at separate positions in a molecular entity of four identical inorganic oxoacid residues; e.g. inositol 1,3,4,5-tetrakisphosphate.

**tetrakisphosphate** any compound containing four independent phosphoric residues in ester linkages, at positions indicated by locants; e.g. inositol 1,3,4,5-tetrakisphosphate.

**tetramer** a molecular complex having four components or subunits. If the subunits are identical, the term homotetramer is used; if anyone is different from any other, the complex is called a heterotetramer.

**tetraose** **tetrasaccharide**; used as a stem name for any oligosaccharide consisting of four residues per molecule of the same sugar in a single type of linkage, as in cellobetaose. *Distinguish from* tetraose and tetrose.

**+tetraose** **suffix** used in nomenclature of glycolipids to indicate a molecule containing an oligosaccharide moiety composed of four sugar residues (which may be the same or different), as in gangliotetraose. *Distinguish from* tetraose.

**tetrapeptide** a four-residue peptide.

**triplex DNA** or **quadruplex DNA** a four-stranded DNA structure adopted by sequences rich in guanine bases. At least two major classes of such structures are known. The first involves the folding back of a repetitive sequence of guanines resulting in antiparallel strands. The other is characterized by the association of four independent parallel strands. *See also* triplex DNA.

**tetrapyrrole** a structure found in heme and other porphyrins, chlorophylls, bacteriochlorophylls, phytochromes, phycobilins, and corrinoids (e.g. vitamin B<sub>12</sub>). It consists of four pyrroles variously substituted and linked to each other through carbons at the  $\alpha$  position; in the case of hemes, these links are formed by one-carbon units (methylidene group). Characteristically, a metal is found coordinated to the pyrrole nitrogens, including iron (in hemes), magnesium (in chlorophylls), copper (in

turacin, the pigment of turaco bird feathers), and nickel (in factor f<sub>430</sub>, a prosthetic group in methanogenic bacteria). Synthesis is via aminolevulinic acid, which is synthesized from glycine and succinyl-CoA in animals and nonphotosynthetic organisms by 5-aminolevulinate synthase. For further steps in the pathway, *see* porphobilinogen synthase, hydroxymethylbilane synthase, uroporphyrinogen-III synthase, and uroporphyrinogen decarboxylase.

**tetraric acid** an aldaric acid derived by oxidation of a tetrose at C-1 and C-4. There are three tetraric acids, *D*-, *L*-, and *meso*-tartric acids.

**tetrasaccharide** an oligosaccharide with four monosaccharide units.

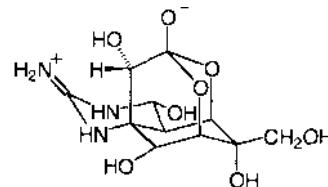

**tetrasomic** describing any polysomic cell, tissue, or individual in which one chromosome is represented four times in an otherwise diploid chromosome complement. *Compare* monosomic, nullisomic, trisomic, -tetrasomy *n*.

**tetratricopeptide repeat abbr.: TPR**; a degenerate consensus sequence of 34 amino acids found in multiple copies in several fungal and other proteins. These sequences participate in RNA synthesis regulation, protein import, and *Drosophila* development. Each sequence has two regions that are stereochemically complementary in a-helical conformation and form a hole and a knob surrounded by hydrophobic residues.

**tetrazolium salt** any of a group of compounds that are readily reduced to highly coloured, sparingly soluble formazan compounds, and are employed in the assay of some dehydrogenases. They include Blue Tetrazolium and Nitroblue Tetrazolium. IH-tetrazole is used in the chemical synthesis of oligonucleotides.

**tetritol** any alditol having a chain of four carbon atoms in the molecule.

**tetrodotoxin abbr.: TTX**; also known as fugu toxin; a toxin found in the liver and ovaries of the fugu, or puffer fish (order Tetraodontiformes, from which the toxin derives its name). It is a specific, reversible blocker of voltage-gated sodium channels. The LD<sub>50</sub> in mice is 8 µg kg<sup>-1</sup>. It does not block potassium or chloride channels.

**tetrose** any aldose having a chain of four carbon atoms in the molecule. *Distinguish from* tetraose.

**tetrulose** any ketose having a chain of four carbon atoms in the molecule.

**T-even phage** anyone of the bacteriophages T2, T4, or T6 of *Escherichia coli*. These DNA phages share a number of morphological, biochemical, and other features that distinguish them as a group from T-odd phages and are important historically in research on phages.

**Texas Red** a red-emitting fluorophore that is a sulfonyl chloride derivative of Sulforhodamine 101. It may be used with FITC in dual-label flow microfluorimetric and fluorescent microscopic studies because its excitation and emission spectra do not overlap with those of fluorescein.

**TF abbr. for** 1 tissue factor. 2 transcription factor.

**TFII** any of a group of transcription factors for eukaryotic RNA polymerase II promoters. TFIIA is needed for TFIID binding. Example from yeast, a heterodimer comprising large and small chains; large chain: database code TOALYEAST, 286 amino acids (32.17 kDa); small chain: database code TOA2\_YEAST,

122 amino acids (13.46 kDa). TFIIIB binds to RNA polymerase. Example from human: database code TF2B\_HUMAN, 316 amino acids (34.79 kDa). TFIID has two components, a TATA-binding protein that binds to the TATA box, and one of a number of accessory factors; it shows weak homology with bacterial sigma factors. Example from human: database code TF2D\_HUMAN, 339 amino acids (37.65 kDa). TFIIIE binds to RNA polymerase; it also shows weak homology with bacterial sigma factors. Example from human, a tetramer of two alpha chains and two beta chains; alpha chain: database code T2EA\_HUMAN, 439 amino acids (49.42 kDa); beta chain: database code T2EB\_HUMAN, 291 amino acids (33.01 kDa).

TFIII any of a group of transcription factors for eukaryotic RNA polymerase III promoters. The examples are all from yeast. TFIIIA is a zinc-finger protein (*see* zinc finger) that binds both DNA and the 5S RNA transcript; database code S20050, 429 amino acids (49.97 kDa). TFIIIB is an RNA polymerase-binding protein. 70 kDa subunit: database code TF3B\_YEAST, 596 amino acids (66.83 kDa). TFIIIC (*or tau*) is a heterotrimer, subunit database codes: TFC1\_YEAST, 649 amino acids (73.47 kDa); TFC3\_YEAST, 1160 amino acids (131.96 kDa); TFC4\_YEAST, 1025 amino acids (120.09 kDa).

TFA *abbr.* for trifluoroacetic acid.

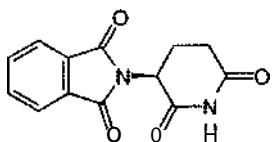

T form *abbr.* for tense form (*or* taut form).

TGF *abbr.* for transforming growth factor.

Th *symbol* for thorium.

thalassemia *or* (*esp. Brit*) thalassaemia any of a group of diseases resulting from inherited defects in the rate of synthesis of one of the types of polypeptide chain of hemoglobin. Such defects lead in turn to ineffective erythropoiesis, hemolysis, and a variable degree of anemia. In alpha thalassemia the defect is in the production of alpha chains and there is concomitant excessive beta- and gamma-chain production leading to the formation of various abnormal hemoglobins. In beta thalassaemia the formation of beta chains is defective with an excessive synthesis of alpha chains and the continued production of fetal hemoglobin (U2Y2').

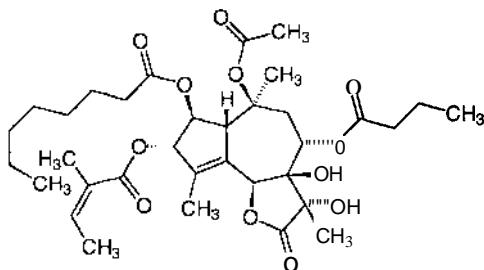

thalidomide N-(2,6-dioxo-3-piperidyl)phthalimide; a-phthalimidoglutarimide; a synthetic tranquillizer and sedative. It was used originally (in the 1950s) as a racemate, which causes severe fetal abnormalities such as the absence or reduction in lengths of one or more limbs. The L(S) enantiomer apparently has the teratogenic activity (*see* teratogen), while the D(R) enantiomer has the desired sedative property. The situation is unclear since thalidomide racemizes rapidly *in vivo*.

(S)-form

THAM *abbr.* for tris(hydroxymethyl)aminomethane; *see* Tris. thanatogene a hypothetical gene whose expression is supposed to lead to cell death in terminally differentiated cells. [From Greek *thanatos*, death.]

thapsigargin a tumour-promoting sesquiterpene lactone. It inhibits endoplasmic reticulum calcium-transporting ATPase and mobilizes intracellular calcium.

thapsigargin

thaumatin a sweet-tasting, basic, 20 kDa protein isolated from the berries of the bushy African plant, *Thaumatococcus danielli*; there are five different forms. Its sweetness in aqueous solution is 2500 times greater than that of sucrose; it has sequence similarities with monellin.

Thd *symbol* for a residue of the ribonucleoside ribothymidine; ribosylthymine; thymine riboside (alternative to T). Compare dThd.

Thd5'P *symbol* for ribothymidine 5'-phosphate.

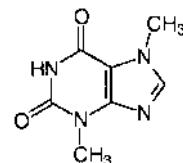

Thd5'PP *symbol* for ribothymidine 5'-diphosphate (alternative to ppT).

Thd5'PPP *symbol* for ribothymidine 5'-triphosphate (alternative to pppT).

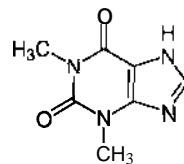

thebaine one of the alkaloids present in opium.

T-helper cell *see* helper cell.

theobromine 3,7-dimethylxanthine; the principal alkaloid of the cacao bean. Its actions are similar to those of theophylline. *See also* caffeine.

theophylline 1,3-dimethylxanthine; a competitive inhibitor of cyclic AMP phosphodiesterase (a 10 mM solution completely inhibits the beef heart enzyme). It has diuretic and cardiac stimulatory action, and relaxes smooth muscle; it is a bronchodilator. *See also* caffeine, theobromine.

Theorell, Axel Hugo Theodor (1903-82), Swedish biochemist; Nobel Laureate in Physiology or Medicine (1955) 'for his discoveries concerning the nature and mode of action of oxidation enzymes'. *See also* Theorell-Chance mechanism.

Theorell-Chance mechanism (*in enzyme kinetics*) an enzyme mechanism in which it is obligatory for substrates to bind in a certain order and in which no kinetically significant ternary complex is formed. [After A. H. T. Theorell and Britton Chance (1913- ), US biochemist.]

theoretical plate a term used in the analysis of chromatography column performance; the higher the number of theor-

## therm+

etical plates achieved, the greater the efficiency of the column. The number of theoretical plates is derived by dividing the peak width by the retention time. The term derives from the concept that the column can notionally be divided into a large number of 'slices' or 'plates' at each of which the separation process will progress. *See also* effective theoretical plate number.

**therm+** a variant form of *thermo+* (before a vowel).

**thermal analysis** *see* differential thermal analysis, differential scanning calorimetry.

**thermal conductance symbol:**  $C$ ; the ability of a material to conduct heat, measured as the ratio of the heat flow rate,  $\Phi$ , to the temperature difference, i.e.  $C = \Phi/\Delta T$ . SI units are watts per kelvin.

**thermal conductivity symbol:**  $\lambda$  or  $k$ ; a measure of the ability of a material to transmit heat. It is the heat flux in  $\text{W m}^{-2}$  divided by the temperature gradient; i.e.  $\lambda = J_q/(dT/dl)$ , where  $J_q$  is the heat flux and  $dT$  is the thermodynamic temperature difference over the length,  $dl$ . It is measured in watts per metre per kelvin.

**thermal denaturation profile** a curve relating some physical property of a biopolymer in solution (e.g. viscosity, optical absorbance, or optical rotation) to temperature. The shape of the curve indicates the occurrence of physical changes in the biopolymer, e.g. separation of the two strands of double-stranded nucleic acid or alteration in the tertiary structure of a protein. *See also* denaturation, melting temperature.

**thermal equilibrium** the condition of a system when there is no tendency for heat to flow within it, or to or from its surroundings; all parts of the system and its surroundings are at the same temperature.

**theristor** a semiconductor whose resistance is sensitive to temperature. [From thermal resistoL]

**thermitase** EC 3.4.21.66; *other name:* thermophilic *Streptomyces* serine protease; an enzyme that catalyses the hydrolysis of proteins, including collagen. It is a  $\text{Ca}^{2+}$ -binding serine proteinase from *Thermoactinomyces vulgaris*, and is a homologue of subtilisin. It is inhibited by p-mercuribenzoate, which reacts with the single cysteine residue near the active-site histidine. Database code THET\_THEVU, 279 amino acids (28.33 kDa); 3-D structure known.

**thermo+** or (before a vowel) **therm+** comb. form indicating a relationship to heat or heat transference.

**thermobarometer** a control manometer and flask used in a Warburg apparatus, or other constant-volume-type respirometer, to compensate for changes in temperature and barometric pressure during the course of an experiment.

**thermochromism** any reversible change of colour of a substance with change of temperature. *Compare* electrochromism, photochromism. -thermochromic adj.

**thermocouple** a device consisting of two pieces of dissimilar metals joined together at a point, their free ends being connected to an instrument to measure electromotive force (emf). The emf produced at the metal-metal junction is a function of the junction temperature, hence a thermocouple may be used to measure temperature. The phenomenon is known as the Seebeck effect.

**thermodynamicase** (sometimes) an alternative name for protein disulfide isomerase.

**thermodynamic equilibrium constant** *see* equilibrium constant.

**thermodynamics** the study of the laws that govern the conversion of energy from one form to another, the direction in which heat will flow from one system to another, and the availability of energy to do work. The zeroth law of thermodynamics states that if two systems are each in thermal equilibrium with a third system, then they must be in thermal equilibrium with each other. The first law of thermodynamics or the law of conservation of energy specifies that in an isolated, adiabatic system the sum of the internal energies of all kinds,  $U$ , remains constant, whatever may be the changes within the system itself. If a system of constant mass gains

heat,  $q$ , and has work,  $w$ , done on it then a change in its internal energy,  $\Delta U$ , occurs such that  $\Delta U = q + w$ . (Where the system loses heat,  $q < 0$ , and where work is done by it,  $w < 0$ .) The second law of thermodynamics is concerned with the restrictions in the direction of energy flow in natural systems and takes account of the irreversibility of natural processes. It specifies that the entropy of any system,  $S$ , unlike energy, is not conserved but increases with time in any spontaneous process in an isolated system. In the limiting case of a reversible process, the increase in entropy of a system,  $dS$ , is defined as the heat absorbed by the system,  $dq_{rev}$  divided by the thermodynamic temperature,  $T$ ; i.e.  $dS = dq_{rev}/T$ . The third law of thermodynamics is concerned with the fact that the difference between the change in enthalpy,  $\Delta H$ , and the change in the free energy,  $\Delta G$ , of a system diminishes as the temperature of the system diminishes, and the value of  $(\Delta H - \Delta G)$  tends to zero as the thermodynamic temperature tends to zero. This requires that the change in the heat capacity of the system (at constant pressure),  $\Delta C_p$ , and  $\Delta S$  must fall to zero at 0 K.

**thermodynamic temperature or (formerly) absolute temperature symbol:**  $T$ ; a fundamental physical quantity - one of the seven SI base quantities - defined in terms of the laws of thermodynamics, independently of any particular substance. The SI unit is the kelvin. *See also* temperature.

**thermogenesis** the generation of heat by specialized tissues in mammals and in flowers or inflorescences of plants, e.g. arum lilies (*Arum maculatum*). In mammals, this function is performed by brown adipose tissue. -thermogenic adj.

**thermogenin** *another name for* brown fat uncoupling protein.

**thermolabile** unstable at elevated temperatures. *Compare* thermostable. -thermolability n.

**thermolysin** EC 3.4.24.27; *other name:* *Bacillus thermoproteolyticus* neutral proteinase; a notably heat-stable, zinc-containing metalloendoproteinase produced by *B. thermoproteolyticus*; it also contains four bound calcium ions. It catalyses the preferential cleavage: Xaa-I-Leu > Xaa-I-Phe. Thermolysin is typical of several such bacterial enzymes: database code NRL\_3TLN, 316 amino acids (34.30 kDa); 3-D structure is known.

**thermolysis** the uncatalysed cleavage of one or more covalent bonds caused by exposing a chemical compound to a raised temperature. *See also* pyrolysis. -thermolytic adj.

**thermometer** any instrument for measuring temperature. All thermometers depend on the change with temperature of some easily measured physical property such as the expansion of mercury (or other liquids) or the change in electrical resistance. *See also* thermocouple.

**thermometry** the branch of physics concerned with thermometers and the measurement of temperature.

**thermoneutron activation analysis** *an alternative name for* radioactivation analysis.

**thermosmosis** the flow of solvent, especially water, across a membrane as a result of a temperature gradient across the membrane.

**thermophile** an organism, especially a microorganism, that can tolerate high temperatures and that grows optimally at temperatures above 45 °C. *Compare* mesophile, psychrophile. -thermophilic adj.

**thermoregulator** any device or mechanism (including physiological) that controls the temperature of an environment. -thermoregulatory adj.

**thermospray** or electron spray mass spectrometer (abbr.: ESMS); an instrument that directly applies a proportion of the eluent of a liquid chromatograph to a mass spectrometer for analysis of resolved components.

**thermostable** maintaining characteristics or function under a change (normally increased) of temperature. *Compare* thermolabile. -thermostability adj. *Compare* thermolabile.

**thermostat** 1 an automatic device for regulating temperature, especially maintaining a constant temperature. Such devices often work by cutting off the supply of heat when the required

## thermostat

## thermotitration

temperature is exceeded and restoring it when the temperature falls below the required value. 2 to provide with or to control using a thermostat. *-thermostatic adj.*

**thermotitration** the determination of the endpoint of a reaction, or the point at which the reaction reaches equilibrium, by measurement of heat of reaction.

**THESIT** *an alternative name for C<sub>12</sub>E<sub>9</sub> (see C<sub>x</sub>E<sub>y</sub>), or Lubrol PX (see Lubrol).*

**theta symbol:** θ (lower case) or Θ (upper case); the eighth letter of the Greek alphabet. For uses see Appendix A.

**theta structure** the structure that forms during replication of circular duplex DNA by the opening up of the two strands. Under electron microscopy it has the appearance of a Greek theta.

**L-thevetose** 6-deoxy-4-O-methyl-L-glucose; a component of some cardiac glycosides.

**THF** *abbr. for 1 tetrahydrofuran. 2 tetrahydrofolate (often used but not encouraged; H<sub>4</sub>folate preferred).*

**thia+** *or (before a vowel) thi+ comb. form* containing sulfur, especially in place of carbon. *See also thio+.*

**thiamine** *or (sometimes) thiamin or (formerly) aneurin(e) an alternative name for vitamin 8..*

**thiamine diphosphate** *or (sometimes) thiamin diphosphate or (formerly) thiamin pyrophosphate abbr.: TPP; see vitamin 8..*

**thick filament** a longitudinal assembly of myosin molecules occurring in muscle. The thick filaments are the major constituents of the A band of the sarcomere in skeletal muscle; they interact with the thin filaments to bring about muscle contraction (*see sliding filament model*).

**thin filament** a molecular complex of actin, tropomin (composed of the three peptides troponins I, T, and C), and tropomyosin, found in muscle tissue. In striated muscle the thin filaments span the I band and interdigitate between the ends of the thick filaments in the A band. Interaction between the thin and thick filaments brings about muscle contraction (*see sliding filament model*).

**thin-film dialysis** a type of dialysis that maintains the diffusate and the retentate in thin layers in intimate contact with the dialysis membrane in order to lessen the contribution to the overall rate of the process made by diffusion of solutes in free solution. Very rapid removal or exchange of small molecules can occur, especially if the volume ratio of diffusate to retentate is high. With appropriate membranes the technique may also be used for analytical studies of the size and conformation of peptides and proteins in solution.

**thin-layer chromatography** *abbr.: TLC;* chromatography on a thin layer of any of various powdered materials, including silicic acid, aluminium oxide, or cellulose. The layer, characteristically between 0.05 and 1 mm thick, is made to adhere to a sheet of glass, aluminium, or plastic. Thicker layers accept heavier loading, while thinner layers resolve more efficiently and rapidly. Resolving power is high, runs are rapid, and, because support materials such as silicic acid or aluminium oxide are inert to them, corrosive sprays, such as sulfuric acid, can be used to convert organic materials to carbon (a process known as charring), revealing them as black spots.

**thio+ or (sometimes before a vowel) thi+ comb. form** 1 relating to or containing sulfur. 2 (*in chemical nomenclature*) denoting replacement of oxygen in a compound by (bivalent) sulfur. In trivial names of compounds it is used as a prefix (as in thiouracil; *compare* uracil), whereas in the systematic names of individual compounds it is used as an affix and is usually placed before the affix denoting an oxygen atom or an oxygen-containing group (as in ethanethiol; *compare* ethanol), although for organic sulfides, if named analogously to ethers by substitutive nomenclature, it replaces oxy+ (as in 3-(methylthio)propionate). *Compare* thia+. *See also* mercapto+.

**thioacetal** *see acetal.*

**thioctic acid** *a less common name for lipoic acid.*

**thiocyanate** 1 the anion, N≡C-S<sup>-</sup>, derived from thiocyanic acid. 2 any salt of thiocyanic acid. 3 any organic compound

## thiolactomycin

containing the monovalent group -S-C≡N. *Compare* isothiocyanate.

**thioester** any organic compound formed, actually or formally, by the elimination of the elements of water either (I) between the carboxyl group of a carboxylic acid and a thiol, or (2) between the thiocarboxyl group of a thiocarboxylic acid and an alcohol or phenol. Thioesters formed by mechanism (I) are of general formula R<sub>1</sub>-CO-SR<sub>2</sub>, whereas those formed by mechanism (2) may be of general formula either R<sup>1</sup>-CO-SR<sup>2</sup> or R<sup>1</sup>-CS-OR<sup>2</sup>.

**thioether** *an old name for any organic sulfur-containing compound of general formula RI-S-R2.* Sulfide is now the recommended generic name.

**thiogalactoside transacetylase** *see galactoside acetyltransferase.*

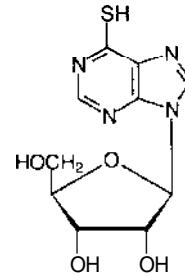

**thioglucosidase** EC 3.2.3.1; *systematic name:* thioglucoside glucohydrolase; *other name:* sinigrase. An enzyme that hydrolyses thioglucosides to the constituent thiol and sugar, e.g. sinigrin to glucose and N-(sulfoxy)-3-mercaptopro-3-buteneimidate. **thioglycoside** or **S-glycoside** any glycoside in which a glycosyl group is substituted into a thiol group in another compound. A naturally occurring example is sinigrin.

**thiohemiacetal** *see acetal.*

**thiohemiketal** *see acetal.*

**thiohypoxanthine** *an alternative name for mercaptoperazine.*

**thiinosine** *symbol: sI or Sno; 6-thiinosine; thiohypoxanthine riboside; mercaptoperazine ribonucleoside; 9-ji-D-ribofuranosyl-6-mercaptopurine; a nucleoside not occurring naturally. See also mercaptoperazine.*

**thioketal** *see acetal.*

**thiokinase** *(sometimes)* any of certain ATP-requiring enzymes of sub-subclass EC 6.2.1 (acid thiol ligases) that synthesize CoA thioesters of various fatty acids. These enzymes (recommended names given first) are: (1) acetate-CoA ligase, which acts on acetate, propanoate, and propenoate; (2) butyrate-CoA ligase; EC 6.2.1.2; *other names:* fatty acid thiokinase (medium chain); butyryl-CoA synthetase; butanoate-CoA ligase (AMP forming); this acts on C<sub>4</sub> to C<sub>12</sub> acids and on corresponding 3-hydroxy- and 2,3- or 3,4-unsaturated acids; (3) long-chain-fatty-acid-CoA ligase; EC 6.2.1.3; *other names:* fatty acid thiokinase (long chain); acyl-CoA synthetase; acid:CoA ligase (AMP forming); this acts on a wide range of long-chain saturated fatty acids, the exact range of chain lengths varying somewhat according to the tissue of origin of the enzyme; and (4) acetate-eoA ligase (ADP-forming); also acts on propionate and (very slowly) on butanoate.

**thiol** 1 *or (formerly) mercaptan* any organic compound containing -SH as the principal group directly attached to a carbon atom. 2 *or sulphydryl* the (covalently linked) -SH group in any chemical compound.

**+thiol suffix** (*in organic chemical nomenclature*) indicating the presence of a thiol group attached to a carbon atom. *Compare* mercapto+.

**thiolactomycin** an antibiotic isolated from *Nocardia* spp. It selectively inhibits type II straight-chain fatty-acid synthases (i.e. the monofunctional enzyme system such as that in

## thiolase

*Escherichia coli*) but not the type I enzymes (i.e. the multi-functional enzyme system such as that in *Saccharomyces cerevisiae*).

thiolase a commonly used but misleading generic name for certain enzymes of differing chain-length specificity within sub-subgroup EC 2.3.1 (acyltransferases) that catalyse the thiolysis by coenzyme A of CoA thioesters of *fJ*-*oxo* fatty acids according to the general equation:

Thiolases are thiol enzymes, their S-acyl derivatives being formed as intermediates in the reactions catalysed. Although the overall reactions are reversible, the equilibrium positions are greatly in favour of cleavage. These enzymes include: acetyl-CoA C-acetyltransferase; EC 2.3.1.9 and acetyl-CoA C-acetyltransferase, EC 2.3.1.16.

thiolate 1 the anion, R-S<sup>-</sup>, derived from a thiol (def. I). 2 any salt of a thio!. 3 to introduce a thiol group into an organic compound. -thiolation *n*.

thiol proteinase *an old name for cysteine* endopeptidase.

thioltransacetylase A *see dihydrodilipoamide S-acetyltransferase*. thiolysis lysis of a covalent organic compound by a thiol; a reaction analogous to alcoholysis in which bond cleavage is mediated by nucleophilic attack by the -SH group of an alkanethiol!. The term is applied in particular to the thiolase-catalysed cleavage of a *fJ*-*oxo*acyl-CoA by coenzyme A in each cycle of chain-length reduction during fatty-acid catabolism. -thiolytic *adj*.

thionein the apoprotein of a metallothionein.

thionin any of a group of small proteins, characterized by two conserved motifs, that occur in plants and are toxic to animals. Example, leaf thionin from barley (precursor): database code THN3\_HORVU, 137 amino acids (14.65 kDa); the toxic principle is formed from amino-acid residues 29-34.

thionucleoside any N-glycoside of any thiopurine or thioPrimididine.

thionucleotide any phosphoric ester of any thionucleoside.

thiopurine any purine in which a thiol group has replaced a hydroxyl group. *Compare mercaptopurine*.

thiopyrimidine any pyrimidine in which a thiol group has replaced a hydroxyl group.

thioredoxin any member of a widely occurring class of heat-stable hydrogen-carrier proteins of  $\approx 12$  kDa that serve as hydrogen donors in various reduction reactions, notably of ribonucleoside diphosphates to the deoxy analogues, and in the light-dependent reductive activation of various chloroplast enzymes (including a number of those in the pentose-phosphate cycle). Chloroplast thioredoxin occurs in two forms (designated *f* and *m*), which show specificity in their enzyme-activating properties; a third form (designated *c*), of unknown function, occurs outside chloroplasts. Thioredoxins can exist in disulfide (i.e. oxidized) and dithiol (i.e. reduced) states, interconversion being catalysed by ferredoxin-thioredoxin reductases. Example, thioredoxin I from *Anacystis nidulans*: database code THII\_ANANI, 106 amino acids (11.52 kDa). *See also thioredoxin reductase (NADPH)*.

thioredoxin reductase (NADPH) EC 1.6.4.5; a flavoprotein (FAD) enzyme that catalyses the reaction:

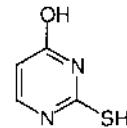

Example from *Escherichia coli*: database code TRXB\_ECOLI, 320 amino acids (34.45 kDa); a homodimer.

thiotemplate mechanism or protein thiotemplate mechanism the mechanism of biosynthesis of *Bacillus brevis* peptide antibiotics, e.g. gramicidin S and tyrocidin A, in which the precursor amino acids, after activation, are bound as thioesters to the synthetase enzymes.

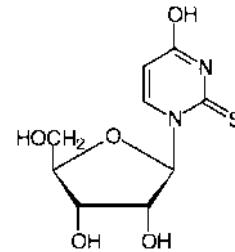

thiouracil *symbol*: Sur; 2-thiouracil; 4-hydroxy-2-mercaptopurimidine; 4-oxy-2-thiopyrimidine; a naturally occurring thiopyrimidine, found in seeds of members of the cabbage

## threonine

family (e.g. *Brassica* spp.) and as a minor base in certain types of ribonucleic acid, especially transfer RNA (*see also thio-uridine*). Thiouracil, 6-methylthiouracil, and 6-propylthiouracil are clinically useful for treatment of hyperthyroidism and thyrotoxicosis, their action being to inhibit biosynthesis of the thyroid hormones at the peroxidase-catalysed iodination and coupling steps.

thiouridine *symbol*: S or sU or Srd; either of two constitutional isomers occurring as minor nucleosides in certain types of ribonucleic acid, especially transfer RNA (tRNA): 2-thiouridine (2-thiouracil riboside; 1-*fJ*-o-ribofuranosyl-4-oxy-2-thiopyrimidine; *symbol*: 2S or S2U), or its 5-methyl, 5-(methylaminomethyl), or 5-(methoxycarbonylmethyl) derivatives, which are found in some tRNA species in the first position of the anticodon; and 4-thiouridine (4-thiouracil riboside; 1-*fJ*-o-ribofuranosyl-2-oxy-4-thiopyrimidine; *symbol*: 4S or S<sup>4</sup>U), which is found in some tRNA species elsewhere than in the anticodon.

2-thiouridine

third law of thermodynamics *see thermodynamics*.  
thixotrope a gel that exhibits thixotropy.

thixotropy the property shown by certain fluids and gels of becoming less viscous when subjected to stress, e.g. by shaking or stirring, and of becoming more viscous again when the stress is relieved. -thixotropic *adj*.

Thr *symbol* for a residue of the a-amino acid L-threonine (alternative to T).

THR a gene family encoding thyroid receptors; part of a superfamily including receptors for steroids, retinoic acid, and vitamin D<sub>3</sub>; *see erbA*.

threitol active erythritol, threo-I,2,3,4-tetrahydroxybutane, threo-I,2,3,4-butanetetrol; an enantiomeric pair of polyols, configurationally isomeric with erythritol. o-Threitol occurs in certain fungi, e.g. the honey fungus, *Armillaria mellea*.

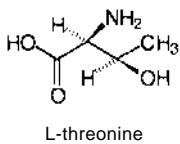

**threo-** a configurational prefix to the systematic name of a polyhydric alcohol, especially of a monosaccharide, used to indicate the particular stereochemical configuration of a set of two contiguous >CHOH groups that occurs in o-threose (see *threose* for structure) or L-threose, e.g. o-threo-2-pentulose for o-xylulose. *Compare erythro-*.

threoninate 1 threonine anion; the anion, CH<sub>3</sub>-CH(OH)-CH(NH<sub>2</sub>)-COO<sup>-</sup>, derived from threonine. 2 any salt containing threonine anion. 3 any ester of threonine.

threonine *the trivial name for* a-amino-*fJ*-hydroxybutyric acid; (2*R*\*,3*S*\*)-2-amino-3-hydroxybutanoic acid; CH<sub>3</sub>-CH(OH)-CH(NH<sub>2</sub>)-COOH; an a-amino acid with two chiral centres.

## threonine aldolase

Because molecules of threonine possess a second chiral centre, at C-3, in addition to the chiral centre at C-2 common to all  $\alpha$ -amino acids other than glycine, the enantiomers L-threonine, (2S,3R)-2-amino-3-hydroxybutanoic acid (*symbol*: T or Thr), and D-threonine, (2R,3S)-2-amino-3-hydroxybutanoic acid (*symbol*: D-Thr or DThr), are diastereoisomeric with those of allothreonine, (2R\*,3R\*)-2-amino-3-hydroxybutanoic acid. [Note: The enantiomers of threonine may also be named semi-systematically as derivatives of threose: L-threonine in amino-acid nomenclature is synonymous with 2-amino-2,4-dideoxy-D-g-threonic acid in carbohydrate nomenclature, and Ds-threonine with 2-amino-2,4-dideoxy-L-g-threonic acid (the subscript letters d or g being added to the configurational prefixes where there might be uncertainty regarding the reference centre of chirality; see *OL* convention).] L-Threonine is a coded amino acid found in peptide linkage in proteins; codon: ACA, ACC, ACG, or ACU. In mammals it is an essential dietary amino acid, is glucogenic, and its deficiency causes fatty liver. The fungal toxins phalloidin and phalloidin contain one residue of D-threonine per molecule.

L-threonine

threonine aldolase *see* glycine hydroxymethyltransferase.

threonine dehydratase EC 4.2.1.16; *systematic name*: L-threonine hydro-lyase (deaminating); *other names*: threonine deaminase; L-serine dehydratase; serine deaminase. A pyridoxal-phosphate enzyme that catalyses a reaction between L-threonine and water to form 2-oxobutanoate, NH<sub>3</sub>, and water; it acts also on L-serine. There are two types (examples from *Escherichia coli*): type I is responsible for the first step of isoleucine biosynthesis (serine is an alternative but poorer substrate); database code THDLECOLI, 514 amino acids (56.13 kDa); type 2 is a catabolic enzyme that acts on both serine and threonine, and is properly considered as a hydroxy-amino-acid deaminase; database code THD2\_ECOLI, 329 amino acids (35.19 kDa).

threonine synthase EC 4.2.99.2; *systematic name*: O-phospho-L-homoserine phospho-lyase (adding water). A pyridoxal-phosphate enzyme that catalyses the formation of L-threonine from O-phospho-L-homoserine and water with release of orthophosphate. Example from *Escherichia coli*; database code THRC\_ECOLI, 428 amino acids (47.06 kDa); it shows sequence homology with the serine dehydratase/threonine dehydratase group.

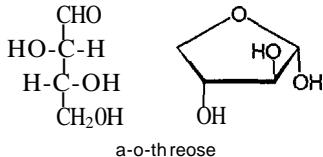

threoninium threonine cation; the cation, CH<sub>3</sub>-CH(OH)-CH(NH<sub>3</sub><sup>+</sup>)-COOH, derived from threonine.

threonino the alkylamino group, CH<sub>3</sub>-CH(OH)-CH(COOH)-NH-, derived from threonine.

**threonin-O<sup>3</sup>-yl** the alkyloxy group, HOOC-CH(NH<sub>2</sub>)-CH(CH<sub>3</sub>)-O-, derived from threonine.

threonyl the acyl group, CH<sub>3</sub>-CH(OH)-CH(NH<sub>2</sub>)-CO-, derived from threonine.

threose the trivial name for the aldötetrose *threo-tetrose*; it has D and Lenantiomers, which are respectively diastereoisomeric with those of erythrose. *See also* threo-.

## thromboxane

threshold the value that must be achieved or exceeded for an effect to become discernible. For example, the kidney threshold of excretion, for any substance, is the plasma concentration at which not all of the substance that appears in the filtrate can be reabsorbed, so that it appears in the urine.

**THRF** *abbr.* for thyrotropic hormone releasing factor; i.e. thyrotropin-releasing hormone.

**THRH** *abbr.* for thyrotropic hormone releasing hormone; i.e. thyrotropin-releasing hormone.

thrombin EC 3.4.21.5; *other name*: fibrinogenase; a serine proteinase, M<sub>r</sub> 33 700-33 900, the natural coagulant of fibrinogen. Thrombin appears in the blood following activation of the coagulation system, as a result of proteolysis of prothrombin. It catalyses the preferential cleavage of Arg-I-Gly, activating fibrinogen to fibrin and releasing fibrinopeptides A and B. Its effects are mediated by the thrombin receptor. *See also* blood coagulation.

thrombin receptor a protein of platelets and vascular endothelial cells that binds thrombin and mediates its intracellular effects. It is a G-protein-coupled receptor. Example from human (precursor): database code THRR\_HUMAN, 425 amino acids (47.35 kDa); this is a glycoprotein; the signal peptide comprises amino acids 1-26, and amino acids 27-41 are removed by thrombin, after which the new N terminus functions as a tethered ligand and the receptor is thereby activated.

thrombocyte *an alternative name for* platelet.

thrombogenic 1 tending to promote the formation of a blood clot (i.e. a thrombus). 2 having a precursor function for, or tending to promote, the formation of thrombin.

**$\beta$ -thromboglobulin** a homotetramer of a peptide derived from platelet basic protein precursor by removal of the first four N-terminal residues from LA-PF4. It is released by activated platelets. It belongs to the intercrine *a* family (*see* chemokine) and mediates a number of actions in the inflammatory response, including chemotaxis of leukocytes.

thrombokinase *an alternative name for* factor Xa; *see* blood coagulation.

thrombolysis the degradation of a blood clot (i.e. thrombus) as a result of physiological or pharmacological action.

thrombolytic 1 tending to promote thrombolysis. 2 a drug or other substance promoting thrombolysis.

thrombomodulin *abbr.*: TM; *other name*: fetomodulin; a specific endothelial cell receptor that forms a 1:1 stoichiometric complex with thrombin, the complex being responsible for conversion of protein C to activated protein C. It is a type I membrane protein. Example (precursor) from human: database code TRBM\_HUMAN, 575 amino acids (60.26 kDa).

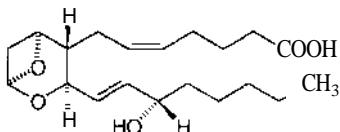

thromboplastin *an alternative name for* factor III; *see* blood coagulation.

thrombospondin or glycoprotein G a thrombin-sensitive major glycoprotein located in the alpha granules of human platelets. It is secreted on thrombin activation and binds to the platelet membrane in the presence of Ca<sup>2+</sup>. It is an adhesion molecule that mediates cell-cell and cell-matrix interactions and can bind to fibrinogen, fibronectin, laminin, and type V collagen. It is a trimeric disulfide-linked protein and contains three types of repeating amino-acid sequence; the first is 57 amino acids long and shows homology with circumsporozoite protein from a malarial parasite; the second is 50-60 amino acids long and shows homology with epidermal growth factor; the third occurs as a continuous eightfold repeat of a 38-residue sequence; structural homology with calmodulin indicates that these repeats constitute multiple calcium-binding sites. Example, human thrombospondin 1 precursor: database code TSP1\_HUMAN, 1170 amino acids (129.27 kDa). There are at least three such related proteins in humans.

thromboxane any of a class of prostanoids synthesized by thromboxane-A synthase (EC 5.3.99.5) from prostaglandin H (the product of prostaglandin-endoperoxide synthase) as thromboxane A (TXA). Depending on whether the substrate of the enzyme is dihomo-(6,9,12)-linolenate, arachidonate, or eicos-

## thromboxane-A synthase

5,8,11,14,17-pentaenoate, the product is TXA<sub>1</sub>, TXA<sub>2</sub>, or TXA<sub>3</sub> respectively. TXA<sub>2</sub> is the major thromboxane *in vivo*. It is synthesized in platelets when these are activated by other aggregatory compounds and strongly reinforces the aggregatory reaction. Its biological lifetime is a few minutes, TXA<sub>2</sub> being converted to the inactive metabolite thromboxane B<sub>2</sub> (TXB<sub>2</sub>) by addition of water across the endoperoxide. Oxidation of the II-hydroxy group of TXB<sub>2</sub> to an oxo group yields II-dehydro-thromboxane A<sub>2</sub>, a major long-lived metabolite in human plasma, useful for measurement as an index of thromboxane production. Beta-oxidation of TXB<sub>2</sub> yields 2,3-dinor-thromboxane B<sub>2</sub>, the major human urinary metabolite. Dideoxy-epoxymethanoprostaglandin F<sub>2α</sub> is a stable analogue that mimics TXA<sub>2</sub>.

**thromboxane-A synthase** EC 5.3.99.5; *other names*: thromboxane synthase; thromboxane synthetase (*abbr.*: TXS); an enzyme that catalyses the formation from (52,13E)-(15S)-9a,IIa-epidioxy-15-hydroxyprosta-5,13-dienoate of (52,13E)-(15S)-9a,IIa-epoxy-15-hydroxythromba-5,13-dienoate (thromboxane A<sub>2</sub>). It is a heme-thiolate protein. 1-(7-Carboxyheptyl)imidazole and benzylimidazole inhibit thromboxane-A synthase, as does the drug U-63557A, sodium furegrelate. Example from human: database code THAS\_HUMAN, 533 amino acids (60.42 kDa).

**thrombus** (*pl.* thrombi) a blood clot forming within a blood vessel. Thrombus formation may occur as a normal response during physiological blood coagulation. It may also occur pathologically, triggered by atheroma, and is the immediate cause of ischemia in a heart attack. Thrombi may also form, especially in veins, at other times, e.g. after surgery, and if they reach the lungs cause pulmonary embolism.

**Thunberg method** an early method for detecting and estimating dehydrogenases depending on the rate and extent of decolorization of Methylene Blue in solution in the presence of dehydrogenase and substrate. The apparatus, known as a Thunberg tube, consists of a stoppered glass tube (sometimes with a side-arm for addition of reagents) that may be evacuated through the stopper, and then sealed by a twist of the stopper. [After Torsten Ludvig Thunberg (1873-1952), Swedish physiological chemist]

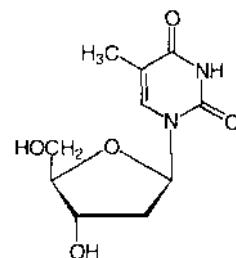

**Thx symbol** for a residue of the α-amino acid and thyroid hormone L-thyroxine (alternative to T<sub>4</sub>).

**Thy symbol** for a residue of the pyrimidine base thymine (alternative to T).

**Thy-1** an allelic variable molecule, encoded on mouse chromosome 9, that is present on all T lymphocytes and also occurs in brain. It is a GPI-anchored membrane glycoprotein of the immunoglobulin superfamily, with a simple structure homologous to the variable region of an immunoglobulin molecule. Example (precursor) from human: database code THY1\_HUMAN, 161 amino acids (17.94 kDa). *See also* thymopoietin. **thylakoid** a saclike vesicle that bears the photosynthetic pigments in photosynthetic organisms. In prokaryotes the thylakoids are of various shapes and are attached to the plasma membrane. In eukaryotes they are flattened, membrane-bound disk-like structures located in the chloroplasts; in the chloroplasts of higher plants the thylakoids form dense stacks called grana. Isolated thylakoid preparations can carry out photosynthetic electron transport and the associated phosphorylation. **thymic hormones** *see* thymopoietin, thymosin.

## thymidine 5'-phosphate

**thymidine or deoxyribosylthymine symbol:** dT or dThd; thymine 2'-deoxyriboside; 1-(2-deoxy-p-D-ribofuranosyl)-5-methyluracil; a deoxynucleoside very widely distributed but occurring almost entirely as phosphoric esters in deoxynucleotides and deoxyribonucleic acid, DNA. *Compare* ribothymidine. Because thymidine is absent from ribonucleic acid, the incorporation of radioisotope-labelled thymidine into cells has been made the basis of a procedure frequently used for measuring the rates of DNA synthesis and cell growth.

**thymidine 5'-diphosphate symbol:** dThd5'PP or ppdT; *the recommended name for* thymidine diphosphate (*abbr.*: dTDP), 5'-diphosphothymidine, 5'-thymidyl phosphate, thymidine 5'-(trihydrogen diphosphate). It is an intermediate in the formation of thymidine 5'-triphosphate from thymidine 5'-phosphate. Derived compounds are the rare nucleosidediphosphosugars thymidinediphosphorhamnose and its biosynthetic precursor thymidinediphosphoglucosamine.

**thymidine kinase** EC 2.7.1.21; *systematic name*: ATP:thymidine 5'-phosphotransferase; an enzyme that catalyses the phosphorylation by ATP of thymidine to thymidine 5'-phosphate with release of ADP. It acts on thymidine taken into a cell, or on free thymidine released within a cell, as a first step in its further metabolism. Mitochondrial and cytosolic forms are known, the latter showing much greater activity in proliferating than in resting cells. Example from herpes simplex type 2: database code KITH\_HSV23, 375 amino acids (40.32 kDa).

**thymidine monophosphate** *abbr.*: dTMP; *an alternative name for* any thymidine phosphate, but in particular for thymidine 5'-phosphate, especially when its distinction from thymidine (5')diphosphate and thymidine (5')-triphosphate requires emphasis.

**thymidine phosphate symbol:** dThdP; thymidine monophosphate (*abbr.*: dTMP); any phosphoric monoester or diester of thymidine. There are two monoesters - thymidine 3'-phosphate and thymidine 5'-phosphate - and one diester - thymidine 3',5'-phosphate - although thymidine 5'-phosphate is the ester commonly denoted (the locant being omitted if no ambiguity may arise). Thymidine 3'-phosphate (*symbol*: dThd3'P), also named thymidine 3'-monophosphate (*abbr.*: 3'dTMP) or 3'-thymidylic acid, is released from deoxyribonucleic acid by the action of certain endo- or exonucleases, e.g. deoxyribonuclease II (EC 3.1.22.1) or spleen exonuclease (EC 3.1.16.1). The monophosphoric diester thymidine 3',5'-phosphate (*symbol*: dThd-3',5'-P), also named thymidine 3',5'-(cyclic)phosphate or cyclic thymidine 3',5'-monophosphate (*abbr.*: 3',5'-cyclic dTMP or cyclic dTMP or cdTMP), has been isolated as an intermediate formed during the acid hydrolysis of deoxyribonucleic acid but is not known to be of significance otherwise.

thymidine 3'-phosphate *see* thymidine phosphate.

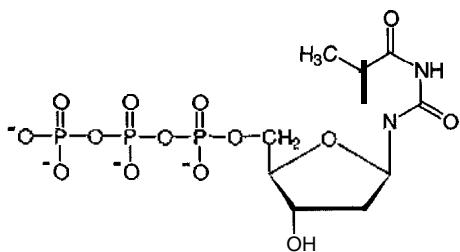

**thymidine 5'-phosphate or 5'-thymidylic acid or 5'-phosphothymidine or 5'-O-phosphothymidine symbol:** dThd5'P; *alternative recommended names for* thymidine monophosphate (*abbr.*: dTMP), thymidine 5'-(dihydrogen phosphate), thymine (mono)deoxynucleotide. (The locant is commonly omitted if there is no ambiguity as to the position of phosphorylation.) It

## thymidine phosphorylase

is synthesized (very indirectly) from uridine 5'-phosphate, its immediate precursor being 2'-deoxyuridine 5'-phosphate - see thymidylate synthase. In addition, resynthesis of dTMP from free thymidine formed by degradation of DNA can be effected via a salvage pathway.

**thymidine phosphorylase** *see* pyrimidine-nucleoside phosphorylase.

**thymidine 5'-triphosphate symbol:** dThd5'PPP or pppdT; *the recommended name for* thymidine triphosphate (*abbr.:* dTTP), 5'-triphosphothymidine, 5'-thymidylyl diphosphate, thymidine 5'-(tetrahydrogen triphosphate); a substrate for DNA synthesis. It is formed from thymidine 5'-phosphate by the successive action of nucleoside-phosphate kinase (BC 2.7.4.4) and nucleoside-diphosphate kinase (EC 2.7.4.6), which transfer in turn the terminal phosphoric residues from two molecules of adenosine 5'-triphosphate.

**thymidyl either** of the chemical groups formed by the loss of a 3'- or a 5'-hydroxyl group from the deoxyribose moiety of thymidine.

**thymidylate** 1 either the monoanion or the dianion of thymidylic acid. 2 any mixture of thymidylic acid and its anions. 3 any salt or ester of thymidylic acid.

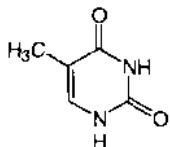

**thymidylate synthase** BC 2.1.1.45; *systematic name:* 5,10-methylenetetrahydrofolate:dUMP C-methyltransferase; an enzyme responsible for the formation of thymidylate, dTMP, by the *de novo* pathway. It catalyses reductive methylation of 2'-deoxy-5'-uridylate, dUMP, by reaction with 5,10-methylenetetrahydrofolate to form dihydrofolate and dTMP. (The dihydrofolate thus formed is reduced again to tetrahydrofolate by dihydrofolate reductase.) Thymidylate synthase is important as a target for the antineoplastic agents fluorouracil and fluorodeoxyuridine. These drugs are metabolized to fluorodeoxyuridylate, which is a potent irreversible inhibitor of the enzyme. Example from *Escherichia coli* (homodimer): database code TYSY\_ECOLI, 264 amino acids (30.44 kDa); 3-D structure known; five motifs. *See also* thymineless death.

**thymidylic acid** *the trivial name for* any phosphoric monoester of thymidine. The position of the phosphoric residue on the deoxyribose moiety of a given ester may be specified by a pre-fixed locant - *see* thymidine phosphate. However, 5'-thymidylic acid is the ester commonly denoted, its locant usually being omitted if no ambiguity may arise. 5'-Thymidylic acid is also an alternative recommended name for thymidine 5'-phosphate.

**thymidylyl** the thymidine[mono]phospho group; the acyl group derived from thymidylic acid.

**thymin** *a former name for* thymopoietin.

**thymine symbol:** T or Thy; 5-methyluracil; 2,4-dihydroxy-5-methylpyrimidine; one of the two major pyrimidine bases present (as thymidine) in DNA but not found in RNA other than (as ribothymidine) in transfer RNA, where it is a minor base.

## thymus nucleic acid

**thymine dimer** a pyrimidine dimer formed within a DNA strand from two adjacent thymine residues by photodimerization. It is most commonly of the cyclobutadipyrimidine type.

**thymineless death** the death of an animal or bacterial cell following a period of thymine (or thymidylate) deprivation. Although such a deprived cell may continue to produce protein and RNA, it can no longer synthesize DNA in the absence of thymidylate, and it eventually loses its vitality and dies, perhaps because it is also unable to repair altered or damaged DNA. The phenomenon may be demonstrated with a thymine-requiring auxotrophic bacterial mutant by omitting thymine from the suspending medium, or with any cell by adding fluorouracil or its metabolite fluorodeoxyuridine, with consequent inhibition of thymidylate synthase. A rapidly metabolizing animal cell, such as a tumour cell, is particularly susceptible to thymineless death.

**thymine deoxyriboside** *an alternative name for* thymidine.

**thymine riboside** *an alternative name for* ribothymidine.

**thyminose** *a former name for* 2-deoxyY-D-ribose (*see* deoxyribose).

**thymo+** *comb. form of, or pertaining to, the thymus.*

**thymocyte** (*sometimes*) any lymphocyte found in the thymus.

**thymocyte mitogenic factor abbr.:** TMF; *an alternative name for* interleukin 2.

**thymocyte-stimulating factor abbr.:** TSF; *an alternative name for* interleukin 2.

**thymoma** a tumour of thymic tissue.

**thymonuclease** *another name for* deoxyribonuclease I.

**thymonucleic acid** *an alternative term for* thymus nucleic acid.

**thymopentin** a synthetic pentapeptide that corresponds to residues 32-36 of thymopoietin.

**thymopoietin abbr.:** TP; anyone of three polypeptide hormones that result from alternative splicing of the same gene, and originally isolated from bovine thymus. They have pleiotropic actions on prothymocytes, inducing expression of the differentiation antigens such as Thy-1, and are important in T-cell development and function. They were discovered in studies on myasthenia gravis and impair neuromuscular transmission after injection in mice, due to an effect on the nicotinic acetylcholine receptor. A synthetic pentapeptide corresponding to positions 32-36, named thymopentin and with the sequence Arg-Lys-Asp<sup>34</sup>-Val-Tyr, has full activity. Splenin, a corresponding peptide in spleen, contains a similar pentapeptide, called splenopentin; bovine splenin has Glu in place of Asp<sup>34</sup>, and human splenin has Ala in the corresponding position. These replacements affect the biological activity. Thymopoietin was formerly known as thymin.

**thymosin** any of several related polypeptide hormones of thymic origin that are involved in differentiation of T lymphocytes in the thymus. They include  $\alpha_1$  and  $\beta_4$  thymosins, which are of known structure. Thymosin  $\beta_4$  (human, bovine, rat) has the sequence SDKPDMAEIEKFDKSKLKKTETQEKNPL-PSKETIEQEKGAGES.

**thymulin** a zinc-requiring immunomodulatory thymic nonapeptide hormone known to induce intra- and extra-thymic T-cell differentiation. Its level is decreased in immunodeficiency and in autoimmune disease.

**thymus** (gland) a bilobed glandular organ located in the posteroventral part of the neck. In mammals the thymus is encapsulated and divided into lobules, each lobule consisting of cortex and medulla; the cortex consists mainly of lymphocytes (thymocytes). The thymus is responsible for populating the blood, lymph, and thymus-dependent areas with T lymphocytes during the neonatal period. The thymus is large at birth but diminishes in size with increasing age and may be difficult to identify in adults. It is important in cell-mediated immunity. - thymic ad.

**thymus nucleic acid** *a former name for* deoxyribonucleic acid. It was so termed because the thymus gland was found to be a particularly rich source of nucleic acid of a type that was thought at the time to be characteristic of animal tissues and

**thyro+**

that was distinct from the type believed to be characteristic of plant tissues and known as **yeast nucleic acid**.

**thyro+** *comb. form* of, or pertaining to, the **thyroid gland**.

**thyrocalcitonin** *see calcitonin*.

**thyroglobulin** a protein in the **thyroid gland**, tyrosyl residues of which are modified to form the principal thyroid hormone, **thyroxine**, which is released by proteolysis. Thyroglobulin, a dimer of molecular mass about 660 kDa, is the main constituent of the so-called colloid of the thyroid follicles. Iodination of certain tyrosyl residues results in the formation of 3,5-iodotyrosyl residues; there is then transfer of the iodinated phenolic moiety of one of these tyrosyls (in the free form this would be a 2,6-iodophenyl group) to the phenolic oxygen of another iodinated tyrosyl to form a tetraiodo compound which, on release by proteolysis, is thyroxine ( $T_4$ ) (some tri-iodo forms are also produced). The proteolysis occurs as colloid migrates from the basal to the apical surfaces of the thyroid cell. Example (precursor) from human: database code THYG\_HUMAN, 2767 amino acids (304.45 kDa). The colloid containing the modified thyroglobulin is taken into vesicles by phagocytosis to form periodic acid-Schiff positive (PAS) vesicles. Dense granules containing proteolytic enzymes then fuse with the vesicles to digest the thyroglobulin with the loss of PAS-positive material. The vesicles containing triiodothyronine and thyroxine are then extruded.

**thyroidectomy** the surgical removal of the thyroid gland.

**thyroid gland** a ductless gland, located near the larynx in most species, that secretes the hormones **thyroxine** and **triiodothyronine**. Thyroid tissue is confined to vertebrates. The gland contains closely packed follicles, or acini, each consisting of a sac that has a peripheral single layer of cuboidal follicular cells forming an epithelium on an outer basement membrane; the centre of the follicle is occupied by a colloid of which the major component is **thyroglobulin**. This is synthesized and secreted into the colloid space by the follicular cells; microvilli extend from the apical surface of the follicular cells into the colloid. The thyroid also contains parafollicular cells, or C cells, that synthesize **calcitonin**. Enlargement of the thyroid in iodine deficiency is the basis of **goitre**. The thyroid concentrates iodide, a property that can be used for thyroid imaging, and for the treatment of cancer of the thyroid.

**thyroid hormone** either of the compounds secreted by the **thyroid gland**, namely **thyroxine** and **triiodothyronine**.

**thyroid hormone receptor** a nuclear receptor for **triiodothyronine** that mediates the effects of thyroid hormones on cells. These receptors bind triiodothyronine and directly regulate gene expression. The proteins belong to a superfamily of eukaryotic transcription factors and the steroid/thyroid/lretinoic acid family of nuclear receptors for hormones. The ligand-binding domain is in the C-terminal region, the zinc-finger DNA-binding domain in a central region, and a function-modulating domain in the N-terminal region. Binding of hormone induces changes in receptor conformation that control transcriptional activation and repression, and also regulates homo- or heterodimerization. In the absence of ligand, these receptors repress basal gene expression, probably through co-repressor proteins. Example,  $\alpha$ -1 receptor from *Mus musculus*: database code THAI\_MOUSE, 410 amino acids (46.79 kDa).

**thyroid hormone** either of the compounds secreted by the **thyroid gland**, namely **thyroxine** and **triiodothyronine**.

**thyroid response element** abbr.: TRE; *see response element*.

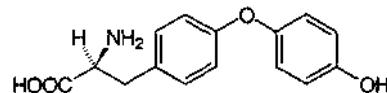

**thyroid-stimulating hormone** abbr.: TSH; *recommended name*: thyrotropin; *other name*: thyrotropic hormone; a hormone, secreted by the adenohypophysis, that stimulates the activity of the thyroid gland. The bovine hormone is a glycoprotein,  $M_r$  28 300, and a heterodimer of two chains,  $\alpha$  ( $M_r$  13 600) and  $\beta$  ( $M_r$  14700). The  $\alpha$  chain has an amino-acid sequence identical with that of the  $\alpha$  chain of **luteinizing hormone** of the same species. TSH increases the uptake of iodide by the thyroid, increases the rate of conversion of diiodotyrosine to thyroxine, and increases the release of thyroid hormones from

**thyroxine**

the thyroid. The release of TSH from the adenohypophysis is influenced by **thyrotropin-releasing hormone**. Examples,  $\alpha$  chain (precursor) from human: database code GLHA\_HUMAN, 116 amino acids (13.06 kDa);  $\beta$  chain (precursor) from human: database code TSHB\_HUMAN, 138 amino acids (15.59 kDa).

**thyroliberin** *recommended name for thyrotropin-releasing hormone*.

**thyronine** 4-(4-hydroxyphenoxy)phenylalanine; the structure from which thyroid hormones may be notionally derived by iodination. It is not naturally occurring, even in bound form, since in the synthesis of thyroid hormones the tyrosyl residues of thyroglobulin are iodinated before addition of the further phenolic group (*see thyroglobulin*).

**thyrotoxicosis** *see hyperthyroidism*.

**thyrotroph** a thyrotropic cell.

**thyrotrophic** having the effect of nourishing the thyroid gland, stimulating its growth and maintaining its size.

**thyrotropic** or (esp. Brit.) **thyrotrophic** having a modulating effect on the thyroid gland, especially in stimulating the synthesis of thyroid hormones. *See thyrotropin*.

**thyrotropic hormone** *an alternative name for thyroid-stimulating hormone*.

**thyrotropic hormone releasing factor** (abbr.: THRF) or **thyrotropic hormone releasing hormone** (abbr.: THRH) *an alternative name for thyrotropin-releasing hormone*.

**thyrotropin** *the recommended name for thyroid-stimulating hormone*.

**thyrotropin receptor** an integral membrane protein that binds thyrotropin (i.e. **thyroid-stimulating hormone**) and mediates its intracellular effects. It is a G-protein-linked receptor, with different forms produced by alternative splicing. Example from human (precursor): database code TSRR\_HUMAN, 764 amino acids (86.70 kDa). Mutations are associated with hyperfunctioning thyroid adenomas. The hyperthyroidism of **Graves' disease** is thought to be due to the presence in the blood of these patients of autoantibodies that stimulate the thyroid through the thyrotropin receptor.

**thyrotropin-releasing factor** abbr.: TRF; *an alternative name for thyrotropin-releasing hormone*.

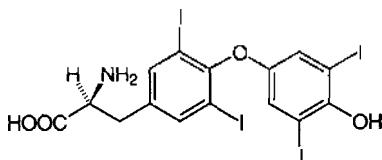

**thyrotropin-releasing hormone** abbr.: TRH; *recommended name*: thyroliberin; *other names*: thyrotropin-releasing factor (abbr.: TRF); thyrotropic hormone releasing factor (abbr.: THRF); thyrotropic hormone releasing hormone (abbr.: THRH); a hormone, released by the mammalian hypothalamus into the hypophyseal-portal circulation in response to neural and/or chemical stimuli, that regulates the secretion of **thyroid-stimulating hormone** (TSH) by the adenohypophysis. It has a wide distribution, being present not only in primitive vertebrates but also in *Amphioxus* (a provertebrate) and in nerve ganglia of snail. It is the tripeptide pyroGlu-His-Pro-NH<sub>2</sub>, the cyclized glutamate and intact prolylamide being essential for activity. It is synthesized as part of a large prohormone that has six repeats of the TRH sequence. TRH is present in many other parts of the brain, in pancreatic islets, and in the gastrointestinal tract; it probably serves widely as a neurotransmitter or neuromodulator, being known in mammals to alter sleep patterns, increase motor activity, increase blood pressure, and affect norepinephrine turnover, among many activities. Its regulation of TSH secretion is controlled by the pituitary-thyroid axis.

**thyroxine** abbr.: Thx or  $T_4$ ; 4-(4-hydroxy-3,5-diodophenoxy)-3,5-diodophenylalanine; 3,3',5,5'-tetraiodothyronine; the main hormone secreted by the thyroid gland, although its ac-

## thyroxine-binding globulin

titrate

tivity is lower than that of triiodothyronine (T<sub>3</sub>). Its synthesis from L-tyrosyl residues of thyroglobulin means that the L-isomer is the naturally occurring form. Thyroxine is essential for normal metabolism and physical development. It stimulates the metabolic rate, causing increased oxygen consumption and heat production in tissues. Although in humans the plasma levels of T<sub>4</sub> are 20- to 50-fold higher than those of T<sub>3</sub>, T<sub>4</sub> is converted to T<sub>3</sub> in tissues and the effects are thought to be mediated by T<sub>3</sub> binding to receptors in the cell nucleus (chromatin fraction), leading to mRNA and protein synthesis. The normal range in human blood is 60–150 nmol L<sup>-1</sup> (total of bound and free), 9–26 pmol L<sup>-1</sup> (free). The chemical constitution of thyroxine was deduced by the British biochemist Sir Charles R. Harington (1897–1972), and confirmed by synthesis (1927).

**thyroxine-binding globulin** abbr.: TBG; a major thyroid hormone transport protein found in mammalian serum. It is synthesized in liver, and variations in its concentration in serum result in similar variations in the level of circulating thyroid hormones. Alterations in its affinity for thyroid hormone also affect circulating thyroid hormone levels, decreased affinity being accompanied by decreased serum concentration. In the human, this variation may result from non-thyroidal illness, the presence of drugs (salicylates and phenytoin block thyroid-binding sites), or genetic variation, many variants being known, and listed in the example from human: database code THBG\_HUMAN, 415 amino acids (46.32 kDa).

**Ti symbol** for titanium.

**tight coupling** a term applied to mitochondrial function implying a high degree of efficiency in the yield of ATP (or other functional response) in relation to electron flow. The nearer the yield approaches the optimal value, the tighter the coupling is said to be. Tight coupling is obtained in isolated mitochondria only if gentle procedures, preserving membrane integrity, are employed during isolation. *See also* chemiosmotic coupling hypothesis, phosphorus:oxygen ratio.

**tight junction or zona occludens (in vertebrate tissues)** a belt-like region of very close contact between the plasma membranes of adjacent cells, such that the intercellular space is completely occluded. Tight junctions occur in epithelia and brain endothelia, and are effective barriers to the passage of water and solutes. *Compare* gap junction.

**tight turn** *see* beta turn.

**time symbol:** t; one of the seven SI base physical quantities, usually indicating duration or a precise moment. The SI base unit of time is the second.

**time constant** a characteristic time taken by a system or a process to respond to a perturbation.

**time course** a graph plot of a parameter (that changes with time) scaled on the ordinate and time scaled on the abscissa.

**time-resolved fluorescence spectrometry** a method in which a sample is irradiated using a laser delivering a short (sub-nanosecond) pulse of light, after which the exponential decay of fluorescence is measured using a photomultiplier. The sensitivity of detection must be at the single photon level ('single photon counting'), and fluorescence lifetimes as short as a few nanoseconds can be determined. However, a disadvantage of the technique is that many measurements over possibly several hours may be needed to obtain reliable and sufficient data. *See also* steady-state fluorescence anisotropy.

**TIMP** abbr. for tissue inhibitor of metalloproteinases; any of a

group of proteins that inhibit metalloproteinases. An example is TIMP-1, also known as EPA (erythroid potentiating activity), a protein that mediates erythropoiesis. It forms complexes with enzymes such as collagenases, bringing about irreversible inactivation. Example (precursor) from human: database code TIM1\_HUMAN, 207 amino acids (23.14 kDa). *See also* matrix metalloproteinase.

**tintometer** an apparatus formerly used for determining the colour of a solution by comparison with a graded colour scale. **Ti plasmid** abbr. for tumour-inducing plasmid; any of a class of large conjugative plasmids found in the soil bacterium *Agrobacterium tumefaciens* and responsible for crown-gall disease of broad-leaved plants – a segment of the Ti plasmid, the T-DNA, is found in the genome of the tumour tissue of affected plants. With appropriate modifications the Ti plasmid can carry foreign DNA sequences of any desired kind into the genome of a susceptible plant.

**Tiselius**, Arne Wilhelm Kaurin (1902–71), Swedish protein chemist; Nobel Laureate in Chemistry (1948) 'for his research on electrophoresis and adsorption analysis, especially for his discoveries concerning the complex nature of the serum proteins'.

**Tiselius apparatus** an apparatus for performing moving boundary electrophoresis in which there is a U-tube with sliding joints. This enables the protein (or other) solution and the buffer to be placed in separate parts of the U-tube and sharp boundaries made between them when the parts are slid into position to complete the U-tube.

**tissue** any collection of cells that is organized to perform one or more specific function. *Compare* organ.

**tissue culture** 1 the technique or process of growing or maintaining tissue cells (cell culture), whole organs (organ culture), or parts of an organ, from an animal or plant, in artificial conditions. 2 any living material grown or maintained by such a technique.

**tissue extract** an alternative name for factor III; *see* blood coagulation.

**tissue factor** abbr.: TF; a transmembrane glycoprotein (eight motifs), also known as factor III, that initiates blood coagulation by forming a complex with factor VII or VIIA. The complex activates factors IX or X. Tissue factor plays a role in normal hemostasis by initiating cell-surface assembly and propagation of the coagulation protease cascade. Example from human (precursor): database code TF\_HUMAN, 295 amino acids (33.03 kDa).

**tissue grinder** any device for disrupting tissue by a crushing or shearing action. The term may embrace devices ranging from a meat grinder (mincer), mechanical pestle and mortar, or mill, to the more precise Potter-Elvehjem homogenizer or the Dounce homogenizer.

**tissue kallikrein** *see* kallikrein.

**titer** the US spelling of titre.

**titin** or connectin a giant protein that forms a single molecule elastic filament extending from the M line to the Z line in the striated muscle sarcomere and is one of the largest polypeptides yet described. The sequence consists mainly of repeats of two types of approximately 100-amino-acid motifs, known as class I and class II that show homology to the fibronectin type-III domain and immunoglobulin superfamily C2 domain, respectively. There is also a domain characteristic of protein kinases near the C terminus. It is thought to play an important role in sarcomere alignment during muscle contraction. Example from human: database code HSTITIN, 4650 amino acids (521.48 kDa). *See also* twitchin.

**titratable acidity** 1 a measure of the acidity of a urine sample, expressed as the volume of 0.1-M NaOH required to neutralize, usually to a phenolphthalein endpoint, a 24-hour volume of urine. 2 a measure of the acidity of any solution, etc.

**titrate** 1 to add acid of known concentration to base of unknown concentration (or vice versa) until the point of equivalence is reached, from which can be determined the con-

## titration curve

Toll

centration of the unknown. 2 more generally, to add any standard solution to an unknown until some detectable equivalence point is reached, enabling the amount of the unknown to be determined. 3 (esp. in microbiology or immunology) to determine the maximum dilution at which activity can be detected. See titre (def. 2). -titratable adj.; titration n.

**titration curve** originally, a curve relating pH to the equivalents of strong base added per equivalent of acid in the solution. Similar curves are obtained when the logarithm of ligand concentration is plotted against the degree of association (or dissociation) of a ligand to its acceptor, or when redox potential is plotted against the degree of oxidation (or reduction) of a redox system.

**titration pK symbol:** pG; a kind of pK that characterizes the titration curve of a multibasic acid. If this acid has  $n$  hydroxyl groups that titrate over the pH range of interest, then its titration curve is identical to that of an equimolar mixture of  $n$  (hypothetical) monobasic acids. The pK values of these acids are the titration pK values of the multibasic acid. They differ little from the molecular pK values if the differences between sequential molecular values exceed unity. See also group pK.

**titre or (esp. US) titer** 1 a value found by titration; see titrate (def. 1, 2). 2 (in microbiology and immunology) a measure of the concentration or activity of an active substance, e.g. an antibody, in a solution, usually expressed as the highest dilution of the solution in which the activity can be detected. By convention, if the highest dilution giving activity is 100-fold, the titre is said to be 100.

**titrimetry** the technique of measurement by titration, particularly using instrumentation and automation.

**Tl symbol** for thallium.

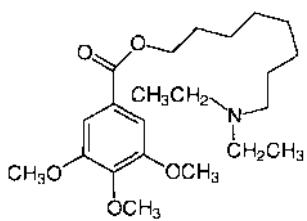

**TLC abbr.** for thin-layer chromatography.

**tid** gene in *Drosophila* for Toll-like protein, which is required for normal dorsal development. Mutations in tid lead to a partial transformation of dorsal ectoderm into ventral ectoderm.

**T lymphocyte or T cell** any of a class of lymphocytes that undergo maturation and differentiation in thymus. They are responsible for immune reactions involving cell-cell interaction, i.e. cell-mediated immunity. Subsets of T lymphocytes include: (1) cytotoxic T-lymphocytes, directly responsible *in vivo* for the death of cells identified for elimination; they include nonspecific killer cells (NK cells) and specific cytotoxic T-lymphocytes primed by antigen activation; (2) helper cells, which collaborate with antigen-presenting cells in the initiation of an immune response; and (3) suppressor cells, which down-regulate the response of helper cells.

**Tm symbol** for thulium.

**TMB-8 abbr.** for (8-diethylamino)octyl-3,4,5-trimethoxybenzoate; a Ca<sup>2+</sup> antagonist that blocks intracellular Ca<sup>2+</sup> channels.

**TMF abbr.** for thymocyte mitogenic factor; i.e. interleukin 2.

**TMP abbr.** for 1 ribosylthymine monophosphate or ribothymidine monophosphate, the common names for ribosylthymine 5'-phosphate, ribothymidine 5'-phosphate, 5'-ribothymidyl phosphate, thymine riboside 5'-phosphate. 2 (sometimes) thymidine monophosphate. dTMP is recommended.

**TMR spectroscopy abbr.** for topical magnetic resonance spectroscopy.

**TMS abbr.** for 1 tetramethylsilane; a water-soluble reference

substance used in nuclear magnetic resonance spectroscopy.

2 the trimethylsilyl group; the symbol Me<sub>3</sub>Si- is preferred.

**TMV abbr.** for tobacco mosaic virus, an RNA plant virus.

Tn abbr. for 1 troponin. 2 transposon.

**TNBS abbr.** for 2,4,6-trinitrobenzenesulfonate; a reagent that combines readily with amino groups. It may be used either to protect these groups or to introduce a chromophore. It is removable using hydrazine.

Tn-C abbr. for troponin C.

**TNF abbr.** for tumour necrosis factor.

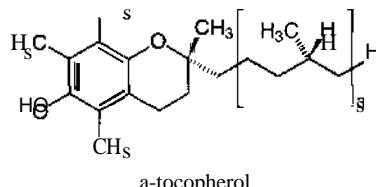

Tn-I abbr. for troponin I.

**TNMR or tnmr abbr.** for tritium nuclear magnetic resonance (spectroscopy).

**TNS abbr.** for 2-p-toluidylnaphthalene-6-sulfonate; a fluor used in extrinsic fluorescence studies of proteins.

Tn-T abbr. for troponin T.

**tocopherol** a generic term for di- and trimethyltocols;  $\alpha$ -tocopherol is 5,7,8-trimethyltocol, and is active as vitamin E;  $\beta$ -tocopherol is 5,8-dimethyltocol;  $\gamma$ -tocopherol is 7,8-dimethyltocol; and  $\delta$ -tocopherol is 8-methyltocol.

α-tocopherol

**Todd**, Alexander Robertus Todd, Lord Todd (1907-97), British organic chemist; Nobel Laureate in Chemistry (1957) 'for his work on nucleotides and nucleotide co-enzymes'.

**T-odd phage** anyone of the bacteriophages T1, T3, T5, or T7 of *Escherichia coli*. These DNA phages share a number of morphological, biochemical, and other features that distinguish them as a group from T-even phages.

**togavirus or (formerly) arbovirus** any of a group of RNA animal viruses consisting of enveloped, icosahedral, 50-70 nm capsids with single-stranded infectious RNA (plus strand) of 4 MDa. The group contains mosquito- and tick-borne viruses causing encephalitis and yellow fever.

**tolbutamide** 1-butyl-3-(p-tolylsulfonyl)urea, N-[(butylamino)carbonyl]-4-methylbenzenesulfonamide; one of a number of sulfonylurea drugs, of which it is the prototype, that exert a hypoglycemic action by stimulating release of insulin from the pancreas and are used therapeutically to treat type II diabetes mellitus.

**tolerance** 1 the progressive attenuation of the response to an agent (usually a drug) whereby increasing concentrations of the agent are required to maintain the response. Underlying mechanisms confer either functional (or pharmacodynamic) tolerance, where the loss of response is due to desensitization of effector mechanisms, or metabolic (or pharmacokinetic) tolerance, whereby elimination of the agent is accelerated usually by induction of catabolic enzymes or other inactivating mechanism. 2 the ability of an organism to grow and thrive in an unfavourable environment. 3 an allowable deviation from a standard. 4 immunological tolerance.

**tolerogen** an antigen that, in given circumstances, induces immunological tolerance when administered to an animal. Tolerogens may, when presented in different circumstances, induce an immune response. -tolerogenic adj.

**Toll** a developmental protein in *Drosophila melanogaster*, the product of toll gene, that is required for embryonic dorsal-ventral polarity. It is a type I transmembrane signalling receptor protein with a leucine-rich repeat segment. Precursor: database code TOLL\_DROME, 1097 amino acids (124.51 kDa).

## tolloid

toUoid a developmental protein in *Drosophila melanogaster* encoded by the *tid* gene; it is a member of the astatin subfamily of metalloproteinases. Database code TLD\_DROME, 1057 amino acids (120.44 kDa).

**tomography** a radiographic technique that can image a thin plane or section of a body. An X-ray beam is focused on an area of a body, the beam is then rotated, and successive images are stored and subsequently analysed by computer (computer-assisted tomography, or CAT scanning). Positron emission tomography (or PET scanning) involves the detection of X-rays emitted from radionuclides that decay by positron emission and are located within the patient's body, e.g. from  $^{150}$  (oxygen-15) after administration of  $H_2^{15}O$ .

**ton** 1 or (esp. US) long ton a unit of mass equal to 2240 pounds avoirdupois (1016.05 kg). 2 or (esp. US) short ton or net ton a unit of mass equal to 2000 pounds avoirdupois (907.18 kg). 3 metric ton; see *tonne*.

**tone** 1 (*in physiology*) or tonus the state of sustained partial tension adopted by muscles in order to maintain posture, etc. It is brought about by the contraction of only a certain proportion of the muscle fibres at any given time. 2 (*in clinical medicine*) the state or degree of firmness of a muscle on palpation.

**tonicity** 1 the osmotic pressure of a solution; often used in the sense of the ratio of the osmotic pressure of a solution to that of a given reference solution. 2 (of a muscle) the condition of possessing tone or tension. See also *hypertonic*, *hypotonic*, *isotonic*.

**tonin** EC 3.4.21.35; other names: esterase I; 82 kallikrein; RGK-2; RSKG-5; an endopeptidase, present in several rat tissues, that can cleave angiotensinogen and angiotensin-tetra-decapeptide renin substrate to produce angiotensin II directly. It also acts on the Phe-I-His bond of angiotensin I to form angiotensin II. It is a trypsin- and chymotrypsin-like serine protease. Example (precursor) from rat: database code KLK2\_RAT, 259 amino acids (28.22 kDa).

**tonne or metric ton symbol:** t; a unit of mass equal to  $10^3$  kg. 1 tonne = 0.984 207 UK ton or 1.102 31 short (US) tons.

**tonometer** 1 an apparatus, usually a closed glass vessel, used to equilibrate a liquid, especially blood, with a particular gas of known partial pressure. When equilibrium is established the phases are separated and the gas in question determined in both phases. 2 a device for measuring vapour pressure.

**tonus** an alternative term for tone (def. 1).

**tooth-lid factor** a name originally given to epidermal growth factor.

**top+** a variant form of *topo+* (before a vowel).

**TOPA abbr.** for 3,4,6-trioxyphenylalanine; 6-hydroxydopa. See also *TOPA-quinone*.

**TOPA-quinone** 6-hydroxydopa quinone; the covalently bound redox prosthetic group of bovine plasma amine oxidase and some other copper-containing oxidases.

**topical** relating to a particular place or part of the body; local; (of a medicament, nutrient, etc.) applied locally rather than systemically. -topically *adv.*

**topical magnetic resonance spectroscopy abbr.:** TMR spectroscopy; a method for obtaining high-resolution nuclear magnetic resonance spectra from a selected place in a larger specimen (e.g. a specific organ of a living body). The sensitive volume is generated by superimposing high-order magnetic field gradients onto the main magnetic field of the spectrometer in such a manner as to define a central region of uniform field and adjustable size, surrounded by rapidly changing fields. Signals may be detected from individual nuclei, and the signals can be attributed to specific metabolites, enabling measurement of the level of these metabolites *in situ*.

**topo+** or (before a vowel) top+ comb. form denoting place or region.

**topochemical** 1 of, or pertaining to topochemistry. 2 of, pertaining to, or constituting a locally confined chemical reaction. 3 describing a combined tactile and chemical sense in

## torsion

some animals that is important in the perception of odours in relation to track or position.

**topochemistry** the characteristic chemical activity of a topomer.

**topogenesis** an alternative term for morphogenesis, especially in regard to biomolecular structures. -topogenic *adj.*

**topogenic sequence** any part of the sequence of a nascent polypeptide that is involved in getting the mature protein to its proper position in the cell. See (e.g.) mannose 6-phosphate, signal peptide.

**topogenic signal** any feature of the structure of a macromolecule that directs it to a particular organelle in a cell. The term comprehends topogenic sequence.

**topography** 1 the science and practice of describing the arrangement in space of shapes and surfaces, and of components in relation to one another. 2 the detailed description, or representation on a map, diagram, etc., of the surface features of a three-dimensional object, or part of one, with reference to the underlying structure. Compare topologV. —topographic or topographical *adj.*; topographically *adv.*

**topoinhibition** the inhibition of a cellular process by an action at the cell membrane, especially through contact with, or proximity to, other cells.

**topoisomer** or topological isomer any of two or more isomers of a macrocyclic molecule, or system of two or more macrocyclic molecules or molecular subunits, that differ in the degree of knotting of a loop or the degree of interlocking of rings. Topoisomers of a given molecule, or system of molecules, display the same connectivity, bond orders, and configurations but can be interconverted only by breaking and reforming a covalent bond; they have different linking numbers. Compare topomer. -topoisomeric *adj.*; topoisomerism *n.*

**topoisomerase** see DNA topoisomerase.

**topological bond** the force equivalent to a chemical bond that may be conceived as holding together any two interlocked rings of a catenated molecular structure or two loops of a knot in a cyclic molecule. Such a bond is the property not of a pair of atoms but of the complete molecule, the strength of the union being that of the weakest chemical bond in the entire structure.

**topological isomer** an older name for topoisomer.

**topological isomerism** an alternative term for topoisomerism; see topoisomer.

**topological winding number** see supercoil.

**topology** 1 (*in molecular biology*) the study of deformability and deformation of structures, including macromolecules. The basic concept is founded on whether a particular figure or surface can be continuously deformed without rupture and remaking of, e.g., a chemical bond. 2 (*in botany*) the study of localities where plants are found. 3 (*in mathematics*) the branch of geometry that deals with general types of shape rather than with particular shapes and sizes; the study of relationships that remain invariant under one-to-one transformation. Compare topography. -topological or topologic *adj.*; topologically *adv.*

**topomer** any of two or more conformers of a macromolecule that have differing topography (def. 2). Any topomer (or its exact mirror image) is characterized by a unique set of interactions between any two residues of the complete sequence of the macromolecule. Compare topoisomer.

**topotactic** describing a chemical reaction in which the product has an ordered geometric relationship to the reactant.

**top yeast** see bottom yeast.

**toroid** 1 an alternative term for torus. 2 the solid enclosed by a torus. -toroidal *adj.*

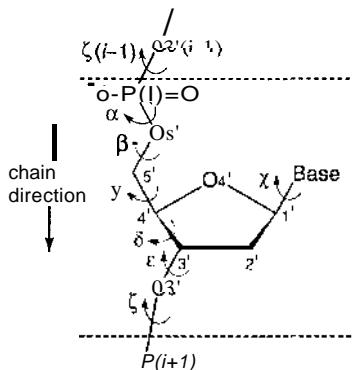

**torr symbol:** torr; a non-SI unit of pressure, used especially in connection with low pressures. It is defined as equal to 11760 of an atmosphere; i.e. 1 torr = 101 3251760 Pa = 133.322 Pa. Its use is now discouraged, in favour of the pascal. [After Evangelista Torricelli (1608-47), Italian physicist.]

**torsion** 1 the twisting of something about an axis by the appli-

## torsion angle

cation of equal and opposite rotational forces acting in parallel planes. 2 the twist so produced. -torsional *adj.*

**torsion angle symbol:**  $\theta$  or  $\omega$ ; consider an assembly of attached atoms represented by the generalized partial structure X-A-B-Y where neither X nor Y is collinear with A and B; then the torsion angle is the smaller angle subtended by the bonds X-A and Y-B in a plane projection obtained by viewing the assembly along the axis A-B from either direction. The angle is considered positive or negative according as the bond to the atom nearest the viewer, X or Y, requires to be rotated to the right or left, respectively, for its direction to coincide with that of the bond to the furthermost atom, Y or X. The multiplicity of the bonding of the various atoms is not relevant. A torsion angle may similarly be defined for a partial structure X-A-Z-B-Y where Z represents one or more additional atoms and A, Z, and B are collinear. The torsion angles for the backbone of a polypeptide chain are symbolized as follows: that for rotation about the N-C<sup>a</sup> bond is denoted by  $\phi$ ; that for rotation about the C<sup>a</sup>-C' bond is denoted by  $\psi$ ; that for rotation about the C'-N bond is denoted by  $\omega$ . The torsion angles for the backbone of a polynucleotide chain are as shown below. See also conformation, Ramachandran plot, tight turn.

designation of torsion angles for polynucleotides

**torsion balance** an instrument, used for the rapid weighing of small amounts of substances, in which the sample is balanced by the torsion of a wire and the amount of torsion that has to be applied to restore balance is indicated as a scale calibrated in units of mass.

**torso** a gene for a tyrosine kinase (EC 2.7.1.112) receptor in *Drosophila melanogaster*. The receptor is a type I membrane glycoprotein and is involved in the determination of anterior and posterior structures in the embryo. Precursor: database code KTOR\_DROME, 923 amino acids (105.04 kDa).

**torulin** an obsolete name for extracts of yeast that cure polyneuritis in pigeons fed on a diet of polished rice, no doubt due to the vitamin B<sub>1</sub> content of yeast extract.

**torus** (*pl.* tori) a shape generated by rotating a circle or disk about an axis that is displaced outside the diameter of the circle or disk, but in the same plane; i.e. shaped like a ring doughnut (donut). See also toroid. -toric *ad.*

**Tos** symbol for the tosyl group.

**tosyl symbol:** Tos; a trivial name for the toluene-4-sulfonyl group,  $CH_3-C_6H_4-SO_2^+$ , with which amino groups may be modified by allowing them to react with p-toluenesulfonyl chloride. Compare pipsyl.

**total body water abbr.:** TBW; see body water.

**totipotent** (of a cell) having the potentiality to develop in any of the directions inherently possible, given its particular genetic constitution, and thus to form a new organism or to regenerate any part of an organism.

## trace element

**toxic** 1 poisonous. 2 of, relating to, or caused by a toxin or poison.

**toxicity** 1 the quality or state of being poisonous or toxic. 2 the relative degree of being poisonous or toxic; the potency of a toxin.

**toxicogenic** an alternative term for toxicogenic.

**toxicology** the science dealing with the effects of poisons on living organisms. The term is sometimes restricted to the effects of synthetic poisons and the term toxinology used when dealing with naturally occurring poisons.

**toxify** to poison; to render poisonous. -toxification *n.*

**toxicogenic or toxicogenic or toxinogenic** (especially of bacteria and fungi) producing toxin.

**toxin** any of various specific poisonous substances that are formed biologically. Not all such poisons are so termed, their classification as toxins being somewhat arbitrary and tending to vary with the discipline concerned; furthermore, the term is sometimes extended to include synthetic poisonous substances. Various types of toxin may be designated according to the source of the toxin, e.g. endotoxin, exotoxin, mycotoxin, phycotoxin, phytotoxin, and zootoxin, or according to the specific or prime site of action of the toxin, e.g. hepatotoxin and neurotoxin.

**toxinogenic** an alternative term for toxicogenic.

**toxicology** see toxicology.

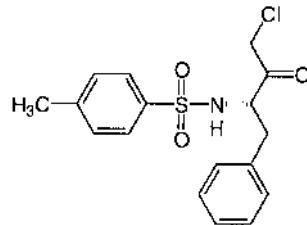

**toxoid** an exotoxin that has been modified (e.g. by formalin treatment) so that its toxicity has been lost while its antigenicity (both immunogenicity and reactivity) is retained.

**toxophore** a term introduced by Ehrlich to denote the specific chemical group in a toxin molecule that is responsible for its toxic effect. Unlike the haptophore, it is destroyed on conversion of the toxin to a toxoid.

**TP** abbr. for thymopoietin.

**TPA** abbr. for tissue-type plasminogen activator; see plasminogen activator.

**TPCK** abbr. for L-(1-tosylamido-2-phenyl)ethylchloromethyl ketone; a modifying reagent for histidine residues.

**TPI (formerly)** abbr. for 1 triphosphoinositide; use *PtdInsP<sub>z</sub>* instead (PIP<sub>z</sub> is also used). 2 phosphatidylinositol 4,5-bisphosphate; use *PtdIns-4,5-P<sub>z</sub>* instead. See phosphoinositide.

**TPN** abbr. for triphosphopyridine nucleotide; obsolete, use **NADP<sup>+</sup>**.

**TPNH** abbr. for reduced triphosphopyridine nucleotide; obsolete, use **NADPH**.

**TPP** abbr. for thiamine diphosphate (formerly thiamin pyrophosphate); see vitamin B<sub>1</sub>.

**TPR** abbr. for tetratricopeptide repeat.

**tpr-met** an oncogene formed by the translocation of the *tpr* (translocated promoter) locus of chromosome I and *MET* (the gene for hepatocyte growth factor receptor).

**tracee** (in tracer kinetics) the non-radioactive compound of which the tracer is the radioactive equivalent; coined to represent unambiguously what has been variously called stable material, mother substance, etc. Compare compartment.

**trace element or microelement** any element that is present in the body of an organism at relatively minute concentrations (often arbitrarily defined as <0.005%), and consequently is required in the organism's diet in extremely small amounts. In higher animals the most important trace elements include:

**trace metal**

iron, zinc, copper, manganese, iodine, cobalt, molybdenum, selenium, and chromium. The extended list includes lead, arsenic, antimony, nickel, bromine, fluorine, boron, silicon, aluminium, silver, cadmium, bismuth, mercury, vanadium, titanium, indium, barium, strontium, and lithium. The term may be extended to cover elements of primarily toxicological interest.

**trace metal** any **trace element** that is a metal.

**tracer** an element or compound containing atoms that can be distinguished from their normal counterparts by physical means, e.g. by virtue of their radioactivity, mass spectrum, colour, etc. Tracers are used in biochemistry for following the metabolic pathways of substances in an organism, cell, or cell-free system.

**track** an individual lane resolving the components of a single sample on a slab electrophoresis gel.

**tracking dye** a dye that is added to a sample on an electrophoresis gel to be the fastest component and thus to indicate visually how far the samples have run at any instant in time.

**tragacanth** 1 any of various thorny leguminous shrubs of the genus *Astragalus*. 2 a gum obtained especially from *A. gummifer* and used extensively in commerce, including pharmacology. It is a complex mixture of polysaccharides, including o-galacturonic acid, o-xylose, L-fucose, and o-galactose.

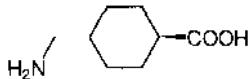

**trailer sequence** a sequence following the termination signal at the 3' end of **messenger RNA**.

**trait** any observable, phenotypic feature of a developing or developed individual.

**TRAM or TRAM protein** abbr. for translocating chain associating membrane protein; a transmembrane protein that spans the **rough endoplasmic reticulum** of mammalian cells and plays a role in the translocation of nascent proteins destined for export from the endoplasmic reticulum. Example from *Canis familiaris*: database code TRAM\_CANFA, 373 amino acids (43.03 kDa).

**TRAMP** abbr. for tyrosine-rich acidic matrix protein; other names: 22 kDa extracellular matrix protein; dermatopontin; a protein of the extracellular matrix that may have various binding and adhesion functions. Example from *Bos taurus*: database code DERM\_BOVIN, 183 amino acids (21.99 kDa).

**tranexamic acid** trans-4-(aminomethyl)cyclohexanecarboxylic acid; a compound that inhibits binding of plasminogen and plasmin to fibrin thereby inhibiting fibrinolysis.

**tranB+** or (sometimes before s-) **tran+** comb. form denoting across, beyond, on the other side, transverse; transfer, interchange. See also **trans-acting**.

**tranB-** abbr.: *t-*; prefix (in chemical nomenclature) denoting a trans-isomer; see **cis-trans isomerism**.

**tran-acting** describing a regulatory genetic element whose effects are insensitive to its position. Examples include the genes for bacterial repressors. Compare **cis-acting**.

**tran.activation** gene activation by means of a **trans-acting** mechanism.

**transacylase** an older name for **acyltransferase**.

**transaldolase** EC 2.2.1.2; other names: dihydroxyacetone transferase, glyceronetransferase; an enzyme of the pentose phosphate pathway that catalyses the transfer of a 3-carbon glycerone moiety from sedoheptulose 7-phosphate to glyceraldehyde 3-phosphate forming erythrose 4-phosphate and fructose 6-phosphate. It has a broad substrate specificity. Example from human: database code TALLHUMAN, 336 amino acids (37.59 kDa).

**transcortin**

**transamidation** a chemical reaction in which the amino group of an amide is exchanged for another amino group, i.e.:

Transamidation is catalysed by such proteolytic enzymes as **trypsin**, **chymotrypsin**, **papain**, and **subtilisin**.

**transamidination** a chemical reaction, catalysed by a transamidinase (aminotransferase) enzyme of sub-subclass EC 2.1.4, in which the amidino moiety of arginine is reversibly transferred to an amino group to form a different guanidino compound. An example is **glycina amidinotransferase**.

**transaminase** an alternative name for **aminotransferase**. See also **alanine transaminase**, **aspartate transaminase**, **transamination**.

**transamination** a chemical reaction, catalysed by any **aminotransferase** (transaminase) enzyme, in which the  $\alpha$ -amino group of one amino acid is transferred to the  $\alpha$ -carbon atom of an  $\alpha$ -oxo acid. As a result, the  $\alpha$ -oxo acid is transformed into an amino acid, and the amino acid that donated the amino group is converted to the corresponding  $\alpha$ -oxo acid:

Transamination plays an important role in the catabolism of amino acids, in which the amino group is eventually or directly transferred to oxaloacetate (to form aspartate) or to  $\alpha$ -oxoglutarate (to form glutamate). If transferred to aspartate, the amino group enters the **urea cycle** at the argininosuccinate step; if transferred to glutamate, the amino group is removed by glutamate dehydrogenase, yielding ammonia, which then enters the urea cycle. Transamination is also involved in amino-acid synthesis. Pyridoxal phosphate is an important coenzyme of aminotransferases. Transamination was discovered by the Russian biochemists Alexander Evseyevich Braunstein (1902-86) and Maria Grigorievna Kritzmann (1904-71).

**transbilayer** signifying across or through the membrane **lipid bilayer**, as in **transbilayer distribution**, transbilayer movement.

**transbilayer distribution** the distribution of various components between the two leaflets of a membrane lipid bilayer, but often referring specifically to lipids. In the plasma membrane this distribution is asymmetric, particularly with regard to phospholipids: phosphatidylcholine and sphingomyelin are relatively enriched in the outer leaflet, and phosphatidylethanolamine and phosphatidylserine are more predominant in the inner leaflet (i.e. the cytoplasmic face).

**transcarboxylase** 1 methylmalonyl-CoA carboxyltransferase; EC 2.1.3.1; systematic name: (S)-2-methyl-3-oxopropanoyl-CoA:pyruvate carboxyltransferase; a biotinyl-protein, containing cobalt and zinc, that is present in prokaryotes and catalyses the transfer of a carboxyl group from methylmalonyl-CoA [(S)-2-methyl-3-oxopropanoyl-CoA] to pyruvate forming oxaloacetate and propanoyl-CoA. 2 a component of the prokaryote form of **acetyl-eoA carboxylase** that transfers the carboxyl group from N-carboxybiotin to acetyl-CoA.

**transcarboxylation** the transfer of a carboxyl group from one compound to another, e.g. as catalysed by a **transcarboxylase**.

**transconjugant** a bacterial cell that has received genetic material from another bacterium by **conjugation**. A transconjugant should be referred to as a **recombinant** only if the transferred genetic material has been inserted into a pre-existing **replicon** in the recipient. If the transferred material is perpetuated *per se* as a plasmid, then the cell is called a **plasmid transconjugant**. If such material is not a plasmid and does not become a resident replicon, it will fail to replicate; the bacterium will be called an **abortive transconjugant**.

**transcortin** a specific plasma IgG-globulin, M, 52000, that binds **cortisol** at one binding site and serves to transport the hormone. It also binds corticosterone and certain other steroid hormones; aldosterone is bound only weakly. Transcortin is synthesized in the liver. The normal serum concentration of transcortin is 3-4 mg dL<sup>-1</sup>; saturation occurs at a cortisol serum concentration of about 28 µg dL<sup>-1</sup>, other cortisol being

## transcribe

less tightly bound to albumin or (about 5%) unbound. *Other names:* corticosteroid-binding globulin; corticosteroid-binding protein; cortisol-binding globulin (*abbr.:* CBG); cortisol-binding protein.

**transcribe** 1 to copy. 2 to use DNA as a template for the synthesis of mRNA, or, in some cases (e.g. as in retrovirus infection), to synthesize DNA from an RNA template. *See transcription.*

**transcribing strand** *an alternative name for noncoding strand (of duplex DNA).*

**transcript** the product of a transcription process; the primary transcript is the immediate product of a polymerase engaged in transcription (e.g. RNA polymerase).

**transcriptase** *an alternative name for DNA-dependent RNA polymerase.*

**transcription** the synthesis of either RNA on a template of DNA or DNA on a template of RNA. The latter is important in the replication of retroviruses by the enzyme reverse transcriptase and will not be further described here. Concerning the transcription of double-stranded DNA the older literature is confusing in terms of the use of the word transcription until the discovery of transfer RNA in 1956 when it became clear that RNA was an intermediary in the transfer of information contained in the base sequence of DNA to the polypeptide chain of protein. In the transcription of double-stranded DNA the RNA is formed on a template comprising only one strand, which we will name the transcribed strand. This is also called the antisense strand since the mRNA is termed the sense strand. Similarly the transcribed strand may also be named the noncoding strand, the coding strand having the same base sequence as the mRNA. Transcription involves many steps. (1) The region of DNA to be transcribed must be unwound approximately one turn to form an open loop to allow the transcribed strand to form a DNA-RNA double helix with the 3' end of the newly synthesized RNA. (2) The mRNA is transcribed by RNA polymerase utilizing nucleoside triphosphates as substrates. The enzyme binds to the promoter, which is a region of DNA on the nontranscribed strand that has a characteristic base sequence (e.g. TATA box). Promoters are mostly located upstream of the start of transcription. However, in the case of eukaryotic RNA polymerase III, the promoter may sometimes be located downstream of the start point. There are substantial differences between prokaryotic systems and eukaryotic systems for the regulation of transcription. In prokaryotes, for transcription to proceed, a complex must be formed on the double-stranded DNA helix with the promoter and an accessory factor, sigma factor. In eukaryotes, an extensive and complex system of transcription factors regulates the process. While prokaryotes appear to utilize only a single RNA polymerase, eukaryotes possess three RNA polymerases, which are responsible for transcribing the various specific types of RNA. Thus RNA polymerase I is located in the nucleolus and is responsible for the synthesis of ribosomal RNA. This polymerase accounts for by far the greatest quantity of RNA synthesized. RNA polymerase II is situated in the nucleoplasm and is responsible for the synthesis of heterogeneous nuclear RNA, for primary transcript from which messenger RNA is formed. This polymerase is thus instrumental in determining the nature of the protein profile of the cell. RNA polymerase III is also in the nucleoplasm and synthesizes transfer RNA. In so far as eukaryotes are concerned, what follows refers mainly to the activity of RNA polymerase II. (3) As the enzyme advances along the DNA template the DNA unwinds ahead of the growing RNA and rewinds behind it thereby stripping the newly synthesized RNA from the transcribed strand of the DNA. The origin of the energy requirements for this movement is not known at present. Eventually the movement is terminated by specific sequences in the transcribed DNA strand. In some cases the protein plays a part in termination. (4) Transcription factors, which may be *cis*-acting or *trans*-acting, control transcription. In prokaryotes the control of transcription

## transduction

tion is induced by the environment and changes are very rapid since transcription and translation are tightly coupled. In eukaryotes such changes are slower. The activity of eukaryotic transcription factors is enhanced by proteins called enhancers, which although lacking promoter activity may nevertheless exert their influence over distances of several thousand base pairs. They may be upstream, downstream, or even in the midst of a transcribed gene. They may also be tissue specific. In the case of eukaryotes where the gene is split by introns the entire gene is transcribed and the introns are subsequently excised from the primary transcript by splicing.

**transcriptional repressor** any transcription factor (usually bacterial) that down-regulates gene expression by binding to an operator.

**transcriptional unit** the segment of DNA within which the transcription occurs that eventually leads to RNA formation. *Compare cistron, gene.*

**transcription factor** *abbr.: TF;* any protein required to initiate or regulate transcription; the term includes enhancers as well as the general transcription factors. Transcription factors bind to DNA sequence elements upstream of the start point and thus participate in the formation of the complex that includes RNA polymerase and initiates transcription. *See, e.g.* NF-KB, Oct, TFII, TFIII.

**transcytosis** the transport of molecules across a cell, especially across a polarized cell, such as an intestinal epithelial cell, which has a basolateral and an apical surface each with its own defined composition, which thus provides a spatially orientated transport system. The molecules undergoing transcytosis are usually contained within vesicles. One example is the absorption of maternal antibodies from the gut in newborn animals. The antibodies are taken into epithelial cells by endocytosis at the apical surface, and are transcytosed through the cell before being exocytosed at the basal surface into the blood. Transcytosis also occurs in thyroid cells: following endocytosis of thyroglobulin from the thyroid follicle, the thyroglobulin is transported across the cell in vesicles with concomitant proteolysis, with release of thyroid hormone into a blood capillary at the opposite face of the cell (*see thyroid gland*). -transcytotic *adj.;* transcytose *vb.*

**transdeamination** *a former term for the coupling of a transamidation reaction and the dehydrogenation of L-glutamate whereby an amino group of an amino acid is transferred to a-oxoglutarate by a transaminase enzyme and the resulting L-glutamate is dehydrogenated to yield a-oxoglutarate, ammonia, and a reduced coenzyme molecule.*

**trans-dominant mutation** a mutation in a regulatory gene that can control the expression of a structural gene on another chromosome.

**transducer** any device that converts a quantity of energy from one form into another.

**transducin** *abbr.: G<sub>T</sub> or G<sub>t</sub>;* a heterotrimeric G-protein of the retina, and a component in the visual transduction pathway. In the vertebrate light response, inactive heterotrimeric transducin with bound GDP ( $G_{\alpha\beta\gamma}$ -GDP) binds the photoactivated rhodopsin, metarhodopsin II, and releases GDP. GTP then binds to the  $\alpha$  subunit, which then separates from both the receptor and the  $\beta\gamma$  heterodimer.  $G_{\alpha}$  then activates cyclic GMP phosphodiesterase, and the resulting fall in cyclic GMP concentration closes cyclic GMP-gated cation channels and hyperpolarizes the retinal rod cell, generating the nerve impulse. Examples from human,  $\alpha$  subunit: database code GBT2\_HUMAN, 353 amino acids (40.04 kDa);  $\beta$  subunit: database code GBB2\_HUMAN, 340 amino acids (37.33 kDa);  $\gamma$  subunit: database code GBG1\_HUMAN, 73 amino acids (8.36 kDa).

**transduction** 1 (*in microbiology*) the transfer of genetic information to a bacterium from a bacteriophage or between bacterial or yeast cells mediated by a phage vector. In generalized transduction any of the donor genes may be transduced, whereas in specialized transduction, i.e. by a lysogenic bacterio-

**transesterification**

phage, only those genes at one of the ends of the prophage can be transduced. **Abortive transduction** occurs when phage DNA is not incorporated into the bacterial genome, but can nevertheless be transmitted in the phage to one of the daughter cells. 2 (*in biochemistry*) the activation of an intracellular effector pathway as a result of receptor activation by an extracellular signal. *See also second messenger, signal transduction.*

**transesterification** a chemical reaction in which the alcohol moiety of an ester is exchanged for another alcohol:

It is catalysed by such proteolytic enzymes as trypsin, chymotrypsin, papain, and subtilisin, and by esterases.

**transfection** originally the process of infection of competent bacterial cells by free bacteriophage or plasmid nucleic acid that results in the subsequent production of normal bacteriophage or plasmids in the infected bacterial cell. It has come to mean the process of bringing about genetic alteration of any cell or organism using recombinant DNA technology.

**transferase** an enzyme that catalyses the transfer of a group - e.g. the methyl group, glycosyl group, acyl group, phosphorus-containing, or other groups - from one compound (generally regarded as the donor) to another compound (generally regarded as the acceptor). Transferases, of which there are many, are EC class 2 enzymes.

**transference number or transport number symbol:**  $t$ ; the fraction of the current being carried by a given type of ion when an electric current is passing through an electrolytic solution.

**transfer factor** a lymphokine extractable from leukocytes and thought to transfer the ability to elicit a **delayed hypersensitivity** reaction from one person or animal to another.

**transfer gene** any gene carried by a **conjugative plasmid** that is responsible for the donor phenotype.

**transfer membrane** a membrane used with **blotting** techniques in recombinant DNA technology or protein studies. Molecules are transferred from an electrophoretic gel to the transfer membrane either by capillary attraction or by using an electric potential (**electroelution**). Transfer membranes may be of three types: (1) nitrocellulose - mixed esters of cellulose acetate and cellulose nitrate; high cellulose nitrate improves binding of biomolecules while a low percentage of cellulose acetate improves handling properties; nucleic acids can be fixed to nitrocellulose membranes by baking; (2) nylon, which is physically more robust and reusable, and to which nucleic acids can be fixed by exposure to ultraviolet light; or (3) polyvinylidene-based membranes.

**transfer potential** another name for **group transfer potential**.

**transfer reaction** another name for **group transfer reaction**.

**transferrin** any of a class of single-chain (76-81 kDa), metal-binding glycoproteins, widely distributed in physiological fluids and cells of vertebrates, with the characteristic property of a stringent association of their metal-combining properties with an anion-binding requirement; iron-binding transport proteins, that bind two  $\text{Fe}^{3+}$  in association with bicarbonate (or other anion). They are monomers with internal homology. An essential component in cell culture media, transporting iron into cells through the **transferrin receptor**. The transferrin family includes proteins such as **lactoferrin**, **melanotransferrin** (with electrophoretic polymorphisms), ovotransferrin (*see conalbumin*), and **serotransferrin**. Examples: serotransferrin (*other names*: siderophilin; p-I-metal binding globulin) from human (precursors); database code TRFE\_HUMAN, 698 amino acids (76.96 kDa); transferrin precursor from *Xenopus laevis*; database code TRFE\_XENLA, 717 amino acids (79.53 kDa).

**transferrinjection** a method of gene transfer in which DNA complexed to transferrin-polycation conjugates is introduced into cells by receptor-mediated endocytosis.

**transferrin receptor** a transmembrane protein involved in the cellular uptake of iron, bound to transferrin, which binds to the receptor and is taken into the cell via receptor-mediated

**transformation**

endocytosis. Structurally it is a dimer (a soluble serum form is a monomer lacking amino acids 1-100), the extracellular domains of the two chains being linked by a disulfide bridge, and carrying the glycan moieties. The intracellular domain is phosphorylated and palmitoylated, i.e. acylated with a palmitoyl group by a process analogous to **myristylation**. Synthesis of the receptor is regulated by binding of aconitase to mRNA when intracellular iron concentrations are low, stimulating receptor synthesis, possibly by stabilizing the mRNA. Example from human: database code TRSR\_HUMAN, 760 amino acids (84.81 kDa).

**transfer RNA abbr.:** tRNA; any of a class of relatively small RNA molecules each of which mediates the insertion of an amino acid at the correct point in the sequence of a nascent polypeptide during protein synthesis. Crick predicted that the amino acids would not directly interact with the triplet nucleotide bases comprising the codons in mRNA but that interaction would involve a small nucleic acid to which the 20 different amino acids would be attached. The discovery of such an RNA molecule in the soluble cell extract required for the synthesis of protein in an *in vitro* system derived from rat liver by Hoagland was greeted as confirmation of Crick's hypothesis. Since the RNA was present in the soluble (non-particulate) extract it was called at first **soluble RNA** or S-RNA. With 73-93 nucleotides, tRNA ( $M_r = 25\ 000$ ) was rather larger than had been expected for adaptor RNA (*see adaptor hypothesis*). It was soon shown that the amino-acid residue was attached by ester link to the 3' terminal of tRNA at either the 2'- or 3'-OH on the ribose. Specific tRNA molecules are found for the various amino acids, but in all cases the amino acid is attached to the adenosine of a CCA sequence at the 3' end of the tRNA molecule. The amino acids are attached to tRNA by specific amino acid-tRNA ligases, which first catalyse a reaction between the amino acid and ATP to form an aminoacyl-adenylate, and then transfer the aminoacyl group to the tRNA. Each tRNA possesses an **anticodon** of three nucleotides that base pairs in an antiparallel fashion with the codons of mRNA. While there are 61 sense codons there are only about 41 different tRNAs in the cytoplasm and even fewer in mitochondria due to flexibility in the base pairing between codon and anticodon (*see wobble hypothesis*). When the sequence of tRNA for phenylalanine was determined by Holley it could be shown that the secondary structure contained three loops reminiscent of a clover-leaf if the maximum amount of base pairing was allowed for. This involved about half the residues. The anticodon was predicted to be on a loop lacking base pairing. This was shown to be true, it being located on the middle of the three loops. The few tertiary structures that have been determined for tRNAs have supported the clover-leaf structure. It has been predicted that **initiator transfer RNA** would have a structure that differentiated it from the other tRNAs but this has not been firmly established. tRNA is characterized by the presence of many unusual **minor bases** the function of which has not been completely established. *Other names:* acceptor RNA; amino-acid-accepting RNA; (*formerly*) soluble RNA (*abbr.:* S-RNA or sRNA). *See also suppressor tRNA.*

**transform** 1 to bring about **transformation**. 2 (*in mathematics*) a process for deriving one mathematical entity from another. b the transformed entity itself.

**transformant** a bacterial cell that has undergone **transformation** (def. I), i.e. one that contains integrated donor genes that can be detected by plating on media selective for some or all of the donor genes.

**transformation 1 or genetic transformation** the intraspecific and interspecific (between members of different but related species) transfer of genetic information by means of 'naked' extracellular DNA in bacteria. In transformation, in contrast to **transduction**, the DNA not integrated into the recipient's genome cannot function and manifest its genetic information phenotypically. 2 characteristic and inherited changes produced in cells in culture when they have been treated with cer-

## transforming growth factor

tain viruses (which may be DNA- or RNA-containing), or with chemical carcinogens, or with X-rays, or when they have been subjected to genetic modification by DNA technology. In animal cells, these changes include certain specific alterations in morphology (especially of the nucleus) and stainability, and the cells usually show a loss of contact inhibition and have a capacity to give rise to neoplastic growth on injection into animals. The term is usually extended to refer to corresponding changes occurring in cells *in vivo*. 3 or blast transformation or lymphocyte transformation the morphological and other changes that occur in both B and T lymphocytes when they are cultured in the presence of an antigen to which they are primed, or that occur nonspecifically in B lymphocytes when they are exposed to a mitogen (e.g. certain lectins). The lymphocytes increase in size and develop a basophilic ribosome-rich cytoplasm, a prominent nucleolus, and a paler-staining nucleus. After about three days these cells resemble blast cells. 4 the alteration produced in certain specific hormone-receptor proteins, present in the extranuclear region of hormone-responsive cells, when the hormone binds to them. This alteration is accompanied by the migration of the hormone-receptor complexes to the nucleus. 5 or nuclear transformation (of an atomic nucleus) the change of one nuclide to another.

**transforming growth factor abbr.:** TGF; either of two types of mitogenic cytokine, *TGFA* and *TGF $\beta$* . *TGFA* was isolated and purified on the basis of its ability to stimulate cell growth in soft agar. It is produced by macrophages, brain cells, and keratinocytes, and is mitogenic for fibroblasts, is angiogenic *in vivo*, and induces epithelial development. It is a glycoprotein and a member of the epidermal growth factor (EGF) family, interacting with the EGF receptor. *TGFA* comprises 50 amino acids with the following sequence (residues invariant in the EGF family are underlined): VVSFHNDCPDSHTQFCFHGTCRFLVQEDKPACVCHSGYVGARCEHADLLA. Example from human (precursor): database code TGFA\_HUMAN, 160 amino acids (16.99 kDa). TGF13 is a multifunctional peptide that controls proliferation, differentiation, and other functions in many cell types. It is produced by fibroblasts, platelets, monocytes, chondrocytes, and osteoblasts. A glycoprotein with EGF repeats, at least five types (TGF $\beta$ 1 to TGF $\beta$ 5) are known; all have 112 amino acids except TGF $\beta$ 5, which has 114. They have a great many biological activities and can be mitogenic or antiproliferative depending on cell type. Platelets contain large amounts, but these proteins are also found in a variety of cell types. Example, TGF $\beta$ 1 precursor (human): database code TGFA\_HUMAN, 1394 amino acids (152.62 kDa); alternative splicing results in different forms in platelets and fibroblasts.

**transforming growth factor receptor** any of the membrane proteins that bind transforming growth factor  $\beta$  (TGF $\beta$ ) and mediate its effects. Three types of receptor for TGF $\beta$  have been distinguished: types I and II have high affinity for TGF $\beta$ 1, with lower affinity for TGF $\beta$ 2; type III has high affinity for TGF $\beta$ 1, 2, and 3. Types I and II have a single transmembrane domain with a cytoplasmic protein serine/threonine domain. The following examples are all from human. Type I receptor: database code KIR4\_HUMAN, 503 amino acids (55.96 kDa); type II receptor: database code TGR2\_HUMAN, 567 amino acids (64.54 kDa); type III receptor (has a single transmembrane domain; little cytoplasmic structure): database code TGR3\_HUMAN, 849 amino acids (93.38 kDa); residues 1-16 are the signal; 17-781 extracellular domain (heavily glycosylated, 808-849 intracellular). It may present TGF $\beta$  to the signalling receptors.

**transforming principle** a historical name for the purified DNA that, when incorporated into a bacterial cell, brings about the transformation (def. 1) of that cell. The term was used, most famously, by Oswald Theodore Avery (1877-1955, US bacteriologist and immunologist) and colleagues in their work establishing that DNA, not protein, was responsible for genetic transformation. In a classic experiment, they used two

## transition element

strains of *Pneumococcus*. The first was a wild strain, known as S (for smooth) strain because of the kind of colony that it forms, that is pathogenic. The other was a mutant strain, known as R (for rough) strain, that is non-pathogenic. When mice were injected with live R strain or heat-killed S strain, they remained healthy, but when injected with a combination of live R strain and heat-killed S strain they died. These workers concluded that the live R strain could be transformed into a pathogenic strain by material from the heat-killed S strain, and were able to demonstrate that the material was DNA. transfuse to transfer blood from one animal into the circulation of another animal, or to inject liquid into the circulation of an animal to maintain the circulating fluid volume. -transfusion *n.*

**transgene** a gene that is inserted, using cDNA technology, into the germ line in a manner that ensures its function, replication, and transmission as a normal gene. See also transgenesis, transgenic. -transgenic *adj.*

**transgenesis** the creation in plants or animals of a stably incorporated gene or genes derived from another cell or organism which can be passed on to successive generations.

**transgenic** describing an organism harbouring in its germ line a gene that has been introduced using cDNA technology (see complementary DNA). In animals, the less transgene is introduced during transient culturing of an egg or early embryo, which is then implanted into a foster mother. Introduction of the transgene may involve any of several distinct techniques: cells may be transferred from one embryo to another (to produce a chimera); pluripotent cells can be introduced into an embryo; cells infected with a retrovirus can be introduced; or cDNA can be introduced by microinjection into the pronucleus of a fertilized egg. In plants, plasmids from *Agrobacterium tumefaciens* have been widely used to produce transgenic varieties. The Ti plasmid is a natural vector for genetically engineering plant cells, because it can transfer its T-DNA to the plant genome. A number of vectors have been constructed based on this system. Expression of the introduced genes can be controlled by suitable promoters, such as the cauliflower mosaic virus promoter.

**transgenomes** large complexes of DNA found inside recipient cells following transfection of the latter with calcium phosphate-precipitated DNA.

**transgenesis** the overall phenomenon of transfer of genetic information between unrelated organisms and the subsequent expression of such information (including gene maintenance, transcription, translation, and function), especially when donor and recipient cells are widely separated by evolution (e.g. bacterial and eukaryotic cells respectively) and when the mechanisms of gene transfer and maintenance are obscure. Compare transgenesis.

**transglycosylation** a chemical (enzymic) reaction in which one glycosyl residue is transferred from a glycoside onto a receptor molecule so as to form a new glycosidic linkage, e.g. in the biosynthesis of polysaccharides. The process therefore involves breaking simple glycosidic linkages and reforming them into different types of glycosidic linkages. Glycosyltransferases are in subclass EC 2.4; also included in the term are glycosyl transfers to water and to inorganic phosphate.

**transient** 1 temporary, transitory, short-lived. 2 a sudden, short-lived disturbance in a system. 3 a short-lived chemical species such as an excited atom or molecule or a free radical. **transient-phase kinetics** an alternative name for pre-steady-state kinetics.

**trans isomer** see *cis-trans* isomer.

**transition (in molecular biology)** a particular type of mutation by single base-pair substitution that occurs by replacement of one purine by another purine, or one pyrimidine by another pyrimidine whether by chemical change or by substitution. Compare transversion.

**transition element** or transition metal any element whose atom has an incomplete d-subshell of extranuclear electrons,

## transition state

or which gives rise to a cation or cations with an incomplete d-subshell. Such elements fall into groups 3 to II inclusive of the IUPAC periodic table. (Elements of group 12, which formerly were also considered as transition elements, have complete d-subshells and are now excluded.) The first series of transition elements is in period 4 of the periodic table and comprises those of proton numbers 21 to 29 inclusive, i.e. the elements scandium, titanium, vanadium, chromium, manganese, iron, cobalt, nickel, and copper; the second series is in period 5 and comprises those of proton numbers 39 to 47 inclusive, i.e. the elements yttrium, zirconium, niobium, molybdenum, technetium, ruthenium, rhodium, palladium, and silver; the third group is in period 6 and comprises those of proton numbers 57 to 79 inclusive, i.e. the lanthanoids together with the elements hafnium through to gold; and the fourth series is in period 7 and contains those of proton numbers 89 to 103 inclusive, i.e. the actinoids, and may well be found also to contain a number of elements of proton number 104 or more that yet remain to be characterized or discovered. The lanthanoids and actinoids are designated inner transition elements of periods 6 and 7 respectively; their atoms also have incomplete inner f-subshells of electrons. All transition elements are metals, they often have more than one valency state, and they form many coordination complexes, which frequently are coloured.

**transition state** or activated complex (*in enzymology*) the state of most positive molar Gibbs energy through which an assembly of atoms must pass on going from the reactants of a single-step chemical reaction to the products. This is the state that occurs immediately after binding of the reactants to the enzyme's active site; it is during this time that transient bonds between reactants and enzyme are first formed, and initial electronic interactions occur. It is followed by a state in which more stable intermediates form, prior to the eventual formation of products.

**transition-state theory** the theory that relates the rate of an enzymic reaction to the difference in Gibbs energy between the transition state and ground state ( $\Delta G^\ddagger$ ). If  $x$  is the ground state and  $x^\ddagger$  the transition state, then the rate of decomposition of  $x$  is given by:

$$-d[x]/dt = \nu[x^\ddagger] = [x](kT/h)\exp(-\Delta G^\ddagger/RT),$$

where  $\nu$  is the vibrational frequency of the bond that is breaking,  $h$  is the Planck constant,  $k$  the Boltzmann constant,  $R$  the gas constant, and  $T$  the thermodynamic temperature.

**transition temperature symbol:**  $T_c$ ; (of a membrane lipid) the surface temperature at which a heated lipid bilayer undergoes transition from one physical state (e.g. liquid crystalline) to another (liquid). See also pretransition temperature, phase transition (of lipids).

**transit peptide** any  $\approx 4$  kDa peptide sequence at the N or C terminus (or both) of cytoplasmically synthesized precursor proteins of certain chloroplast proteins that contains the information to ensure both the specific post-translational transport of the protein into the chloroplast and its localization within the organelle. The transit peptide is removed within the chloroplast.

**transit time** the time taken by a coenzyme or metabolite in travelling between two enzymes. If the two enzyme reactions were infinitely fast, the overall velocity would be determined by the reciprocal of the transit time.

**transketolase** EC 2.2.1.1; *systematic name*: sedoheptulose-7-phosphate:D-glyceraldehyde-3-phosphate glycolaldehyde transferase; *other name*: glycolaldehyde transferase. An enzyme that catalyses the transfer of a glycolaldehyde ( $\text{HOH}_2\text{C-CHO-}$ ) moiety from xylulose 5-phosphate to ribose 5-phosphate to form glyceraldehyde 3-phosphate and sedoheptulose 7-phosphate. A component of the pentose phosphate pathway, it requires thiamine diphosphate (TPP) as coenzyme; a glycolaldehyde-TPP intermediate is formed transiently during the reaction. It has broad substrate specificity.

## transmission

In clinical chemistry, the measurement of transketolase activity in a red cell hemolysate, in the presence and absence of thiamin, gives an indication of the thiamin status of the individual by revealing the degree of activation of the enzyme in the absence of thiamin, compared with the activity in the presence of optimal concentrations. Example from human (homodimer): database code TKT\_HUMAN, 623 amino acids (67.72 kDa).

**translation** 1 (*in molecular biology*) the process by which a particular sequence of bases in messenger RNA (mRNA) determines a sequence of amino acids in the polypeptide chain being assembled during protein and peptide biosynthesis. One or more specific base triplets (codons) code for each of the 20 amino acids that may be incorporated into the polypeptide chain (*see genetic code*). Each codon of the mRNA molecule is recognized by the corresponding anticodon on the transfer RNA to which the amino acid is attached. The transfer RNA binds to a site on the large subunit of the ribosome, which is associated with the small subunit to which the mRNA is bound. The first codon (the initiation codon) in each mRNA molecule is AUG, which codes for formylmethionine (in prokaryotes and mitochondria) or methionine (in eukaryotes). The methionine or formylmethionine, or just the formyl group, is removed before the chain is completed. Completion of translation is signalled by one of three termination codons. Release factors effect the release of the complete polypeptide chain and the dissociation of the two subunits of the ribosome. 2 movement or displacement laterally in space without rotation or change of orientation.

**translational frictional coefficient** *see* frictional coefficient.

**translocase** a system catalysing translocation of a substrate across an osmotic barrier. *See* EF-G, translocator.

**translocation** a vectorial transfer process, e.g. of a solute across a membrane. -translocation *adj.*

**translocator** or porter 1 a system catalysing a secondary translocation reaction, i.e. one not involving primary bond exchanges between different pairs of chemical groups or the donation and acceptance of electrons. 2 any molecular group that is attached to a substrate during transport of the latter across a membrane.

**translocon** a translocation complex that constitutes the specific site of protein translocation across the endoplasmic reticulum. It involves the signal recognition particle receptor. The component proteins are known as translocon-associated proteins (*abbr.*: TRAP). They may be involved in ensuring retention in the endoplasmic reticulum of resident proteins. TRAP proteins form a heterotetramer of  $\alpha$ ,  $\beta$ ,  $\gamma$ , and  $\delta$  subunits. Examples,  $\alpha$  from *Arabidopsis thaliana*: database code SSRA\_ARATH, 253 amino acids (27.5 kDa);  $\beta$  from dog: database code SSRB\_CANFA, 183 amino acids (20.1 kDa);  $\gamma$  from rat: database code SSRG\_RAT, 185 amino acids (21.11 kDa);  $\delta$  from rat: database code SSRD\_RAT, 173 amino acids (18.98 kDa).

**translucent** transmitting light (or other radiation) with some scattering or diffusion. Consequently, objects cannot be clearly distinguished through translucent materials. *Compare* transparent. -translucence or translucency *n.*

**transmembrane protein** any protein that traverses the membrane, especially the plasma membrane. For the different types *see* membrane protein.

**transmethylation** the transfer of a methyl or methylene group, as frequently occurs in one-carbon metabolism. Methyltransferases are in sub-subclass EC 2.1.1, and enzymes concerned with one-carbon metabolism are in sub-subclass EC 2.1.2. *See also* C, compound, folate coenzymes, S-adenosylmethionine.

**transmission** 1 the act, process, or an instance of transmitting. 2 the proportion of radiant energy that is transmitted perpendicularly through a substance or solution; *compare* transmittance. 3 the delivery of a nerve stimulus across a synapse, e.g. by a neurotransmitter.

## transmission coefficient

transmission coefficient (*in nuclear physics*) the probability that a particle striking a nucleus penetrates it.

transmission electron microscope abbr.: TEM; *see* electron microscope.

transmission factor *an alternative name for* transmittance.

transmittance or transmission factor 1 (*in chemistry*) symbol:  $T$ ; the ratio  $I/I_0$ , where  $I_0$  is the intensity of electromagnetic radiation falling on a body or substance and  $I$  the intensity after transmission through it. It is a dimensionless physical quantity. 2 (*in physics*) symbol:  $\tau$ ; the fraction of radiant energy that, having entered an absorbing substance, reaches its far boundary. It is given by

$$\tau = \Phi_{tr}/\Phi_0 = \exp(-Kcl),$$

where  $\Phi_{tr}$  and  $\Phi_0$  are the radiant powers of the transmitted and incident radiation,  $K$  is the molar napierian absorption coefficient,  $c$  the speed of light in the medium, and  $l$  the path length.

transmitter-gated channel *see* ion channel.

transparent transmitting light with little scattering or diffusion so that objects beyond the transparent material can be clearly distinguished. The term can be used in appropriate circumstances to indicate materials allowing the passage of other electromagnetic, particulate, or sonic radiation without disturbance. *Compare* translucent. -transparency  $n$ .

transpeptidase 1 (*sometimes*) *an alternative term for* peptidyl-transferase. 2 (*sometimes*) the enzymic activity of a number of proteinases that catalyse, apart from hydrolysis of peptide links, the replacement of one terminal amino-acid residue in a peptide by another amino acid or other suitable molecule. 3 (*sometimes*) certain aminoacyltransferase enzymes, e.g. D-glutamyl transpeptidase, D-glutamyltransferase (EC 2.3.2.1), and glutamyl transpeptidase (i.e.  $\gamma$ -glutamyltransferase, EC 2.3.2.2).

transpeptidation any of the reactions catalysed by transpeptidases.

transphosphoribosidase *see* adenine phosphoribosyltransferase.

transplantation antigen *an alternative term for* histocompatibility antigen.

transport the movement of a material from one place to another, especially in reference to the movement of substances around the body (e.g. in blood) or across a biological membrane, or of electrons along a series of carriers. This term implies a positive agency, in contradistinction to passive diffusion. *See also* active transport, antiport, facilitated diffusion, symport, transport protein.

transporter a membrane protein catalysing the passage of molecules from one face of a membrane to the other.

transport method *see* transport process.

transport number *an alternative term for* transference number.

transport piece *see* secretory piece.

transport process any process, such as sedimentation, diffusion, or electrophoresis, that is irreversible in the thermodynamic sense. The system in which such a process occurs is removed from a state of equilibrium. Such processes are of particular value in providing information about the dimensions, shapes, and masses of macromolecules.

transport protein a protein (or enzyme) that is instrumental in transporting material, often in a specific manner, across a biological membrane or within a biological fluid (e.g. blood).

transposable element *another name for* transposon.

transposase an enzyme that is responsible for the transposition of transposable elements or transposons. Transposases are involved in site-specific DNA recombination required for transposition in bacteria and other organisms. Example, Tn3 (*Escherichia coli* and *Klebsiella pneumoniae* transposon) transposase; database code TRAL\_ECOLI, 1015 amino acids (114.40 kDa).

transpose 1 to alter the position of; to interchange or place in a different order. 2 (*in mathematics*) a to interchange the rows

## trehalose

and columns of a matrix (def. 8). b the matrix resulting from interchanging the rows and columns of a given such matrix. transposition 1 the process of transposing or the state of being transposed. 2 something that has been transposed; especially a segment of a chromosome or a piece of a DNA molecule.

transposition sequence *an alternative name for* translocation sequence.

transposon or transposable element a specific DNA sequence that is transferred as a unit from one replicon to another. Transposons were first identified as a result of work on transposable elements and also as spontaneous insertions in bacterial operons. The simplest transposons are referred to as insertion sequences. These have the designation IS followed by a number related to the sequence in which they were identified, preceded by an indication of the site of insertion followed by a double colon (thus  $\lambda$ ::IS1 indicates an ISI element inserted into phage lambda). Each end of the transposon is characterized by repeated sequences, due to short sequences copied from the original gene called target repeats or direct repeats, and also due to short inverted repeats that are a property of the insert. More complex transposons, called composite transposons, may have a central portion having a variety of markers, the central portion being flanked by IS elements that are responsible for identifying the transposon for transposition. Composite transposons have the designation Tn followed by a number. In eukaryotes, transposable elements constitute much of the repetitive sequences in the genome, with up to a few hundred repeat copies. They are flanked by terminal inverted sequences; the terminal sequences in each strand characteristically represent the complementary bases of the inverted sequence, i.e. TCAG CGTA. Some transposons move physically from one site to another, while others are replicated, with one copy remaining at the original site and a duplicate inserting elsewhere. Both mechanisms involve a transposase enzyme; the former requires a resolvase enzyme in addition.

transthyretin a thyroid-binding protein occurring in the bloodstream and having an unusual structure. The molecule is a homotetramer; each monomer comprises two four-stranded beta sheets and has the shape of a prolate ellipsoid. Two of the monomers dimerize and the dimers themselves dimerize to form a structure with an internal channel. Example (precursor) from human; database code TTHY\_HUMAN, 147 amino acids (15.87 kDa).

transudate any fluid, with its solutes, that has passed through a membrane or through the interstices of a system.

transude to pass or be passed through a membrane or the interstices of a system as a transudate. -transudation  $n$ .

transversion the particular type of mutation by single base-pair substitution that occurs by the insertion of a purine in a duplex nucleic acid, in place of a pyrimidine, or vice versa. *Compare* transition.

TRAP abbr. for translocon-associated protein; *see* translocon.

trap hypothesis 1 a proposed mechanism for the binding of proteinases by  $\alpha_2$ -macroglobulin (a2M). It is suggested that, when U2M interacts with a proteinase, hydrolysis of one or more of its susceptible peptide bonds in its bait region occurs, whereupon the U2M molecule undergoes a conformational change that physically entraps the proteinase molecule, thus sterically hindering reaction between the proteinase and other large substrate molecules. 2 *see* methyltetrahydrofolate trap hypothesis.

Trasylol a proprietary name for aprotinin.

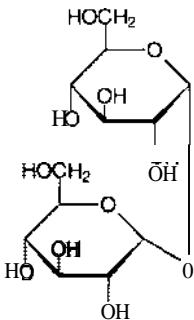

TRE abbr. for 1 TPA response element, a response element for phorbol esters. 2 thyroid response element. *See* response element.

trefoil motif *an alternative name for* P domain.

trehalose a-D-glucopyranosyl-a-D-glucopyranoside;  $\alpha,\alpha$ -trehalose; a nonreducing disaccharide, *also known as* mushroom sugar or mycose, that acts as a reserve carbohydrate in certain fungi (especially yeasts), algae, and lichens. It is cleaved by trehalase but not by most other a-glucosidases. It

## tremerogen

is a component of cord factors, which are a mixture of trehalose 6,6'-mycolates (see mycolic acid). α-D-Glucopyranosyl-β-D-glucopyranoside (α,p-trehalose) and p-*o*-glucopyranosyl-p-D-glucopyranoside (P,p-trehalose) occur naturally, but only very rarely.

**tremerogen** any of a group of oligopeptides that contain non-amino-acid components and are the sex hormones of the jelly fungi. They induce formation of a conjugation tube in compatible cell types. They may contain a farnesyl group bound to cysteine.

**Tresyl** *proprietary name* indicating the 2,2,2-trifluoroethane sulfonyl group; Tresyl-activated Sepharose can be used in the preparation of affinity gels, the sulfonyl groups being readily displaceable by amines, thiols, phenolic groups, or imidazole, which remain bound to the gel as the stationary component; e.g.

**tretinoin** *a WHO-approved nonproprietary name for retinoic acid, especially for pharmacological use.*

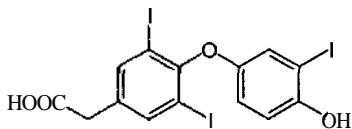

**TRF** *abbr. for 1 thyrotropin-releasing factor; i.e. thyrotropin-releasing hormone. 2 T-cell-replacing factor; see interleukin 5.*

**TRF-III or TRF-m** *see interleukin 1.*

**TRH** *abbr. for thyrotropin-releasing hormone.*

**tri+** *comb. form* 1 denoting three, threefold, thrice, every third; *see also tris+* 2 (*in chemical nomenclature*) (*distinguish from tris+* (deL 2)) a indicating the presence in a molecular entity of three identical specified unsubstituted groups, e.g. trichloroethylene, trimethylamine. b indicating the presence in a molecular entity of three identical oxoacid residues in linear anhydride linkage; e.g. adenosine 5'-triphosphate.

**triac** (*informal*) *abbr. for 3,3',5-triodothyroacetic acid, a catabolite of thyroxine.*

**triaconta+** or (*before a vowel*) **triacont+** *comb. form* denoting thirty or thirty times.

**triacontanoic acid** melissic acid; a 3D-carbon straight-chain aliphatic acid; m.p. 93.6 DC (methyl ester 71.5 DC).

**triacontapeptide** a 3D-residue peptide.

**triacylglycerol** or (*formerly*) triglyceride any triester of glycerol; the three fatty acids may all be the same, or differ in any permutation. Triacylglycerols are important components of plant oils, animal fats, and animal plasma lipoproteins. The degree of unsaturation of the component fatty acids determines the melting point: plant oils, which typically contain a

## tricine

high percentage of (poly)unsaturated fatty acids, are liquid, while animal fats, being more highly saturated, are solid or semisolid. *See also* lipoprotein and individual plant oils and animal fats.

**triacylglycerol lipase** EC 3.1.1.3; *systematic name:* triacylglycerol acylhydrolase; *other names:* lipase; triglyceride lipase; tributyrase. An enzyme that catalyses the reaction:

This is a very widespread enzyme activity, with types ranging from those found in microorganisms to those such as pancreatic lipase, and the hormone-sensitive lipase of mammalian adipose tissue. Example from *Pseudomonas aeruginosa* (precursor): database code LIP\_PSEAE, 311 amino acids (32.69 kDa). Example from *Geotrichum candidum* (yeast): database code NDL\_ITHG, 544 amino acids (59.62 kDa); 3-D structure known; the latter is a globulin with mainly alpha helix and turns, and contains one modified glutamine residue (pyrrolidine carboxylic acid).

**tradin** a major membrane glycoprotein of the sarcoplasmic reticulum triad junction of skeletal and cardiac muscle. The luminal domain has a highly conserved region and can bind both the ryanodine receptor and calsequestrin. Example from rabbit: database code A45990, 706 amino acids (79.04 kDa).

**+triose suffix** used in nomenclature of glycolipids to indicate a molecule containing an oligosaccharide moiety composed of three sugar residues (which may be the same or different), as in gangliotriose. *Distinguish from triose.*

**triazine-dye affinity chromatography (sometimes)** a type of dye-ligand chromatography in which the coupled dye is a triazinyl compound. The technique is not affinity chromatography in the original sense.

**tricaprin** *a trivial name for tridecanoic, the triacylglycerol containing three caproyl (decanoyl) residues. See also tricaproin, tricaprylin.*

**tricaproin** *a trivial name for trihexanoic, the triacylglycerol containing three capric (hexanoic) ester residues. See also tricaprin, tricaprylin.*

**tricapry'in** *a trivial name for trioctanoic, the triacylglycerol containing three caprylic (octanoic) ester residues. See also tricaprin, tricaproin.*

**tricarboxylic acid abbr.:** TCA; any organic compound having three carboxylic-acid groups. The name often has the connotation of relationship with citric acid, as in the tricarboxylic-acid cycle.

**tricarboxylic-acid cycle (abbr.: TCA cycle) or citric-acid cycle or Krebs cycle** a nearly universal metabolic pathway in which the acetyl group of acetyl coenzyme A is effectively oxidized to two CO<sub>2</sub> and four pairs of electrons are transferred to coenzymes. The acetyl group combines with oxaloacetate to form citrate, which undergoes successive transformations to isocitrate, 2-oxoglutarate, succinyl-CoA, succinate, fumarate, malate, and oxaloacetate again, thus completing the cycle. In eukaryotes the tricarboxylic acid is confined to the mitochondria. *See also* glyoxylate cycle.

**trichloroacetic acid abbr.:** TCA; Cl<sub>3</sub>CCOOH; an organic acid widely used for the precipitation of protein from tissue and other cell extracts. A final concentration of 3-9% (w/w) is normally used. TCA can be extracted into diethyl ether.

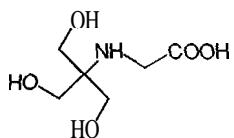

**trichloroethyl alcohol** 2,2,2-trichloroethanol; an active metabolite of chloral hydrate with CNS depressant actions.

**trichohyalin** a structural protein produced and retained in cells of the inner root sheath and medulla of the hair follicle. In the sheep, 75% of its amino acids are glutamate or glutamine, arginine, or lysine; the gene is also expressed in epithelia, hoof, and rumen. Trichohyalin associates in regular arrays with keratin intermediate filaments. Example from human: database code TRHY\_HUMAN, 1898 amino acids (246.95 kDa).

**tricine or TRICINE** *trivial name for N-tris[(hydroxy-*

tricosa+

methyl)methyl]glycine; N-[2-hydroxy-l, l-bis(hydroxymethyl)-ethyl]glycine; a Good buffer substance;  $pK$  ( $20^\circ\text{C}$ ) = 8.15.

tricosa+ or (before a vowel) tricos+ comb. form denoting twenty-three or twenty-three times.

tricosapeptide a 23-residue peptide.

trideca+ or (before a vowel) tridec+ denoting thirteen or thirteen times.

tridentate 1 having three teeth or toothlike projections. 2 (of a ligand) chelating a metal ion by means of three donor atoms.

triene any alkatriene or substituted alkatriene.

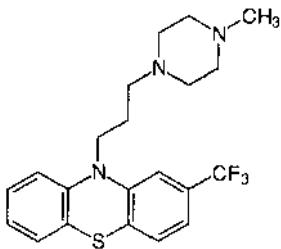

+triene(+) or (before a vowel) +triene (in chemical nomenclature) infix or suffix in systematic names denoting the presence in a molecular structure of an unsaturated aliphatic hydrocarbon chain containing three (conjugated or unconjugated) double bonds. The position of each double bond may be indicated by a locant for its lowest numbered carbon atom; e.g. cycloheptatriene, icosa-8, 11, 14-trienoic acid.

trienoic indicating a compound having a carboxylic-acid group and an aliphatic chain with three double bonds.

trienoyl indicating the acyl group of a trienoic acid.

triflavin a disintegrin from the snake *Trimersurus flavoviridis*, containing an Arg-Gly-Asp (RGD) motif at residues 49-51, that inhibits fibrinogen interaction with platelet receptors, and thereby inhibits platelet aggregation. Database code DIST\_TRIFL, 70 amino acids (7.57 kDa).

trifluoperazine 10-[3-(4-methyl-l-piperazinyl)propyl]-2-(trifluoromethyl)-IOH-phenothiazine; an antagonist with high affinity for  $D_2$ -dopamine receptors. It is used in the treatment of manic and schizophrenic psychoses and as an inhibitor of calmodulin action. One proprietary name: Stelazine (dihydrochloride).

trifluoroacetic acid abbr.: THA;  $\text{CF}_3\text{COOH}$ ; a strong organic acid. It is widely used as a catalyst in organic synthesis, and is used to cleave Cbz- and tBoc- groups from protected amino acids. The anhydride is used to prepare trifluoroacetyl derivatives for the protection of alcohols and amines, and as volatile derivatives for gas-liquid chromatography.

trigger 1 to induce (often rapidly) into activity. 2 a mechanism or agent that brings about such an action. The term is commonly used in connection with membrane receptor activation and signal transduction, as in trigger mechanism.

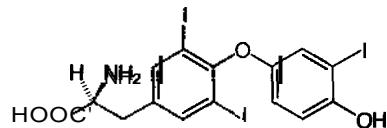

triglyceride a former name for triacylglycerol; the term is still quite commonly used as in, e.g., 'triglyceride fraction', but use is discouraged for such purposes since triglyceride is properly a generic term for compounds having three glycerol residues (e.g. cardiolipin).

trigonelline nicotinic acid N-methylbetaine; 3-carboxy-l-methylpyridinium inner salt; a metabolite of nicotinic acid. It is excreted in the urine after the consumption of relatively large amounts of nicotinic acid.

triose

trihydric (of a chemical compound) containing three hydroxyl groups per molecule; trihydroxy; used especially of alcohols.

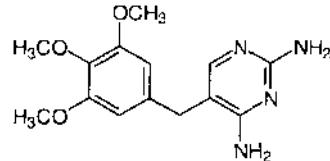

triiodothyronine abbr.: T<sub>3</sub>; 3,3,5-triido-L-thyronine; one of the hormones secreted by the thyroid gland. Plasma levels of T<sub>3</sub> are much lower than those of thyroxine (T<sub>4</sub>) (20- to 50-fold), but the physiological activity of T<sub>3</sub> is higher. The mechanism of action of thyroid hormones involves T<sub>3</sub> binding to a thyroid-hormone receptor, which is then activated to bind to thyroid response element, a transcription-regulatory element. Much of T<sub>4</sub> is converted to T<sub>3</sub> within cells, T<sub>3</sub> being the compound that binds to the thyroid-hormone receptor in target cells. See also thyroglobulin.

trilaurin a triacylglycerol in which all the fatty-acyl moieties are lauroyl (dodecanoyl).

trimer a molecular complex having three components or sub-units. If these are identical, it is referred to as a homotrimer; if anyone is different from any other, it is called a heterotrimer. -trimeric ad.

trimethoprim 2,4-diamino-5-(3,4,5-trimethoxybenzyl)pyrimidine; a specific inhibitor of formylation and a competitive inhibitor of dihydrofolate reductase. The trimethoprim resistance gene can be used as a selectable marker for cloning vectors in animals or plants. See also sulfamethoxazole.

trimethylaminuria see fish-odour syndrome.

trimyristin a triacylglycerol in which all the fatty-acyl moieties are myristoyl (tetradecanoyl).

trinactin a neutral macrotetralide antibiotic with an action similar to that of nonactin.

trinitroglycerin glyceryl trinitrate; trinitrolycerol; the nitrate moiety is metabolized to nitrite and, subsequently, to nitric oxide and nitrosothiol, which activate guanylate cyclase. The resulting increase in cyclic GMP synthesis may explain the potent vasodilator effects of this and similar organic nitrates.

trinor+ prefix (in a trivial name of a compound) indicating replacement of three methyl groups by hydrogen. See also nor+.

trinucleotide repeat an increase in copy number of a normally polymorphic triplet. Some genetic disorders, e.g. fragile X syndrome, result from this.

triol any aliphatic chain having three hydroxyl groups.

triolein a triacylglycerol in which all the fatty-acyl moieties are oleoyl (cis-9-octadecenoyl). See also triolein breath-test.

triolein breath-test a test used as an alternative to fecal fat determination to test for intestinal malabsorption of fat. When  $^{14}\text{C}$ -labelled triacylglycerol (10  $\mu\text{Ci}$ ) is administered by mouth, a proportion of the  $^{14}\text{C}$  will be breathed out as  $^{14}\text{CO}_2$  which is trapped in a solution of hyamine carbonate for scintillation counting.

triose 1 anyone of three monosaccharides having a chain of three carbon atoms in the molecule, these being the chiral enantiomers D- and L-glyceraldehyde, and their achiral constitutional isomer glyceral. 2 trisaccharide; used as a stem name for any oligosaccharide consisting of three residues per mol-

## triose phosphate

ecule of the same sugar in a single type of linkage, as in maltohexose. *Distinguish from +triose.*

**triose phosphate** general term for D-glyceraldehyde 3-phosphate, glyceraldehyde phosphate, or a mixture thereof. These two compounds are interconvertible by the enzyme **triose-phosphate isomerase**.

**triosephosphate dehydrogenase (NADP<sup>+</sup>)** see **glyceraldehyde-3-phosphate dehydrogenase (NADP<sup>+</sup>) (phosphorylating)**.

**triose-phosphate isomerase** EC 5.3.1.1; systematic name: D-glyceraldehyde-3-phosphate ketol-isomerase; other names: triosephosphate mutase; phosphotriose isomerase. The sugar **isomerase** enzyme that is important in the glycolytic pathway, and catalyses the aldose-ketose isomerization of the two **triose phosphates**, i.e. the reaction:

Example from *Saccharomyces cerevisiae*: database code NRL\_IYPIA, 247 amino acids (26.63 kDa); 3-D structure known.

**trioxsalen** 2,5,9-trimethyl-7H-furo[3,2-g][1]-benzopyran-7-one; 4,5',8-trimethylpsoralen (abbr.: TMP); a pigmentation agent (photosensitizer). See also **psoralen**.

**tripalmitin** a triacylglycerol in which all the fatty-acyl moieties are **palmitoyl** (hexadecanoyl).

**tripeptide** a three-residue peptide.

**triphenylmethyl group** abbr.: trityl; a group used in chemical syntheses to protect nitrogen, sulfur, and, particularly, oxygen functions as their trityl derivatives. It has the advantage that, while stable under many conditions, it is readily removed by mild acid. It can be introduced by reagents such as triphenylmethyl chloride.

**triphosphate** 1 the pentavalent ion,  $\text{P}_3\text{O}_{10^{5-}}$ , derived from triphosphoric acid, decaoxotriphosphoric(V) acid, ( $\text{HO}_3\text{PO}-\text{O}-\text{PO}(\text{OH})-\text{O}-\text{PO}(\text{OH})_2$ ) (an acid not known in the free state). 2 any mixture of the anions of triphosphoric acid. 3 any (partial or full) salt or ester of triphosphoric acid. 4 any organic compound containing three phosphoric residues linked linearly by oxygen atoms. 5 name of the univalent group  $-\text{O}-\text{PO}(\text{OH})-\text{O}-\text{PO}(\text{OH})-\text{O}-\text{PO}(\text{OH})_2$  (irrespective of its state of ionization). 6 (formerly) any organic compound containing three independent phosphoric residues attached to different parts of the molecule; now incorrect, use **trisphosphate**.

**triphospho-** 1 prefix to a chemical name indicating the presence in ester linkage of a triphosphoric residue. 2 (formerly) prefix to a chemical name indicating the presence of three independent phosphoric residues in ester linkages; now incorrect, use **trisphospho-**.

**triphosphoinositide** abbr.: TPI; a former name for **phosphatidylinositol 4,5-bisphosphate** (symbol: PtdIns-4,5-P<sub>2</sub>). Current nomenclature requires bisphosphate, triphosphate, etc. for the substituent phosphates on the inositol moiety. Other phosphatidylinositol bisphosphates are known, e.g. PtdIns-phosphatidylinositol 3,4-bisphosphate.

**triphosphopyridine nucleotide (oxidized)** abbr.: TPN+; an obsolete name for **nicotinamide-adenine dinucleotide phosphate**.

**triphosphopyridine nucleotide (reduced)** abbr.: TPNH; an obsolete name for **nicotinamide-adenine dinucleotide phosphate (reduced)**.

**triphosphoric** symbol: PPP or (in the one-letter convention for nucleotides) ppp; general name for a residue of triphosphoric acid, ( $\text{HO}_3\text{PO}-\text{O}-\text{PO}(\text{OH})-\text{O}-\text{PO}(\text{OH})_2$ , whether singly or multiply attached through oxygen to other groups and whether or not any residual hydroxyl groups are dissociated).

**triple bolus test** see **combined test of pituitary function**.

**triple helix** 1 the superhelically coiled arrangement of the three polypeptide chains in **tropocollagen**. 2 or (sometimes) triplex see **triplex DNA**.

**triple membrane** see **unit membrane**.

**triple point** the point on a phase diagram at which three phases may coexist.

**triplet** 1 (in molecular biology) any sequence of three purine

## trisomic

and/or pyrimidine bases in nucleic acids that specifies a particular amino acid. It is synonymous with **codon** in mRNA or **anticodon** in DNA or tRNA. See also **synonym triplet**. 2 a collection of three of a kind. 3 anyone of three offspring born from a single pregnancy.

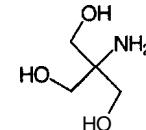

**triplet code** the **genetic code**, which is based on **triplets** (def. I) of purine and pyrimidine bases.

**triplex DNA** a three-stranded structure formed by duplex DNA in association with an oligonucleotide, when purine or pyrimidine bases occupy the major groove of the DNA double helix adopting **Hoogsteen base pairing** with the Watson-Crick base pairs. Triplex DNA may be involved as an intermediate in **crossing over**. See also **tetraplex DNA**.

**triploid** 1 describing a cell, tissue, or organism having three times the haploid (monoploid) number of chromosomes. 2 such a cell, tissue, or organism. -triploidy n.

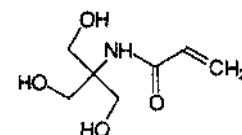

**tris+** prefix 1 denoting three times, thrice, tripled; see also **tri-** (def. I). 2 (in chemical nomenclature) (distinguish from **tri-** (def. 2)) a indicating the presence in a molecular entity of three identical specified groups each substituted in the same way; e.g. tris(2-hydroxyethyl)amine. b indicating the presence at separate positions in a molecular entity of three identical inorganic oxoacid residues; e.g. inositol 1,4,5-trisphosphate.

**Tris** or **TRIS** or **THAM** tris(hydroxymethyl)aminomethane; 2-amino-2-hydroxymethyl-1,3-propanediol; a compound widely used as a biological buffer substance in the pH range 7–9;  $\text{pK}_a$  (20°C) = 8.3;  $\text{pK}_a$  (37°C) = 7.82.

**trisaccharide** an oligosaccharide with three monosaccharide units.

**Trisacryl** 1 a proprietary name for N-acryloyl-2-amino-2-hydroxymethyl-1,3-propanediol;  $\text{CH}_2=\text{CH}-\text{CO}-\text{NH}-\text{C}(\text{CH}_2\text{OH})_3$ ; a compound used in the manufacture, by copolymerization with a cross-linking agent such as N,N'-diallyl L-tartardiamide (abbr.: DATD) or N,N'-methylenebisacrylamide, of a range of strongly hydrophilic artificial support materials of controlled porosity that are useful for gel-permeation chromatography. Copolymerization with a cationic or anionic derivative as a third component yields support materials of utility in ion-exchange chromatography. Such materials are thermally, chemically, and biologically stable, and resistant to high pressures. 2 as modifier describing a range, or any member of a range, of such chromatographic support materials; e.g. Trisacryl polymers, Trisacryl ion-exchangers, Trisacryl gels, Trisacryl GF05, DEAE-Trisacryl M.

**triskelion** a hexamer of **clathrin** molecules, composed of three heavy chains and three light chains. In the **electron microscope** triskelions appear to have three bent arms each linked into a central point. [From triskele, a symbolic figure consisting of three legs radiating from a common centre.]

**trisomic** 1 describing a cell, tissue, or organism having three copies of one or more chromosome(s) in an otherwise diploid chromosome set. In humans, trisomy 21 (i.e. presence of three

**trisphosphate**

copies of chromosome 21) is associated with **Down's syndrome**. 2 such a cell, tissue, or organism. -trisomy n.

**trisphosphate** any compound containing three independent phosphoric residues in ester linkages, at positions indicated by locants; e.g. inositol 1,4,5-trisphosphate. Compare **triposphate**.

**triphospho+** prefix to a chemical name indicating the presence of three independent phosphoric residues in ester linkages, at positions indicated by locants. Compare **triphospho-**.

**tristearin** a triacylglycerol in which all the fatty-acyl moieties are **stearoyl** (octadecanoyl).

**tritiate** to combine or label with **tritium**; to replace one or more atoms of hydrogen with tritium. Tritium may be introduced into specific sites by chemical synthesis but 3H-labelled steroids are prepared by the reduction of unsaturated precursors with  $3\text{H}_2$ , the number of 3H atoms introduced depending upon the degree of unsaturation of the precursor and the catalyst used. Biosynthesis is rarely used for 3H-labelling since intramolecular migration of 3H atoms is often caused by enzymes.

**tritin** a type I **ribosome-inactivating protein** from wheat.

**tritium** the radioactive isotope of hydrogen,  ${}^3\text{H}$  (i.e. the nucleus contains two neutrons and one proton). It decays to produce  $\beta$  particles of low energy (0.018 MeV); half-life 12.26 years. Compare **deuterium, protium**.

**tritium nuclear magnetic resonance spectroscopy** abbr.: tritium NMR spectroscopy or TNMR spectroscopy; the application of **nuclear magnetic resonance spectroscopy** to determine the positions and extents of tritium substitution in substances (generally of known structure) that have been labelled with tritium ( ${}^3\text{H}$ ). The technique depends upon an equality of the displacements of the resonance frequencies (chemical shifts) of tritium and protium ( ${}^1\text{H}$ ) nuclei in corresponding environments relative to those occurring with the tritiated and nontritiated forms, respectively, of a reference substance. The method is quick, nondestructive, and applicable to very small amounts of material. It is thus particularly useful for determining the pattern of labelling in substances that are costly, complex in structure, and/or unstable. The technique is also used to follow the chemical and steric course of biochemical reaction sequences.

**triton** 1 (in chemistry) symbol:  ${}^3\text{H}^+$ ; the cation derived from an atom of **tritium**; a hydron of nucleon number 3. 2 (in nuclear physics) symbol: t; a particle having a charge equal and opposite to that of an electron and having a mass of 3.0155 Da.

**Triton** the proprietary name for any of a series of polyoxyethylene ethers of certain alkylphenols that are surfactants and classed as nonionic detergents. Those used most commonly are based on the formula *tert-octyl-C<sub>6</sub>H<sub>4</sub>-[OCH<sub>2</sub>CH<sub>2</sub>]xOH*; e.g. in Triton X-45,  $x \approx 5$ ; in Triton X-IOO,  $x = 9$  or 10 (aggregation number 100-155, CMC 0.2-0.9 mM); in Triton X-405,  $x \approx 40$ ; Triton CF is a benzyl-polyoxyethylene *tert-octylphenyl* ether; Triton N-IOI is a polyoxyethylene nonylphenyl ether (C<sub>9</sub>H<sub>19</sub>-C<sub>6</sub>H<sub>5</sub>[OCH<sub>2</sub>CH<sub>2</sub>]<sub>10</sub>OH), with  $x = 9$  or 10.

**tritosome** a lysosome that is loaded with Triton. Tritosomes have an isopycnic density in sucrose solution of about 1.14, and can thus be separated readily from other cell constituents.

**tritriaconta+** or (before a vowel) **tritriacont+** comb. form denoting thirty-three or thirty-three times.

**triturate** 1 to rub or grind (solid material) to a very fine powder either dry or in a liquid. 2 a finely ground powder or an even mixture of finely ground powders, especially powdered drugs.

**trituration** 1 the act of triturating or the condition of being triturated; see **triturate** (def. 1). 2 the composing of a dental amalgam.

**trityl** trivial name for the **triphenylmethyl group**.

**trivial name** (in chemical nomenclature) a name of a chemical species that has no part of it used in a systematic sense; e.g. xanthophyll, urea. It generally has historical or colloquial origins, and refers to attributes such as appearance or source. It

**tropine**

makes no pretension to describe molecular structure. The adjective 'trivial' has no perjorative meaning, numerous compounds of biochemical interest having approved or recommended trivial names. Compare **descriptive name, systematic name**.

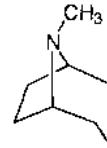

**trixenic** see **synxenic**.

**trk** a protooncogene encoding a transmembrane glycoprotein selectively expressed in the developing nervous system; the product is a tyrosine kinase receptor, the expression of which is restricted *in vivo* to certain neurons of neural crest origin, or, as its counterpart *trkB*, in cells of the neuroepithelium. It is required for high-affinity binding of nerve growth factor, and neurotrophins 3 and 4 and is essential for signal transduction in their action. Example of receptor from human (precursor): database code TRKA\_HUMAN, 790 amino acids (86.88 kDa). It was discovered as the transforming factor of a colon carcinoma and was originally known as *oncD*. The oncogenic activity resulted from a genomic rearrangement event in which nonmuscle tropomyosin sequences were aberrantly fused onto the transmembrane and cytoplasmic domains of Trk (tropomyosin receptor kinase).

**tRNA** abbr. for transfer RNA.

**Trojan horse inhibitor** see **affinity label**.

**tropane** 8-methyl-8-azabicyclo[3.2.1]octane; the basic ring system in tropane alkaloids.

**+tropic** suffix denoting turning.

**+troph** suffix denoting an organism with a specified mode of nutrition, e.g. **autotroph**, **chemotroph**.

**trophic** of, or concerning, nourishment, nutrition. Compare **tropic** (def. 1).

**+trophic** suffix denoting nourishment, nutrition; e.g. organotrophic, saprotrophic. See also **+tropic**.

**+trophin** noun suffix denoting a substance having a **trophic** function. See also **+tropin**.

**tropho+** or (before a vowel) **troph+** comb. form denoting food or nourishment.

**trophoblast** the outer part of the blastocyst stage of a mammalian conceptus. Its outermost layer consists of syncytial cells concerned with penetration and implantation into the uterine endometrium; these cells secrete extracellular hydrolases that facilitate movement of the blastocyst into the previously organized endometrial structure.

**+trophy** noun sufflx 1 denoting food or nourishment. 2 denoting growth or size.

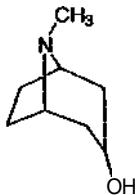

**tropic** 1 or (sometimes, esp. Brit.) **trophic** having a stimulating effect (especially of a hormone, etc.). 2 of or relating to a **tropism**.

**+tropic** or (sometimes, esp. Brit.) **+trophic** suffix denoting a stimulatory function; e.g. gonadotropic. See also **+trophic**, **+tropin**.

**tropic acid** a-phenyl-p-hydroxypropionic acid; (S)-3-hydroxy-2-phenylpropanoic acid; a compound that occurs in ester form in **atropine** and other tropane alkaloids.

**+tropin** or (sometimes, esp. Brit.) **+trophin** noun suffix denoting a substance having a stimulatory function, especially a hormone produced by the adenohypophysis. See also **+trophin**.

**tropine** tropan-3a-ol; 2-hydroxytropane; N-methyl-8-azabicyclo[3.2.1]octan-3-ol; **atropine** is the ester with (i)-tropic acid. Tropine is a meso structure. The -OH group is *trans* to the CH<sub>3</sub>N- group. In the geometrical isomer, **pseudotropine**, this relationship is *cis*.

tropine

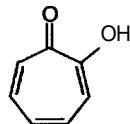

**tropinone** N-methyl-8-azabicyclo[3.2.1]octan-3-one; the oxidation product of tropine.

**tropism** movement directed towards some positive stimulus, or away from some negative stimulus.

+**tropism** noun suffix denoting a specific type of tropism as indicated by the prefixed word.

**tropocollagen** or soluble collagen a rod-shaped molecule, 3000 Å long and 15 Å in diameter, consisting of two α1 and one α2 polypeptide chains each of about 1000 amino-acid residues, of which about a third are glycine and 21% are proline plus hydroxyproline. They also contain hydroxylysine. The three polypeptide chains wind around each other to form a super-helical cable; the chains are hydrogen-bonded to each other. Tropocollagen fibres spontaneously associate with each other, with their N-terminal sequences overlapping C-terminal sequences of adjacent chains in a staggered array, to form collagen molecules. Compare procollagen. See also registration peptide.

**tropolone** 2-hydroxy-2,4,6-cycloheptatrien-1-one; a structure found in some mould metabolites and in colchicine.

**tropomodulin** a cytoskeletal tropomyosin-regulatory protein that binds to the end of erythrocyte tropomyosin and blocks its head-to-tail association along actin filaments; it does not bind to F actin. It has no homology to other proteins. Its modulation of the spectrin-actin complex in the erythrocyte membrane skeleton affects the viscoelastic properties of erythrocytes. Example from human: database code TMOD\_HUMAN, 359 amino acids (40.52 kDa).

**tropomyosin** a protein found in smooth, skeletal, and cardiac muscle. It comprises α and β subunits and is bound to actin forming a component of the troponin complex that regulates calcium-dependent binding of actin and myosin and, consequently, muscle contraction. Tropomyosin forms a characteristic coiled coil with a prominent seven-residue periodicity (five motifs). Different isoforms are produced by differential splicing; e.g. isoforms of α-tropomyosin differ in striated and smooth muscle. Example from human fibroblasts: database code TPM3\_HUMAN, 284 amino acids (32.84 kDa).

**tropomyosin kinase** EC 2.7.1.132; an enzyme that catalyses the phosphorylation by ATP of tropomyosin to form O-phosphotropomyosin with release of ADP.

**tropone** 2,4,6-cycloheptatrien-1-one.

tropane

**troponin** abbr.: Tn; a central regulatory protein of striated muscle contraction, comprising three subunits: troponin T (Tn-T), which binds to tropomyosin; troponin I (Tn-I), which regulates actinomyosin ATPase; and troponin C (Tn-C), which binds Ca<sup>2+</sup> and with Ca<sup>2+</sup> bound abolishes the inhibition on the binding of myosin to actin filaments produced by the other two troponins. Examples, Tn-T (human slow skeletal muscle isoform): database code TRTLHUMAN, 277 amino acids (32.77 kDa). Tn-I (human cardiac muscle form): database code TRIC\_HUMAN, 209 amino acids (23.85 kDa). Tn-C (human slow skeletal and cardiac form; bovine and porcine sequences are the same): database code TPCC\_HUMAN, 161 amino acids (18.40 kDa).

+**tropy** noun suffix denoting turning.

**Trp** symbol for a residue of the α-amino acid L-tryptophan (alternative to W).

**Trp-2** tyrosinase-related protein 2; this is a product of the *tyrp-2* gene. See also *slaty*.

**trp genes** a family of tryptophan biosynthetic genes found in bacteria. The following examples of *trp* gene products are all from *Escherichia coli*.

(1) TrpA (database code TRPA\_ECOLI, 268 amino acids (28.69 kDa)) and TrpB (database code TRPB\_ECOLI, 396 amino acids (42.80 kDa)) are the α and β subunits of tryptophan synthase (EC 4.2.1.20); it catalyses the formation of L-tryptophan from L-serine and 1-(indol-3-yl) glycerol 3-phosphate; glyceraldehyde 3-phosphate is also formed. The enzyme is a tetramer (α<sub>2</sub>,β<sub>2</sub>); the subunits have half-activities (α for aldol cleavage of indoleglycerol phosphate and β for tryptophan synthesis).

(2) TrpC (database code TRPC\_ECOLI, 452 amino acids (49.36 kDa)) is a monomeric bifunctional enzyme: the 'TrpF domain' is *N*-(S'-phosphoribosyl)anthranilate isomerase (EC 5.3.1.24); it catalyses the interconversion of *N*-5'-phosphoribosyl-anthraniolate and 1-(2-carboxyphenylamino)-I-deoxyY-D-ribulose 5-phosphate. The 'TrpC domain' is indole-3-glycerol-phosphate synthase (EC 4.1.1.48; abbr.: IGPS); it catalyses the decarboxylation of 1-(2-carboxyphenylamino)-I-deoxyY-D-ribulose 5-phosphate to form 1-(indol-3-yl) glycerol 3-phosphate, CO<sub>2</sub>, and H<sub>2</sub>O.

(3) TrpE/G, anthranilate synthase (EC 4.1.3.27); it catalyses a reaction between chorismate and L-glutamine to form anthranilate, pyruvate, and L-glutamate. This enzyme is a tetramer with two molecules of component I - TrpE, database code TRPE\_ECOLI, 520 amino acids (57.46 kDa) - and two of component II - TrpG, TRPG\_ECOLI, 530 amino acids (56.68 kDa). (4) TrpR, aporepressor (*trp* is co-repressor) for the operators of the *trp* operon, *trpR* itself, and *aroH*; a homodimer of known 3-D structure; database code TRPR\_ECOLI, 107 amino acids (12.21 kDa).

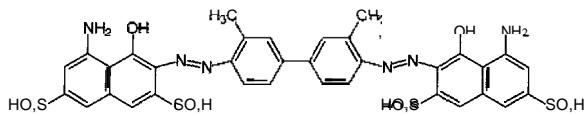

**true cholinesterase** an alternative name for acetylcholinesterase.

**truncate** 1 to shorten by cutting. 2 to terminate prematurely. -truncation n.

**Trypan Blue** a blue dye that is water-soluble and possesses sulfate and amino groups, whose charge prevents it from penetrating the plasma membrane of healthy cells. Dead cells or cells with damaged membranes take it up, making it a useful

## trypanosomatid

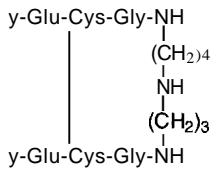

stain for determining cell viability (*see* dye-exclusion test). It does, however, stain healthy macrophages.

**trypanosomatid** *a common word for* any protozoan of the order Kinetoplastida, which includes trypanosomes and other genera.

**trypanosome** any member of the genus *Trypanosoma* (order Kinetoplastida), comprising parasitic flagellate protozoans. Infection causes disease (trypanosomiasis) in a range of animals. In humans there are two main forms of the disease: African trypanosomiasis (or sleeping sickness), which is caused by *T. brucei* and transmitted by tsetse flies, and South American trypanosomiasis (or Chagas' disease), which is caused by *T. cruzi* and transmitted by insects such as the assassin bug. Invasion of the nervous system, with attendant signs, is more common with the African form than with the South American form, which mainly affects the heart.

**trypanothione** the oxidized form of *N<sup>1,N<sup>6</sup></sup>*-bis(glutathionyl)sperrmidine; a compound purified from the trypanosomatid *Cryptosilicula fasciculata*, a parasite of insects. Members of the Kinetoplastida lack glutathione reductase, and glutathione is converted to the conjugate, trypanothione. *See also* trypanothione reductase.

**trypanothione reductase** EC 1.6.4.8; *systematic name*: NADPH:trypanothione oxidoreductase; an enzyme found uniquely in trypanosomatids, and hence a potential chemotherapeutic target. It catalyses the reaction:

FAD is a cofactor. Example from *Trypanosoma cruzi* (homodimer); database code TYTR\_TCR, 492 amino acids (53.81 kDa). *See also* trypanothione.

**trypsin** EC 3.4.21.4; a serine endopeptidase occurring in two forms, known as  $\alpha$  and  $\beta$  trypsin. These result from proteolytic cleavage,  $\beta$  being formed directly from the precursor, trypsinogen, and  $\alpha$  and other forms by further cleavage. Trypsin is of major importance in protein digestion in the small intestine, trypsinogen being a constituent of pancreatic juice. Trypsin is also widely used as a proteolytic agent experimentally, e.g. in protein sequencing. It preferentially cleaves at Arg-I-Xaa and Lys-I-Xaa. Example (bovine): database code NRL\_INTP, 223 amino acids (23.28 kDa); 3-D structure known. *See also* trypsin inhibitor.

**trypsin inhibitor** any of various naturally occurring substances that inhibit the activity of trypsin. The most-studied example is bovine pancreatic trypsin inhibitor (*see* pancreatic trypsin inhibitor). *See also* soybean trypsin inhibitor.

**trypsinize or trypsinise** to treat something, especially intact cells or membrane preparations with trypsin. Cells are released from adhesion to tissue-culture plates by trypsinization; treatment of membranes with trypsin can be used to indicate exposure of protein domains, as subsequent analysis will reveal unattacked bonds that might be expected to be bro-

## tryptophan 2,3-dioxygenase

ken, indicating that they may be shielded from attack by inclusion within the membrane. - trypsinization or trypsinisation *n.*

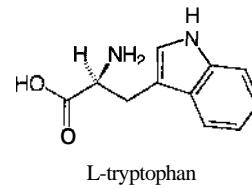

**trypsinogen** the pancreatic zymogen precursor of trypsin. It is secreted in pancreatic juice and in the duodenum is cleaved by enteropeptidase, which cleaves the Lys<sup>23</sup>-Ile<sup>24</sup> (in the precursor; in the mature molecule, these are Lys-Ile<sup>9</sup>) bond in trypsinogen, to yield  $\beta$  trypsin. Example, human precursor TRYLHUMAN, 247 amino acids (26.56 kDa); residues 1-15 are the signal peptide, 16-247 trypsinogen (residues 16-23 are a propeptide).

**tryptamine** p-3-indolylethylamine; 3-(2-aminoethyl)indole; 2-(IH-indol-3-yl)ethanamine; (CSH<sub>6</sub>N)CH<sub>2</sub>-CH<sub>2</sub>NH<sub>2</sub>; a biogenic amine, formed by enzymic decarboxylation of tryptophan. Of widespread occurrence in mammalian tissues, it is found also in plants and is a product of microbial degradation of proteinaceous material.

**tryptase** EC 3.4.21.59; *other names*: mast cell tryptase; mast cell protease II; skin tryptase; lung tryptase; pituitary tryptase. An enzyme that catalyses the preferential cleavage: Arg-I-Xaa, Lys-I-Xaa, but with more restricted specificity than trypsin. It is a trypsin-like serine endopeptidase released from the secretory granules upon mast-cell activation. Example  $\beta$ -tryptase from human (precursor) homotetramer: database code TRYB\_HUMAN, 275 amino acids (30.49 kDa). Cytotoxic T-lymphocyte tryptase, or CTL tryptase, is also known as granzyme A.

**tryptic** of, or relating to, trypsin; effected or produced by the action of trypsin; especially tryptic digestion, the partial hydrolysis of a protein by trypsin.

**tryptophan or (formerly) tryptophane** the trivial name for fl-3-indolylalanine; a-amino-p-3-indolepropionic acid; 2-amino-3-(IH-indol-3-yl)propanoic acid; (CSH<sub>6</sub>N)CH<sub>2</sub>-CH(NH<sub>2</sub>)-COOH; a chiral a-amino acid. L-tryptophan (*symbol*: W or Trp), (S)-2-amino-3-(IH-indol-3-yl)propanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: UGA (only in mitochondria) or UGG. In mammals it is an essential dietary amino acid and is glycogenic. The peptide antibiotic, tyrocidin C, contains one residue per molecule of D-tryptophan (*symbol*: D-Trp or DTp), (R)-2-amino-3-(IH-indol-3-yl)propanoic acid.

L-tryptophan

**tryptophanal** a-amino-p-3-indolepropionaldehyde; 2-amino-3-(IH-indol-3-yl)propanal; (CSH<sub>6</sub>N)CH<sub>2</sub>-CH(NH<sub>2</sub>)-CHO; the a-amino-aldehyde analogue of tryptophan.

**tryptophanase** 1 EC 4.1.99.1; *recommended name*: tryptophanase; *systematic name*: L-tryptophan indole-lyase (deaminating). An enzyme that catalyses a reaction between water and L-tryptophan to form indole, pyruvate, and NH<sub>3</sub>. It is responsible for indole formation in *Escherichia coli* and other enteric bacteria and bacilli. The reaction is comparable to that of  $\beta$ -tyrosinase (*see* tyrosinase (def. 2)). 2 *an alternative name for* tryptophan 2,3-dioxygenase.

**tryptophanate** 1 tryptophan anion; the anion, (CSH<sub>6</sub>N)CH<sub>2</sub>-CH(NH<sub>2</sub>)-COO<sup>-</sup>, derived from tryptophan. 2 any salt in which tryptophan is anionic. 3 any ester of tryptophan.

**tryptophan 2,3-dioxygenase** EC 1.13.11.11; *systematic name*: L-tryptophan:oxygen 2,3-oxidoreductase (decyclizing); *other names*: tryptophan pyrolase; tryptophanase; tryptophan oxygenase; tryptamine 2,3-dioxygenase. An enzyme that catalyses a reaction between dioxygen and L-tryptophan to form L-

## tryptophan 5-hydroxylase

tumor

formylkynurenine. It is a heme protein in mammalian liver, and it shows broad specificity towards tryptamine and derivatives including D- and L-tryptophan, 5-hydroxytryptophan, and serotonin. Example (homotetramer) from rat: database code T230\_RAT, 406 amino acids (47.80 kDa).

**tryptophan 5-hydroxylase EC 1.14.16.4; recommended name: tryptophan 5-monooxygenase; systematic name: L-tryptophan,tetrahydrobiopterin:oxygen oxidoreductase (5-hydroxylating); other name: tryptophan oxygenase.** An enzyme that catalyses a reaction between dioxygen, L-tryptophan, and tetrahydrobiopterin to form 5-hydroxy-L-tryptophan, dihydrobiopterin, and water. This is the rate-limiting enzyme in the biosynthesis of the neurotransmitter 5-hydroxytryptamine. Example from rat: database code TR5H\_RAT, 444 amino acids (51.01 kDa).

**tryptophanium** tryptophan cation; the cation,  $(C_8H_6N)CH_2-CH(NH_3^+)-COOH$ , derived from tryptophan.

**tryptophan 2-monooxygenase EC 1.13.12.3; systematic name: L-tryptophan:oxygen 2-oxidoreductase (decarboxylating); other name: tryptophan oxygenase.** An enzyme that catalyses a reaction between dioxygen and L-tryptophan to form indole-3-acetamide,  $CO_2$  and water. This is the first step in auxin biosynthesis. Example from *Pseudomonas syringae*: database code TR2M\_PSESS, 557 amino acids (61.79 kDa).

**tryptophan 5-monooxygenase the recommended name for tryptophan 5-hydroxylase.**

**tryptophano** the alkylamino group,  $(C_8H_6N)CH_2-CH(COOH)-NH^-$ , derived from tryptophan.

**tryptophanol** 3-(2-amino-3-hydroxypropyl)indole; 2-amino-3-(1H-indol-3-yl)propanol;  $(C_9H_{11}N)CH_2-CH(NH_2)-CH_2OH$ ; the  $\alpha$ -amino-alcohol analogue of tryptophan.

**tryptophan oxygenase an alternative name for 1 tryptophan 2,3-dioxygenase. 2 tryptophan Z-monooxygenase. 3 tryptophan 5-hydroxylase.**

**tryptophan pyrrolase an alternative name for tryptophan Z,3-dioxygenase.**

**tryptophan repressor** see *IIP* genes.

**tryptophan synthase** see *IIP* genes.

**tryptophan tryptophylquinone abbr.: TTQ;** a quinoprotein cofactor of methylamine dehydrogenase, EC 1.4.99.3, an enzyme of methylotropic bacteria. TTQ consists of a tryptophanyl side-chain cross-linked to the tryptophyl 6,7-dione side-chain of a modified tryptophan residue.

**tryptophyl** the acyl group,  $(C_9H_{11}N)CH_2-CH(NH_2)-CO-$ , derived from tryptophan.

**TSF abbr. for thymocyte-stimulating factor, i.e. interleukin Z.**

**TSH abbr. for thyroid-stimulating hormone.**

**T state** see *Tform*.

**TTP abbr. for 1 ribosylthymine triphosphate or ribothymidine triphosphate, common names for ribosylthymine 5'-triphosphate, ribothymidine 5'-triphosphate, 5'ribothymidyllyl triphosphate, thymine riboside 5'-triphosphate.** 2 (sometimes) thymidine triphosphate. dTTP is recommended.

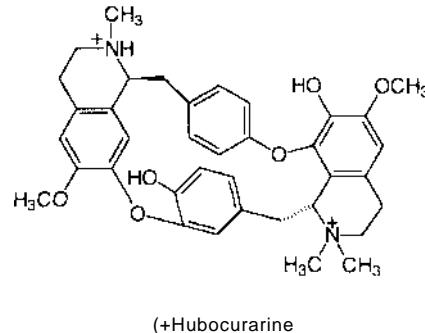

**TTQ abbr. for tryptophan tryptophylquinone.**

**T tubule abbr. for transverse tubule;** a type of tubule in a muscle fibre that arises as an invagination of the plasma membrane and penetrates the fibre, running mostly transversely among the fibrils and surrounding each of them with a ring. Each ring is shared by adjacent fibrils and the whole forms an intercommunicating system of tubules across the fibre. The function of these tubules is to pass the excitation signal from the muscle cell plasma membrane to the sarcomeres, ensuring rapid and synchronous activation. See also sarcoplasmic reticulum.

**TTX abbr. for tetrodotoxin.**

**tubocurarine (+)-tubocurarine** is the active principle of curare; it is a nicotinic cholinergic receptor competitive antagonist, and is used as a muscle relaxant. The molecule contains groups that are arranged in space in a rigid framework such that the atoms of acetylcholine that are important in its action have the correct geometry. In particular, two positively

charged nitrogens are fixed at a distance of 1.4 nm, possibly corresponding to the N<sup>+</sup> atoms of two acetylcholine molecules. Tubocurarine competes with acetylcholine at the neuromuscular junction and the endplate potential falls dramatically. The spacing of N<sup>+</sup> atoms appears crucial to the action of drugs such as suxamethonium.

**tubulin** a widely distributed globular subunit protein, filaments of which form the structural elements of a microtubule. It is a heterodimer of two chains,  $\alpha$  and  $\beta$ , each  $\approx 50$  kDa. The stable form of isolated tubulin is a dimer in which  $\alpha$ - $\beta$  pairing is believed to predominate; such a heterodimer is also the basic component of the microtubule. The dimer binds two molecules of GTP, one at an exchangeable site on the  $\beta$  chain and one at a nonexchangeable site on the  $\alpha$  chain. The GTP is hydrolysed to GDP at the plus end, more slowly than assembly of heterodimers, to give a GTP cap at that end. GDP-tubulin is disassembled more readily than GTP-tubulin, so the rate of GTP hydrolysis could regulate tubulin assembly. Examples from human:  $\alpha$ -1: database code TBALHUMAN, 451 amino acids (50.10 kDa);  $\beta$ -1: database code TBBLHUMAN, 444 amino acids (49.70 kDa).

**$\alpha$ -tubulin acetylase** see tubulin N-acetyltransferase.

**tubulin *N*-acetyltransferase EC 2.3.1.108; other name:  $\alpha$ -tubulin acetylase;** an enzyme that catalyses the reaction:

**tubulinyl-Tyr carboxypeptidase EC 3.4.17.17; other names: carboxypeptidase-tubulin; soluble carboxypeptidase;** an enzyme that catalyses the cleavage of the Glu-I-Tyr bond to release the C-terminal tyrosine residue from the native tyrosinated tubulin. It is inactive on carbobenzoxy-Glu-Tyr. tuftelin or enamelin an acidic enamel protein of teeth with a composition similar to tuft proteins. It is found in association with the crystal component and secreted at a very early stage of enamel formation in vertebrate teeth. Example (bovine): database code ENAM\_BOVIN, 389 amino acids (43.81 kDa).

**tuftsin** the tetrapeptide Thr-Lys-Pro-Arg, isolable from leukokinin (leukophilic human IgG); the sequence occurs in the Fc fragment of IgG. The tetrapeptide binds to and stimulates the bactericidal, phagocytic, and tumoricidal activities of macrophages and granulocytes, and may also stimulate the migration of polymorphonuclear leukocytes. [After Tufts University, where it was discovered.]

**tumble** 1 to rotate in a plane vertical to the axis of rotation; 'head over heels'. Proteins and other macromolecules tumble in solution whereas integral membrane proteins rotate on an axis normal to the plane of the membrane but cannot tumble through the membrane surface. 2 in bacterial chemotaxis, to change direction by a rapid reversal of the direction of flagellar rotation, the bacterium then 'tumbling' in response to Brownian motion.

**tumor** a variant spelling (esp. US) of tumour.

**tumorigenic** describing a substance or treatment that has the

tendency to cause the formation of a tumour.  
**tumour** or (*esp. US*) **tumor** a mass of proliferating cells lacking, to varying degrees, normal growth control. Tumours may be benign, i.e. proliferating very slowly, or malignant, i.e. growing aggressively, invading neighbouring tissues, and spreading to distant parts of the body by releasing cells into the bloodstream or lymph. These cells form secondary tumours (*see metastasis*). *See also adenoma, carcinoma, lymphoma, sarcoma.* -tumorous or tumoral *adj.*

**tumour initiator** any compound having the ability, when administered to an animal, to cause the formation of a tumour.

**tumour necrosis factor abbr.:** TNF; either of two structurally and functionally related proteins: TNF- $\alpha$  is produced mainly by monocytes and macrophages, whereas TNF- $\beta$  is produced by lymphoid cells. The two proteins are about 30% homologous at the amino-acid level, and bind to the same cell-surface receptors; both exist as homotrimers. Both TNF- $\alpha$  (cachectin) and TNF- $\beta$  (lymphotoxin) were originally thought of as selective antitumour agents, but are now known to have a multiplicity of actions. In binding to their receptors, present on virtually all cells examined, they activate a large array of cellular genes and also multiple signal-transduction pathways, kinases, and transcription factors. Their genes are single-copy genes, closely linked within the MHC cluster. *See tumour necrosis factor  $\alpha$ ; tumour necrosis factor  $\beta$ , tumour necrosis factor receptor.*

**tumour necrosis factor  $\alpha$  (abbr.: TNF- $\alpha$ ) or (formerly) cachectin** a cytokine that is produced by macrophages, monocytes, endothelial cells, neutrophils, smooth muscle cells, activated lymphocytes, and astrocytes. It is a transmembrane glycoprotein and cytotoxin with a variety of functions, including the ability to mediate the expression of genes for growth factors, cytokines, transcription factors, and receptors. It can cause cytolysis of certain tumour cell lines, it has been implicated in the induction of cachexia (but *see* cachectic factor), it is a potent pyrogen, causing fever by direct action or by stimulation of interleukin I secretion, and it can stimulate cell proliferation and induce cell differentiation under certain conditions. The molecule is a homotrimer. Example: database code NRL\_ITNFA, 152 amino acids (16.82 kDa); 3-D structure known (high beta content, disulfide bond). *See also tumour necrosis factor.*

**tumour necrosis factor  $\beta$  (abbr.: TNF- $\beta$ ) or (formerly) lymphotoxin** a cytokine produced by T lymphocytes that is cytotoxic for a wide range of tumour cells. It binds to the same ligands as tumour necrosis factor  $\alpha$ . Example from human (precursor): database code TNFB\_HUMAN, 205 amino acids (22.27 kDa). *See also tumour necrosis factor.*

**tumour necrosis factor receptor abbr.:** TNF receptor; either of two distinct receptors for tumour necrosis factor (TNF), one of *Mr* 55 000 and the other of 75 000. The two types have related extracellular domains, based on eDNA sequencing, and these are also related to the extracellular domains of nerve growth factor receptor and some other cell-surface molecules. These form a receptor family characterized by four domains with regularly spaced cysteine residues; each has a single transmembrane domain; the intracellular domains show no significant homologies. Either TNF receptor type alone appears sufficient for high-affinity binding and full biological activity, and binds either tumour necrosis factor  $\alpha$  or tumour necrosis factor  $\beta$  with high affinity. The signal transduction mechanism remains speculative, but receptor activation leads to a number of events, including activation of protein kinase C, protein kinase A, phospholipase A<sub>2</sub>, and phosphatidylcholine-specific phospholipase C, and accumulation of cyclic AMP and diacylglycerol. Example, tumour necrosis factor receptor I precursor from *Rattus norvegicus*: database code TNRI\_RAT, 461 amino acids (50.97 kDa).

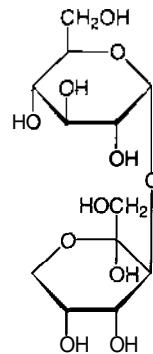

**tumour promoter** any compound that, when administered to an animal, sensitizes tissues to the action of a tumour initiator, or predisposes tissue to become tumorous in any other way,

such that tumours form in greater numbers or grow more rapidly than if a tumour promoter had not been administered. **tumour-suppressor gene** a normal gene one function of which is to suppress tumorigenesis. Certain cancers have been shown to be associated with mutant tumour-suppressor genes; *see* (e.g.) p53, RB.

**tunnel effect** the phenomenon in which an electron or a proton, because of its small mass, does not behave kinetically according to the laws of classical mechanics. These particles can sometimes penetrate an energy barrier that is greater than their kinetic energy.

**turacacin** *see* tetrapyrrole.

**turanose** 3-O-a-D-glucopyranosyl-D-fructose; an early product of the acid hydrolysis of melezitose.

**turbid** (of a solution) opaque due to the presence of suspended particles. -turbidity *n.*

**turbidimeter** an instrument for measuring the degree to which turbidity hinders the passage of light through a solution.

**turbidimetry** the quantitative determination of the concentration of substances in suspension by measurement of the decrease in light transmission caused by the suspended particles. *Compare nephelometry.*

**turnaround sequence** (in DNA) a sequence of nucleotides between two inverted repeats. A turnaround sequence will cause a 'bubble' of noncomplementary nucleotides at one end of a hairpin.

**turnover number** an obsolete expression of enzymic activity, variously defined on different occasions as the number of substrate molecules converted to product per catalytic site per minute, or as the number of moles of substrate converted per mole of enzyme per minute or second; it has the dimension of reciprocal time. *Compare catalytic constant, katal.*

**turret** a multiple cuvette holder that rotates in a spectrophotometer.

**Tween** the proprietary name for a series of surfactants based on polyoxyethylene sorbitan esters. For example, Tween 20 is polyoxyethylene sorbitanmonolaurate (CMC 0.059 mM). Similarly the sorbitan moiety in other Tweens is: Tween 40, sorbitanmonopalmitate; Tween 60, sorbitanmonostearate; Tween 65, sorbitantristearate; Tween 80, sorbitanmonooleate (aggregation number 58, CMC 0.012 mM); Tween 85, sorbitantrioleate.

**twist** a *Drosophila* gene for a MYC family helix-turn-helix transcription factor involved in the establishment of germ layers. It is a homodimer. Database code TWST\_DROME, 490 amino acids (54.34 kDa).

**twist conformation** 1 a median conformation of a non-planar, six-membered, saturated ring compound through which one boat conformation passes during conversion into another boat conformation, or through which a boat conformation passes during conversion into a chair conformation or vice versa. It is similar to skew conformation (def. I). 2 any conformation of the five-membered ring form of a monosaccha-

## twist number

ride or monosaccharide derivative when three adjacent ring atoms are coplanar and the other two lie on opposite sides of the plane. The conformational descriptor  $-T$  may be added to the name of such a compound. *See also* conformation.

**twist number** or twisting number symbol: T; the total number of base pairs in a DNA molecule divided by the number of bases per turn of the double helix. It is one of the properties that identifies topological isomers of DNA. *See also* linking number, writhing number.

**twitchin** the protein product of *unc-22*, one of about 40 genes important for muscle assembly and function in the nematode *Caenorhabditis elegans*. Twitchin is a giant myosin-associated protein (*compare* titin) that is autophosphorylated on threonine; repeats are homologous to fibronectin type III. The protein was named for a mutation that results in twitching. Database code S07571, 6048 amino acids (667.72 kDa). It has a counterpart in *Aplysia californica* and presumably other invertebrates.

**two-carbon fragment** 1 any group of atoms containing two carbon atoms. 2 *an early term for* a metabolically active acetyl radical, as in acetyl coenzyme A.

**two-dimensional chromatography** a chromatographic method in which separation is first effected in one direction and, after rotation of the chromatogram through  $90^\circ$ , then in a second direction, often with a different solvent (or a different pH). Two-dimensional electrophoresis works on the same principle.

**two-dimensional polymer** a macromolecular structure in which approximately parallel chains extending in one direction are cross-linked by another series of approximately parallel chains extending in a second direction. Bacterial cell-wall peptidoglycans are two-dimensional polymers with glycan chains extending in one direction that are cross-linked to peptide chains.

**TXA** abbr. for thromboxane A (*see* thromboxane).

**TXB** abbr. for thromboxane B (*see* thromboxane).

**Tylenol** *see* acetaminophen.

**tyndallization** or **tyndallisation** a method of sterilization in which the sample is heated at 80–100 °C on successive days, with a period of incubation in between. The aim is to kill cells on each occasion, but to allow spores (which are not killed by heating) to germinate to produce susceptible cells during the periods of incubation. [After John Tyndall (1820–93), British natural philosopher, alpinist, and popularizer of science.]

**type III system** a protein secretory system found in Gram-negative bacteria that is responsible for the secretion of proteins known as Yop. The system is known as type III because it was the third type of secretory system found in the membrane of Gram-negative bacteria.

**typing** (*in immunology*) the identification of the classes of histocompatibility antigens, blood groups, or other surface markers present in a sample of serum, or on white blood cells or red blood cells.

**Tyr** symbol for a residue of the a-amino acid L-tyrosine (alternative to Y).

**tyramine** tyrosamine; p-(p-aminoethyl)phenol; 2-(4-hydroxyphenyl)ethylamine; a biogenic amine with adrenergic action, formed by enzymic decarboxylation of tyrosine. Of widespread occurrence in mammalian tissues, it is also found in several plant species and in ergot, and is a product of microbial action in the intestine, in the putrefaction of animal tissue, and in the ripening of cheese.

**Tyr(Iz)** or (if the context does not imply the locants) Tyr(3,S-1<sub>2</sub>) symbol for a residue of the a-amino acid 3,5-diido-L-tyrosine (*see* diiodotyrosine).

**tyrocidine** or **tyrocidin** any of several peptide antibiotics produced by *Bacillus brevis* that are cyclic decapeptides. The structure of tyrocidine A is (amino acids are L unless otherwise stated) cyclic -Leu-D-Phe-Pro-Phe-D-Phe-Asn-Gln-Tyr-Val-Orn-. Tyrocidine B is similar, but with L-Tyr in place of L-Phe, and in tyrocidine C D-Trp replaces the D-Phe attached to the

## tyrosine kinase

Asn. Structurally tyrocidines are similar to gramicidin S, and they have a similar action, increasing the permeability of bacterial membranes, promoting leakage of cytoplasmic constituents, and permitting entry into the cell of ions larger than those normally transported. *Bacillus brevis* is immune from this action. This group of compounds has little application in medicine. Biosynthesis is independent of ribosomes (*see* protein and peptide biosynthesis).

**Tyrode's solution** or **Tyrode solution** or **Ringer-Tyrode solution** a balanced salt solution modified from Locke's solution, initially for experiments on mammalian intestine. The solution usually contains (in g L<sup>-1</sup>, approx.): NaCl (8.0); KCl (0.2); MgCl<sub>2</sub>·6H<sub>2</sub>O (0.1); CaCl<sub>2</sub> (anhydrous, 0.2); NaHCO<sub>3</sub> (0.1); NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O (0.05); and glucose (1.0). [After Maurice Vejux Tyrode (1878–1930), US pharmacologist, who devised this solution in 1910.]

**tyrosinase** 1 *an alternative name for* monophenol monooxygenase. 2 l-tyrosinase EC 4.1.99.2; *recommended name*: tyrosine phenol-lyase; an enzyme that catalyses a reaction between L-tyrosine and water to form phenol, pyruvate, and NH<sub>3</sub>. Pyridoxal-phosphate is a coenzyme. The protein is a homotetramer, similar to tryptophanase (def. I). Example from *Citrobacter freundii*: database code TPL\_CITFR, 456 amino acids (51.44 kDa).

**tyrosinate** 1 tyrosinate(1-); tyrosine monoanion. In theory, the term denotes any ion or mixture of ions formed from tyrosine and having a net charge of -I, although the species HO-C<sub>6</sub>H<sub>4</sub>-CH<sub>2</sub> CH(NH<sub>2</sub>)-COO<sup>-</sup> predominates in practice. 2 *the systematic name for* tyrosinate(2-); tyrosine dianion; -O-C<sub>6</sub>H<sub>4</sub>-CH<sub>2</sub> CH(NH<sub>2</sub>)-COO<sup>-</sup>. 3 any salt containing an anion of tyrosine. 4 any ester of tyrosine.

**tyrosine** *the trivial name for* P-(p-hydroxyphenyl)alanine; a-amino-p-hydroxyhydrocinnamic acid; a-amino-f(p-hydroxyphenyl)propionic acid; 3-(4-hydroxyphenyl)alanine; 2-amino-3-(4-hydroxyphenyl)propanoic acid; HO-C<sub>6</sub>H<sub>4</sub>-CH<sub>2</sub>-CH(NH<sub>2</sub>)-COOH; a chiral a-amino acid. L-Tyrosine (*symbol*: Y or Tyr), (S)-2-amino-3-(4-hydroxyphenyl)propanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: UAC or DAU. In mammals it is an essential dietary amino acid, and is both glucogenic and ketogenic. One residue per molecule of D-tyrosine (*symbol*: D-Tyr or DTyr), (R)-2-amino-3-(4-hydroxyphenyl)propanoic acid, occurs as its O-methyl ether in the antibiotic cycloheptamycin.

**tyrosine decarboxylase** EC 4.1.1.25; an enzyme that catalyses the decarboxylation of L-tyrosine to tyramine. Pyridoxal-phosphate is a coenzyme. Example from parsley: database code A44405, 514 amino acids (57.38 kDa).

**tyrosine hydroxylase** EC 1.14.16.2; *recommended name*: tyrosine 3-monooxygenase; *systematic name*: L-tyrosine, tetrahydrobiopterin:oxygen oxidoreductase. An enzyme that catalyses a reaction between dioxygen, L-tyrosine, and tetrahydrobiopterin to form 3,4-dihydroxy-L-phenylalanine, dihydrobiopterin, and water; it requires ferric ion. It is the rate-limiting enzyme in the synthesis of catecholamine neurotransmitters. In humans four types are produced by alternative splicing. Example, type 3: database code TY3H\_HUMAN, 528 amino acids (58.46 kDa).

**tyrosine kinase** EC 2.7.1.112; *recommended name*: protein-tyrosine kinase; *other names*: tyrosylprotein kinase; protein kinase (tyrosine); hydroxyaryl-protein kinase. An enzyme that

## tyrosine 3-monooxygenase

transfers the terminal phosphate of ATP to a specific tyrosine residue on its target protein; i.e. it catalyses the phosphorylation by ATP of protein-tyrosine to form protein-tyrosine phosphate with release of ADP. The enzyme molecule has five motifs. The tyrosine kinase family is of profound importance due to its involvement in the signalling processes associated with mitogenic stimulation, cell growth, and oncogenesis. The tyrosine kinases fall into two major classes, those that are cell membrane receptors and integral membrane proteins, and those that are intracellular and function downstream of the receptors. The membrane receptors have been grouped into subclasses according to their structure (all individual polypeptides have a single transmembrane domain, with the kinase activity in an intracellular domain); examples include subclass I, proteins having two cysteine-rich repeat sequences in the extracellular domain of a monomeric receptor, a group that includes the epidermal growth factor receptor; subclass II, disulfide-linked heterotetrameric  $\alpha_2\beta_2$  structures with extracellular cysteine-rich repeat sequences similar to subclass I, an example being the insulin receptor; subclass III, proteins with five immunoglobulin-like repeats in the extracellular domain, and with a non-kinase insert in the kinase region, typified by the platelet-derived growth factor receptor; and subclass IV, proteins with three immunoglobulin-like repeats in the extracellular domain, with a non-kinase insert in the kinase region. This classification continues to be extended. The intracellular non-receptor tyrosine kinases include, among many, the products of *FGR*, *FYN*, and *src*. See also protein kinase.

**tyrosine 3-monooxygenase** the recommended name for tyrosine hydroxylase.

**tyrosine transaminase** or tyrosine aminotransferase (abbr.: TAT) EC 2.6.1.5; systematic name: L-tyrosine:2-oxoglutarate aminotransferase; an enzyme that catalyses the reaction:

It is a pyridoxal-phosphate enzyme and it catalyses the first step in tyrosine catabolism; defects lead to tyrosinemia type II

## tyvelose

(Richner-Ranhart syndrome). Example from human (homodimer): database code ATTY\_HUMAN, 454 amino acids (50.34 kDa).

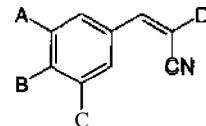

**tyrosinium** tyrosine cation; the cation,  $\text{HO-C}_6\text{H}_4-\text{CH}_2-\text{CH}(\text{NH}_3^+)-\text{COOH}$ , derived from tyrosine.

**tyrosino** the alkylamino group,  $\text{HO-C}_6\text{H}_4-\text{CH}_2-\text{CH}(\text{COOH})-\text{NH}-$ , derived from tyrosine.

**tyrosin-O<sup>4</sup>-yl** the aryloxy group,  $\text{HOOC-CH}(\text{NH}_2)-\text{CH}_Z-\text{C}_6\text{H}_4\text{O}-$ , derived from tyrosine.

**tyrosyl** the acyl group,  $\text{HO-C}_6\text{H}_4-\text{CH}_Z-\text{CH}(\text{NH}_2)-\text{CO-}$ , derived from tyrosine.

**tyrphostin** any of a series of inhibitors of protein tyrosine kinases. The structures are derived from the substituted benzylidene malononitrile shown as the core structure; A, B, and C can be  $-\text{NO}_2$  ( $\text{CH}_3\text{hC}_-$ ,  $-\text{OH}$ , or  $-\text{H}$ ). In tyrphostin 25, [(3,4,5-trihydroxyphenyl)-methylene]-propanedinitrile, D is  $-\text{CN}$ . Other actions are known for some members of the series, including uncoupling of oxidative phosphorylation and inhibition of lipoxygenases.

tyrphostin 25

**tyvelose** a trivial name for the aldohexose 3,6-dideoxy-D-mannose, 3,6-dideoxy-D-arabino-hexose, a monosaccharide isolated from various lipopolysaccharides elaborated by some Gram-negative bacteria, e.g. certain serotypes of *Salmonella typhi*. In such serotypes it contributes to the antigenic specificity of the organism's O antigens. The L-enantiomer is separately named as ascarylose.

# Uu

**u** 1 symbol for unified atomic mass unit. 2 see **IU**.

**u** symbol for 1 speed (alternative to *v*, *w*, or *c*). 2 (bold italic) velocity (alternative to *v*, *w*, or *c*).

**U** symbol for 1 a residue of the base uracil in a nucleic-acid sequence. 2 a residue of the ribonucleoside uridine (alternative to Urd). 3 uniformly labelled. 4 enzyme unit (obsolete; superseded by **katal**). 5 uranium.

**U** symbol for 1 electric potential difference (alternative to  $\Delta V$  or  $\Delta \phi$ ). 2 internal energy.

**U46619** a stable thromboxane A<sub>2</sub> analogue and mimetic; another name for **9,11-dideoxy-11a,9a-epoxymethanoprostaglandin**

**I<sub>a</sub>**:

**UAU** a codon in mRNA for chain termination; the **ochre codon**.

**UAC** a codon in mRNA for L-tyrosine.

**UAG** a codon in mRNA for chain termination; the **amber codon**.

**UAS** abbr. for upstream activator sequence; the counterpart in yeast of an **enhancer**.

**UAU** a codon in mRNA for L-tyrosine.

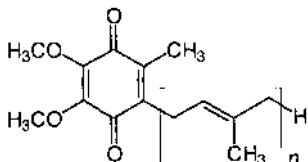

**Ubbelohde viscometer** see **capillary viscometer**.

**UBIP** abbr. for ubiquitous immunopoietic polypeptide.

**ubiquinol** abbr.: QH<sub>2</sub>; reduced **ubiquinone**.

**ubiquinol-cytochrome c reductase** EC 1.10.2.2; systematic name: ubiquinol:ferricytochrome-c oxidoreductase; other name: complex III. An enzyme complex that catalyses the oxidation of ubiquinol by two molecules of ferricytochrome *c* to form ubiquinone and two molecules of ferrocyanochrome *c*. It contains cytochromes *b*<sub>562</sub>, *b*<sub>566</sub>, and *c*<sub>1</sub>, as well as nonheme iron and Fe-S complexes.

**ubiquinone** or (formerly, but not recommended) **coenzyme Q** abbr.: Q; a lipid-soluble electron-transporting coenzyme that is an essential component in the **respiratory chain**. The structure is shown in the diagram; *n* has values from 6 to about 12. The side-chain length is indicated by the abbreviation *Qn*. Ubiquinone is biosynthesized in mammals from tyrosine, and in bacteria and other organisms by the **shikimate pathway**. See also **protonmotive Qcycle**.

**ubiquinone reductase** see **NADH dehydrogenase (ubiquinol)**.

**ubiquitin** 1 a small, highly conserved, heat-stable protein of 76 amino-acid residues first isolated from bovine thymus but subsequently found in the cells of all tissues studied, in animals, yeast, bacteria, and higher plants. Located in both nuclei and cytoplasm, it derives its name from its widespread distribution. It undergoes an ATP-dependent reaction with proteins that results in condensation of its terminus with lysine amino groups; this process is mediated by a large multiprotein complex, the 26S **proteasome**. For example, cyclin degradation in the control of the cell cycle is triggered by ubiquitination. Thus the cell has two means of protein degradation, ubiquitination and proteolysis in lysosomes. Such modified proteins are degraded rapidly. Ubiquitin is synthesized as a polyubiquitin precursor with exact head-to-tail repeats, the number of repeats differing between species. In some species there is a final amino acid after the last repeat (e.g. Val in human).

Some ubiquitin genes encode a single copy of ubiquitin fused to a ribosomal protein. Human, bovine, and porcine ubiquitins and those from long-tailed hamster, rat, mouse, rabbit, *Xenopus laevis*, and the following insects - *Drosophila melanogaster*, *Ceratitis capitata*, *Spodoptera frugiperda*, and *Manduca sexta* - all have the sequence: MQIFVKTLTGKTIT-LEVEPSDTIENVKAKIQDKEGIPPDQQQLFAGKQLED-GRTLSDYNIQKESTLHLVRLRGG. Example from human: database code UBIQ\_HUMAN, 76 amino acids (8.56 kDa); 3-D structure known; database code; NRL\_1UBQ; three motifs. 2 a former name for **Ubiquitous immunopoietic polypeptide**.

**ubiquitin activating enzyme** E1 an enzyme that activates ubiquitin by first adenylating, with ATP as co-substrate, its C-terminal glycine residue and thereafter linking this to itself via the side chain of a cysteine residue, releasing AMP. The protein is a monomer and can accommodate two ubiquitin molecules. Example from human: database code UBA1\_HUMAN, 1058 amino acids (117.66 kDa).

**ubiquitin-conjugating enzyme** see **ubiquitin-protein ligase**.

**ubiquitin-protein ligase** EC 6.3.2.19; other names: ubiquitin-conjugating enzyme; ubiquitin-activating enzyme; an enzyme that couples ubiquitin to a protein lysine to form protein N-ubiquityllysine with hydrolysis of ATP to ADP and pyrophosphate. Examples from yeast: database code UBCLYEAST, 215 amino acids (24.15 kDa); database code UBC2\_YEAST, 172 amino acids (19.68 kDa); UBC3\_YEAST, 295 amino acids (34.03 kDa); UBC8\_YEAST, 218 amino acids (24.61 kDa). Examples from human: database code UBC2\_HUMAN (also in rat and rabbit), 152 amino acids (17.29 kDa); UBC8\_HUMAN, 183 amino acids (20.63 kDa).

**ubiquitous immunopoietic polypeptide** abbr.: UBIP; a polypeptide that has lymphocyte-differentiating properties and can stimulate adenylate cyclase. It is involved in maintenance of chromatin structure, regulation of gene expression, stress response, and ribosome biogenesis. It was formerly called ubiquitin. See also **proteasome**.

**UCA** a codon in mRNA for L-serine.

**UCC** a codon in mRNA for L-serine.

**UCG** a codon in mRNA for L-serine.

**UCP** abbr. for brown fat uncoupling protein.

**UCU** a codon in mRNA for L-serine.

**Udo** symbol for the undecanoyl group, CH<sub>3</sub>-[CH<sub>2</sub>]<sub>9</sub>-CO-

**UDP** abbr. for uridine (5')diphosphate.

**UDP-N-acetylglucosamine 6-dehydrogenase** EC 1.1.1.136; an enzyme that catalyses the reaction:

**UDP-N-acetylglucosamine-ciolichyl-phosphate-N-acetylglucosamine phosphotransferase** EC 2.7.8.15; an enzyme that catalyses a reaction between UDP-N-acetyl-o-glucosamine and dolichyl phosphate to form N-acetyl-o-glucosaminyl-diphosphodolichol and UMP.

It catalyses the first reaction in the synthesis of oligosaccharide lipids. Example from Chinese hamster: database code UAGT\_CRIGR, 408 amino acids (46.19 kDa). **UDP-N-acetylglucosamine 2-epimerase** EC 5.1.3.14; an enzyme that catalyses the reaction:

**UDP-N-acetylglucosamine 4-epimerase** EC 5.1.3.7; an enzyme that catalyses the reaction:

**UDPG**

**UDPG** abbr. for uridinediphosphoglucose; UDPGIC is preferred (to avoid possible ambiguity in context with galactose).

**UDPGal or UDPgalactose** abbr. for uridinediphosphogalactose.

**UDPgalactose 4-epimerase** an alternative name for **UDPGlucose 4-epimerase**.

**UDPGIC** (preferred) abbr. for uridinediphosphoglucose; see also **UDPG**.

**UDPglucose 6-dehydrogenase** EC 1.1.1.22; an enzyme that catalyses the reaction:

Example from *Streptococcus pyogenes*: database code UDHG\_STRPY, 402 amino acids (45.43 kDa).

**UDPglucose 4-epimerase** the recommended name and systematic name for the isomerase EC 5.1.3.2; other names: UDPgalactose 4-epimerase; (formerly) galactowaldenase; one of the enzymes that can interconvert uridinediphosphoglucose and uridinephosphogalactose. The mechanism involves oxidation of the C-4 hydroxyl group of the hexose moiety of either uridinediphosphosugar to an oxo group by a tightly bound molecule of NAD<sup>+</sup>; the resultant NADH is then reoxidized by the intermediate oxo derivative with inversion of configuration of the resulting hydrogen and hydroxyl groups at C-4. Compare **UDPglucose-hexose-1-phosphate uridylyltransferase**. Example from *Escherichia coli*: database code GALE\_ECOLI, 338 amino acids (37.22 kDa); 3-D structure known.

**UDPglucose-hexose-1-phosphate uridylyltransferase** EC 2.7.7.12; systematic name: UDPglucose:a-D-galactose-1-phosphate uridylyltransferase; other names: **uridyl transferase**; galactose-1-phosphate uridylyltransferase; one of the enzymes that can interconvert uridinediphosphoglucose and uridinediphosphogalactose. An enzyme important in the metabolism of galactose, it catalyses the exchange reaction:

A deficiency of the enzyme is associated with one form of **galactosemia**. Example from human: HUMGALT, 380 amino acids (43.01 kDa). Compare **UDPglucose 4-epimerase**.

**UDPglucose pyrophosphorylase** an alternative name for **UTP-glucose-1-phosphate uridylyltransferase**.

**UDPglucuronate 4-epimerase** EC 5.1.3.6; an enzyme that catalyses the reaction:

**UDPglucuronate 5'-epimerase** EC 5.1.3.12; an enzyme that catalyses the reaction:

NAD<sup>+</sup> is a cofactor.

**UDPGlucuronosyltransferase** EC 2.4.1.17; abbr.: UDPGT or UGT; recommended name: glucuronosyltransferase; an enzyme involved in the formation of **glucuronosides**. It catalyses a reaction between UDPglucuronate and an acceptor to form UDP and acceptor fJ-D-glucuronoside. There are many variants. The numbering follows several systems; the one followed here has UDPGT followed by a number, letter, and sometimes a number, e.g. UDPGT1F, UDPGT2B10. Examples from human: isozyme 1a precursor, microsomal (UDPGT1a) (bilirubin-specific isozyme I): database code UDIV\_HUMAN, 533 amino acids (59.52 kDa); UDPGT1b: database code UDIV\_HUMAN, 530 amino acids (59.95 kDa); UDPGT1c (other name: UGT13): database code UDIC\_HUMAN, 534 amino acids.

**UDPGP** abbr. for UDPglucose pyrophosphorylase (i.e. **UTP-glucose-1-phosphate uridylyltransferase**).

**UGA** 1 a codon in nonmitochondrial mRNA for chain termination; the **opal codon**. 2 a codon in mitochondrial mRNA for L-tryptophan.

**UGC** a codon in mRNA for L-cysteine.

**ultraviolet (radiation)**

**UGG** a codon in mitochondrial mRNA, and the only codon in nonmitochondrial mRNA, for L-tryptophan.

**UGU** a codon in mRNA for L-cysteine.

**+ulose** noun suffix denoting a **ketose**; it may be expanded to **+ulofuranose** or **+ulopyranose** according to whether the cyclic form of the sugar is five-membered or six-membered respectively.

**+ulosonic acid** noun suffix denoting a **ketoaldonic acid**; it may be expanded to **+ulofuranosonic acid** or **+ulopyranosonic acid** according to whether the cyclic form of the sugar acid is five-membered or six-membered respectively.

**ultimate carcinogen** or **ultimate carcinogenic metabolite** any metabolite of a **chemical carcinogen** that reacts with cellular constituents in a specific way to initiate carcinogenesis. See also **proximate carcinogen**.

**ultimobranchial body** one of a pair of glandlike structures derived during embryogenesis from the last branchial (gill) pouches. They occur in all vertebrates except cyclostomes. In most mammals they become embedded in the respective lobes of the thyroid gland, forming **C cells**, which secrete the polypeptide hormone **calcitonin**.

**ultra+** prefix 1 beyond in space; on the other side (of). Compare **infra+**, **trans+**. 2 beyond a specified (esp. in scientific usage, lower) limit, range, value, etc. Compare **super+**. 3 beyond the common, ordinary, natural, etc.; extremely. Compare **hyper+**.

**ultracentrifuge** any centrifuge that operates at high rotational velocities, i.e. one that generates high gravitational fields. Ultracentrifuges can be operated at known speeds with small variations and without temperature fluctuations. They may be either analytical or preparative.

**ultradian** (of a biological activity) occurring less often than once per 24-hour period. Compare **circadian**, **infradian**.

**ultrafilter** a filter of small pore size suitable for **ultrafiltration**.

**ultrafiltration** a separation process whereby a solution containing a solute of molecular size significantly greater than that of the solvent molecule is removed from the solvent by the application of a hydraulic pressure, which forces only the solvent to flow through a suitable membrane (usually one having a pore size in the range 0.001–0.1 μm), thereby concentrating the solute.

**ultramicrotome** a device for preparing very thin sections of cells or tissues, after fixing and embedding or freezing, for inspection in the transmission electron microscope.

**ultrasonic** of, pertaining to, or producing **ultrasound** waves.

**ultrasonication** the process of exposing material to **ultrasound**. It is used for cell disruption, for denaturation of proteins, and for cleaning solid surfaces. See also **sonicate**.

**ultrasonic disintegrator** an apparatus for disintegrating cells and other material, or for cleaning solid surfaces, by exposing them to **ultrasound**. See also **sonicator**.

**ultrasound** propagated waves, of the same nature as sound but inaudible, with frequencies of >20 kHz. Frequencies of ≈25 kHz can be used for disintegrating cells and subcellular components and also in cleaning baths for the removal of deposits on a wide variety of objects. In physiotherapy ultrasound in the range of 0.5–3 MHz is used for the relief of painful muscles and has its effect by the delivery of warmth and by changing the permeability of cell membranes which allows for the removal of fluid. For diagnostic purposes ultrasound in the range of 3–12 MHz is commonly used and is a popular method of non-invasive imaging e.g. in pregnant women. There is also ultrasonic microscopy which mimics light microscopy and employs sound in the GHz range. Ultrasound is also being developed for the disintegration of tumours using sound in the MHz range.

**ultrastructure** the fine structure of an organ, tissue, cell, or subcellular particle, especially that beyond the resolution of a light microscope but demonstrable with an electron microscope.

**ultraviolet (radiation)** abbr.: UV or uv; electromagnetic radiation of wavelengths in the range 13.6–400 nm (frequencies

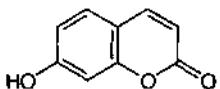

750 THz-22.1 PHz). This range overlaps the wavelengths of soft X-radiation and ends just across the short-wavelength limit of visible light. Ultraviolet radiation is often divided into near ultraviolet (200–400 nm) and far ultraviolet (or vacuum ultraviolet) <200 nm); radiation in the far ultraviolet is absorbed by O<sub>2</sub> and requires the use of evacuated apparatus or flushing with N<sub>2</sub>.

**ultraviolet-endonuclease** an enzyme involved in the repair of ultraviolet-irradiated DNA in microorganisms. *See also* deoxyribonuclease (pyrimidine dimer), *uvr*.

**ultraviolet reactivation** *see* W reactivation.

**Ultrogel** the proprietary name for a range of bead-form rigid support materials used in gel filtration, affinity chromatography, and related procedures. It consists of a lattice of polyacrylamide in a matrix of agarose gel.

**umbelliferone** 7-hydroxycoumarin; a common component of plant extracts, used as a fluorescent pH indicator and as a fluorescent label.

**UMP** abbr. for uridine monophosphate; i.e. uridine phosphate. **UMP synthase** a loose term applied to the combination of enzymes that form uridine 5'-phosphate from orotate: these are orotate phosphoribosyltransferase (forming orotidylic acid) and orotidine 5'-phosphate decarboxylase. *See also* uridine-5'-monophosphate synthase.

**umu** bacterial genes encoding proteins that are involved in the error-prone SOS repair process, probably by allowing bypass synthesis across a damaged template. Protein examples from *Escherichia coli*: UmuC: database code UMUC\_ECOLI, 422 amino acids (47.68 kDa); UmuD: database code UMUD\_ECOLI, 139 amino acids (15.05 kDa).

**un+** prefix 1 (used with adjectives, adverbs, and nouns) not; opposite of; contrary to. 2 (used with verbs) reversal of an action or state; release; removal from.

**unary operator** an arithmetic or logical operator (e.g. NOT) that operates on only one variable. *Compare* binary operator.

**unc-86** a gene of *Caenorhabditis elegans* that encodes a transcription factor containing the POU domain and contributes to the naming of the domain. Example, Unc-86: database code UN86\_CAEEL, 467 amino acids (52.31 kDa).

**uncoating enzyme** (sometimes) an enzyme that catalyses the removal of the protein coat from a virus.

**uncoded amino acid** an alternative term for noncoded amino acid.

**uncompensated acidosis** an acidosis in which there is a fall of the blood pH, due to the inadequacy of the physiological compensating mechanisms.

**uncompensated alkalosis** an alkalosis in which there is a rise of the blood pH, due to the inadequacy of the physiological compensating mechanisms.

**uncompetitive inhibition** the inhibition of the activity of an enzyme system when the inhibitor does not combine with the free enzyme, but only with one of the enzyme-substrate intermediates.

**uncoupled** 1 disconnected; unfastened. 2 (in biochemistry) describing an organism, tissue, cell, or mitochondrion in which phosphorylation is dissociated from oxidation in the respiratory chain. *See also* uncoupling.

**uncoupler** an alternative name for uncoupling agent (*see* uncoupling).

**uncoupling** (in biochemistry) the dissociation of phosphorylation from oxidation in the respiratory chain, so that electron transport proceeds without the esterification of phosphate and

without the need for inorganic phosphate. An uncoupling agent (or uncoupler) is a substance that causes uncoupling of phosphorylation from electron transport at one or more points in the electron-transport chain. A classical example is dinitrophenol. Uncoupling agents probably act by causing leakage of protons across the mitochondrial inner membrane thereby destroying the proton gradient that drives oxidative phosphorylation. *See also* chemiosmotic coupling hypothesis.

**uncoupling protein** *see* brown fat uncoupling protein.

**undec+** or **undeca+** prefix denoting eleven.

**undecaprenol** or **bactoprenol** a polyunsaturated long-chain (C<sub>55</sub>) primary alcohol containing 11 prenyl units.

**undecaprenyl phosphate** or **undecaprenol phosphate** a very hydrophobic phosphate ester of undecaprenol. It acts as a membrane-soluble carrier to which intermediates are combined in the course of the biosynthesis of bacterial cell-envelope components, e.g. peptidoglycan and lipopolysaccharide. *Other names:* bactoprenyl phosphate; carrier lipid; C<sub>55</sub> carrier lipid; C<sub>55</sub> lipid carrier.

**underivatized** or **underivatised** (of a substance) in the naturally occurring state.

**undulin** a noncollagenous glycoprotein of the interstitial extracellular matrix, associated with collagen. Isolated from skin or placenta, it is found mainly between densely packed mature collagen fibrils as bundles of uniform wavy fibres. It is a member of the fibronectin-tenascin family, and is related to collagen type XIV. It is associated with dense collagen matrices in soft tissues and is likely to be involved in the supramolecular organization of interstitial collagens. Example (sequence fragments) from human, undulin 2: database code B40970, 445 amino acids (49.06 kDa); the sequence shows homology with fibronectin type III.

**ung** *see* uracil-DNA N-glycosylase.

**Uni** *see* reactivity of enzymes.

**uni+** comb. form consisting of, having, or relating to one. **unified atomic mass unit** or (formerly) atomic mass unit (abbr.: amu or a.m.u.) symbol: u; a non-SI unit of mass equal to one-twelfth of the mass of one atom of carbon-12; i.e.

$$1 \text{ u} = m_a(^{12}\text{C})/12 \approx 1.660540 \times 10^{-27} \text{ kg.}$$

It is identical with dalton.

**uniformly labelled** symbol: U; describing a labelled compound in which the label is distributed in a statistically uniform, or nearly uniform, manner between all the possible positions in the molecule.

**unimolecular reaction** *see* molecularity.

**uniparental disomy** the inheritance of two copies of a chromosome from one parent.

**uniport** the process of noncoupled solute translocation or facilitated diffusion. The term includes reactions in which a single solute equilibrates across an osmotic barrier, normally mediated by a carrier protein known as a uniporter; e.g. the glucose-transport protein of mammalian erythrocytes. *Compare* antiport, symport.

**unique (sequence)** DNA or single-copy DNA any unique and specifically ordered nucleotide sequence in DNA that occurs only once in a genome. *Compare* repetitive sequences.

**unit cell** the smallest portion of a crystal that, by translation in three dimensions, is able to account for the structure of the entire crystal. The array of unit cells, arranged along parallel straight lines, makes up the crystal lattice.

**unit membrane** or **double membrane** or **triple membrane** any membrane, irrespective of cellular location, that on staining with osmium or other heavy metals appears in section in the electron microscope as a pair of parallel dark lines separated by a less dense layer, the whole being 6–10 nm thick. Unit membranes include the plasma membrane and the membranes of organelles such as mitochondria, nuclei, and endoplasmic reticulum.

**unit of replication** *see* replicon.

**unit of transcription** *see* transcriptional unit.

## univalent

## urease

univalent 1 or monovalent (of a chemical species) having a valency of one. 2 an unpaired chromosome seen during meiosis when bivalents are also present. Such a chromosome either lacks a homologue or results from asynapsis. -univalence n.

**universal buffer mixture** any solution containing several buffering systems chosen so as to provide a relatively high buffer capacity over a wide pH range.

**universal donor** an individual with O-type blood; such blood may be transfused into any recipient. *See ABO system.*

**universal recipient** an individual with AB-type blood; such individuals may be transfused with blood from any donor. *See ABO system.*

**UNIX** an operating system implemented on many current workstations and large computers.

**unmediated transport** or nonmediated transport the movement of a solute across a barrier by diffusion (def. 1).

**unpaired electron** an electron in an atom or molecule whose spin is not paired with the oppositely directed spin of another electron in the same atom or molecule. Only systems containing unpaired electrons will give an electron spin resonance signal. *See electron spin resonance spectroscopy.*

**unsaponifiable lipid** or uDsaponifiable material part of a lipid sample that is not solubilized by saponification. It consists principally of steroids and terpenes.

**unsaturated** 1 (of a solution) able to dissolve more of the solute in question. 2 (of an organic compound) containing double bonds; *see also* polyunsaturated. 3 (of any chemical system, e.g. an enzyme or antibody) not fully saturated with ligand (e.g. substrate or antigen).

**unsaturated-fatty-acid oxidation** the degradation of unsaturated fatty acids to  $\text{CO}_2$  and  $\text{H}_2\text{O}$ ; this is achieved in large part by enzymes of the beta'-oxidation system, but at certain points enzymes specific for unsaturated fatty acids are required. The first of these occurs when beta-oxidation reactions have removed carbons to the point at which the resulting acyl-CoA molecule has a  $\Delta^3\text{-cis}$  double bond; this is not a substrate for enoyl-eoA hydratase, but an enoyl-CoA isomerase (*see dodecenoyl-CoA Ll-isomerase*) converts it to a substrate with a  $\Delta^2\text{-trans}$  double bond. Another problem occurs when an acyl-CoA with a  $\Delta^4\text{-cis}$  double bond is produced, which again is not a substrate for enoyl-CoA hydratase, but the problem is solved by the action of 2,4-dienoyl-CoA reductase, followed by enoyl-CoA isomerase; this combination yields the substrate with a  $\Delta^2\text{-trans}$  double bond.

**untranscribed spacer** a region of genomic DNA, lying between genes or groups of genes, that is not transcribed. *See spacer* (def. I).

**untranslated region** any part of an mRNA molecule not coding for a protein; e.g. in eukaryotes the poly(A) tail.

**unwinding protein** any of the proteins concerned in DNA replication that have a higher affinity for single-stranded DNA than for double-stranded DNA and act to hold the strands apart during replication.

**UPA** abbr. for urokinase-type plasminogen activator; *see plasminogen activator.*

**U5'pp1Gal** symbol for uridinediphosphogalactose (alternative to UrdPPGal or Urd-5'PP-Gal).

**U5'pp1Glc** symbol for uridinediphosphoglucose (alternative to UrdPPGlc or Urd-5'PP-Glc).

**up-promoter** a mutation that increases promoter strength in the expression of a gene.

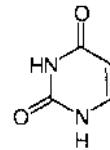

**upsilon symbol:**  $\nu$  (lower case) or  $\Upsilon$  (upper case); the twentieth letter of the Greek alphabet.

**upstream** in or towards positions in a DNA molecule lying in the 5' direction relative to the start of transcription of a gene.

**Ur or UR** abbr. for uridine (the symbol Urd is recommended).

**Ura** symbol for a residue of the pyrimidine base uracil.

**uracil symbol:** U or Ura ; 2,4-dioxypyrimidine; 2,4-pyrimidine-diol; one of the pyrimidine bases occurring in RNA (but not in DNA).

uracil

**uracil-DNA N-glycosylase** an enzyme (sub-subclass EC 3.2.2) that removes from DNA any uracil resulting from misincorporation of dUTP that has escaped the action of dUTPase (EC 3.6.1.23, dUTP pyrophosphatase). The enzyme hydrolyses the bond at C-1 of the deoxyribose to yield free uracil and DNA containing an apyrimidinic site; another enzyme, apyrimidine endonuclease, recognizes this site and cleaves the phosphodiester bond on the 5' side of the deoxyribose moiety. Uracil-DNA N-glycosylase may represent the evolutionary basis for the presence of T (not U) in DNA. Cytosine deamination leads to U residues, which would generate transition mutations on replication. In *Escherichia coli* the enzyme is the product of the ung gene and mutations in this can be used in certain forced site-directed mutagenesis protocols. The enzyme is a monomer, and is highly conserved in all species. Example, the product of the ung gene: database code UNG\_ECOLI, 228 amino acids (25.53 kDa).

**urate oxidase** EC 1.7.3.3; systematic name: urate:oxygen oxidoreductase; other name: uricase. An enzyme that catalyses the reaction: urate +  $\text{O}_2 \rightarrow$  intermediate(s) that lead(s) to allantoin. It is a conserved (five motifs) peroxisomal enzyme and a copper protein. Some mammals (e.g. humans, gorillas, etc.) that lack the enzyme are prone to gout. Example from rat: database code URIC\_RAT, 302 amino acids (34.76 kDa).

**Urd** symbol for a residue of the ribonucleoside uridine (alternative to U).

**UrdP** symbol for any uridine phosphate.

**Urd2'P** symbol for uridine 2'-phosphate.

**Urd-2'3'-P** symbol for uridine 2',3'-phosphate.

**Urd3'P** symbol for uridine 3'-phosphate.

**Urd-3'5'-P** symbol for uridine 3',5'-phosphate.

**Urd5'P** symbol for uridine 5'-phosphate.

**Urd5'PP** symbol for uridine 5'-diphosphate (alternative to ppU).

**UrdPPGal** or **Urd-5'PP-Gal** symbol for uridinediphosphogalactose (alternatives to U5'ppIGal).

**UrdPPGlc** or **Urd-5'PP-Glc** symbol for uridinediphosphoglucose (alternatives to U5'ppIGlc).

**Urd5'PPP** symbol for uridine 5'-triphosphate (alternative to pppU).

**urea** the water-soluble compound  $\text{H}_2\text{N}-\text{CO}-\text{NH}_2$ , produced in the liver via the ornithine-urea cycle. It is the main nitrogen-containing (urinary) excretion product in ureotelic animals. It is used as source of nonprotein nitrogen in ruminant livestock feeds.

**urea cycle** *see ornithine-urea cycle.*

**urease** EC 3.5.1.5; systematic name: urea amidohydrolase; a nickel-protein enzyme that catalyses the hydrolysis of urea to carbon dioxide and ammonia. A carbamoylated lysine provides an oxygen ligand to each nickel, thus explaining a requirement for  $\text{CO}_2$  as an activator of urease apoenzyme. Example from *Proteus vulgaris*; a decamer of three subunits (probably in two  $\alpha\beta_2\gamma_2$  complexes);  $\alpha$  subunit: database code URELPROVU, 567 amino acids (60.86 kDa);  $\beta$  subunit: database code URE2\_PROVU, 108 amino acids (12.14 kDa);  $\gamma$  subunit: database code URE3\_PROVU, 100 amino acids (10.94 kDa). The 3-D structure is known for the *Klebsiella aerogenes* enzyme.

## ureido

ureido the  $\text{NH}_2\text{-CO-NH-}$  group, derived from urea by loss of a hydrogen atom.

ureidosuccinase EC 3.5.1.7; an enzyme that hydrolyses *N*-carbamoyl-L-aspartate (ureidosuccinate) to L-aspartate,  $\text{CO}_2$ , and  $\text{NH}_3$ .

ureogenic describing an organism (or species) that possesses the full complement of ornithine-urea cycle enzymes, and that potentially, but not necessarily, can biosynthesize significant amounts of urea.

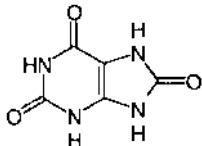

ureosmotic describing an organism (or species) that adjusts urea production or retention in a manner that assists the maintenance of osmotic equilibrium, rather than as a means of disposing of surplus nitrogen.

ureotelic describing an organism (or species) in which urea is the principal end product of the degradation of nitrogen-containing compounds. Mammals and marine fishes are typically ureotelic.

Urey, Harold Clayton (1893-1981), US physical chemist; Nobel Laureate in Chemistry (1934) 'for his discovery of heavy hydrogen'.

+uria *comb. form* signifying (in relation to a substance specified) presence unusually, or at a supranormal concentration, in urine. Hence also used to denote a morbid condition so marked, e.g. phenylketonuria.

uric acid 2,6,8-trioxypurine; purine-2,6,8-triol; the end product of purine metabolism in certain mammals (including humans) and the main nitrogenous excretory product in uricotelic animals. It is formed from xanthine by xanthine oxidase. Uric acid is very sparingly soluble in water, and crystalline deposits of monosodium urate occur in the tissues of humans affected by gout.

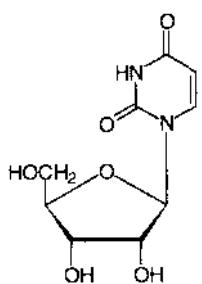

uricase *an alternative name for* urate oxidase.

uricosuric (of a drug) tending to promote urinary excretion of uric acid.

uricotelic describing an organism (or species) in which uric acid is the principal end product of the degradation of nitrogen-containing compounds. Uricotelic animals include birds, terrestrial reptiles, and insects. The low solubility of uric acid in water means that it is present as a solid in the excreta of these animals, enabling excretion with little water loss.

uridine symbol: U or Urd; uracil riboside; I-p-o-ribofuranosyluracil; a ribonucleoside very widely distributed but occurring almost entirely as phosphoric esters in ribonucleotides and ribonucleic acids. Compare pseudouridine.

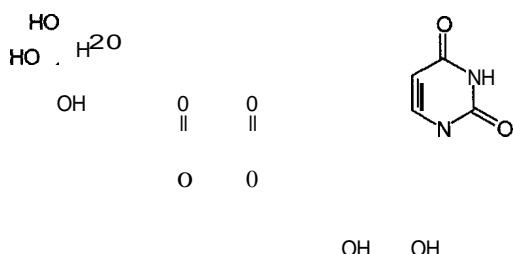

## uridinediphosphosugar

uridine 2',3'-cyclicphosphate *see* uridine phosphate.

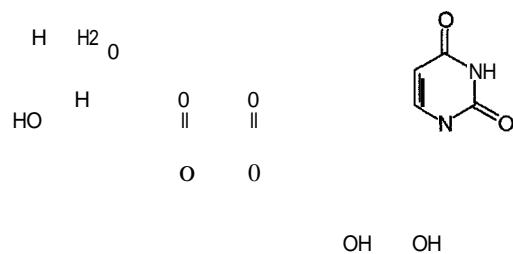

uridine 3',5'-cyclicphosphate or uridine 3',5'-cyclophosphate *see* uridine 3',5'-phosphate.

uridine 5'-diphosphate symbol: Urd5'PP or ppU; the recommended name for uridine diphosphate (abbr.: UDP); 5'-diphosphouridine; 5'-diphosphouridine; 5'-uridylyl phosphate; uridine 5'-(trihydrogen diphosphate); a universally distributed nucleotide that occurs both in the free state and as a component of a number of important uridinediphosphosugars. It is the intermediate in the formation of uridine 5'-triphosphate, UTP, from uridine 5'-phosphate, UMP.

uridine diphosphate galactose symbol: Urd-5'-PP-Gal or U5'pp1Gal or UDPGal; uridine 5'-( $\alpha$ -D-galactopyranosyl diphosphate); recommended name: uridine(5')diphospho( $\alpha$ -D-galactose); an important intermediate in the metabolism of D-galactose and in the formation of numerous derivatives. It is formed by the reaction of galactose I-phosphate with UDP-glucose (catalysed by uridyl transferase), or with UTP (catalysed by UTP-hexose-1-phosphate uridyltransferase).

uridine diphosphate glucose symbol: Urd-5'-PP-Glc or U5'pp1Glc or UDPGlc or UDPG; uridine 5'-( $\alpha$ -D-glucopyranosyl diphosphate); recommended name: uridine(5')diphospho( $\alpha$ -D-glucopyranose); an important intermediate in the formation of other sugars from glucose. It is formed by the reaction of glucose I-phosphate with UTP, catalysed by UTP-glucose-1-phosphate uridyltransferase.

uridinediphosphosugar abbr.: UDPsugar; the recommended name for uridine diphosphate sugar; any of many nucleoside-diphosphosugars in which the distal phosphoric residue of uridine 5'-diphosphate is in glycosidic linkage with a monosaccharide (or a derivative of a monosaccharide). UDPsugars are particularly important as coenzymes for many types of reaction involving the transfer of monosaccharide residues in the biosynthesis of oligosaccharides and polysaccharides (especially in plants) and in the formation of the oligosaccharide moieties of glycoconjugates. The main UDPsugars in this category are: UDP-L-arabinose, UDP-D-galactose (*see* uridine diphosphate galactose), UDP-D-galacturonate, UDP-D-glucose (*see* uridine diphosphate glucose), UDP-D-glucuronate, and UDP-D-xylose, all of which are (directly or indirectly) inter-

## uridine kinase

convertible where they occur together; UDP-L-iduronate, which is formed by epimerization of UDP-D-glucuronate; UDP-N-acetyl-D-galactosamine and UDP-N-acetyl-D-glucosamine, which are interconvertible; and UDP-N-acetylmuramate, which is synthesized from UDP-N-acetyl-D-glucosamine. In addition, certain UDPsugars, particularly UDP-D-glucose and UDP-D-glucuronate, are coenzymes for the formation in animals or plants of glycosides with a variety of aglycons such as bilirubin, phenols, plant pigments and sterols, and steroid hormones.

**uridine kinase** EC 2.7.1.48; *other name*: uridine monophosphokinase; an enzyme that catalyses the phosphorylation by ATP of uridine to uridine 5'-phosphate with formation of ADP. Example from yeast: database code URKLYEAST, 501 amino acids (56.23 kDa).

**uridine monophosphate abbr.**: UMP; *an alternative name for* any uridine phosphate, but in particular for uridine 5'-phosphate, especially when its distinction from uridine (5')-diphosphate and uridine (5')-triphosphate requires emphasis.

**uridine 5'-monophosphate synthase abbr.**: UMP synthase; a multifunctional enzyme that in higher eukaryotes carries out the following two reactions: (1) orotate phosphoribosyltransferase, EC 2.4.2.10; *other names*: orotidylic acid phosphorylase, orotidine-5'-phosphate pyrophosphorylase; *systematic name*: orotidine-5'-phosphate:pyrophosphate phospho-a-D-ribosyltransferase; a reaction of the pathway for *de novo* biosynthesis of pyrimidine nucleotides. It catalyses a reaction between orotate and 5-phospho-a-D-ribose 1-diphosphate to form orotidine 5'-phosphate and pyrophosphate. (2) orotidine-5'-phosphate decarboxylase, EC 4.1.1.23; *systematic name*: orotidine-5'-phosphate carboxy-lyase; a decarboxylation reaction that forms uridine 5'-monophosphate and CO<sub>2</sub> from orotidine 5'-phosphate. Example from *Bos taurus*: database code PYR5\_BOVIN, 480 amino acids (52.23 kDa).

**uridine phosphate symbol**: UrdP; *uridine monophosphate (abbr.): UMP)*; any phosphoric monoester or diester of uridine. There are three monoesters – uridine 2'-phosphate, uridine 3'-phosphate, and uridine 5'-phosphate – and two diesters – uridine 2',3'-phosphate and uridine 3',5'-phosphate – although uridine 5'-phosphate is the ester commonly denoted (the locant being omitted if no ambiguity may arise). Uridine 2',3'-phosphate (*symbol*: Urd-2',3'-P), *also named* uridine 2',3'-(cyclic)phosphate or cyclic uridine 2',3'-monophosphate (*abbr.*: 2',3'-cyclic UMP), is formed as an intermediate during the alkaline hydrolysis of ribonucleic acid. This diester then readily hydrolyses to a mixture of the two monoesters uridine 2'-phosphate (*symbol*: Urd2'P), *also named* uridine 2'-monophosphate (*abbr.*: 2'UMP) or 2'-uridylic acid or uridylic acid a, and uridine 3'-phosphate (*symbol*: Urd3'P), *also named* uridine 3'-monophosphate (*abbr.*: 3'UMP) or 3'-uridylic acid or uridylic acid b.

**uridine 2'-phosphate** *see* uridine phosphate.

**uridine 2',3'-phosphate** *see* uridine phosphate.

**uridine 3'-phosphate** *see* uridine phosphate.

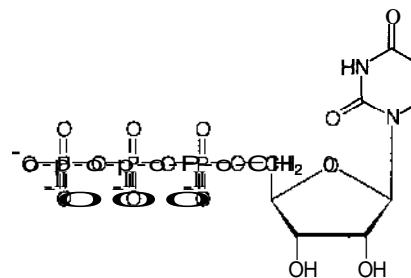

**uridine 3',5'-phosphate symbol**: Urd-3',5'-P; *the recommended name for* cyclic uridine 3',5'-monophosphate (*abbr.*: 3',5'-cyclic UMP or cyclic UMP or cUMP); uridine 3',5'-cyclic phosphate; uridine 3',5'-(cyclic)phosphate; a monophosphoric diester of uridine found in practically all mammalian tissues. It is a cyclic nucleotide similar in structure and metabolism to adenosine 3',5'-phosphate, cyclic AMP. It has been reported to inhibit the growth of certain transplantable tumours.

**uridine 5'-phosphate or 5'-uridylic acid or 5'-phosphouridine or 5'-O-phosphouridine symbol**: Urd5'P; *alternative recommended names for* uridine 5'-monophosphate (*abbr.*: 5'UMP); uridine 5'-(dihydrogen phosphate); uridine (mono)ribonucleotide. (The locant is commonly omitted if there is no ambiguity as to the position of phosphorylation). It is biosynthesized from aspartate, the last stage of the reaction sequence being the decarboxylation of orotidine 5'-phosphate,

## uridylyltransferase

orotidylic acid. In addition, resynthesis of UMP from free uridine formed by degradation of ribonucleic acid can be effected via a salvage pathway. UMP is a key intermediate in the formation of uridine 5'-triphosphate, UTP, and hence in the biosynthesis of other pyrimidine nucleotides.

**uridine phosphorylase** *see* pyrimidine-nucleoside phosphorylase. **uridine 5'-triphosphate symbol**: Urd5'PPP or pppU; *the recommended name for* uridine triphosphate (*abbr.*: UTP); 5'-triphosphouridine; 5'-uridylyl diphosphate; uridine 5'-(tetrahydrogen triphosphate); an important nucleotide present in all cells. It is formed from uridine 5'-phosphate via uridine 5'-diphosphate by the successive action of nucleoside-phosphate kinase (EC 2.7.4.4) and nucleoside-diphosphate kinase (EC 2.7.4.6), which transfer in turn the terminal phosphoric residues from two molecules of adenosine 5'-triphosphate. UTP is the starting point for the biosynthesis, first of cytidine triphosphate, next of cytidine diphosphate, and then, in a succession of further reactions, of various deoxyribonucleotides of cytosine, uracil, and thymine. It is important also for the formation of uridinediphosphogalactose and uridinediphosphoglucose through the action of certain uridylyltransferases, and thence of a number of other uridinediphosphosugars.

**uridyl** 1 any chemical group formed by the loss of a 2'-, a 3'-, or a 5'-hydroxyl group from the ribose moiety of uridine. 2 *a misnomer for* uridylyl.

**uridylate** 1 either the monoanion or the dianion of uridylic acid. 2 any mixture of uridylic acid and its anions. 3 any salt or ester of uridylic acid.

**uridylic acid** *the trivial name for* any phosphoric monoester of uridine. The position of the phosphoric residue on the ribose moiety of a given ester may be specified by a prefixed locant; *see* uridine phosphate. However, 5'-uridylic acid is the ester commonly denoted, its locant usually being omitted if no ambiguity may arise. 5'-Uridyllic acid is also an alternative recommended name for uridine 5'-phosphate.

**uridyl transferase** *another name for* UDPglucose-hexose-1-phosphate uridylyltransferase. This is a misnomer; *compare* uridyl with uridyl.

**uridyl** the uridine[mono]phospho group; the acyl group derived from uridylic acid. *Distinguish from* uridyl.

**uridylate** to introduce uridyl groups into a compound (e.g. a protein, a ribonucleic acid, or a sugar phosphate), generally through the action of a uridylyltransferase. -uridylated *adj.*; uridylylation *n.*

**uridylyl-removing enzyme** *the provisional name for* a putative enzyme present in *Escherichia coli* that detaches uridyl groups from uridylated nitrogen regulatory protein P<sub>n</sub> by hydrolysis, with formation of uridylate. *See also* nitrogen regulatory protein, uridylyltransferase.

**uridylyltransferase** EC 2.7.7.12; *recommended name*: UDPglucose-hexose-1-phosphate uridylyltransferase; *systematic name*: UDPglucose:a-D-galactose-1-phosphate uridylyltransferase; *other names*: uridyllyl removing enzyme; P<sub>n</sub> uridyllyl-transferase. An enzyme that catalyses the reaction:

## UTP-hexose-'-phosphate uridylyltransferase

The *Escherichia coli* enzyme comprises 890 amino acids (102.31 kDa) and modifies the nitrogen regulatory protein PII' urinalysis the chemical and physical analysis of urine. urinary of, or pertaining to, urine.

urinary stone protein see osteopontin.

urine the aqueous excretion produced by the kidneys in higher animals. It serves as a vehicle for the elimination of certain metabolic waste products, e.g. urea and uric acid, and for the removal of excess ions and water. In mammals and fishes it is fluid, while in birds and reptiles it is semi-solid.

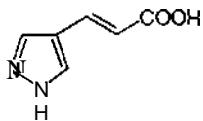

urinometer a hydrometer specifically designed and calibrated for measuring the specific gravity of (mammalian) urine.

urobilin or urobilin {Xu a yellow coloured linear tetrapyrrole.

It is formed in kidney and is an oxidation product of urobilinogen; the central methylene group linking pyrrole units has been converted to  $-\text{CH}=$ . Urobilin gives urine its characteristic yellow colour. See also stercobilin.

urobilinogen or mesobilirubinogen or urobilinogen {Xu a colourless linear tetrapyrrole formed in heme catabolism. It arises by reduction of free bilirubin released from its glucuronide by intestinal bacterial hydrolases. The four pyrrole rings are linked by three methylene groups. See also stercobilinogen.

urocanoate 4-imidazoleacrylate; 3-(IH-imidazol-4-yl)propanoate: an intermediate in the degradation of L-histidine, from which it is formed through the action of histidine ammonia-lyase by elimination of ammonium.

urocanic acid

urodinatin a 32-amino-acid peptide, isolated from human urine that is identical in sequence to human natriuretic peptide (ANP) but with an N-terminal Thr-Ala-Pro-Arg tetrapeptide extension. It has actions similar to ANP.

uroflavin or uroflavine a former name for riboflavin.

urogastrone a name given (by analogy with enterogastrone) to a proteinaceous agent present in human urine that potently inhibits gastric secretion. It is now believed to be identical or nearly identical with human epidermal growth factor.

urokinase a proteolytic enzyme found in urine, blood, and kidney cells, that converts plasminogen to plasmin. See plasminogen activator.

uromodulin another name for Tamm-Horsfall glycoprotein.

uronate 1 the anion of uronic acid. 2 any mixture of a uronic acid and its anion. 3 any salt or ester of a uronic acid.

uronic acid any monocarboxylic acid formally derived by oxidizing to a carboxyl group the terminal hydroxymethylene group either of an aldose having four or more carbon atoms in the molecule, or of any glycoside derived from such an aldose. The carbon atom of the (potential) aldehydic carbonyl group is numbered C-1.

uroptonin see osteopontin.

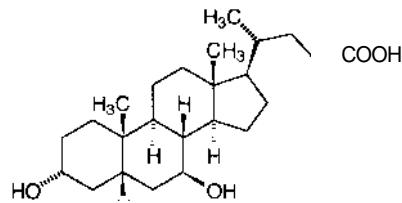

uroporphyrin-III C-methyltransferase EC 2.1.1.107; systematic name: S-adenosyl-L-methionine:uroporphyrin-III C-methyltransferase (abbr.: SUMT); other names: urogen-III methylase; uroporphyrin-III methylase. An enzyme that catalyses a reaction between two molecules of S-adenosyl-L-methionine and uroporphyrin III to form two molecules of S-adenosyl-L-homocysteine and sirohydrochlorin. It is a compo-

nent of siroheme synthase, and effects a step in the biosynthesis of siroheme and cobalamin.

uroporphyrinogen decarboxylase EC 4.1.1.37; systematic name: uroporphyrinogen-III carboxy-lyase. An enzyme that catalyses the decarboxylation of uroporphyrinogen-III to coproporphyrinogen with loss of four molecules of  $\text{CO}_2$ ; this is a step in the pathway of heme synthesis, whereby the four carboxymethyl groups of uroporphyrinogen are converted to methyl groups. Example from yeast: database code DCUP\_YEAST, 362 amino acids (41.30 kDa).

uroporphyrinogen-III synthase EC 4.2.1.75; systematic name: hydroxymethylbilane hydro-lyase (cyclizing); other names: uroporphyrinogen-III cosynthetase; uroporphyrinogen-III cosynthase. An enzyme that catalyses the conversion of hydroxymethylbilane to uroporphyrinogen-III and  $\text{H}_2\text{O}$ . Example from *Escherichia coli*: database code HEM4\_ECOLI, 246 amino acids (27.77 kDa).

ursodeoxycholate 3a,7fl-dihydroxy-5fl-cholan-24-oate; an epimer of chenodeoxycholate found in the bile of bears (hence the name, from Ursidae), as a conjugate with taurine. Used therapeutically, it prevents the synthesis and absorption of cholesterol and can lead to the dissolution of gallstones.

U-snRNA abbr. for uridylate-rich small nuclear RNA; a family of snRNA molecules, often designated U1 to U6 snRNA, that contain 100-215 nucleotides and a 'capped' 5' end. They usually occur in combination with proteins as small nuclear ribonucleoprotein particles. Their function is unclear, but may be related to splicing heterogeneous nuclear RNA (hnRNA) to mature mRNA.

USP abbr. for United States Pharmacopeia.

USPHS abbr. for United States Public Health Service.

uterine metalloendopeptidase see matrilysin.

uteroglobin or blastokinin a protein regulator of progesterone concentrations reaching the blastocyst and a potent inhibitor of phospholipase A<sub>2</sub>. It is a disulfide-linked homodimer. Example (precursor) from *Oryctolagus cuniculus*: database code UTER\_RABBIT, 91 amino acids (9.97 kDa).

uterus (pl. uteri) a muscular part of the reproductive tract of female mammals (except Monotremata) that contains the developing embryo and fetus during pregnancy. -uterine adj.

UTP abbr. for uridine (5')-triphosphate.

UTP-glucose-1-phosphate uridylyltransferase EC 2.7.7.9; systematic name: UTP:a-D-glucose-1-phosphate uridylyltransferase; other names: UDPglucose pyrophosphorylase; glucose-1-phosphate uridylyltransferase; one of the enzymes that can form uridinediphosphoglucose. It catalyses a reaction between UTP and a-D-glucose I-phosphate to form UDPglucose and pyrophosphate. Example from *Escherichia coli*: database code GALU\_ECOLI, 302 amino-acid residues (32.90 kDa).

UTP-hexose-1-phosphate uridylyltransferase EC 2.7.7.10; systematic name: UTP:u-D-hexose-I-phosphate uridylyltransferase; one of the enzymes that can form uridinediphosphogalactose. It catalyses a reaction between UTP and u-D-galactose I-phosphate to form UDPgalactose and pyrophosphate. u-D-Glucose I-phosphate can also act (but more slowly) as an acceptor, forming uridinediphosphoglucose. Example from human: database code GAL7\_HUMAN, 379

**UTP-xylose-1-phosphate uridyltransferase**

UWGCG

amino acids (43.16 kDa). The absence of the enzyme in infancy causes a mild form of galactosemia.

**UTP-xylose-1-phosphate uridyltransferase** EC 2.7.7.11; *other name:* xylose-1-phosphate uridyltransferase; an enzyme that catalyses a reaction between UTP and a-D-xylose 1-phosphate to form UDPxylose and pyrophosphate.

**utrophin** or dystrophin-related protein (*abbr.:* DRP) a protein that is highly homologous to dystrophin and found in normal adult human muscle, primarily at the neuromuscular junction. In the absence of dystrophin in Duchenne muscular dystrophy it is also present in the sarcolemma. It is an actin-binding protein related to a-actinin. Both gene and protein sequences resemble those for dystrophin. Overexpression of utrophin in a dystrophin-deficient (*mdx*) mouse demonstrates that it can functionally replace dystrophin; it has been suggested that this could offer a therapeutic strategy for Duchenne muscular dystrophy. Example from human: database code 828381, 3433 amino acids (394.05 kDa).

UUA a codon in mRNA for L-Ieucine.

UUC a codon in mRNA for L-phenylalanine.

UUG a codon in mRNA for L-leucine.

UUU a codon in mRNA for L-phenylalanine.

UV or *uv abbr.* for ultraviolet (radiation).

**uvomorulin** or epithelial cadherin or E-cadherin a type I membrane protein and cadherin of non-neuronal epithelial tissues.

**uvr** any of four genes in *Escherichia coli* that are induced by the SOS repair system and whose products are involved in the repair of damage to DNA caused by UV light and DNA-reactive chemicals. Three of these genes, *uvrA*, *uvrB*, and *uvrC*, encode the three subunits of the ABC excision nuclease; this recognizes the structural distortion created by a thymine dimer and cleaves the damaged strand at two sites, leaving a gap that is subsequently filled by polymerase and ligase action. Because the enzyme cuts at two sites it is not a classical endonuclease, but is referred to as an excinuclease. The fourth gene, *uvrD*, encodes a DNA helicase with ATPase activity, similar to the *rep* (*see RepA*) gene product; it promotes the ATP-dependent unwinding of the DNA duplex during repair; example, database code **UVRD\_ECOLI**, 720 amino acids (81.90 kDa).

**UWGCG** *abbr.* for University of Wisconsin Genetics Computer Group. *See GCG.*

# V V

*v* symbol for 1 specific volume. 2 volume (alternative to *V*). 3 velocity of reaction (i.e. rate of reaction); a subscript (in small capital letters) may be added (e.g. *V<sub>A</sub>*) to denote rate of consumption, or rate of formation, of a specified reactant (e.g. A). 4 initial velocity of an enzymic reaction; *see also v<sub>o</sub>*. 5 (bold italic) velocity (alternative to *u*, *w*, or *c*).

*v<sub>o</sub>* symbol for initial velocity (i.e. initial rate) of an enzymic reaction. The subscript may be omitted when rates at other times are not in question.

*v<sub>i</sub>* symbol for chemical flux through the (enzymic) step with rate constant *k<sub>i</sub>*. Similarly, flux through steps with rate constants *k<sub>-i</sub>* or *k<sub>j</sub>* are denoted by *v<sub>i</sub>* and *v<sub>j</sub>* respectively.

*v<sub>max</sub>* symbol for the true maximum value of the rate of reaction.

Compare *V<sub>max</sub>*.

*V* symbol for 1 volt. 2 a residue of the a-amino acid L-valine (alternative to Val). 3 vanadium. 4 variable region (of an immunoglobulin chain).

*V* symbol for 1 electric potential. 2 potential energy. 3 volume (alternative to *V*). 4 maximum velocity (i.e. limiting rate, or maximum rate) of an enzymic reaction (alternative to *V<sub>max</sub>*).

*V<sub>m</sub>* symbol for molar volume.

*V<sub>M</sub>* symbol for hold-up volume.

*V<sub>max</sub>* symbol for maximum velocity (Le. limiting rate) of an enzyme reaction (alternative to *V*).

*Vac* symbol for vaccenic acid.

vaccenate 1 numerical symbol: 18:I(II); the trivial name for either of the isomers (*cis*-vaccenate and *trans*-vaccenate) of octadec-II-enoate,  $\text{CH}_3-\text{[CH}_2\text{]}_5-\text{CH}=\text{CH}-\text{[CH}_2\text{]}_9-\text{COO}^-$ , the anions derived from *cis*-vaccenic acid, (*Z*)-octadec-II-enoic acid, and *trans*-vaccenic acid, (*E*)-octadec-II-enoic acid, a stereoisomeric pair of monounsaturated straight-chain higher fatty acids. *See also* octadecenoic acid. 2 any mixture of either *cis*- or *trans*-vaccenic acid and its corresponding anion. 3 any salt or ester of either isomer of vaccenic acid.

vaccenoyl symbol: Vac; the trivial name for either of the isomers (*cis*-vaccenoyl and *trans*-vaccenoyl) of octadec-II-enoyl,  $\text{CH}_3-\text{[CH}_2\text{]}_5-\text{CH}=\text{CH}-\text{[CH}_2\text{]}_9-\text{CO}$ , the acyl groups derived from *cis*-vaccenic acid, (*Z*)-octadec-II-enoic acid, and *trans*-vaccenic acid, (*E*)-octadec-II-enoic acid. The *cis*-vaccenoyl group is a major fatty-acyl component of many bacterial lipids and a constituent of the oils of marine organisms. The *trans*-vaccenoyl group is present in a minor proportion of the acyl-glycerols in the body and milk fats of ruminants.

vaccination the process of administering a vaccine to produce immunity.

vaccine any preparation of immunogenic material suitable for the stimulation of active immunity in animals without inducing disease. Vaccines may be based on dead or attenuated microorganisms; altered toxins (toxoids); or viruses.

vaccinia virus a DNA virus and the type species of the genus *Orthopoxvirus* (or 'vaccinia subgroup'), which also includes the viruses responsible for cowpox, buffalopox, catpox, mousepox, and (formerly) smallpox (variola virus). Vaccinia infection usually causes only mild symptoms. Because of its serological similarity to the smallpox virus, vaccinia virus was formerly used as the basis of a live vaccine to protect humans against smallpox. Viral antigens are often on the surface of virus particles, and some of these antigens can be engineered into the coat of vaccinia. For example, engineered vaccinias with surface antigens of hepatitis B, influenza virus, and vesicular stomatitis virus (which kills cattle, horses, and pigs) have produced useful vaccines in animal tests. However, the known adverse reactions with vaccinia-virus vaccines are well documented and their incidence and severity must be carefully weighed.

vacuolar apparatus the cellular digestive system, consisting

of lysosomes and closely related, hydrolase-free, vacuolar structures. It is concerned with the digestion of both endogenous and exogenous materials.

vacuolar ATPase an enzyme of the synaptic vesicle membrane that pumps protons into the vesicle as it loses acetylcholine during nerve transmission; subsequently, the hydrons are released as the vesicle is recharged with acetylcholine. The enzyme (at least 10 subunits) resembles H<sub>+</sub>-transporting ATP synthase, but functions as a proton pump. Example from bovine: database code VATA\_BOVIN, 617 amino acids (68.31 kDa). The catalytic subunits are highly conserved; e.g. the enzyme from carrot comprises 623 amino acids (68.76 kDa).

vacuole a closed structure, found only in eukaryotic cells, that is completely surrounded by unit membrane and contains liquid material. Compare vesicle.

vacuum (*pl.* vacuums or vacua) a space containing a gas at low pressure; i.e. a space in which there are relatively few atoms or molecules. A perfect vacuum would contain no atoms or molecules, but this is unobtainable owing to the vapour pressure of materials containing any vacuum. Vacuums may be classified into low (or soft) vacuum,  $\approx 10^{-2}$  Pa; high (or hard) vacuum,  $10^{-2}$ – $10^{-7}$  Pa; and ultrahigh vacuum,  $< 10^{-7}$  Pa.

vacuum evaporation a technique for depositing a thin film of some solid material on a surface by evaporating the material at a high temperature in a vacuum. Atoms leaving the hot material travel directly to the cool surface to form a coating without colliding with other molecules in the gas phase; they condense on the cool surface and build up a layer of solid. *See also* shadow casting.

vacuum ultraviolet see ultraviolet radiation.

vagusstoff the German name for 'active factor'. The existence of such a factor was first demonstrated by Loewi (1903); it was secreted into plasma after stimulation of the vago-sympathetic trunk, and was found to inhibit cardiac function. It was later identified by Dale as acetylcholine.

Val symbol for 1 the a-amino acid L-valine (alternative to *V*). 2 the (*cis*- or *trans*-) vaccenoyl group.

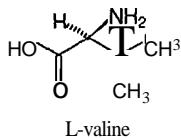

valency or (esp. US) valence 1 the numerical combining power of an atom (and thus of a chemical element), ion, or chemical group, equal to the number of hydrogen atoms that the atom, ion, or group could combine with or replace. *See also* covalence, electrovalence. 2 the number of antigenic determinants with which one antibody molecule, or fragment thereof, will combine.

valerate 1 the trivial and preferred name for pentanoate; the anion,  $\text{CH}_3-\text{[CH}_2\text{]}_3-\text{COO}^-$ , derived from valeric acid (i.e. pentanoic acid). 2 any mixture of free valeric acid and its anion. 3 any salt or ester of valeric acid.

valeryl symbol: VI; the trivial and preferred name for pentanoyl; the acyl group,  $\text{CH}_3\text{[CH}_2\text{]}_2\text{-CO}$ , derived from valeric acid (i.e. pentanoic acid).

valinate 1 valine anion; the anion,  $(\text{CH}_3\text{CH}-\text{CH}(\text{NH}_2)\text{-COO})^-$ , derived from valina. 2 any salt containing valine anion. 3 any ester of valine.

valine the trivial name for a-aminoisovaleric acid; a-amino-p-methylbutyric acid; 2-amino-3-methylbutanoic acid;  $(\text{CH}_3\text{CH}-\text{CH}(\text{NH}_2)\text{-COOH}$ ; a chiral a-amino acid. L-valine (symbol: *V* or Val), (*S*)-2-amino-3-methylbutanoic acid, is a coded amino acid found in peptide linkage in proteins; codon: GUA, GUC, GUG, or GUU. In mammals it is an essential dietary amino acid and is glucogenic. Residues of D-valine (symbol: D-Val or DVal), (*R*)-2-amino-3-methylbutanoic acid, occur in a number of peptide antibiotics, e.g. several members of the actinomycin family, gramicidins A, B, C, and D, and valinomycin (the latter also contains residues of L-valine). (Illustrated overleaf).

valine-isoleucine aminotransferase *see* valine-3-methyl-2-oxovalerate aminotransferase.

valine-3-methyl-2-oxovalerate aminotransferase EC 2.6.1.32; *recommended name:* valine-3-methyl-2-oxovalerate transaminase; *other names:* valine-isoleucine transaminase; valine-isoleucine aminotransferase; an enzyme that catalyses the reaction:

*See also* transamination.

valinium valine cation; the cation  $(\text{CH}_3)_2\text{CH}-\text{CH}(\text{NH}_3^+)-\text{COOH}$ , derived from valine.

valino the alkylamino group,  $(\text{CH}_3)_2\text{CH}-\text{CH}(\text{COOH})-\text{NH}-$ , derived from valine.

valinomycin a cyclic 12-residue depsipeptide antibiotic that consists of three moieties, each having one molecule each of L-valine, o-a-hydroxyvaleric acid, o-valine, and L-lactic acid. The linkage from the o-valine carboxyl group is directly onto the a-carbon of L-lactic acid. Valinomycin is produced by *Streptomyces fulvissimus*. It is active especially against *Mycobacterium tuberculosis*. It can act as an ionophore, the molecule being folded to produce a hydrophobic surface with an interior that binds a univalent cation such as  $\text{Rb}^+$ ,  $\text{Cs}^+$ ,  $\text{NH}_4^+$ , or, especially,  $\text{K}^+$ . This property equips valinomycin to interfere with oxidative phosphorylation by rendering the mitochondrial membrane permeable to  $\text{K}^+$  ions.

valium *see* diazepam.

valproic acid 2-propylpentanoic acid;  $(\text{CH}_3-\text{CH}_2-\text{CH}_2)_2\text{CH}-\text{COOH}$ ; an antiepileptic, also used as the sodium salt, sodium valproate (*one proprietary name:* Epilim).

valyl the acyl group,  $(\text{CH}_3)_2\text{CH}-\text{CH}(\text{NH}_2)-\text{CO}-$ , derived from valine.

VAMP *abbr. for* vesicle-associated membrane protein; *another name for* synaptobrevin.

vancomycin a complex glycopeptide, C66H75C12N9O24, from *Streptomyces orientalis*. It inhibits a specific step in the synthesis of the peptidoglycan layer in the Gram-positive bacterium *Staphylococcus aureus*. *See also* vancosamine.

vancosamine the aminodeoxy sugar 3-amino-2,3,6-trideoxy-3-C-methyl-L-lyxo-hexose; the carbohydrate component of vancomycin.

van den Bergh reaction a colorimetric reaction for the determination of bilirubin that depends on the formation of a red azo dye by bilirubin and diazotized sulfanilic acid. A direct van den Bergh reaction in aqueous solution is given by bilirubin glucuronide, and an indirect van den Bergh reaction is given in alcoholic solution by free bilirubin. [After A. A. Hijmans van den Bergh (1869-1943), Dutch physician.]

van der Waals forces long-range forces between molecules or submolecular groups, effective from >50 nm to interatomic spacings. They are always present, albeit rather weak, but often compete with electrostatic forces. In general the van der Waals forces do not follow a simple power law; e.g. the force may be attractive at large separations but repulsive at small ones, or vice versa. The van der Waals free energy between two molecules or submolecular groups usually depends on their mutual orientation, i.e. these forces tend to align two molecules so as to minimize their free energy of interaction. [After Johannes Diderik van der Waals (1837-1923), Dutch physicist.]

van der Waals radius one half of the internuclear distance be-

tween atoms at equilibrium when the long-range attractive forces balance the short-range repulsive forces. It is larger than the atom's covalent radius and is about equal to the ionic radius of monovalent ions.

Van Dyke protein *an old name for* neurophysin.

Vane, (Sir) John Robert (1927- ), British pharmacologist; Nobel Laureate in Physiology or Medicine (1982) jointly with S. K. Bergstrom and B. I. Samuelsson 'for their discoveries concerning prostaglandins and related biologically active substances'.

vanillylmandelate *see* hydroxy-methoxymandelate.

van Niel, Cornelius Bernardus (1897-1984), US microbiologist who inherited the traditions of the Delft school; he proposed the general equation for photosynthesis as

He was renowned for his summer course in microbiology at the Hopkins Marine Station, Pacific Grove, California.

Van Slyke apparatus 1 a volumetric apparatus formerly widely used for the determination of oxygen and carbon dioxide contents of blood samples. 2 an apparatus for the gasometric determination of aliphatic amino-nitrogen, e.g. in proteins, by measurement of the nitrogen gas evolved on reaction with nitrous acid. [After Donald Dexter Van Slyke (1883-1971), US biochemist.]

van't Hoff, Jacobus Henricus (1852-1911), Dutch physical chemist and stereochemist distinguished, *inter alia*, for postulating the tetrahedral disposition of the bonds to a singly bonded carbon atom, for being the first to apply the laws of thermodynamics to chemical reactions, and for showing that osmotic pressure varies directly with absolute (i.e. thermodynamic) temperature; Nobel Laureate in Chemistry (1901) 'in recognition of the extraordinary services he has rendered by the discovery of the laws of chemical dynamics and osmotic pressure in solutions'.

van't Hoff equation *or* van't Hoff isochore a relation describing the temperature variation of an equilibrium constant,  $K$ , of a reaction in terms of the change in heat content,  $\Delta H'$ , i.e. in terms of the heat of reaction at constant pressure. It is:  $d\ln K/dT = \Delta H'/RT^2$ , where  $R$  is the gas constant and  $T$  the thermodynamic temperature.

van't Hoff law the principle that the osmotic pressure exerted by a solute is equal to the pressure the solute would exert if it were an ideal gas at the same temperature as the solution and of the same volume. Hence  $IIV = RT$ , where  $II$  is the osmotic pressure,  $V$  is the volume of solution containing  $I$  mole of solute,  $R$  the gas constant, and  $T$  the thermodynamic temperature.

van't Hoff limiting law a relation giving the limiting value for the osmotic pressure exerted by an ideal solute:

$$\text{limit } (c \rightarrow 0) II = RT/M_r,$$

where  $II$  is the osmotic pressure,  $c$  the solute concentration,  $M_r$  the relative molecular mass of the solute,  $R$  the gas constant, and  $T$  the thermodynamic temperature.

variable 1 liable to change; having a range of possible values; liable to deviate from an established type. 2 something that is subject to variation; a quantity or function that can assume any of a set of specified values; a symbol for any unspecified number or quantity.

variable arm *an alternative name for* extra arm of tRNA.

variable number tandem repeats *abbr.:* VNTR; a multi-allelic DNA polymorphism that results from insertions or deletions of DNA between two restriction sites. The existence of these repeats is exploited in genetic profiling.

variable region *symbol:* V; a region of a chain of an immunoglobulin molecule having an amino-acid sequence that characteristically varies between molecules of the same immunoglobulin class. There are typically four variable regions: the N-terminal halves of the two light chains ( $V_L$ ) and the N-terminal halves of the Fd fragments ( $V_H$ ) of the two heavy chains. The amino-acid sequences of these variable regions de-

termine the structure of the antibody-combining site. Compare constant region.

variance a measure of the dispersion of a population, the mean square average of the deviations from the mean. It is the square of the standard deviation,  $\sigma$ , of that population.

variant 1 something that deviates from the norm; used especially of abnormal proteins (e.g. hemoglobins). 2 different; showing variation; used especially of different amino-acid residues in the corresponding positions of polypeptide chains from different sources.

Varmus. Harold Eliot (1939- ), US microbiologist and molecular biologist; Nobel Laureate in Physiology or Medicine (1989) jointly with M. J. Bishop 'for their discovery of the cellular origin of retroviral oncogenes'.

vascular of, or relating to vessels that conduct fluid from one part of an organism to another, e.g. the blood vessels in animals, or the xylem and phloem in plants.

vascular cell adhesion molecule see YCAM.

vascular endothelial growth factor abbr.: VEGF; also known as vascular permeability growth factor or vasculotropin; a protein that is produced by epithelial cells, macrophages, and smooth muscle cells, and is active in angiogenesis and endothelial cell growth; it induces endothelial proliferation and vascular permeability. Related to platelet-derived growth factor, it is a disulfide-linked homodimer. Example (precursor) from human: database code VEGF\_HUMAN, 215 amino acids (25.14 kDa).

vascular endothelial growth factor receptor abbr.: VEGF receptor; a type I membrane protein of the immunoglobulin superfamily (seven immunoglobulin-fold domains in the extracellular part) found in the lung and elsewhere. It is a tyrosine kinase receptor related to the platelet-derived growth factor receptor, with a nonkinase insert between the kinase domains. Example (precursor of receptor I) from human: database code VGRI\_HUMAN, 1338 amino acids (150.56 kDa).

vascular permeability growth factor see vascular endothelial growth factor.

vasculature the vascular system in animals.

vasculotropin see vascular endothelial growth factor.

vaso+ comb. form denoting a blood vessel.

vasoactive describing any agent that affects the diameter of blood vessels. See also vasoconstrictor, vasodilator.

vasoactive intestinal contractor see endothelin.

vasoactive intestinal polypeptide abbr.: VIP; a basic 28-residue peptide amide, similar in sequence to gastric inhibitory polypeptide, glucagon, and secretin, that is widely distributed in the body, mainly in nervous tissue (especially of the gut) and appears to act as a neurotransmitter in peptidergic autonomic nerves. It has a wide range of biological activities, including potent hypotensive and vasodilatory effects. It has the sequence

vasoactive intestinal polypeptide receptor or vasoactive intestinal peptide receptor any of a family of proteins that bind vasoactive intestinal polypeptide (VIP) and mediate its intracellular effects. The receptor is a G-protein-coupled seven-transmembrane-domain protein (362 residues, human). The effector pathway involves adenylate cyclase activation; other endogenous ligands include peptide HI (PHI), GHRH, and secretin, the order of potency being VIP > PHI > GHRH > secretin.

vasoconstrictor a vasoactive agonist that causes vasoconstriction, i.e. a decrease in the diameter of blood vessels.

vasodilator a vasoactive agonist that causes vasodilation, i.e. an increase in the diameter of blood vessels.

vasopressin or antidiuretic hormone (abbr.: ADH); either of two nonapeptide hormones secreted by the neurohypophysis and structurally very similar to vasotocin and oxytocin. 18-Argi-

nine)vasopressin (abbr.: [Arg<sup>8</sup>]vasopressin or AVP) has the sequence

with a disulfide bridge between the half-cystine residues at positions 1 and 6. It has a pressor action by causing vasoconstriction in the peripheral arterioles and capillaries. It also has an antidiuretic action by accelerating water reabsorption from the proximal region of the distal convoluted tubules of the kidney. AVP is synthesized as part of a large precursor molecule, vasopressin/neurophysin 2-coopeptin precursor, which includes its associated carrier protein (neurophysin), and is then packaged into granules in which the nonapeptide is formed by proteolytic cleavage. Subsequently it is released, on action of a specific stimulus, into the blood, in which it circulates in unbound form. Deficiency of AVP is the cause of autosomal dominant neurohypophyseal diabetes insipidus (ADNDI). The analogue, [8-lysine]vasopressin (abbr.: [Lys<sup>8</sup>]vasopressin), in which lysine is substituted for arginine at position 8, is formed, either singly or together with arginine vasopressin, in the pig family.

vasopressin-neurophysin 2-coopeptin precursor the precursor of vasopressin, neurophysin 2 (see neurophysin), and a third peptide, coopeptin. Example from human: database code NEU2\_HUMAN, 164 amino acids (17.31 kDa). Copeptin is a glycopeptide that contains 38 amino-acid residues forming the third domain of mammalian vasopressin-neurophysin precursor. It is released during intra-axonal processing of the precursor.

vasopressin receptor any of a family of membrane proteins that bind [8-arginine]vasopressin (AVP; see vasopressin) and mediate its intracellular effects; peptides related to AVP, including oxytocin, are also bound. Two types of vasopressin receptor have been defined: VI – subdivided into VIa (vascular/hepatic) and VIb (anterior pituitary) – and V<sub>2</sub> (kidney); these can be distinguished pharmacologically on the basis of selective agonists. V<sub>2</sub> receptors are restricted to the kidney and colocalize at the chromosomal locus for nephrogenic diabetes insipidus. VI receptors are coupled to phosphoinositide-specific phospholipase C, and V<sub>2</sub> receptors to adenylate cyclase, which is activated by occupied receptor. AVP is a more potent agonist for both V<sub>1</sub> and V<sub>2</sub> receptors than oxytocin. These receptors are seven-transmembrane-domain proteins characteristic of G-protein-coupled receptors. Examples, from *Rattus norvegicus*: VIa receptor: database code VIAR\_RAT, 395 amino acids (44.48 kDa); VIb receptor: database code VIBR\_RAT, 425 amino acids (47.08 kDa); V<sub>2</sub> receptor: database code V2R\_RAT, 371 amino acids (40.75 kDa). See also oxytocin receptor.

vasostatin a 76 amino-acid peptide released by proteolytic cleavage of chromogranin A; it lowers vascular tension.

vasotocin a vasoactive peptide, closely related in amino-acid sequence to arginine vasopressin and oxytocin, that is secreted by the posterior pituitary gland in birds, reptiles, and some amphibians. It has the sequence

with a disulfide bond between the two cysteines.

VASP abbr. for vasodilator-stimulated phosphoprotein; a substrate for cyclic AMP- and cyclic GMP-dependent protein kinases in platelets. It is associated with actin filaments and focal adhesions and is a proline-rich prolinilin ligand. Example from *Canis familiaris*: database code VASP\_CANFA, 384 amino acids (40.41 kDa).

VCAM abbr. for vascular cell adhesion molecule; a class of adhesion molecules belonging to the immunoglobulin superfamily. The class is exemplified by VCAM-1 (CD106; molecular mass 90-110 kDa). This is expressed on endothelial cells, macrophages, dendritic cells, fibroblasts, and myoblasts, and is inducible within 6-10 h by interleukin 1 $\beta$ , interleukin 4,

tumour necrosis factor  $\alpha$ , or interferon  $\gamma$ . It binds to VLA-4 (see VLA) and integrin  $\alpha_4\beta_7$  (see integrin), and mediates adhesion of lymphocytes, monocytes, and eosinophils to activated endothelium. Example from human: database code VCALHUMAN, 739 amino acids (81.28 kDa). Residues 1-24 are the signal, 25-698 the extracellular domain, with seven Ig-like C<sub>2</sub> domains.

**vector** 1 or vector quantity a quantity specified by its direction and sense as well as by its magnitude. 2 (in pathology) an organism that carries an organism of a different species from one place to another, especially one that transfers a pathogen between hosts, either mechanically (mechanical vector) or by playing a specific role in the pathogen's life cycle (biological vector). Compare vehicle (def. 2). 3 (in genetics) see cloning vector.

**vectorette** a synthetic DNA oligonucleotide with a mismatched region. Vectorettes are ligated to genomic fragments and serve in a variety of polymerase chain reaction (PCR) systems in which the sequence of only one primer is available.

**vectorial enzyme** any enzyme, such as one fixed in a membrane, that is directional in its action, e.g. sodium/potassium ATPase.

**vectorial processing** processing of a fully formed precursor polypeptide into a mature protein when used to drive the movement of the protein from one aqueous compartment (e.g. the cytoplasm) through a membrane into a second aqueous compartment (e.g. an intramitochondrial or intrachloroplastal space). Compare vectorial translation.

**vectorial translation** the stage of translation in the biosynthesis of any protein destined for export from a cell, where a nascent polypeptide being produced on a polysome bound to the membrane of the rough endoplasmic reticulum in a eukaryote is conducted through the membrane by its N-terminal signal peptide. Compare vectorial processing.

**vegetal hemisphere glycoprotein 1 abbr.: Vg-I;** a glycoprotein, belonging to the TGF- $\beta$  family (see transforming growth factor), that serves to facilitate the differentiation of either mesoderm or endoderm, either as a cofactor in an instructive signal or by providing a permissive environment. Example from *Xenopus*: database code DVRI\_XENLA, 360 amino acids (41.72 kDa).

**vegetal pole** the end at which most of the yolk is located e.g. in an amphibian egg; the end opposite the animal pole.

**vegetative** describing cells or tissues that are engaged in nutrition and growth rather than sexual reproduction, and excluding dormant forms.

**vegetative bacteriophage** the intrabacterial genome of a bacteriophage when it is noninfective but is controlling the synthesis by the host of components necessary for the production of new, infective bacteriophage particles.

**vegetative reproduction** 1 (in plants) a form of asexual reproduction in which new individuals develop from specialized multicellular organs (e.g. bulbs, corms, tubers) that break off from the parent plant. 2 (sometimes) a term used to describe budding (def. 2) and similar forms of asexual reproduction in animals such as coelenterates and sponges.

**VEGF abbr.: for vascular endothelial growth factor.**

**vehicle** 1 any inert medium with which a biologically active substance (e.g. a drug) is mixed or in which it is dissolved, suspended, or emulsified in order to increase its bulk and/or to facilitate its absorption after administration. 2 any agent (animate or inanimate) of transmission, especially of infection; see also vector (def. 2).

**vein** 1 (in animals) the blood vessels conducting blood from the tissues. 2 (in plants) a vascular bundle in a leaf.

**velocity of reaction** an alternative name for rate of reaction.

**venom** any toxic animal secretion that is produced by discrete glands and is delivered by a specific mechanism for defensive or offensive purposes.

**venombin** either of two serine proteinases found in snake venom. Venombin AB EC 3.4.21.55; other name: gabonase

(from the venom of the gaboon viper, *Bitis gabonica*); it cleaves Arg-I-Xaa bonds in fibrinogen to form fibrin and release fibrinopeptides A and B; it is not inhibited by antithrombin III or hirudin. Venombin A EC 3.4.21.74; it cleaves Arg-I-Xaa bonds in fibrinogen to form fibrin and release fibrinopeptide A, but further reaction depends on species; it is a trypsin-like enzyme; example: precursor (zymogen) from *Bothrops atrox* (fer-de-lance); database code BATX\_BOTAT, 255 amino acids (28.16 kDa); six putative S-S bonds and two glycosylation sites.

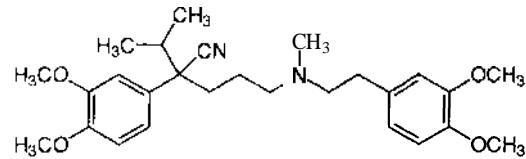

**venous** of, or relating to, a vein, or to the blood in the veins. ventilation the passage of air into and out of the respiratory tract, or other confined space.

**Ventolin** see sambutamol.

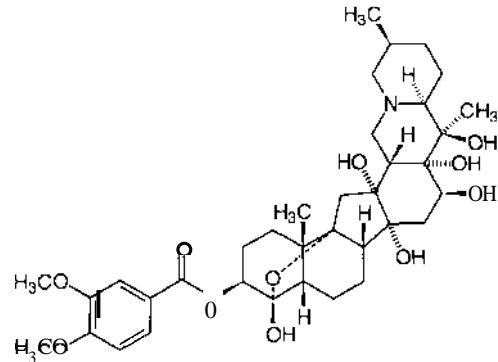

**Vent polymerase or (sometimes) Deep Vent polymerase** the proprietary name for thermostable DNA polymerases used as alternatives to *Taq* DNA polymerase in the polymerase chain reaction. These enzymes provide a higher fidelity than the *Taq* DNA polymerase, derived in part from their exonuclease activity. They derive from the archaeon *Thermococcus litoralis*, isolated from a submarine thermal vent, hence the enzyme's name.

**ventral** situated towards the belly surface of an animal.

**verapamil** a-3-{[2-(3,4-dimethoxyphenyl)ethyl]methylamino} propyl-3,4-dimethoxy-a-(1-methylethyl)benzenecacetonitrile; iproveratril; D365; a Ca<sup>2+</sup>-blocking agent used clinically in the treatment of cardiac disorders and in the laboratory to inhibit the movement of calcium ions across biological membranes. Its action is similar to that of nifedipine. Nifedipine binds to the dihydropyridine binding site of vascular voltage-operated calcium channels, but verapamil probably acts at another related site. See also 0600.

**veratridine** a toxic alkaloid, C<sub>36</sub>H<sub>51</sub>NO<sub>11</sub>, found in the seeds of a plant, *Schoenocaulon officinalis*, of the lily family; it also occurs in the rhizome of *Veratrum album*. It blocks the development of the action potential involved in axonal conduction, binding to the Na<sup>+</sup> channels and blocking them in the open configuration.

**v-erbA related protein** see COUP

**verbacose** the tetrasaccharide, O-a-D-galactopyranosyl-(1→6)-O- $\alpha$ -D-galactopyranosyl-(1→6)-O- $\alpha$ -D-glucopyranosyl-

## verdoperoxidase

vinblastine

( $1\rightarrow 2$ )- $\beta$ -D-fructofuranoside. It occurs in roots of the mullein, *Verbascum thapsus*.

verdoperoxidase *see* myeloperoxidase.

verification 1 establishment of the correctness of a theory, fact, etc. 2 a term used to describe the deacylation of misacylated tRNA molecules by the specific aminoacyl-tRNA synthase.

Verner-Morrison syndrome or pancreatic cholera or WDHA syndrome a disease syndrome of humans characterized by the following features, the first three of which are obligatory: tumour, severe watery diarrhoea, achlorhydria or hypochlorhydria, weight loss, and dehydration. The tumours (VIPomas) are mostly of pancreatic origin (some are neurogenic) and produce vasoactive intestinal polypeptide (VIP), the circulating levels of which are raised. [After John Victor Verner (1927- ), US physician and Ashton Byrom Morrison (1922- ), US pathologist.]

Veronal a proprietary name for barbital.

Versene a proprietary name for the tetrasodium salt of edetate. versican or large fibroblast proteoglycan or chondroitin sulfate proteoglycan core protein 2 a protein that plays a role in intercellular signalling. The N-terminal part is similar to a glial hyaluronate-binding protein; in the middle of the protein there are glucosaminoglycan attachment sites; the C-terminal part contains EGF-like repeats (*see* epidermal growth factor) and a lectin-like domain. Example (precursor) from human: database code PGCS\_HUMAN, 2409 amino acids (264.76 kDa).

vertical rotor a rotor for use in an ultracentrifuge. The wells holding the tubes are drilled parallel to the axis of rotation and at right angles to the lines of the centrifugal force.

very-low-density lipoprotein *abbr.:* VLDL; one of the classes of lipoproteins found in blood plasma in many animals (data normally relate to humans). VLDL is also known as pre- $\beta$ -lipoprotein because its electrophoretic mobility is slightly greater than that of low-density, or  $\beta$ -lipoprotein. VLDL particles have diameter 25–70 nm, solvent density for isolation ( $\text{g mL}^{-1}$ )  $<1.006$ , hydrated density ( $\text{g mL}^{-1}$ ) 0.97. Their approximate composition (% by weight) is 5–8% unesterified cholesterol, 11–14% esterified cholesterol, 20–23% phospholipid, 44–60% triacylglycerol, 4–11% protein. Their apolipoprotein composition (% by weight total apolipoprotein) is 36.9% B-100, 49.9% C-I + C-II + C-III, 13% E-II + E-III + E-IV. They are synthesized in liver and are the precursor of low-density lipoprotein.

very-low-density-lipoprotein receptor *abbr.:* VLDL receptor; a membrane protein that binds VLDL, accumulates in clathrin-coated pits, and internalizes VLDL. It has a large extracellular domain, a single transmembrane domain, and a small intracellular domain. Example from human: database code LDVR\_HUMAN, 873 amino acids (96.09 kDa); residues 1–27 are the signal, 28–797 the extracellular domain, and 820–873 the cytoplasmic domain.

vesicle a closed structure, found only in eukaryotic cells, that is completely surrounded by a unit membrane but, unlike a vacuole, contains material that is not (or is not known to be) in the liquid state.

Vg-1 *abbr. for* vegetal hemisphere glycoprotein 1.

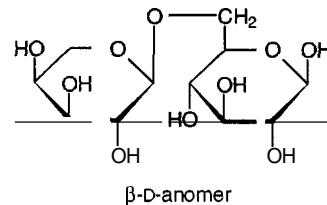

VHDL *abbr. for* very-high-density lipoprotein.

viability a measure of the capacity of a cell for metabolism and division. It is often estimated experimentally by determining the number of cells that exclude normally membrane-impermeant dyes, e.g. Trypan Blue.

Viagra a proprietary name for sildenafil; 5-[2-ethoxy-5-(4-methylpiperazin-1-yl)phenyl]-1-methyl-3-propyl-1,6-dihydro-7H-pyrazolo[4,3-d]pyrimidin-7-one; used clinically for the oral treatment of male erectile dysfunction. It selectively and potently inhibits a specific phosphodiesterase that hydrolyses cyclic GMP; this second messenger mediates the action of nitric oxide in normal erectile function, an action which is thus potentiated.

VIC *abbr. for* vasoactive intestinal contractor; *see* endothelin. vic- prefix (*in chemical nomenclature*) denoting the presence of vicinal (def. 2) substituents.

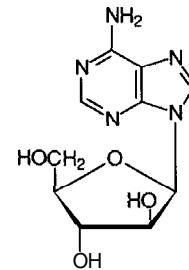

vicianose the disaccharide 6-O-a-L-arabinosyl-o-glucose, obtained from a glycoside in seeds of *Vicia angustifolia*.

vicillinpeptidohydrolase *see* legumain.

vicinal 1 adjacent, neighbouring. 2 (*in organic chemistry*) describing two (usually identical) atoms or groups attached one to each of two linked carbon atoms in a molecular structure. The presence of vicinal substituents is denoted by the prefix *vic-* attached to the name of the compound. *Compare* geminal. vicilin a major storage protein in seeds of *Pisum sativum* (pea); it comprises 124 amino acids,  $M_r$  170 000. Legumin-like and vicilin-like globulins are the main storage proteins of most angiosperms and gymnosperms.

vidarabine adenine arabinoside; 9-p-o-arabinofuranosyladenine; a purine nucleoside, a metabolite of hypoxanthine arabinoside, produced by *Streptomyces antibioticus*. Its triphosphate derivative inhibits viral DNA polymerase and may be incorporated into viral DNA; it also inhibits DNA synthesis.

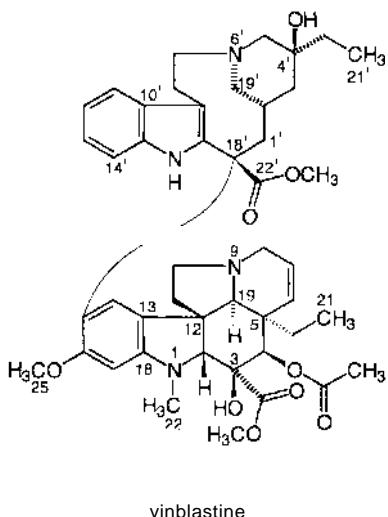

vigabatrin  $\gamma$ -vinyl- $\gamma$ -aminobutyric acid;  $\gamma$ -vinyl GABA; 4-amino-5-hexenoic acid; an irreversible inhibitor of the enzyme GABA transaminase (4-aminobutyrate transaminase), which metabolizes the neurotransmitter  $\gamma$ -amino-n-butryric acid.

Vigneaud *see du* Vigneaud.

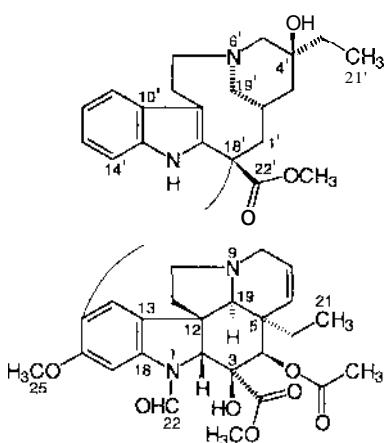

villin a  $\text{Ca}^{2+}$ -regulated actin-binding protein occurring in the microvilli of intestinal epithelial cells and kidney proximal tubule cells. Villin consists of a large core fragment, the N-terminal portion, and a small headpiece, the C-terminal portion; the headpiece binds F-actin (*see* actin) strongly in both the presence and absence of  $\text{Ca}^{2+}$ ; it is similar to gelsolin. Example from human: database code VILLHUMAN, 826 amino acids (92.46 kDa).

vimentin a protein found in class III intermediate filaments in mesenchymal and other nonepithelial cells and in the Z disk of skeletal and cardiac muscle cells. It is a phosphoprotein, phosphorylation being enhanced during cell division. Example from human: database code VIME\_HUMAN, 465 amino acids (53.49 kDa).

vinblastine a structurally complex alkaloid,  $C_{46}H_{55}N_{4}O_{19}$  obtained from *Vinca rosea*, that binds to spindle microtubules and arrests metaphase of mitosis. It is used as an antineoplastic agent.

vincristine an alkaloid, C<sub>46</sub>H<sub>56</sub>N<sub>4</sub>O<sub>10</sub>, obtained from *Vinca rosea* and with a structural relationship to vinblastine, that binds to spindle microtubules and arrests metaphase of mitosis. It is used as an antineoplastic agent.

vinculin a cytoskeletal protein associated with the cytoplasmic face of the focal adhesion plaques that anchor actin microfilaments to the plasma membrane and that attach a cell to the substratum. It associates with talin in binding integrins to the cytoskeleton. Vinculin is phosphorylated (on serines, threonines, and tyrosines) and acylated by myristic acid and/or palmitic acid. Vinculin and metavinculin are produced by alternative splicing of the same gene. Metavinculin differs from vinculin in having a 68-residue additional domain near the C terminus. Example from human: database code VINC\_HUMAN, 1065 amino acids (116.46 kDa).

vindoline the major alkaloid from *Vinca rosea*; C<sub>22</sub>H<sub>32</sub>N<sub>2</sub>O<sub>6</sub>. It is without physiological activity but constitutes a pentacyclic moiety of vinblastine and vincristine.

vinyl ether alk-*I*-enyl ether; a class of compounds characterized by a bond formed between a long-chain aldehyde and one (in the case of monoalk-*I*-enyl ethers) or two (for dialk-*I*-enyl ethers) of the hydroxy groups of the glycerol moiety of a glycerolipid; only the *sn*-*I* isomers occur naturally, and chains of

16 or 18 carbons are usual. Such glycerophospholipids are known as plasmalogens; ethanolamine glycerophospholipids characteristically contain larger amounts of plasmalogens than other classes, and heart tissue is rich in plasmalogens. *y*-vinyl GABA see vigabatrin.

viosamine 4-amino-4,6-dideoxy-D-glucose; a component of the lipopolysaccharide of some strains of *Escherichia coli*.

VIP abbr. for vasoactive intestinal polypeptide.

VIPoma a tumour producing vasoactive intestinal polypeptide (VIP). It is often associated with a watery diarrhoea and other pathological signs known as Verner-Morrison syndrome.

viral particle see virion.

viral RNA RNA that constitutes the genome of certain viruses - the RNA viruses. Examples are poliovirus, which has single-stranded RNA, and cytoplasmic polyhedrosis virus of the tussock moth, which has 10 double-stranded RNA molecules. All retroviruses contain RNA as the genome.

virino a name coined for a putative novel type of particulate, noncellular, submicroscopic, transmissible, pathogenic agent, as typified by the agent responsible for scrapie. The infective particle was believed to consist of a small nucleic-acid molecule covered with host-specified protein. See prion.

virion or viral particle the complete particle of a virus, found extracellularly and capable of surviving in crystalline form and of infecting a living cell. It comprises the nucleic-acid core and the protein capsid; the latter may be enclosed by an envelope in some viral families.

virogene see oncogene hypothesis.

viroid any member of a group of about 30 autonomously replicating plant pathogens. They consist of single-stranded circular RNA of about 350 nucleotides containing much self-complementarity. They have no genes, so do not express protein. It is assumed that the viroid RNA acts as its own template, subverting host cell enzymes to carry out the replication. The product consists of concatamers of daughter strands that undergo self-cleavage to form new viroid RNA genomes. It is likely that hammerhead structures (see ribozyme) are involved. An example is potato spindle tuber viroid (PSTV). This is similar to human hepatitis delta which is part viroid and part virus in that the mechanism of replication is like that of a viroid and part of the genome is homologous with PSTV.

virology the scientific study of viruses and the diseases caused by them. -virological adj.; virologist n.

viropexis the process by which virus particles are adsorbed onto the surface of a cell and then taken into the cytoplasm.

Virtanen. Artturi Ilmari (1895-1973), Finnish agricultural chemist; Nobel Laureate in Chemistry (1945) 'for his research and inventions in agricultural and nutrition chemistry, especially for his fodder preservation method'.

virulence the capacity of a microorganism or virus to cause disease in a host under certain conditions. -virulent adj.

virulent phage a bacteriophage that invariably lyses the bacterium it infects. Virulent phages have no alternative but to follow the lytic cycle.

virus a noncellular infective agent that is capable of reproducing only in an appropriate host cell. Viruses are typically smaller than bacteria, and can infect animal, plant, or bacterial cells (see bacteriophage); many are important agents of disease. The infective particle (virion) consists of a core of nucleic acid (either DNA or RNA) surrounded by a proteinaceous capsid and, in some cases, an outer envelope. A virus can interact with its host cell in several different ways. In a lytic interaction the cell's replicative and protein biosynthetic apparatus is directed by the viral genes to produce numerous progeny virions, which are released upon disintegration of the host cell (see lytic cycle). However, in a persistent infection, low levels of virus production may be sustained without destruction of the host cell. In a latent infection, the virus resides in a host cell without undergoing replication, although it may be provoked to enter the lytic phase by some stimulus. Oncogenic viruses, which include both DNA viruses and RNA viruses

(retroviruses) carry oncogenes and are potentially capable of transforming their host cells into tumour cells. Animal viruses have been divided into seven classes according to the nature of their genome and the mechanism of synthesis of messenger RNA (*see* Baltimore classification).

virusoids *see* satellite RNA.

visceral layer *see* serous membrane.

viscometer or viscosimeter an apparatus for measuring the viscosity or resistance to flow of a liquid.

viscosity symbol:  $\eta$ ; the resistance to flow of a fluid due to the sum of the effects of adhesion and cohesion. Consider a liquid between two parallel plates, one of which is moving in the  $x$  direction with a velocity  $v$ . The liquid is thought of as a number of layers, each of which slides along the adjacent layer; the frictional resistance between adjacent layers generates a velocity gradient in the  $y$  direction. The deformation of the liquid produced by the velocity gradient is known as shear (def. I). The frictional force,  $f$ , between the liquid layers is proportional to the area,  $A$ , of the layers and to the velocity gradient between them, such that  $f = \eta A(dv/dy)$ , where  $\eta$  is the coefficient of viscosity or simply the viscosity;  $f/A = F$ , the shear stress; and  $dv/dy = G$ , the shear gradient or shear rate. If  $\eta$  is independent of  $F$  or  $G$ , the fluid is a Newtonian fluid; if  $\eta$  is a function of  $F$  or  $G$ , the fluid is a non-Newtonian fluid.

visinin a calcium-binding protein specific to cone photoreceptors; a chicken isoform with homology to bovine recoverin has three  $\text{Ca}^{2+}$ -binding sites. Example from *Gallus gallus*: database code VISLCHICK, 191 amino acids (22.39 kDa).

visual cascade the sequence of reactions occurring after the absorption of a photon by a rhodopsin molecule. It eventually leads to a rapid fall in cyclic GMP levels, which closes  $\text{Na}^+$  channels in the membrane of the visual receptor and activates the nerve impulse in the optic nerve. The activated rhodopsin stimulates the G-protein transducin which initiates the signal-transduction cascade.

visual purple *see* rhodopsin.

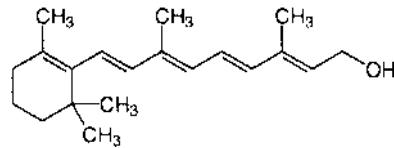

vitalism a doctrine stating that that the phenomena of biology are due to a vital principle distinct from physicochemical forces, and cannot be explained by the laws of physics and chemistry alone. The accidental discovery, in 1890, by the brothers Buchner that a cell-free extract of yeast could catalyse alcoholic fermentation did much to convince any lingering adherents that such a doctrine was untenable. Also important was Wohler's synthesis of urea (a natural product) from ammonium cyanate in 1828.

vitamer any of two or more chemically and metabolically related compounds that display qualitatively the same biological activity as a vitamin. For example, retinol, retinal, retinoic acid, 3,4-didehydroretinol, and various carotenes are all vitamers of vitamin A.

vitamin an organic substance that is distributed in foodstuffs (and sometimes in intestinal bacteria) in relatively minute amounts, is distinct from the main organic components of food (i.e. protein, carbohydrate, and fat), and is needed for the normal nutrition of the organism (or species) in question. Deficiency or absence of any particular vitamin causes a corresponding specific deficiency disease. Vitamins A, D, E, and K are the fat-soluble vitamins; vitamins B<sup>1</sup>, B<sub>2</sub>, B<sub>6</sub>, B<sub>12</sub>, and C, plus biotin, choline, folic acid, nicotinic acid, and pantothenic acid (*see* pantothenate), are the water-soluble vitamins.

vitamin A 1 a common name for retinol. 2 a generic name for any retinoid exhibiting qualitatively the biological activity of retinol. Included, in addition to retinol (relative activity 100) are: retinal (91); retinoic acid (>65); 3,4-didehydrominol (40); 3,4-didehydroretinol; and 3,4-didehydroretinoic acid (the activities relative to retinol being measured by the standardized growth test on vitamin A-deficient rats). Vitamin A is fat-soluble, and is present in various lipid-containing animal preparations, especially liver and dairy products. Vitamin A activity is displayed also by various carotenes; these act as provitamins, which are converted to retinol in the small intestine in most vertebrates.

The vitamin A of commerce was originally a preparation of, or extract from, fish-liver oils, which contain large amounts of retinol, principally as its palmitate; it is now largely derived chemically. Proper vitamin A nutrition is necessary for: (1) somatic function, including growth and differentiation, e.g. of epithelial structures and bone; (2) reproduction, including spermatogenesis, oogenesis, placental development, and embryonic growth; and (3) visual processes (*see* retinal, 3,4-didehydroretinol). Vitamin A deficiency signs include stunted growth, thickening of various membranes by keratinization, and, in the eye, night blindness, xerophthalmia, keratomalacia, and eventually complete blindness. In moderate excess, vitamin A is highly toxic.

vitamin A, an alternative name (not recommended) for retinol.

vitamin A<sub>2</sub> an alternative name (not recommended) for 3,4-didehydroretinol.

vitamin A acid or vitamin A<sub>1</sub> acid an alternative name (not recommended) for retinoic acid.

vitamin A<sub>2</sub> acid an alternative name (not recommended) for 3,4-didehydroretinoic acid.

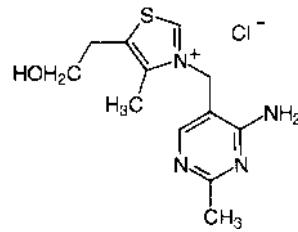

vitamin A alcohol or vitamin A<sub>1</sub> alcohol an alternative name (not recommended) for retinol.

vitamin A<sub>2</sub> alcohol an alternative name (not recommended) for 3,4-didehydroretinol.

vitamin A aldehyde or vitamin A<sub>1</sub> aldehyde an alternative name for (not recommended) retinal.

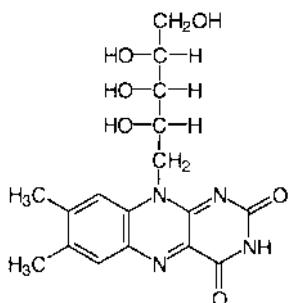

vitamin A<sub>2</sub> aldehyde an alternative name (not recommended) for 3,4-didehydroretinal.

vitamin 8, or thiamine or (sometimes) thiamin or (formerly) aneurin(e) 3-(4-amino-2-methylpyrimidin-5-ylmethyl)-5-(2-hydroxyethyl)-4-methylthiazolium chloride; a water-soluble vitamin, present in fresh vegetables and meats, especially liver. Deficiency in humans causes beriberi, signs of which include cardiopathy and neuropathy; in pigeons, a characteristic head-drop is an overt sign of deficiency. Its diphosphoric ester, thiamine diphosphate (abbr.: TPP), formerly known as cocarboxylase, is a coenzyme for oxidative decarboxylation and other enzymic reactions, including ones catalysed by pyruvate and oxo-glutarate dehydrogenases, pyruvate decarboxylase, and transketolase.

vitamin 8<sub>2</sub> or riboflavin 6,7-dimethyl-9-ribitylisoalloxazine; formerly also called lactoflavin, hepatoflavin, ovoflavin, uroflavin, vitamin G, vitamin H. A water-soluble vitamin, present in most foods but especially in milk and meat products. It is a component of the flavin nucleotide coenzymes (e.g. FAD, FMN). Isolated from milk and eggs by Kuhn and co-

workers in 1933 and chemically synthesized by them and others in 1935. Significant deficiency seldom occurs, but can cause inflammation of the tongue and lips and sores in the corners of the mouth.

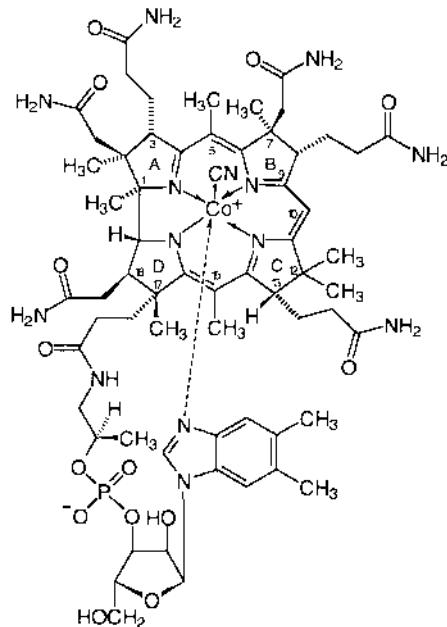

**vitamin B<sub>5</sub>** (*rarely*) an alternative name for pantothenic acid; see pantothenate.

**vitamin B<sub>6</sub>** or pyridoxine 2-methyl-3-hydroxy-4,5-bis(hydroxymethyl)pyridine; a water-soluble vitamin; pyridoxal and pyridoxamine also act as vitamers. It is present in many foods, including meats (largely as pyridoxal or pyridoxamine), and plant sources (largely as pyridoxine) such as cereals, lentils, nuts, and vegetables. Pyridoxal phosphate is a coenzyme for many enzyme reactions including those involving transamination, amino-acid decarboxylation, racemization, and modifications to amino-acid side chains. Deficiency is not a major problem and signs are difficult to produce.

**vitamin B<sub>12</sub>** or cobalamin or cobamide a water-soluble vitamin, of which there are several structurally related forms. All are characterized by possession of a corrin nucleus containing a cobalt atom. Four of the cobalt coordinate bonds are liganded by nitrogens of the four pyrrole rings found in the corrin nucleus; the fifth position is occupied by the ribonucleotide of 5,6-dimethylbenzimidazole, which is also linked via a 1-amino-2-propanol moiety to one of the pyrrole rings; the sixth position is variously occupied by a cyanide group (cyanocobalamin, the form in which the molecule was first isolated, the cyanide group having been introduced during extraction), or a methyl group (methylcobalamin, one of the forms in which the molecule acts as a coenzyme), or a 5'-deoxyadenosyl group (deoxyadenosylcobalamin, the other active coenzyme form). Vitamin B<sub>12</sub> is present only in foods of animal origin, especially liver, fish, and eggs. The coenzyme forms are needed for two classes of enzyme: members of the first class, exemplified by methylmalonyl-CoA mutase, require the deoxyadenosyl form; members of the second, exemplified by 5-methyltetrahydrofolate-homocysteine S-methyltransferase, (EC 2.1.1.13) require the methyl form (*see* 5-methyltetrahydrofolate). In normal individuals, deficiency rarely occurs, but is precipitated by lack of intrinsic factor, a protein secreted by gastric mucosa and required for efficient absorption of the vitamin. Lack of intrinsic factor leads to pernicious anemia, investigation of which first led to the discovery of cobalamin.

cyanocobalamin

**vitamin B<sub>12i</sub>** reductase *see* **cob(II)alamin** reductase.

**vitamin C** ascorbic acid; a water-soluble vitamin, and the first vitamin to be recognized. Awareness of the ability of fresh vegetables and fruit to prevent scurvy is attributed to the British physician James Lind (1716-94), who published *A Treatise on Scurvy* in 1757. The active compound was first isolated by A. Szent-Györgyi in 1928 as 'hexuronic acid', a strong reducing substance from rat adrenals and citrus fruits. This was shown four years later to be identical with the anti-scorbutic substance isolated by Zilva and associates. Vitamin C is widely distributed in vegetables and fruit, but easily destroyed by cooking. *See* ascorbic acid for structure. *See also* L-gulonolactone oxidase.

**vitamin D** the common and class name for any steroid that exhibits qualitatively the biological activity of calcidiol (= vitamin D<sub>2</sub>; *see below*); the antirachitic vitamin. All such compounds are fat-soluble substances structurally related to either the parent hydrocarbon, cholestan, or its 24-methyl derivative, ergostane, and all are 9,10-seco-sterols, i.e. 3-hydroxysteroids in which bond breakage has occurred between C-9 and C-10 in ring B of the steroid nucleus. Separately numbered variants of vitamin D, with their recommended trivial names in parentheses, are: vitamin D<sub>2</sub> or calciferol (ercalcidiol or ergocalciferol), the variant formed in plants by the action of UV light on the endogenous provitamin ergosterol and produced industrially by UV-irradiation of ergosterol isolated from yeast; vitamin D<sub>3</sub> (calcidiol or cholecalciferol), the variant occurring naturally in particularly high concentrations in the liver oils of certain fish, especially cod, halibut, or tunny, and produced non-enzymically in the skin of animals by the action of a UV component (230-313 nm) of sunlight on the provitamin 7-dehydrocholesterol; vitamin D<sub>4</sub> (22,23-dihydroercalcidiol or (24S)-methylcalcidiol or (*formerly*) 22,23-dihydroergocalciferol), the variant produced by irradiation of 22,23-dihydroergosterol; vitamin D<sub>5</sub> ((24S)-ethylcalcidiol); and vitamin D<sub>6</sub> ((22E)-(24R)-ethyl-22,23-dihydrocalcidiol). (Vitamin D<sub>t</sub>, a designation now obsolete, was found to be a mixture of ercalcidiol and lumisterol.) Of these variants, calcidiol (D<sub>1</sub>) and ercal-

## vitamin O binding protein

volkensin

ciol ( $D_2$ ) are the most significant. In addition, vitamin D activity is displayed by several unnumbered synthetic derivatives or isomers of calcidiol (or of ercalcidiol) and by the 25-hydroxylated and 1 $\alpha$ ,25-dihydroxylated metabolites calcidiol and calcitriol (or ercalcidiol and ercalcitriol). Calcidiol (or ercalcidiol) is formed in liver from calcidiol (or ercalcidiol) and converted in kidney to calcitriol (or ercalcitriol), the physiologically active form of vitamin D<sub>3</sub> (or D $2$ ). Vitamin D mediates the absorption of calcium and phosphate ions from the intestine and promotes the mineralization of bone. The vitamin D deficiency conditions of rickets (in children) and osteomalacia (in adults) may be treated by administration of the vitamin, commonly as D $2$ . Overdosage of vitamin D results in disturbances of calcium metabolism and ultimately leads to decalcification of bone. *See also* calcitriol. For structures see entries for individual compounds.

**vitamin D binding protein** abbr.: DBP; a multifunctional protein found in plasma, ascitic fluid, cerebrospinal fluid, and urine, and on the surface of many cell types. In plasma it carries the vitamin D sterols; it also prevents polymerization of actin by binding its monomers. DBP associates with membrane-bound immunoglobulin on the surface of B lymphocytes, and with IgG Fc receptor on the membranes of T lymphocytes. Example (precursor) from human: database code VTDB\_HUMAN, 474 amino acids (52.90 kDa).

**vitamin E a-tocopherol**; a fat-soluble vitamin considered to act primarily as an antioxidant. Other tocopherols (*see* tocopherol for structure) have vitamin E activity. Vitamin E is thought to prevent the formation of lipid autoxidation products, an action resulting from its ability to trap free radicals and thus to prevent the chain reaction leading to further peroxide formation. It is present in vegetable-seed oils, and also in meat, milk, and eggs. Deficiency occurs in practice only in pathological states in which absorption is affected, and can result in premature red cell death. A relative deficiency may occur when the intake of polyunsaturated fatty acids is high unless the diet is supplemented with a-tocopherol.

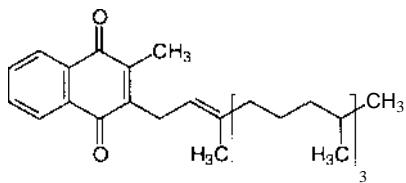

**vitamin F** (*formerly*) a collective term for essential fatty acids.

**vitamin G** an old name for riboflavin (i.e. vitamin 8 $\beta$ ).

**vitamin H 1** (*sometimes*) an alternative name for biotin. 2 an old name for riboflavin (i.e. vitamin 8 $\beta$ ).

**vitamin H**, (*sometimes*) an alternative name for p-aminobenzoic acid.

**vitamin K** 2-methyl-3-phytyl-1,4-naphthoquinone; phylloquinone; 3-phytylmenadione; vitamin K<sub>1</sub>; a fat-soluble vitamin required for the synthesis of prothrombin and certain other blood coagulation factors. The menaquinones (vitamins K<sub>2</sub>) are also active. Vitamin K is found in green leafy vegetables, meat, and milk. Deficiency is uncommon because it is produced by gut bacteria, but gut sterilization may trigger symptoms (decrease in plasma prothrombin) if intake is defective. Vitamin K acts as a cofactor in the post-translational formation of 4-carboxyglutamyl residues in certain proteins, e.g. blood coagulation factors VII, IX, X, and especially prothrombin, during which an epoxidase reaction occurs to convert vitamin K<sub>1</sub> to its epoxide form, which is converted back by a reductase. This reductase can be inhibited by warfarin, which thus reduces vitamin K<sub>1</sub> levels, thereby reducing prothrombin formation and so acting as an anticoagulant.

**vitamin-K-epoxide reductase** (warfarin-sensitive) EC 1.1.4.1; an enzyme that catalyses the formation of 2-methyl-3-phytyl-1,4-naphthoquinone, oxidized dithiothreitol, and H<sub>2</sub>O from 3-epoxy-2,3-dihydro-2-methyl-3-phytyl-1,4-naphthoquinone and 1,4-dithiothreitol.

**vitellogenin** the precursor protein of lipovitellin and phosphitin, a major egg-yolk protein synthesized in the liver of chickens and *Xenopus*. It has an M<sub>r</sub> of 135 000 and is split in the ovary into its constituent proteins. In *Xenopus*, two genes, for vitellogenin I and II, are spread over more than 21 kbp of DNA, their primary transcripts consisting of 6 kbp of pre-mRNA with 33 introns. Example from *Gallus gallus* (precursor): database code VIT2\_CHICK, 1850 amino acids (204.81 kDa). A related protein is found in *Drosophila melanogaster*. Example (precursor) from *D. melanogaster*: database code VIT1\_DROME, 439 amino acids (48.66 kDa).

**vitronectin** or serum spreading factor an adhesion protein, present in plasma and on the external surface of membranes of tissues, that promotes the adhesion of cells in tissue culture. The  $\alpha_v\beta_3$  integrin binds vitronectin, fibrinogen, laminin, von Willebrand factor, fibronectin, and thrombospondin. Example from human (precursor): database code VTNC\_HUMAN, 478 amino acids (54.31 kDa). Residues 1-19 are the signal, 20-478 vitronectin; residues 20-63 are somatomedin B (*see* somatomedin).

**VI symbol** for the valeryl group.

**VLA** a family of integrins all having the  $\beta_1$  subunit. They comprise VLA-1,  $\alpha_1\beta_1$  ( $\beta$  subunit also called VLA $\beta$ , glycoprotein IIa or gpIIa, CD29;  $\alpha$  subunit also called CD49a), which binds laminin (and collagen); VLA-2,  $\alpha_2\beta_1$  (a subunit also called gpla, CD49b), which binds collagen (and laminin); VLA-3,  $\alpha_3\beta_1$  (a subunit also called CD49c), which binds fibronectin, laminin, and collagen; VLA-4,  $\alpha_4\beta_1$  ( $\alpha$  subunit also called CD49d), which binds VCAM-1 and fibronectin; VLA-5 (*or* fibronectin receptor),  $\alpha_5\beta_1$  (CD4ge), which binds fibronectin; VLA-6 (*or* laminin receptor),  $\alpha_6\beta_1$  (CD49f), which binds laminin;  $\alpha_7\beta_1$ , which binds laminin;  $\alpha_8\beta_1$ , ligand doubtful; and  $\alpha_9\beta_1$  ( $\alpha$  subunit also called vitronectin receptor subunit, CD51), which binds fibronectin.

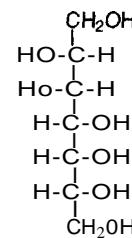

**VLDL** abbr. for very-low-density lipoprotein.

**VMA** abbr. for vanillylmandelic acid; *see* hydroxymethoxy-mandelate.

**VMS** an operating system implemented on DEC VAX computers.

**void volume** 1 (*in column chromatography*) the volume of the mobile phase, i.e. total bed volume of the column minus the volume occupied by the support particles. 2 (*in gel chromatography*) or (*sometimes*) exclusion volume the volume of the mobile phase passing through the gel required to elute a molecule that never entered the stationary phase.

**volemitol** D-glycero-D-talo-heptitol; a substance widely distributed in plants, fungi, and lichens. It is used as a sweetening agent.

**volkensin** a ricin-like toxic glycoprotein, purified from the roots of *Adenia volkensii*, a Kenyan shrub. It consists of two subunits, A (M<sub>r</sub> 29 000) and B (M<sub>r</sub> 36 000), linked by disulfide bonds.

**volt symbol:** V; the SI derived unit of electric potential or electromotive force. It is equal to the difference in electric potential between two points on a conductor carrying a constant current of one ampere when the power dissipated between the points is one watt.  $1\text{ V} = 1\text{ W A}^{-1} = 1\text{ J C}^{-1}$ . [After Alessandro Volta (1745-1827), Italian physicist.]

**voltage-gated ion channel** a channel in a cell membrane whose opening is governed by the membrane potential.

**voltmeter** *an old term for coulometer.*

**voltammetry** *an old term for coulometry.*

**voltammetry** an electroanalytical procedure for identifying and determining the concentrations of various ions in solution by studying the relation between a varied electric potential applied between two electrodes immersed in a test solution and the resultant faradaic current. It includes anodic stripping voltammetry and polarography. -voltammetric *adj.*; voltammetrically *adv.*

**volume of distribution symbol:**  $V_d$ ; the theoretical volume of fluid in which a specified dose of drug is distributed, based on measurement of the concentration of free drug (i.e. that not bound to plasma proteins) in plasma.  $V_d = Q/C_p$ , where Q is the amount of drug administered and  $C_p$  is the concentration in plasma.

**volutin granule** or metachromatic granule an electron-dense cytoplasmic inclusion found in various bacteria, yeasts, and other microorganisms. It exhibits metachromasia on staining with certain basic dyes, contains polymetaphosphate, and is believed to serve as a phosphate store. *See also* Babes-Ernst body.

**von Euler** 1 Hans von Euler, *see* Euler (def. I). 2 VIC Svante von Euler (1905-83), son of H. von Euler (*see* Euler (def. I)), Swedish neurophysiologist and pharmacologist notable for his recognition of the importance of norepinephrine as the main neurotransmitter in mammalian adrenergic neurons; Nobel Laureate in Physiology or Medicine (1970) jointly with J. Axelrod and B. Katz 'for their discoveries concerning the humoral transmitters in the nerve terminals and the mechanism of their storage, release and inactivation'.

**von Gierke's disease** *see* glycogen disease.

**von Hevesy** *see* Hevesy.

**von Laue** *see* Laue.

**von Willebrand factor abbr.:** vWF<sub>a</sub>; a blood protein involved in blood clotting. It performs two important hemostatic functions: it links specific platelet membrane receptors to collagen and possibly other components of subendothelial connective tissue, so mediating platelet adhesion to sites of vascular damage, and it binds to and stabilizes factor VIII (*see* blood coagu-

lation). Deficiency results in bleeding from skin due to failure of platelet adhesion, with a prolonged bleeding time, and also results in spontaneous bleeding into joints and soft tissues due to the secondary factor VIII deficiency caused by the instability of factor VIII. The primary translation product, synthesized by vascular endothelial cells and megakaryocytes, is a protein of 2813 amino acids (309.29 kDa): database code VWF\_HUMAN. Residues 1-22 are a signal peptide, 23-763 a peptide that is cleaved off and is known as von Willebrand antigen II, and the mature protein, residues 764-2813. Cysteine is the most abundant amino acid. Before the mature factor is secreted from cells of origin, many intermolecular disulfide bridges between vWF molecules are formed that lead to a complex that may vary in mass from dimers of about 500 kDa to species of more than 20 megadaltons. Inherited defects of vWF affect nearly 1% of the population, but most are not clinically significant. The majority of patients have a quantitative deficiency of vWF, with autosomal dominant inheritance and are known as type I. Type II variants have an abnormal vWF. In vWF deficiency (*abbr.:* vWD) type IIA intermediate and large complexes are absent. Mutations cluster near Tyr<sup>842</sup>-I\_Met<sup>843</sup>, a site that is sensitive to proteolysis. vWD type III is rare, and is a severe autosomal recessive disease characterized by virtual absence of vWF, in some cases known to be due to total or partial deletion of the vWF gene. Unactivated platelets bind vWF through gpIb-IX complex, deficiency of which leads to a bleeding disorder, Bernard-Soulier syndrome. After activation, platelets bind vWF through the integrin gpIIb-IIIa complex, which is defective in Glanzmann thrombasthenia, another bleeding disorder. [After Erik Adolph von Willebrand (1870-1949), Finnish physician.]

**VB proteinase** *see* glutamyl endopeptidase.

**vps34** or vacuolar sorting protein 34 a protein trafficking protein that is involved in the sorting and segregation of vacuoles. It is a homologue of 1-phosphatidylinositol3-kinase, having that enzymic activity, which may be the mechanism by which it acts. It is in turn activated by phosphorylation by a serine/threonine protein kinase, vps15. Example from *Saccharomyces cerevisiae*: database code VP34\_YEAST, 875 amino acids (100.92 kDa).

**VRE abbr.** for vancomycin-resistant *Enterococcus* (erstwhile *Streptococcus*). It is one of a number of drug-resistant pathogens (*compare* MRSA) found in hospital populations of bacteria. The resistance is due to an enzymic modification of the peptidoglycan precursor that is the target for vancomycin.

**v-yes** *see* YES.

# Ww

w symbol for 1 mass fraction. 2 work (alternative to W). 3 speed (alternative to u, v, or c). 4 (bold italic) velocity (alternative to v, u, or c).

W symbol for 1 watt. 2 a residue of the a-amino acid L-tryptophan (alternative to Trp). 3 a residue of an incompletely specified base in a nucleic-acid sequence that may be adenine or may be thymine (in DNA) or uracil (in RNA). 4 a residue of the minor nucleoside wyosine (alternative to V). 5 tungsten.

W symbol for 1 weight (alternative to G or P). 2 work (alternative to w). 3 radiant energy (alternative to Q). 4 writhing number.

W3 one abbr. for World Wide Web.

Waksman, Selman Abraham (1888-1973), Russian-born US soil microbiologist; Nobel Laureate in Physiology or Medicine (1952) 'for his discovery of streptomycin, the first antibiotic effective against tuberculosis'. See also Schatz.

Wald, George (1906-97) US physiologist; Nobel Laureate in Physiology or Medicine (1967) jointly with R. Granit and H. K. Hartline 'for their discoveries concerning the primary physiological and chemical visual processes in the eye'.

Walden inversion the inversion of the configuration at a chiral centre in a bimolecular nucleophilic substitution reaction. [After its discoverer, Paul Walden (1863-1957), Latvian chemist.]

Waldenström's macroglobulinemia a lymphoid tumour that arises from the most mature B lymphocytes and invariably produces IgM, which appear as a paraprotein. [After Jan Goesta Waldenström (1906- ), Swedish physician.]

wall effect 1 (in centrifugation) the collision of sedimenting molecules with the wall of the cell. This occurs because the centrifugal field is radial, so can be avoided by using sector-shaped cells. 2 (in chromatography) the curving and spreading of a zone as it migrates down a chromatographic column because of inhomogeneities in solvent flow near the wall of the column.

Warburg, Otto Heinrich (1883-1970), German physiologist and biochemist; Nobel Laureate in Physiology or Medicine (1931) 'for his discovery of the nature and mode of action of the respiratory enzyme'.

Warburg apparatus a sensitive, constant-volume respirometer for measuring gas exchange of cells, homogenates, or tissue slices. It consists of a small flask, with one or more side arms for the addition of reagents, and a centre well, connected to a U-tube manometer of about 1 mm<sup>2</sup> internal cross-section, fitted with a reservoir for manometer fluid. The vessel is immersed in a constant temperature bath and shaken continually to equilibrate the gas in the liquid phase, where the reaction is taking place, with the gas in the gas phase, where the reaction is being measured. It was used extensively for metabolic studies before the wide availability of radioactive tracers, but is now virtually obsolete.

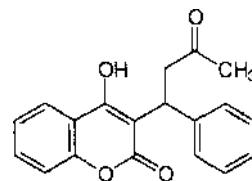

Warburg-Dickens-Horecker pathway or Warburg-Dickens pathway an alternative name for hexose monophosphate pathway.

Warburg effect 1 the relative overproduction of lactate that occurs in many tumours. 2 the inhibitory effect of high oxygen concentrations on photosynthesis.

Warburg's enzyme an alternative name for old yellow enzyme; see yellow enzyme.

warfarin 3-(a-phenyl- $\beta$ -acetylethyl)-4-hydroxycoumarin; 1-(4'-hydroxy-3'-coumarin-3'-yl)-1-phenylbutan-3-one; an anti-coagulant and rodenticide. Its action derives from its ability to inhibit the reductase that converts the epoxide form of vitamin K<sub>1</sub> to its reduced form, which is a cofactor for the production of the 4-carboxyglutamyl residues essential for the activity of, among other proteins, the blood coagulation factors II (i.e. prothrombin), VII, IX, and X. [From the name of the patentees,

Wisconsin Alumni Research Foundation, + coumarin.] See also vitamin-K-epoxide reductase (warfarin-sensitive).

Waring blender the proprietary name for a blender used in the preparation of tissue homogenates. It consists of a hydrodynamically designed vessel (of tetrafoil cross-section) in the bottom of which a specially shaped blade rotates at high speed. [After the manufacturers, Waring Products Corporation.]

washing soda see soda.

Wasserman reaction a form of complement-fixation test for human blood and cerebrospinal fluid, widely used in the past to detect syphilitic infection, although false positive reactions were often given by yaws, leprosy, paroxysmal hemoglobinuria, and even malarial infection. The antigen on which the test was based proved to be cardiolipin. [After August von Wassermann (1866-1925), German bacteriologist.]

water balance (of an organism) the water intake (as a liquid, the water in food, and water of oxidation) less the water output (water in urine, feces, or other excreta, water expended in saturating respiration air, water lost through the integument).

waterfall sequence an alternative name for cascade sequence.

water regain (of an ion-exchange resin) for cationic resins,

the weight of water taken up by 1 g dry resin in the hydrogen form; for anionic resins, the weight of water taken up by 1 g

dry resin in the chloride form.

water-soluble B an old name for a fraction rich in water-soluble vitamins prepared from egg yolk.

Watson, James Dewey (1928- ), US biologist; Nobel Laureate in Physiology or Medicine (1962) jointly with F. H. C. Crick and M. H. F. Wilkins 'for their discoveries concerning the molecular structure of nuclear [*sic!*] acids and its significance for information transfer in living material'. See also Franklin.

Watson-Crick model of DNA a model that envisages one form of DNA (deoxyribonucleic acid) as consisting essentially of two antiparallel helical polynucleotide chains coiled around the same axis to form a double helix. The deoxyribose-phosphate backbones lie on the outside of the helix and the purine and pyrimidine bases lie approximately at right angles to the axis on the inside of the helix. The diameter of the helix is 2.0 nm and there is a residue on each chain every 0.34 nm in the z direction. The angle between each residue on the same chain is 36°, so that the structure repeats after 10 residues (3.4 nm) on each chain. The two chains are held together by hydrogen bonds between pairs of bases, each member of the pair belonging to a different polynucleotide chain. Adenine is always paired with thymine and guanine with cytosine. The two chains are therefore complementary. Watson and Crick's paper, published in *Nature* in 1953, also contained a prescient statement: 'It has not escaped our notice that the specific pairing we have postulated immediately suggests a possible copying mechanism for the genetic material.' The structure of DNA proposed by Watson and Crick has stood the test of time. It is difficult to exaggerate the importance of the short paper. To quote from L. Stryer's *Biochemistry* (fourth edi-

watt

tion), 'This brilliant accomplishment ranks as one of the most significant in the history of biology because it led the way to an understanding of gene function in molecular terms.' See also double helix. [After J. D. Watson and F. H. C. Crick.]

watt symbol: W; the SI derived unit of power or radiant flux; it is the power dissipated when one joule is expended in one second; i.e.  $1\text{ W} = 1\text{ J s}^{-1}$ . [After James Watt (1736-1819), British engineer.]

wave function symbol:  $\psi$  or  $\Psi$  or  $\Phi$  or  $\phi$ ; the amplitude of the wave associated with a particle, e.g. an electron, as obtained from the Schrödinger wave equation. The square of the value of  $\psi$  at any point is proportional to the probability of finding the particle at that point.

wavelength symbol:  $\lambda$ ; the distance between successive points of equal phase of a wave. Wavelength is equal to the velocity of the wave motion divided by its frequency. For electromagnetic radiation,  $\lambda = c_0/\nu$ , where  $c_0$  is the velocity of light in *vacuo* and  $\nu$  the frequency of the radiation.

wavenumber or repetency for an electromagnetic radiation (e.g. light), the reciprocal of the wavelength; i.e. the number of waves in unit distance. Compare kayser.

wax 1 any lipid fraction from living organisms or from crude petroleum that is a plastic substance, hard when cold, easily moulded when warm, and insoluble in water. 2 any fatty-acid ester of a long-chain monohydroxy alcohol.

wax synthase see long-chain-alcohol O-fatty-acyltransferase.

Wb symbol for weber.

WBC or wbc or w.b.c. abbr. for white blood cell(s); see leukocyte.

WDHA syndrome abbr. for watery diarrhoea, hypokalemia, plus achlorhydria syndrome; i.e. Verner-Morrison syndrome.

weak interactions noncovalent interactions between molecules and parts of molecules, including charge-charge interactions, those involving permanent dipoles, van der Waals forces, and hydrogen bonds. They are particularly important in protein and nucleic-acid structure.

weber symbol: Wb; the SI derived unit of magnetic flux. It is equal to the flux that, linking a circuit of one turn, produces in it an emf of one volt as it is reduced to zero at a uniform rate in one second; i.e.  $1\text{ Wb} = 1\text{ V s}$ . [After Wilhelm Eduard Weber (1804-91), German physicist.]

**wee1** a gene in *Schizosaccharomyces pombe* encoding a protein kinase (EC 2.7.1.112) that can phosphorylate tyrosine and serine/threonine residues. In yeast it phosphorylates a single tyrosine of cdc2; in the human it phosphorylates both a tyrosine and a threonine of the equivalent protein. It has conserved catalytic domains of the other (serine/threonine) type of protein kinase. The protein acts as a negative regulator for entry to mitosis; it closely resembles the corresponding human protein kinase. Example from *S. pombe*: database code WEELSCHPO, 877 amino acids (96.26 kDa). See also *cdc* gene.

weight average molecular mass old name for mass average molar mass; see average molar mass.

Weigle reactivation see W reactivation.

**Wernicke-Korsakoff syndrome** a combination of Wernicke's disease (gliosis and capillary proliferation leading to ocular manifestations and polyneuropathy) and Korsakoff's psychosis (difficulty in recording and retaining new impressions). Wernicke's disease is due to vitamin B<sub>1</sub> deficiency, and manifests particularly in patients with a genetic abnormality in transketolase resulting in its reduced affinity for thiamine diphosphate. In such patients, even mild B<sub>1</sub> deficiency, as often occurs in alcoholics, may produce symptoms. [After Karl Wernicke (1848-1905), German alienist, and Sergei Sergeyevich Korsakoff (1854-1900), Russian neurologist.]

Western blotting a technique for blotting proteins onto nitrocellulose, nylon, or other transfer membrane after they have been resolved by gel electrophoresis. The proteins can then be detected by one of several methods, including autoradiography (if labelled), or through binding to fluorescently la-

belled, 125I-labelled, or enzyme-linked (see ELISA) antibody, lectin, or other specific binding agent. The name derives by extension through the cardinal points from Southern blotting, the first such blotting technique, with a capital initial by similar extension.

Whitaker plot a plot that, ideally, gives a linear correlation between the logarithm of the relative molecular mass of a macromolecule and the ratio of the elution volume,  $V$ , to the void volume,  $V_o$ , when the macromolecules in solution are passed through a suitable gel filtration column; i.e.  $\log M_r = V/V_o$ . [After John Robert Whitaker (1929- ), US biochemist.]

white adipose tissue or white fat a highly specialized tissue developed particularly in mammals and birds to store fat to supply energy to the whole animal. The cells contain a single large droplet of fat that, in the nourished state, fills most of the cell. The nucleus is somewhat flattened and is in the narrow band of cytoplasm around the cell's periphery. Adipose tissue is found in many parts of the body but tends to be concentrated under the skin (subcutaneous) and around internal organs (heart and kidney). The stored fat consists principally of triacylglycerols. Compare brown adipose tissue.

white blood cell see leukocyte.

white fat see white adipose tissue.

white muscle pale, skeletal, usually involuntary muscle that is relatively deficient in myoglobin and cytochromes. Compare red muscle.

Wieland, Heinrich Otto (1877-1957), German chemist; Nobel Laureate in Chemistry (1927) 'for his investigations of the constitution of the bile acids and related substances'.

wild-type the phenotype that is characteristic of most of the members of a species occurring naturally and contrasting with the phenotype of a mutant. Compare auxotroph.

Wilkins, Maurice Hugh Frederick (1916- ), New Zealand-born British biophysicist; Nobel Laureate in Physiology or Medicine (1962) jointly with F. H. C. Crick and J. D. Watson 'for their discoveries concerning the molecular structure of nuclear [sic] acids and its significance for information transfer in living material'. See also Franklin.

Wilkinson, (Sir) Geoffrey (1921-96), British inorganic chemist noted for his extensive studies of transition-metal complexes with organic compounds and for the discovery of rhodium complexes now used as catalysts in industrial hydrogenation reactions; Nobel Laureate in Chemistry (1973), the prize being shared with E. O. Fischer 'for their pioneering work, performed independently, on the chemistry of the organometallic, so called sandwich compounds'.

Willstatter, Richard Martin (1872-1942), German organic chemist; Nobel Laureate in Chemistry (1915) 'for his researches on plant pigments, especially chlorophyll'.

Wilms's tumour or nephroblastoma a malignancy in human infants (incidence 1 in 10000) associated with protein WT33. [After Marx Wilms (1867-1918), German pathologist.]

Wilson, Charles Thomson Rees (1869-1959), British physicist; Nobel Laureate in Physics (1927) 'for his method of making the paths of electrically charged particles visible by condensation of vapour' [prize shared with A. H. Compton].

Wilson's disease or hepatolenticular degeneration a rare autosomal recessively inherited disease characterized by degenerative changes in the brain, particularly in the basal ganglia, and cirrhosis of the liver. There are excessive deposits of copper in the liver, brain, cornea, and kidney; the serum copper is usually low and there is a ceruloplasmin deficiency. Patients may be effectively treated with British antilewisite (dimercaprol) or other chelating agents. [After (Samuel Alexander) Kinnier Wilson (1878-1937), US-born British neurologist.]

Wilzbach method a method for the random labelling of a compound with tritium by exposing it to isotopically pure tritium gas in a sealed container for several weeks. The exchange is promoted by the radiation.

## Windaus

Windaus. Adolf Otto Reinbold (1876-1959), German chemist; Nobel Laureate in Chemistry (1928) 'for the services rendered through his research into the constitution of the sterols and their connection with the vitamins'.

winding angle (of a DNA double helix) the angle of rotation between successive base pairs.

winding number the number of double-helical turns in a closed-circular DNA measured relative to a surface on which the DNA helix lies. *See also* supercoil.

windowless counter a counter for radioactive (or X-ray) ionization in which the sample (or source) is not separated from the detector by a membrane or 'window'.

wingless a gene in *Drosophila melanogaster* that codes for a protein in the WNT family, probably a growth factor that acts on neighbouring cells to regulate the *enailagene*. Database code WNTG\_DROME, 468 amino acids (51.93 kDa). A gene for a homologous protein is present in the brachiopod *Terebratulina retusa*.

WNT family a protein family that includes several proteins (e.g. WNT-2 from human and mouse) that are probably signalling molecules in tissue development. They are encoded by *WNT* genes. The *WNT-1* gene is closely homologous to *wingless*. Example, WNT-2 (precursor) from human: database code WNT2\_HVMAN, 360 amino acids (40.37 kDa).

wobble base the third base in the anticodon of transfer RNA (5' end). It can bind to one of several possible bases at the 3' end of the codon in mRNA. *See also* wobble hypothesis.

wobble hypothesis a hypothesis that in translation during protein synthesis a less strict specificity in the base pairing of the 5' base of the anticodon of transfer RNA (tRNA) allows it to make alternative hydrogen-bonding with the third base of the codon of messenger RNA (mRNA) beyond the usual G-C and A-V pairings. Specifically, anticodon V may recognize A or G and anticodon G may recognize C or V; then A no longer has a unique meaning at this position, since the V that recognizes it also recognizes G; the same applies to the codon V, which can also be recognized by G. In practice, although the hypothesis has been fully supported by experiment, VGG and AVG are the only examples of the first type of wobble, and no examples of the second type are known. The presence of bases other than V, A, G, or C at the anticodon 5' position also contributes to more general pairing at this position than would be the case if G-C, A-V specificity were strictly observed. Thus, bases such as wyoine, queosine, and inosine may be present (I always substitutes for A) with less strict pairing constraints. The degeneracy at the third codon position is consistent with the fact that about 40 different tRNA molecules interact with the 61 possible sense codons. Not all of the different tRNA structures have been determined, so it is not possible to state with certainty the structure of all the anticodons, although possible structures can be predicted. In the case of tRNA<sub>Ala</sub> the structure of the two tRNAs is known.

Wolfgram proteolipid protein one of the three principal classes of central nervous system myelin protein, extractable by chloroform:methanol (2:1, v/v) and consisting of three main fractions of 235, 54, and 62 kDa. *Compare* Folch-Lees protein. [After F. Wolfgram, who first discovered it.]

Wood. Harland Goff (1907-91), VS biochemist distinguished particularly for work on fixation of CO<sub>2</sub>; the reaction between pyruvate and CO<sub>2</sub> became known eponymously as the Wood-Werkman reaction. For 46 years he worked in the Department of Biochemistry at Case Western Reserve University. Described by Hanson as an 'American original' born and raised in the American heartland.

Woodward. Robert Burns (1917-79), VS organic chemist; Nobel Laureate in Chemistry (1965) 'for his outstanding achievements in the art of organic synthesis'.

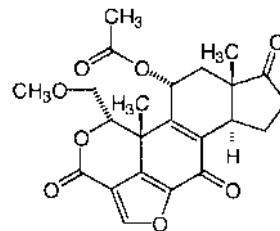

work symbol: *W* or *w*; the transfer of energy expressed as the product of a force, *F*, and the distance, *s*, through which its

## wyosine

point of application moves in the direction of the force; i.e.  $W = \int F ds$ . The SI unit of work is the joule. The manifestation of work in productive form usually involves transduction by a mechanical device of the action of a force through a distance. A relationship between the work done on (or by) a system of constant mass, the heat it gains (or loses), and the change in the internal energy of the system is provided by the first law of thermodynamics (*see* thermodynamics).

World Wide Web *abbr.*: WWW; or W3; an Internet facility for viewing and recovering archival material including an extensive range of biochemical and molecular biological data. Examples are included in Appendix B and Appendix C. *See also* Appendix D.

wortmannin or MS-54 or KY 12420 a potent inhibitor of smooth muscle myosin light chain kinase and protein kinase C produced by the fungal strain *Talaromyces wortmanni* KY12420. It is also a potent selective, cell-permeable and irreversible inhibitor of '-phosphatidylinositol3-kinase.

W reactivation or Weigle reactivation or (formerly) VV reactivation the phenomenon whereby the survival of VV-irradiated bacteriophage is higher in a VV-irradiated host than in an unirradiated host. [After Jean Jacques Weigle (1901-68), who discovered it and described it in 1953.]

writhing number symbol: *W*; an index of the superhelical coiling of DNA, termed writhe. The writhing number and the twist number between them determine the linking number (*L*). The writhing number does not have a precise quantitative definition, but represents the degree of supercoiling. A decrease in *L* involves some decrease in supercoiling, and an increase in *L* an increase in supercoiling. *See also* supercoil.

wt or wt. *abbr.* for weight.

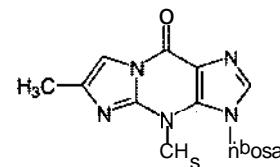

WT33 a protein that is related to early growth response proteins and is associated with Wilms' tumour; it is probably a tumour suppressor. Other mutations are associated with Denys-Drash syndrome. It has alternative splice sites, a zinc finger, and four motifs. Example from human: database code WTLHVMAN, 449 amino acids (49.13 kDa).

w/v or wtlvol. *abbr.* for weight per unit volume (of a solution or mixture).

w/w or wtlwt *abbr.* for weight per unit weight (of a solution or mixture).

WWW *abbr.* for World Wide Web.

wyosine symbol: *W* or *Y*; any of a number of modified forms of guanosine present in the anticodon loop of some species of transfer RNA. All are based on the structure N2-(2-methyl-etheno)guanosine, and carry varying side chains on the five-carbon imidazole ring. The structure of one such compound is shown. *See also* minor nucleoside.

# Xx

**X** symbol for 1 amount-of-substance fraction (i.e. mole fraction) or number fraction for condensed phases. Compare *y*, 2 a Cartesian space coordinate, complementary to *y* and *z*.

**X** 1 symbol for a residue of an unknown, unspecified, or (specified) unusual α-amino acid (alternative to Xaa). b a residue of the ribonucleoside **xanthosine** (alternative to Xao). 2 abbr. for X Windows.

**X** symbol for (electric) reactance.

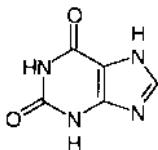

**X-53<sup>A</sup>** an alternative name for **lasalocid**.

**Xaa** symbol for a residue of an unknown, unspecified, or (specified) unusual α-amino acid (alternative to X).

**Xan** symbol for a residue of the purine base **xanthine**.

**xanthan gum** a capsular complex heteropolysaccharide formed by strains of the pseudomonad bacterium *Xanthomonas campestris* and believed to promote adhesion of the organism to its plant host. It is widely used in the cosmetic, food, and other industries as a crystallization inhibitor, emulsifier, gelling agent, etc.

**xanthine** symbol: Xan; 2,6-dihydroxypurine; 2,6-dioxopurine; 3,7-dihydro-1H-purine-2,6-dione; a purine formed in the metabolic breakdown of guanine but not present in nucleic acids. Compare **hypoxanthine**. See also **allopurinol**.

**xanthine oxidase** EC 1.1.3.22; the recommended name for hypoxanthine oxidase; systematic name: xanthine:oxygen oxidoreductase; a flavoprotein (FAD) enzyme containing iron and molybdenum, abundant in milk and liver, that catalyses the oxidation of **xanthine** to urate and superoxide (or hydrogen peroxide) and also the oxidation of hypoxanthine to xanthine. It was formerly known as **Shardinger** enzyme. The enzyme can exist in two forms. One, known as xanthine dehydrogenase, has NAD as coenzyme, and urate and NADH as products. The other form, xanthine oxidase, reacts with dioxygen and has urate and H<sub>2</sub>O<sub>2</sub> as products. The dehydrogenase is converted reversibly to the oxidase by oxidation of sulphydryl groups or irreversibly by proteolysis. Example from *Rattus norvegicus*: database code XDH\_RAT, 1330 amino acids (146.11 kDa). Example from human (homodimer): database code XDH\_HUMAN, 1338 amino acids (147.76 kDa).

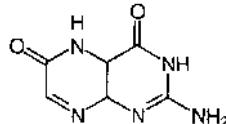

**xanthinuria** the excretion of excessive amounts of xanthine in the urine. It is sometimes due to a hereditary disease in which there is a gross deficiency of **xanthine oxidase** activity in the tissues.

**xantho+** or (before a vowel) **xanth+** comb. form denoting yellow.

**xanthophyll** any **carotenoid** in which one or more oxygenated functions are present in the molecule.

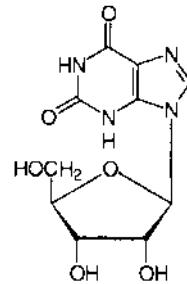

**xanthoproteic test** a qualitative test for protein in which a yellow colour (or precipitate from solution) is formed on addition of conc. nitric acid; the yellow colour turns orange when made alkaline.

**xanthopterin** a yellow pterin pigment of insect wings, e.g. of the common sulfur butterfly. Compare **leukopterin**.

xanthopterin

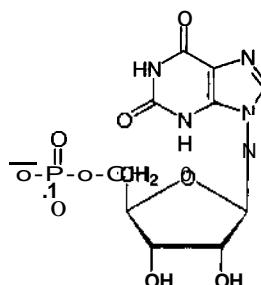

**xanthosine** symbol: X or Xao; xanthine riboside; 9-p-o-ribofuranosylxanthine; a nucleoside formed by the deamination of guanosine.

**xanthosine monophosphate** abbr.: XMP; an alternative name for any xanthosine phosphate, but in particular for xanthosine 5'-phosphate, especially when its distinction from xanthosine (5')-diphosphate and xanthosine (5')-triphosphate requires emphasis.

**xanthosine phosphate** xanthosine monophosphate (abbr.: XMP); any phosphoric monoester or diester of xanthosine. Of the three possible monoesters - the 2'-phosphate, the 3'-phosphate, and the 5'-phosphate - and the two possible diesters - the 2',3'-phosphate and the 3',5'-phosphate - only **xanthosine 5'-phosphate** is known to occur naturally (the locant being omitted if no ambiguity may arise).

**xanthosine 5'-phosphate or 5'-xanthyllic acid or 5'-phosphoxanthosine or 5'-O-phosphonoxanthosine** symbol: Xao5'P; alternative recommended names for xanthosine monophosphate (abbr.: XMP); xanthosine 5'--(dihydrogen phosphate); xanthine (mono)ribonucleotide. (The locant is commonly omitted if there is no ambiguity as to the position of phosphorylation.) It is an intermediate in the biosynthesis of guanosine 5'-phosphate, 5'-guanylic acid, GMP. XMP is formed from inosine 5'-phosphate, 5'-inosinic acid, by an NAD<sup>+</sup>-dependent dehydrogenase on the pathway for synthesis of guanine nucleotides; a glutamine-requiring amidotransferase reaction (catalysed by **GMP synthase**) then converts XMP to GMP.

## xanthyllic acid

xanthyllic acid *the trivial name for any phosphoric monoester of xanthosine. The position of the phosphoric residue on the ribose moiety of a given ester may be specified by a prefixed locant (see xanthosine phosphate). However, 5'-xanthyllic acid is the ester commonly denoted, its locant usually being omitted if no ambiguity may arise. 5'-Xanthyllic acid is also an alternative recommended name for xanthosine 5'-phosphate.*

Xao symbol for a residue of the ribonucleoside xanthosine (alternative to X).

Xao<sup>5'</sup>P symbol for xanthosine 5'-phosphate.

Xao<sup>5'</sup>PP symbol for xanthosine 5'-diphosphate (alternative to ppX).

Xao<sup>5'</sup>PPP symbol for xanthosine 5'-triphosphate (alternative to PPPX).

X cell see X-V-Z cell theory.

X chromosome a sex chromosome. It is often found paired in the homogametic sex, which in many species is the female, and single in the heterogametic sex, in many species the male. The X chromosome carries a large number of genes which control many aspects of development and function. A mutant gene which is so carried is called X linked. Since males possess only one X chromosome an abnormal gene that it carries cannot be paired with a normal allele; the male is then said to be hemizygous for that particular mutant gene. The female in whom both members of a pair of X-linked genes are identical is said to be homozygous for that gene; if the members of a gene pair are dissimilar the woman is called a heterozygote or carrier for the abnormal allele. One X chromosome is inactivated during early embryonic development so that individuals do not have a double dose of genes on the X chromosome. Since the descendants of each cell retain the same inactivated X chromosome, a proportion of cells have the paternal X chromosome in an inactive state while in the other cells the maternal X chromosome is active. Hence the female who is heterozygous for an abnormal gene will have two types of cells, one with the normal and one with the mutant gene. She is said to be a mosaic. Compare Y chromosome. See also sex determination.

X-chromosome inactivation inactivation in females of one of the two X chromosomes during early embryonic development; this phenomenon occurs randomly in all cells of the embryo. Thus, the cells in a female are mosaic in respect to which of the X chromosomes is functional – that from the father or the mother. See also X chromosome.

XDP abbr. for xanthosine (5')-diphosphate.

Xe symbol for xenon.

xenin a 25-residue peptide isolated from human gastric mucosa. The six C-terminal amino acids are identical to those of the octapeptide, xenopsin, present in the skin of amphibians. It stimulates exocrine pancreatic secretion, rising in plasma after a meal. Example from human: database code XENI\_HUMAN, 25 amino acids (2.97 kDa).

xenite a subsidiary organism in a synxenic culture.

xeno+ or (before a vowel) xen+ comb. form indicating something strange or foreign.

xenobiochemistry the biochemistry of organic compounds foreign to the organism.

xenobiotic 1 any substance that does not occur naturally but interacts with the metabolism of any organism. 2 of, or relating to, substances that are foreign to living systems.

xenobiotic-response element abbr.: XRE; a DNA-regulatory sequence that binds transcription factors responsible for activation of gene expression for enzymes that detoxify a number of xenobiotics, including halogenated and other aryl hydrocarbons. See also Ah.

xenogeneic or xenogenic originating in a different species, especially of a tissue transplant. See also xenograft.

xenograft a tissue graft between individuals of different species.

*Xenopus laevis* the South African clawed toad, the oocytes and embryos of which have been extensively exploited in molecular genetics and vertebrate embryology. The large oocytes

## X-ray diffraction

were used for pioneering studies of the microinjection of nucleic acids directly into the nucleus, a technique now extended to other species.

xenotope an antigenic epitope that is foreign to a particular animal.

xenotype a class or group of related xenotypes; i.e. an antigenic epitope that is foreign to a particular animal.

xeroderma pigmentosum an autosomal recessive hereditary skin disease of humans in which homozygotes show a marked tendency to develop skin cancers following exposure to sunlight. It is due to a reduced ability to excise UV-induced cyclobutane pyrimidine dimers from DNA.

xerophthalmia a condition in which there is progressive drying and wrinkling of the conjunctiva of the eye. One cause is vitamin A deficiency.

X-gal abbr. for 5-bromo-4-chloro-3-indolyl-fJ-o-galactoside, a colourless substrate that is hydrolysed by fJ-galactosidase to a blue product. It is used with cloning vectors containing part of the lacZ gene to select recombinants in molecular cloning: the peptide produced by the lacZ fragment complements the defective fJ-galactosidase enzyme in host cells. Insertion of foreign DNA into the vector inactivates the lacZ gene, so host cells containing recombinant plasmids will grow as white colonies on medium containing X-gal, whereas host cells containing 'empty' vectors will have a functional fJ-galactosidase and thus produce blue colonies.

xi symbol: ξ (lower case) or Ξ (upper case); the fourteenth letter of the Greek alphabet. For uses see Appendix A.

*Xiphophorus* a genus of fish, that includes the South American minnow, some species of which have been much used for the study of inherited characteristics involved in carcinogenesis. Crossing of certain species, e.g. backcrossing *X. maculatus* (platyfish) with *X. helleri* (swordtail: recurrent parent) leads to spontaneous development of melanoma.

Xis protein or excisionase the product of the xis gene in lambda phage; database code VXIS\_LAMBD, 72 amino acids (8.60 kDa). It plays an essential role in the excision step of release of phage DNA from prophage. See also integrase.

XMP abbr. for xanthosine monophosphate; i.e. xanthosine (5')-phosphate.

xotch a transmembrane protein in *Xenopus* that is similar in sequence, and presumably in role, to the product of notch. It is uniformly expressed in early embryos. It contains 36 EGF-like domains and three notch-type repeats. Example from *Xenopus laevis*: database code NOTC\_XENLA, 2524 amino acids (275.12 kDa).

X-Pro dipeptidase EC 3.4.13.9; other names: proline dipeptidase; imidodipeptidase; prolidase; peptidase D; y-peptidase; an enzyme that catalyses the hydrolysis of Xaa-i-Pro dipeptides; it also acts on aminoacyl-hydroxyproline analogues, but has no action on Pro-J-Pro. It requires manganese. Example from human: database code PEPD\_HUMAN, 492 amino acids (54.19 kDa).

XPS abbr. for X-ray photoelectron spectroscopy; see photoelectron spectroscopy.

X-ray crystallography the study of the geometric forms of crystals by X-ray diffraction. Myoglobin was the first protein for which the structure was solved by X-ray crystallography.

X-ray diffraction a method that uses the diffraction pattern obtained by passing X-rays through crystals, or other regular molecular arrays, to measure interatomic distances and to determine the three-dimensional arrangement of atoms (or molecules) in the structure studied. For the pattern to be sharp, the wavelength of the radiation used must be shorter than the regular spacing between the elements of the structure. X-rays typically have wavelengths of only a few tenths of a nanometre, making them suitable for biological samples. X-ray diffraction is used extensively in the determination of structures of proteins and nucleic acids and many other natural products (an early landmark was, together with chemical evidence, the determination of the structure of penicillin). In order to re-

## X-ray photoelectron spectroscopy

solve the phase differences, much use has been made of isomorphous replacement with heavy metal atoms in these structural studies.

**X-ray photoelectron spectroscopy abbr.: XPS; see photo-electron spectroscopy.**

**X-rays or (sometimes, esp. US) x-rays or (formerly) rontgen rays** electromagnetic radiation emitted by atoms during extranuclear loss of energy of incident radiation (e.g. high-energy electrons, gamma radiation) or by atoms of certain radionuclides during transformation by electron capture. X-rays have wavelengths in the range 1 pm–10 nm (frequencies 3 PHz–3 EHz). This range lies above that of gamma radiation and overlaps the wavelengths of the far ultraviolet. Characteristic X-rays have specific wavelengths of a particular nuclide or target element. *See also bremsstrahlung, synchrotron.*

**XRE abbr. for xenobiotic-response element.**

**XTP abbr. for xanthosine (5')-triphosphate.**

**Xul symbol** for a residue (or sometimes a molecule) of the ketopentose xylulose.

**X Windows** a graphical interface, often simply called X, for UNIX and VMS computers. Many molecular graphical and other programs (including ACeDB) use X.

**xyl+ a variant (sometimes before a vowel) of xylo+.**

**Xyl symbol** for a residue (or sometimes a molecule) of the aldopentose xylose.

**xylan** any of a group of homopolysaccharides of xylose, consisting mainly of P-1A-linked xylopyranose units with various substituent groups, that occur in the cell walls of higher plants, and in some marine algae. Xylans form the major glycans of the hemicellulose component of the fibrous parts of plants.

**xylaric acid** the aldaric acid derived from xylose.

**xy/E** a gene in *Escherichia coli* that encodes a xylose transport protein. A 12-transmembrane-domain protein, it functions as an H<sup>+</sup>-xylose symporter. The gene is induced by xylose. Protein product: database code XYLE\_ECOLI, 491 amino acids (53.55 kDa). *See also sugar transporter.*

**xylem** the vascular tissue that conducts water and mineral salts from the roots to the aerial parts of a plant and provides it with mechanical support.

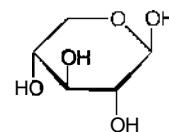

**xylo+ or (sometimes before a vowel) xyl+ comb. form indicating the trivial name for the aldopentose xylose.**

**xy/o- prefix (in chemical nomenclature)** indicating a particular configuration of a set of three contiguous >CHOH groups, as in the acyclic form of D- or L-xylose. *See monosaccharide.*

**xylose symbol:** Xyl; **xylo-pentose;** a constituent of plant polysaccharides (see xylan); the naturally occurring enantiomer is

## X-Y-Z-cell theory

always D-xylose. The metabolism of xylose in the human is restricted, and most is excreted unchanged in the urine. In clinical chemistry this forms the rationale for the xylose absorption test, the most widely used test of carbohydrate absorption.

poD-pyranose form

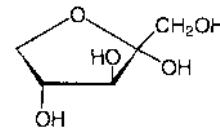

**xylose isomerase EC 5.3.1.5; systematic name: D-xylose ketol-isomerase;** an enzyme that catalyses the reaction:

magnesium ions are a cofactor. Example from *Streptomyces olivochromogenes*: database code NRL\_3XIA, 377 amino acids (41.90 kDa); 3-D structure known; it is a beta-barrel protein.

**xylose-1-phosphate uridylyltransferase** see UTP-xylose-1-phosphate uridylyltransferase.

**xylulose symbol:** Xul; *the trivial name for the ketopentose threo-2-pentulose; D-xylulose is the naturally occurring enantiomer.*

a-o-xylulose

**D-xylulose 5-phosphate** the 5-phosphate ester of D-xylulose and a component of the pentose phosphate pathway. It is formed from D-ribulose 5-phosphate by ribulose-phosphate 3-epimerase (EC 5.1.3.1); D-xylulose 5-phosphate then reacts with D-ribose 5-phosphate, catalysed by transketolase, to give glyceraldehyde 3-phosphate and sedoheptulose 7-phosphate.

**X-Y-Z-cell theory** a theory describing immunocyte maturation in which the first committed immunocyte, the X cell, is transformed by antigen into a memory cell, the Y cell, in the primary response, and is further stimulated in the secondary response to become an antibody producer, the Z cell.

# Vy

y symbol for yocto+ (SI prefix denoting  $10^{-24}$  times).

y symbol for 1 amount-of-substance fraction (Le. mole fraction) or number fraction for gases. Compare x, 2 a Cartesian space coordinate, complementary to x and z.

V symbol for 1 yotta+ (SI prefix denoting  $10^{24}$  times). 2 a residue of the a-amino acid L-tyrosine (alternative to Tyr). 3 a residue of an incompletely specified base in a nucleic-acid sequence that may be either cytosine or thymine. 4 a residue of an unspecified pyrimidine nucleoside (alternative to Pyd). 5 a residue of the minor nucleoside wyo sine (alternative to W). 6 yield. 7 yttrium.

Y symbol for admittance (reciprocal of impedance).

VAC abbr. for yeast artificial chromosome.

Valow, Rosalyn Sussman (1921– ), US physicist; Nobel Laureate in Physiology or Medicine (1977) 'for the development of radioimmunoassays of peptide hormones' [prize shared with R. Guillemin and A. V. Schally].

Vb symbol for ytterbium.

V cell see X-V-Z-cell.

Y chromosome a sex chromosome found only in the heterogametic sex and usually different in size from the X chromosome. In many animals it carries the testis-determining factor that triggers male embryonic development.

yeast any of a group of unicellular fungi that reproduce asexually - by budding or fission - and sexually - by the production of ascospores. Yeast cells may occur singly or in short chains, and some species produce a mycelium. The term 'yeast' is often used to mean members of the genus *Saccharomyces*, e.g. *S. cerevisiae*, which is an example of a budding yeast, or *Schizosaccharomyces pombe*, which is an example of a fission yeast.

yeast artificial chromosome abbr.: YAC; a specialized cloning vector that contains a centromere, an autonomously replicating sequence (ARS), a pair of telomeres, selectable marker genes, and the fragment of DNA to be cloned. Usually, genomic DNA is digested to produce fragments containing the genes, which are separated by pulsed field gel electrophoresis; the large fragments are then ligated into YACs. They are capable of propagation in yeasts, where they function as 'artificial chromosomes', being efficiently replicated. YACs are essential in large mapping projects, such as the Human Genome Project (see HUGO), as they are stable and can carry vast DNA inserts of 100 to 1000 kbp.

yeast cloning any of a number of methods of cloning using yeast as the host; cloning in yeasts and other microbial eukaryotes has a number of advantages. Expression of eukaryote genes in these organisms is subject to eukaryotic regulatory systems, and the products undergo post-translational modification in contrast to when they are expressed in prokaryotes. Thus, yeast clones are often used for the expression of glycoproteins.

yeast eluate factor a former term for vitamin B<sub>6</sub>.

yeast filtrate factor a former term for pantothenic acid. See pantothenate.

yeast nucleic acid a former term for ribonucleic acid.

yeast two-hybrid system a system that exploits two hybrid proteins, one containing a protein, X, fused to the GAL4 DNA-binding domain, and the other containing a different protein, Y, fused to the GAL4 activation domain. Plasmids encoding each of the hybrid proteins are introduced together into yeast, which leads to the expression of both hybrids. The system is used to test whether protein Y binds to protein X, for example in investigating the role of newly discovered proteins. If the proteins do bind, the resulting complex will be

bound to the upstream activation sequence for the yeast *GAL* genes by the GAL4 DNA-binding domain, and the presence of the GAL4 activation domain will lead to transcriptional activation of the reporter gene, i.e. p-galactosidase. The system has the advantage over immunoprecipitation that if Y binds to X, the gene encoding it is already available as a clone. The hybrid containing X is referred to as the bait.

yellow enzyme 1 old yellow enzyme, EC 1.6.99.1; NADPH dehydrogenase; a flavoprotein (FMN in yeast, FAD in plants). 2 new yellow enzyme an alternative name for D-amino-acid oxidase; see amino-acid oxidase.

yellow marrow see bone marrow.

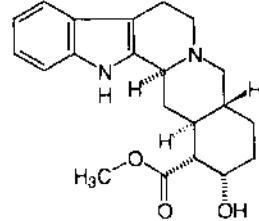

YESv-yes is the oncogene of the Yamaguchi sarcoma virus, and has a cellular counterpart, c-yes, the product of which is a member of the *src* family of non-receptor tyrosine kinases, having a myristylation site, and SH2, SH3 and tyrosine kinase domains. Example, p61 from *Gallus gallus*: database code YES\_CHICK, 541 amino acids (60.79 kDa).

yield symbol: Y; a ratio expressing the efficiency of a mass conversion process. The yield coefficient is defined as the amount of cell mass or product formed related to the consumed substrate or to the intracellular ATP production.

yin-yang hypothesis (of biological control) a concept of biological regulation based on the opposing actions of certain cyclic nucleotides. It arises from the observation that hormones or other biologically active substances that promote the cellular accumulation of cyclic GMP produce cellular responses that are antagonistic to ones occurring when the concentration of cyclic AMP is increased in the same tissues or cells. Hence cyclic GMP and cyclic AMP may have opposing or antagonistic regulatory influences in certain biological systems, somewhat analogous to the oriental concept of yin and yang symbolizing a dualism between opposing natural forces.

yocto+ symbol: y; SI prefix denoting  $10^{-24}$  times.

yoohimbine a complex indole alkaloid, C<sub>21</sub>H<sub>26</sub>N<sub>2</sub>O<sub>3</sub>, with  $\alpha_2$ -adrenoceptor antagonist activity. It is produced by *Corynanthe johimbe* and *Rauvolfia serpentina*.

Vop abbr. for *Yersinia* outer protein; any of a number of proteins, known as virulence proteins, originally found on the surface of Gram-negative bacteria of the genus *Yersinia*; they are now known to be characteristic of proteins pathogenic to plants, that are secreted by bacteria of genera as diverse as *Pseudomonas*, *Xanthomonas*, and *Erwinia*. They are also produced by animal pathogens such as *Shigella flexneri*, *Salmonella typhimurium*, and *Escherichia coli*. They are secreted by the type III system. Unlike other secreted proteins they lack a signal sequence.

yotta+ symbol: Y; SI prefix denoting  $10^{24}$  times.

Vphantis method an alternative name for meniscus depletion method (sedimentation equilibrium).

# Zz

**z symbol** for zepto+ (SI prefix denoting  $10^{-21}$  times).

**z symbol** for I charge number of an ion. 2 a Cartesian space coordinate, complementary to x and y.

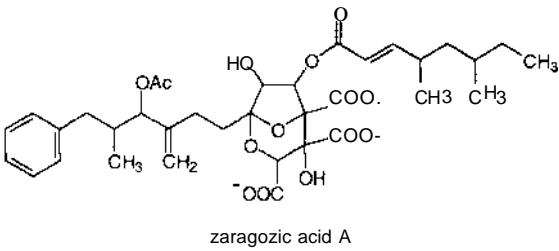

**Zsymbol** for 1 zetta+ (SI prefix denoting  $10^{21}$  times). 2 a residue of either of the a-amino acids L-glutamic acid or L-glutamine when the state of amidation is uncertain (alternative to Glx). It may also be used to represent a residue of any other substance, such as 4-carboxy-L-glutamic acid (as alternative to Gla) or 5-oxo-L-proline (as alternative to Glp), that yields glutamic acid on acid hydrolysis of peptides. 3 the **benzyloxycarbonyl** group (alternative to Cbz).

**Z symbol** for 1 proton number. 2 impedance.

**(Z)-prefix** (in chemical nomenclature) denoting a geometric isomer in which the highest priority substituent groups, determined according to the Cahn-Ingold-Prelog rules (see sequence rule), are located on the same side of a double bond. See also ElZconvention.

**Zantac** see ranitidine.

**zaragozic acid** any of a family of closely related fungal metabolites that are potent inhibitors of squalene synthase.

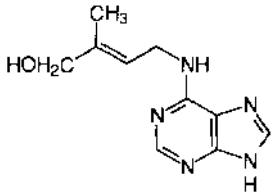

**Z-average relative molecular mass** see average relative molecular mass.

**Z cell** see X-Y-Z cell theory.

**Z disk** or **Z line** a platelike region of a muscle **sarcomere** to which the plus ends of actin filaments are attached. It is seen as a dark transverse line in micrographs.

**Z-DNA** abbr. for Z form of DNA.

**zeatin** *trans*-zeatin; (E)-2-methyl-4-(1H-purin-6-ylamino)-2-but-en-I-ol; a plant hormone of the **cytokinin** class. Its derivative, *trans*-zeatin riboside (*N'*-(*trans*-4-hydroxy-3-methyl-*cis*-2-but-en-I-yl)adenosine) is also a cytokinin. The *cis* form is a rare component in some RNA structures.

**t,am,-zeatin-producing protein** an isopentenyl transferase (dimethylallyl transferase) of sub-subclass EC 2.5.1.-. It introduces the isopentenyl moiety (2-methylbut-2-en-I-ol group) into zeatin. Example from *Burkholderia solanacearum* (*Pseudomonas solanacearum*): database code IPT\_BURSO, 238 amino acids (26.41 kDa).

**zebrafish** *Brachydanio rerio*; a small, highly fertile species of characinoid teleost fish with a shiny blue body and four longitudinal yellowish stripes along its sides. It is much used in

studies on the molecular biology of differentiation and development in metazoan animals.

**Zeeman effect** the splitting of a single line in a spectrum, indicative of the degeneration of the excited state of a particular chromophore, into two or more components of slightly different wavelengths brought about by the application of an external magnetic field. [After Pieter Zeeman (1865-1943), Dutch physicist.]

**zein** the principal storage protein of maize (corn) seeds. It is relatively deficient in the essential amino acids lysine and tryptophan, and tryptophan deficiency can occur in human populations dependent on maize as the major protein source. The zein genes are clustered. Example, an  $\alpha$  zein from maize: database code ZEAW\_MAIZE, 261 amino acids (28.43 kDa)

**zeolite** any of a family of porous, naturally occurring (or processed) alkali metal- or alkaline earth-aluminium silicates that show ion-exchange properties. They may be used for water softening or as molecular sieves. -zeolitic adj.

**zepto+** symbol: z; SI prefix denoting  $10^{-21}$  times.

**zero-order kinetics** kinetics shown by a zero-order reaction.

**zero-order reaction** a chemical reaction whose velocity is independent of the concentration of one or more of the reactants. See order of reaction.

**zeroth law of thermodynamics** see thermodynamics. laws of. **zervamicin** see peptaibolophil.

**zeta** symbol:  $\zeta$  (lower case) or Z (upper case); the sixth letter of the Greek alphabet. For uses see Appendix A.

**zeta potential** symbol:  $\zeta$ ; the potential at the surface of shear of a charged particle; for macromolecular ions it is the potential at the surface of the hydrodynamic particles formed by such ions.

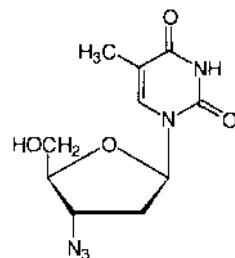

**zeta protein** an alternative name for cellular fibronectin.

**zetta+** symbol: Z; SI prefix denoting  $10^{21}$  times.

**zeugmatography** a technique in which the addition of carefully controlled inhomogeneous magnetic fields enables measurements of nuclear magnetic resonance (NMR) to be made at selected regions of heterogeneous samples and hence the formation of two-dimensional maps of the distribution of almost any property measurable by NMR.

**Z form of DNA** abbr. Z-DNA or DNA-Z; a form of DNA consisting of a left-handed double helix in which the pyrimidine residues are always in the anti orientation and the purine residues in the syn. So-called because of the zig-zag appearance of its conformation. See also Aform (def. I), Bform, Cform.

**zidovudine** 3'-azido-3'-deoxythymidine (abbr.: AZT); an analogue of thymidine, the phosphorylated form of which is an inhibitor of reverse transcriptase in retroviruses; it also terminates DNA synthesis. Zidovudine undergoes phosphorylation in human T cells to a nucleoside 5'-triphosphate, which competes with thymidine triphosphate (TTP) and serves as a chain-terminating inhibitor of HIV reverse transcriptase. It is used clinically to treat patients with HIV infection and AIDS. Proprietary name: Retrovir.

## Zimm-erother viscometer

Zimm-Crothers viscometer a modified Couette viscometer in which the inner cylinder is a self-centring float containing a steel pellet. The inner cylinder is caused to rotate by an external rotating magnetic field, the speed of rotation being dependent, *inter alia*, on the viscosity of the fluid. The instrument only measures the viscosity of a sample relative to a standard.

Zimmermann reaction the reaction of m-nitrobenzene in strongly alkaline solution with the methylene group at position 16 in 17-ketosteroids to give a purple colour with an absorption maximum at 520 nm. It may be used to estimate such steroids.

Zimm plot a graphical double extrapolation used to analyse most macromolecular light-scattering data. Measurements are made of  $KcI R_O$  at various concentrations as a function of the scattering angle,  $2\theta$ , where  $K$  is an optical constant,  $c$  is the concentration, and  $R_O$  is the Rayleigh ratio. A series of plots of  $KcI R_O$  against  $(\sin^2 \theta + K'c)$  are made, where  $K'$  is an arbitrary constant chosen to provide a convenient spread. The data are then extrapolated separately to  $c = 0$  and  $\theta = 0$ . The intersection of the two extrapolated curves yields the relative molecular mass.

**zinc symbol** Zn; a metal of group 12 of the IUPAC periodic table; relative atomic mass 65.38; atomic number 30. The principal ore is zincblende, ZnS. Its oxidation state is Zn(II). Zinc oxide is used as an antiseptic. Naturally occurring nuclides include (relative abundance follows each)  $^{64}\text{Zn}$  (48%),  $^{66}\text{Zn}$  (28%),  $^{68}\text{Zn}$  (18%). Radionuclides include zinc-52, zinc-65, and zinc-72. Dietary deficiency in the rat is manifested by retarded growth, alopecia, and lesions in the skin, esophagus, and cornea. Deficiency is rare in normal individuals, but can manifest itself in alcoholics and in patients with renal disease or malabsorption.  $\text{Zn}^{2+}$  is an essential cofactor for many enzymes. Recent work suggests zinc is bactericidal.

zinc-62 the artificial radioactive nuclide  $^{62}\text{Zn}$ ; it emits a positron ( $\beta^+$  particle) (0.66 MeV), and  $\gamma$ -radiation of four energies (0.041, 0.25, 0.51, and 0.60 MeV). It has a half-life of 9.26 h.

zinc-65 the artificial radioactive nuclide  $^{65}\text{Zn}$ ; it emits a positron ( $\beta^+$  particle) (0.325 MeV) and  $\gamma$ -radiation (1.12 MeV). It has a half-life of 244.1 days.

zinc-72 the artificial radioactive nuclide  $^{72}\text{Zn}$ ; it emits an electron ( $\beta^-$  particle) (0.3 MeV) and  $\gamma$ -radiation of three energies (0.016, 0.145, and 0.192 MeV). It has a half-life of 1.938 days.

zinc finger a polypeptide motif present in many DNA-binding proteins and having the consensus sequence

-CX2-4CX3FXsLX2HX3H-.

The motif takes its name from its zinc-binding site, which forms a finger-like loop in the peptide, also described as the Cys21His2 finger, the Cys and His residues coordinating a zinc ion. Zinc fingers are most notably present in transcription factors (e.g. TFIIIA and SPI), which have several repeats of the motif; they are required for binding of the transcription factor to DNA. See also Appendix E.

**ZIP abbr.** for the leucine zipper domain. See also bZIP.

**Z line** another name for Zdisk.

**Zn symbol** zinc.

**Zollinger-Ellison syndrome** a disease syndrome caused by excessive secretion of gastrin, either from (type 1) G-cell hyperplasia in the antrum of the stomach, or from (type 2) a benign or malignant pancreatic islet tumour (gastrinoma). The manifestations include multiple peptic ulcers, or peptic ulcers in unusual sites, with a marked tendency to bleeding, often associated with hyperparathyroidism. [After Robert M. Zollinger (1903– ) and Edwin H. Ellison (1918–70).]

**zona adherens** see desmosome.

**zona fasciculata** see adrenal gland.

**zona glomerulosa** see adrenal gland.

**zonal centrifugation** an alternative name for density-gradient centrifugation.

**zymase**

**zonal centrifuge** a centrifuge designed to allow large-scale and continuous fractionation by density-gradient centrifugation.

**zonal rotor** any centrifuge rotor of high capacity used preparatively in a zonal centrifuge.

**zona occludens** an alternative name for tight junction.

**zona pellucida sperm-binding protein abbr.**: ZP; any of several sulfated transmembrane glycoproteins (ZPI, ZP2, ZP3) that together form the zona pellucida of the oocyte. ZP3 functions as a sperm receptor. Example ZP3a from *Sus scrofa*: database code ZPB\_PIG, 536 amino acids (59.33 kDa).

**zona reticularis** see adrenal gland.

**zone electrophoresis** a method of electrophoresis in which the protein (or other) solution is placed at the starting position as a thin band or spot in an inert supporting medium (paper, starch gel, polyacrylamide gel, etc.), containing buffer solution. An electric potential is then applied to the supporting medium, causing the proteins (or other substances) to migrate to give distinct bands or zones. These may be located *in situ* by staining, light absorption, etc., or by analysis after elution of discrete pieces of the supporting medium.

**zone precipitation** a technique in which protein is precipitated as a zone in a gel-filtration column by eluting with a gradient of a protein-precipitating agent. See gel-permeation chromatography.

**zone spreading** the broadening of a zone in electrophoresis or chromatography due to eddy currents or other disturbances in the supporting medium.

**zoo blot** a method for detecting conservation of DNA sequence during evolution. A segment of DNA being investigated is used as a probe to hybridize against a series of DNA samples from various species, and hence establish whether the DNA sequence has been conserved during evolution.

**zoonosis (pl. zoonoses)** any disease that can be transmitted to humans from other animals in natural circumstances.

**zooplankton** see plankton.

**zootoxin** any poisonous substance formed by animal cells.

**Zovirax** a proprietary name for acyclovir.

**Zr symbol** for zirconium.

**Z scheme** a term sometimes applied to two-system photosynthetic light reactions, utilizing both photosystems I and II. It is descriptive of the mode of photosynthesis used by higher plants and algae, and by cyanobacteria. The way in which it is normally plotted, with redox potential (on the ordinate) against time, shows there is a sudden jump on excitation by a photon of a reaction centre, followed by a slow decline through electron transport components, and gives a (horizontal) Z-like appearance, hence the name.

**zuotin** a nuclear Z-DNA-binding protein of *Saccharomyces cerevisiae*. Example from yeast: database code ZUOI YEAST, 433 amino acids (49.02 kDa).

**zwischenferment** an obsolete term for an enzyme-coenzyme complex of which glucose-6-phosphate dehydrogenase is the apoenzyme.

**Zwittergent** the proprietary name for any of a group of zwitterionic detergents containing a betaine and a sulfonate group; such molecules retain their amphoteric (zwitterionic) properties over a very wide range of pH. The formula is n-alkyl *N,N*-dimethyl-3-ammonio-1-propanesulfonate. In Zwittergent 3-08, alkyl is octyl (CMC 330 mM); 3-10, decyl (aggregation number 41, CMC 25–40 mM); 3-12, dodecyl (aggregation number 55, CMC 2–4 mM); 3-14, tetradecyl (aggregation number 83, CMC 0.1–0.4 mM); 3-16, hexadecyl (aggregation number 155, CMC 0.01–0.06 mM).

**zwitterion** an alternative name for dipolar ion.

**zwitterionic buffer** a buffer solution whose acid or base component is a zwitterion (i.e. dipolar ion). The term is used especially of solutions of Good buffer substances and newer equivalents.

**zygote** any fertilized ovum before it has undergone cleavage. -zygotic ad.

**zygotene** the second phase of prophase I in meiosis.

**zymase** the name originally given to the heat-labile, nondif-

**zymogen**

fusible fraction of a crude extract of brewers' yeast that, with the addition of the heat-stable, diffusible fraction (i.e. **co-zymase**), would enable the alcoholic fermentation of glucose to occur in a cell-free system. It was later shown to consist of a mixture of enzymes, including those of the **glycolytic pathway**.

**zymogen or proenzyme or (formerly) proferment** the inactive precursor of an enzyme, often convertible to the enzyme by partial proteolysis. The term is applied especially to catalytically inactive forms of pancreatic enzymes such as trypsinogen, chymotrypsinogen, proelastase, and procarboxypeptidase; these are cleaved to remove a peptide to produce the active enzyme after their secretion from granules (**zymogen granules**) in the acinar cells of the pancreas.

**zymogen granule** a membrane-bound, cytoplasmic **secretory granule** visible by light microscopy. Zymogen granules are formed in the Golgi apparatus of enzyme-secreting cells and serve to store a **zymogen**. The term is used especially of a secretory granule containing the proenzyme of a digestive enzyme.

**zymogram** 1 any record of a **zone electrophoresis** separation in which enzymes in a sample have been separated and their posi-

**zyxin**

tions, and relative amounts, revealed by an **activity stain**. 2 any table showing the results of carbohydrate-fermentation tests carried out in the process of identifying a microorganism.

**zymohexase** an obsolete name for **fructose bisphosphate aldolase**.  
**zymology** the science dealing with fermentations. -**zymological** adj.; **zymologist** n.

**zymosan** a crude preparation of yeast cell walls, consisting chiefly of polysaccharide, that activates the alternative pathway of the complement system in the presence of properdin.

**zymosterol** cholesta-8,24-dien-3p-ol; a sterol present in yeasts e.g. *Candida albicans*, *Saccharomyces cerevisiae*.

**zymurgy** the branch of chemistry dealing with the applications of fermentation processes, especially to brewing and wine-making.

**zyxin** a protein component of cell substratum and cell-cell adherens junctions. It is a component of adhesion plaques and the termini of stress fibres near the point of association with the cytoplasmic face of the adhesive membrane and interacts with a-actinin. Example from *Gallus gallus*: database code ZYX\_CHICK, 542 amino acids (58.53 kDa).

# Appendix A

## The Greek alphabet and Greek characters used as symbols

### The Greek alphabet

Name	Capital letter	Lower-case letter	English transliteration
alpha	A	α	a
beta	B	β	b
gamma	γ	γ	g
delta	Δ	δ	d
epsilon	Ε	ε	e
zeta	Z	ζ	z
eta	Η	η	ē ore
theta	Θ	θ	th
iota	I		
kappa	K	κ	k
lambda	Λ	λ	l
mu	M	μ	m
nu	N	ν	n
xi	Ξ	ξ	x
omicron	O	ο	o
pi	Π	π	P
rho	R	ρ	r
sigma	Σ	σ or ζ (at end of word)	s
tau	T	τ	
upsilon	υ	υ	u
phi	Φ	ϕ	ph
chi	χ	χ	kh
psi	Ψ	ψ	ps
omega	Ω	ω	ō oro

### Single-character symbols

- α (or α) 1 a heavy chain of immunoglobulin A. 2 maximal agonist effect. 3 alpha particle.  
α (or a) 1 angle of optical rotation (aob. is used for observed rotation and *raj* for specific optical rotation or specific op-

tical rotatory power; am is used for molar optical rotatory power). 2 absorptance. 3 (linear) napierian absorption coefficient. 4 Bunsen coefficient. 5 partition coefficient. 6 plane angle. 7 (*in organic chemical nomenclature*) a locant for a substituent on the first atom from the atom carrying the principal function in an acyclic structure or in a side chain attached to a cyclic structure. 8 an anomeric configuration (of a sugar molecule or residue; *see anomeric*). 9 winding number (of a helical duplex DNA molecule).

β (or β) beta particle ( $\beta^-$  is used for an electron and  $\beta^+$  for a positron).

β (or β) 1 buffer value. 2 pressure coefficient. 3 plane angle. 4 (*in organic chemical nomenclature*) a locant for a substituent on the second atom from the atom carrying the principal function in an acyclic structure or in a side chain attached to a cyclic structure. 5 an anomeric configuration (of a sugar molecule or residue; *see anomeric*). 6 number of secondary turns (in an unconstrained helical duplex DNA molecule).

y (or y) a heavy chain of immunoglobulin G. 2 a photon of gamma radiation. 3 (*obsolete*) microgram ( $\mu\text{g}$  now used).

y (or y) activity coefficient ( $Y_e$  is used for activity coefficient when expressed on a concentration basis,  $Y_m$  when expressed on a molality basis,  $Y_x$  when expressed on a mole fraction basis, and  $\gamma_{\pm}$  is used for mean ionic activity coefficient). 2 electrical conductivity (alternative to  $\kappa$  or  $a$ ). 3 mass concentration or mass density (alternative to  $pl$ ). 4 plane angle. 5 surface tension or interfacial tension (alternative to  $\sigma$ ). 6 gyromagnetic ratio. 7 (*in organic chemical nomenclature*) a locant for a substituent on the third atom from the atom carrying the principal function in an acyclic structure or in a side chain attached to a cyclic structure.

δ (or δ) 1 a heavy chain of immunoglobulin D. 2 (*in mathematics*) an infinitesimal change or difference.

δ (or δ) 1 chemical shift. 2 number fraction. 3 (*in organic chemical nomenclature*) a locant for a substituent on the fourth atom from the atom carrying the principal function in an acyclic structure or in a side chain attached to a cyclic structure.

Δ (or Δ) (*in mathematics*) a finite change or difference.

$\Delta$	(or $\Delta$ ) (in older organic chemical nomenclature) a locant for a double bond (a right superscript number designates the lower-numbered carbon atom; see <b>fatty-acid nomenclature</b> ); no longer recommended for denoting unsaturation in names of individual compounds although it may still be used in generic terms (e.g. j5-steroid) and in symbols (e.g. $\Delta_2\text{Ach}$ ).
$\epsilon$	(or $\epsilon$ ) a heavy chain of immunoglobulin E.
	(or $\epsilon$ ) 1 molar (decadic) absorption coefficient. 2 permittivity ( $\epsilon_r$ is used for relative permittivity and $\epsilon_0$ for permittivity of vacuum). 3 (in organic chemical nomenclature) a locant for a substituent on the fifth atom from the atom carrying the principal function in an acyclic structure or in a side chain attached to a cyclic structure. 4 (in chemical nomenclature) hapticity of a ligand (less common alternative to $\eta$ ; see <b>haptic</b> ).
	degree of activation (of an enzymic reaction).
$\varepsilon_i$	degree of inhibition (of an enzymic reaction).
	elasticity coefficient (of a specific enzymic step in a metabolic system).
	(or $\zeta$ ) electrokinetic potential or zeta potential.
	(or $\eta$ ) 1 viscosity (alternative to $\mu$ ). 2 (in chemical nomenclature) hapticity (of a ligand; more common alternative to $\epsilon$ ; see <b>haptic</b> ).
9	(or $\theta$ ) 1 Bragg angle (see <b>Bragg's law</b> ). 2 (in surface chemistry) contact angle. 3 plane angle. 4 torsion angle (in a linear sequence of four attached atoms; alternative to $w$ ). 5 Celsius temperature (alternative to $t$ ).
$\Theta_m$	melting temperature (alternative to $T_m$ or $t_m$ ).
$[\Theta]$	molar ellipticity.
$\kappa$	(or $\kappa$ ) one type of light chain of any class of immunoglobulin (the other being $\lambda$ ).
$\kappa$	(or $\kappa$ ) 1 electrical conductivity (alternative to $y$ or $a$ ). 2 electrolytic conductivity or (formerly) specific conductance. 3 molar napierian absorption coefficient. 4 magnetic susceptibility (alternative to $X$ ).
$\lambda$	(or $\lambda$ ) 1 one type of light chain of any class of immunoglobulin (the other being $\kappa$ ). 2 (obsolete) microlitre ( $\mu\text{l}$ now used).
$\lambda$	(or $\lambda$ ) 1 (in thermodynamics) absolute activity (see <b>activity</b> , def. 4). 2 disintegration constant or decay constant. 3 wavelength. 4 thermal conductivity (alternative to $k$ ).
$\Lambda$	(or $\Lambda$ ) molar conductivity (of an electrolyte).
$\mu$	(or $\mu$ ) a heavy chain of immunoglobulin M. 2 micro+ (SI prefix denoting $10^{-6}$ times). 3 (obsolete) micron (now called micrometre; symbol: $\mu\text{m}$ ).
$\mu$	(or $\mu$ ) 1 (in chemical nomenclature) a bridging ligand. 2 viscosity (alternative to $\eta$ ). 3 chemical potential ( $\mu^\circ$ or $\mu^\ominus$ is used for standard chemical potential and $f\bar{\mu}$ is used for electrochemical potential). 4 electric mobility (alternative to $u$ ). 5 (in magnetism) permeability ( $\mu_r$ is used for relative permeability). 6 magnetic dipole moment (bold italic) (alternative to $m$ ). 7 electric dipole moment (bold italic) (alternative to $p$ ).
$\mu_0$	permeability of vacuum (a fundamental physical constant).
$\mu_B$	Bohr magneton (a fundamental physical constant).
$\mu_e$	electron magnetic moment (a fundamental physical constant).
$\mu_N$	nuclear magneton (a fundamental physical constant).
$\mu_p$	proton magnetic moment (a fundamental physical constant).
$v$	(or $v$ ) 1 stoichiometric number (of a chemical reactant). 2 frequency (alternative to $f$ for electromagnetic radiation). 3 kinematic viscosity. 4 endocyclic torsion angle (in a sugar residue).
$\xi$	1 (in organic chemical nomenclature) unknown configuration at a chiral centre. 2 extent of reaction.
$\dot{\xi}$	rate of conversion.
$\pi$	(or $\pi$ ) a transcendental number that is the ratio of the circumference of a circle to its diameter (3.141 592 65359 ...).
$\pi$	(or $\pi$ ) 1 pros. 2 (or $\pi^s$ ) surface pressure.
$n$	(or $N$ ) 1 osmotic pressure ( $iI_D$ may be used to represent colloid osmotic pressure). 2 binding potential (of a ligand).
$p$	(or $P$ ) 1 density or mass density ( $PA$ or $Ps$ is used for surface density). 2 mass concentration or mass density (alternative to $y$ ). 3 radiant energy density (alternative to $w$ ). 4 charge density. 5 resistivity.
$\sigma$	(or $\sigma$ ) 1 surface tension or interfacial tension (alternative to $y$ ). 2 electrical conductivity (alternative to $y$ or $\kappa$ ). 3 wavenumber in a medium. 4 surface charge density. 5 (in surface chemistry) area per molecule. 6 (in nuclear magnetic resonance spectroscopy) shielding constant. 7 superhelix density (of a helical duplex DNA molecule).
$\Sigma$	(or $\Sigma$ ) (in mathematics) a summation sign.
$\tau$	(or $\tau$ ) 1 tele. 2 bond angle. 3 relaxation time or time constant (alternative to $T$ ). 4 transmittance or transmission factor (alternative to $T$ ). 5 mean life. 6 number of superhelical turns (in a helical duplex DNA molecule).
$\phi$	(or $\phi$ ) 1 osmotic coefficient ( $\phi_m$ is used for osmotic coefficient when expressed on a molality basis and $\phi_x$ when expressed on a mole fraction basis). 2 electric potential (alternative to $V$ ). 3 fluidity. 4 plane angle. 5 phase difference. 6 volume fraction. 7 Dalziel coefficient. 8 torsion angle (from the anomeric carbon atom to the oxygen atom of a glycosidic bond). 9 quantum yield (alternative to $\Phi$ ). 10 winding angle (of intercalated helical DNA).
$\Phi$	(or $\Phi$ ) 1 heat flow rate. 2 radiant power or radiant (energy) flux (alternative to $P$ ). 3 magnetic flux. 4 potential energy (alternative to $E_p$ or $V$ ). 5 quantum yield (alternative to $\phi$ ).
$X$	(or $X$ ) 1 electronegativity. 2 magnetic susceptibility (alternative to $K$ ; $Xm$ is sometimes used, but it should be reserved for molar magnetic susceptibility). 3 surface electric potential. 4 exocyclic torsion angle (in a sugar residue).
$\psi$	(or $\psi$ ) 1 replacement of the -CO-NH- group in a peptide by another (indicated) grouping. 2 torsion angle (from the oxygen atom of a glycosidic bond to the glycosylated molecule). 3 wavefunction (alternative to $\Psi$ ).
$\Psi$	(or $\Psi$ ) 1 a residue of the ribonucleoside pseudouridine (alternative to $\Psi_{rd}$ ). 2 electric flux. 3 wave function (alternative to $\psi$ ).
$w$	(or $w$ ) 1 angular frequency. 2 angular velocity. 3 solid angle. 4 torsion angle (in a linear assembly of four attached atoms; alternative to $\theta$ ). 5 (in organic chemical nomenclature) a locant for the terminal atom or group in an acyclic organic compound.
$\Omega$	(or $\Omega$ ) ohm.
$\Omega$	(or $\Omega$ ) solid angle.

## Multi-character biochemical symbols commencing with a Greek character

- αLnn** the linolenoyl or (9,12,15)-linolenoyl or (formerly) α-linolenoyl (i.e. (all-Z)-octadeca-9, 12, 15-trienoyl) group (alternative to Lnn).
- βAad** a residue of the p-amino acid L-p-aminoadipic acid (i.e. L-3-aminohexanedioic acid).
- βAla** a residue of the p-amino acid p-alanine (i.e. 3-amino-propanoic acid).
- γLnn** the (6,9,12)-linolenoyl or (formerly) γ-linolenoyl (i.e. (all-Z)-octadeca-6, 9, 12-trienoyl) group.

- Δ<sub>2</sub>Ach** the (all-Z)-eicosa-8,II-dienoyl group.
- Δ<sub>3</sub>Ach** the (all-Z)-eicosa-5,8,II-trienoyl group.
- Δ<sub>4</sub>Ach** the arachidonoyl (i.e. (all-Z)-eicosa-5,8,11, 14-tetraenoyl) group.
- ΔPam** the palmitoleoyl (i.e. (Z)-hexadec-9-enoyl) group.
- εAcp** see εAhx.
- εAhx** or (formerly) εAcp a residue of the e-amino acid 6-aminohexanoic acid (formerly known as e-amino-caproic acid).
- Ψrd** a residue of the ribonucleoside pseudouridine (alternative to Ψ).

## Nomenclature publications

### Introduction

Brief details are provided below of a selection from the considerable number of publications available on nomenclature and symbolism that are of possible interest to biochemists, biological chemists, clinical chemists, and molecular biologists. The majority of these publications are in the form of approved recommendations from the International Union of Biochemistry (IUB) or its successor the International Union of Biochemistry and Molecular Biology (IUBMB) through their Nomenclature Committees (respectively NC-IUB or NC-IUBMB), from the International Union of Pure and Applied Chemistry (IUPAC), or from IUPAC and IUBMB together through their Joint Commission on Biochemical Nomenclature (JCBN); on occasions the recommendations have been issued by IUPAC in conjunction with IUBMB and the International Union of Pure and Applied Biophysics (IUPAB) or by IUPAC jointly with the International Federation of Clinical Chemistry (IFCC). The full titles of the relevant nomenclature bodies to which the listed publications are attributable have generally been omitted for brevity.

This Appendix has been updated and expanded for the revised edition of the Dictionary. Now incorporated are details of significant nomenclature documents published and made available up to the end of August 1999 (or in certain instances known to be in preparation at that date). Furthermore, the interval following the compilation of the original version of this appendix has seen a considerable increase in the number of specific biochemical and chemical nomenclature recommendations whose full texts have been converted to versions readable on the Internet via the World Wide Web (WWW), and so their current uniform resource locators (URLs) have been added where appropriate. All such recommendations are also currently accessible (directly or indirectly) through links from either of the following URLs:

[www.chern.qrnw.ac.uk/iubrn/](http://www.chern.qrnw.ac.uk/iubrn/)  
(IUBMB Biochemical Nomenclature home page)  
[www.chern.qrnw.ac.uk/iupac/](http://www.chern.qrnw.ac.uk/iupac/)

(IUPAC Chemical Nomenclature home page)

It will be appreciated that, in order for information as up-to-date as possible to be given in this Appendix, details have been included of a number of nomenclature documents that became available too recently for their contents to be taken into consideration during the compilation of this Dictionary.

### Manuals and Compendia

These are volumes covering major subject areas, the majority being assemblages either of previously published nomenclature documents on specific topics or of items extracted from such documents. Some duplication of content between them has inevitably occurred. They are commonly known by the colour of their covers.

- 1 [The Blue Book] IUPAC (1979). *Nomenclature of organic chemistry - sections A, B, C, D, E, F and H - 1979 edn* (ed. J. Rigauby and S. P. Klesney). Pergamon Press, Oxford.

A collection of several previously published separate sets of rules and recommendations, reprinted with correction of material errors. The section headings are listed in item 34. *See also* item 6.

URL for section H (isotopically modified compounds):

[http://www.chern.qrnw.ac.uk/  
iupac/sectionH/](http://www.chern.qrnw.ac.uk/iupac/sectionH/)

- 2 [The Red Book] IUPAC (1990). *Nomenclature of inorganic chemistry - recommendations 1990* (ed. G. J. Leigh). Blackwell Scientific Publications, Oxford.

Recommendations conceived as being Part I of a third edition of the Red Book and mainly concerned with the fundamental areas of inorganic chemistry.

## Appendix B

- A series of chapters includes: the rules for naming simple molecular entities; oxoacids and their derivatives; coordination compounds; and simpler boron compounds. The chapter headings are listed in item 34. Further volumes, which will deal with more specialized aspects of the subject, are expected to be published in about 2001.
- 3 [The Purple Book] IUPAC (1991). *Compendium of macromolecular nomenclature* (ed. W. V. Metanomski). Blackwell Scientific Publications, Oxford.  
A collection of reprints of previously published sets of recommendations providing definitions of terms relating to polymers and rules for naming them based on structure or source. The chapter headings are listed in item 34.
- 4 [The White Book] NC-IUBMB (1992). *Biochemical nomenclature and related documents - a compendium*, 2nd edn (ed. C. Liebecq). Portland Press, London.  
An assemblage of a considerable number of previously published sets of recommendations issued by various nomenclature bodies of IUB, IUPAC, or IVB and IVPAC jointly, together with excerpts from the newsletters of the biochemical nomenclature committees. Most of the nomenclature documents contained in the first (1978) edition of the compendium are either reprinted (with updates where appropriate) or replaced by revised versions, and to these is added a number of new sets of recommendations published between 1978 and 1989. Also included are a list of titles of additional biochemical nomenclature documents (including those printed in the first edition of the compendium but not in this one) and an extensive list of titles of other nomenclature and reference publications of possible interest to biochemists. The main contents are listed in item 34.  
The full texts of the individual recommendations in this compendium are available as World Wide Web versions or (if not superseded) are in course of being converted into this form; the titles and URLs of those currently accessible are included in a list of WWW versions of current biochemical nomenclature recommendations given at:  
[http://www.chem.qmw.ac.uk/  
iubmb/nomenclature/](http://www.chem.qmw.ac.uk/iubmb/nomenclature/)
- 5 [The Green Book] IUPAC (1993). *Quantities, units and symbols in physical chemistry*, 2nd edn (ed. I. M. Mills, T. Cvitas, K. H. Homann, N. Kallay, and K. Kuchitsu). Blackwell Scientific Publications, Oxford.  
The contents are drawn from the resolutions or recommendations of a number of international bodies concerned with the definition and use of physical quantities and units. Included are: the definitions and mandatory symbols for the base and derived units forming the International System (SI), with the names and symbols for SI prefixes signifying decimal multiples and submultiples of SI units; factors for conversion of units from a variety of other systems to the corresponding SI units; sets of tables containing the internationally recommended names and symbols for the base and derived physical quantities most likely to be used by chemists and biochemists, with brief definitions and the corresponding coherent SI units; recommended mathematical symbols; a table of fundamental physical constants; and tables of the properties of chemical elements, nuclides, and particles.
- 6 [The Blue Book II] IUPAC (1993). *A guide to IUPAC nomenclature of organic compounds - recommendations 1993* (ed. R. Panico, W. H. Powell, and J.-C. Richer). Blackwell Science, Oxford.  
For use in conjunction with item 1; it outlines the main principles of organic nomenclature as described in that volume, and presents important changes (published and hitherto unpublished) agreed upon since.
- 7 [The Silver Book] IUPAC and IFCC (1995). *Compendium of terminology and nomenclature of properties in clinical laboratory sciences (recommendations 1995)* (ed. J. C. Rigg, S. S. Brown, R. Dybkær, and H. Olesen). Blackwell Science, Oxford.  
A guide towards a more uniform way of reporting information in clinical sciences, particularly quantitative information in clinical chemistry; it was compiled by harmonizing, updating where appropriate, and consolidating a number of previously published documents and recommendations not readily accessible. Derived physical or chemical quantities are analysed into their dimensions, with the aim of facilitating the interpretation of many of the older names of quantities used in this sphere and the recalculations of data expressed in older units.
- 8 [The Gold Book] IUPAC (1997). *Compendium of chemical terminology - IUPAC recommendations*, 2nd edn (ed. A. D. McNaught and A. Wilkinson). Blackwell Science, Oxford.  
An alphabetical listing of nearly 7000 terms covering the whole range of chemistry. The terms have been selected from a considerable number of internationally approved nomenclature documents and compilations published up to the end of 1995, including all IUPAC recommendations, together with some particularly significant material from 1996. Brief but authoritative definitions are given for each term, together with references to the source documents.
- 9 [The Orange Book] IUPAC (1998). *Compendium of analytical nomenclature, 3rd edn - definitive rules 1997* (ed. J. Inczedy, T. Lengyel, and A. M. Ure). Blackwell Science, Oxford.  
A compilation of previously published documents. The chapter headings are listed in item 34.

## Appendix B

### Enzyme list

- 10 NC-IUBMB (1992). *Enzyme nomenclature - recommendations 1992* (ed. E. C. Webb). Academic Press, San Diego.

A nomenclature and classification of enzymes according to the chemical reactions they catalyse, with systematic names, code numbers, and recommended short names assigned to each one. This, the sixth complete edition of the recommendations, lists 3196 individual enzymes (an increase of 29% on the number in the fifth (1984) edition). Included is a second printing, with corrections, of the contents of item 14 [a further correction is given at: *European Journal of Biochemistry*, 1993, 213, 3, footnote 1].

Supplements giving corrections and additions to the enzyme list are published periodically, the following having appeared in print by the end of August 1999: Supplement (1994) *European Journal of Biochemistry*, 223, 1-5; Supplement 2 (1995) *ibidem*, 232, 1-6; Supplement 3 (1996) *ibidem*, 237, 1-5; Supplement 4 (1997) *ibidem*, 250, 1-6; Supplement 5 (1999) *ibidem*, 264, 610-650. Supplement 6 (1999) is expected to appear in print at a later date. Except for Supplement 5, these supplements all relate to enzyme subclass EC 3.4 (peptidases).

World Wide Web versions of Supplement 5 and of a consolidated list containing the full amended text of subclass EC 3.4 are available.

URL: <http://www.chern.qrnw.ac.uk/iubrn/enzynrel>

Conversion of the remaining text of *Enzyme nomenclature* to a consolidated WWW version is expected to be completed by the end of 2000; changes in format for this version will include expansion of the comments section for each enzyme, more complete and up-to-date references, and citation of references at the end of each entry.

### Documents on specific topics

A selection of nomenclature documents on specific topics, most of them recently published, is given below. Information from some of them has been incorporated into certain of the compendia mentioned above.

All the recommendations by IUPAC and JCBN have been published initially in *Pure and Applied Chemistry*, and all the NC-IUB or NC-IUBMB recommendations have been first published in *European Journal of Biochemistry* (where the JCBN recommendations have usually also been published). Although many of these recommendations have been reprinted in other research journals, only the initial publication is given for each of the documents itemized below; all appearances of the JCBN, NC-IUB, or NC-IUBMB documents, including any in translation, are enumerated in the publications list cited in item 33.

- 11 Baron, D. N., Moss, D. W., Walker, P. G., and Wilkinson, J. H. (1971). Abbreviations for names of enzymes of diagnostic importance. *Journal of Clinical Pathology*, 24, 656-657.

A list of two- or three-letter abbreviations (strictly contractions) of the names of enzymes frequently assayed in clinical biochemistry laboratories. The abbreviations were devised to standardize their use in clinical reports and to facilitate processing of assay data by computer.

- 12 NC-IUB (1979). Units of enzyme activity - recommendations 1978. *European Journal of Biochemistry*, 97, 319-320. Corrections: *ibidem*, 1980, 104, 1-4.
- 13 Eicosanoid Nomenclature Committee (1989). Eicosanoid nomenclature. *Prostaglandins*, 38, 125-133.  
Proposals regarding a systematic leukotriene nomenclature and suggestions on the nomenclature of enzymes involved in eicosanoid metabolism. The spelling 'eicosanoid' is favoured in preference to 'icosanoid'. The ad hoc committee putting forward these proposals and suggestions was constituted by the IUB as an advisory panel but the recommendations have not been adopted by NC-IUB or NC-IUBMB.
- 14 NC-IUB (1991). Nomenclature of electron-transfer proteins — recommendations 1989 (ed. G. Palmer and J. Reedijk). *European Journal of Biochemistry*, 200, 599-611. Corrections: *ibidem*, 1993, 213, 2-3. See also item 10.
- 15 IUPAC (1994). Glossary of terms used in physical organic chemistry, 2nd edn (IUPAC recommendations 1994) (ed. P. Muller). *Pure and Applied Chemistry*, 66, 1077-1184.  
URL: <http://www.chern.qrnw.ac.uk/iupac/gtpocl>
- 16 JCBN (1994). Recommendations for nomenclature and tables in biochemical thermodynamics (recommendations 1994) (ed. R. A. Alberty). *Pure and Applied Chemistry*, 66, 1641-1666.
- 17 IUPAC (1994). Glossary of bioanalytical nomenclature — part I: general terminology, body fluids, enzymology, immunology (IUPAC recommendations 1994) (ed. C. A. Burtis and T. A. Geary). *Pure and Applied Chemistry*, 66, 2587-2604.  
Definitions taken from IUPAC, IUB, and IFCC nomenclature documents and other sources to form a compilation useful for practitioners of clinical chemistry.
- 18 NC-IUBMB (1994). A nomenclature of junctions and branchpoints in nucleic acids — recommendations 1994 (ed. D. M. J. Lilley, R. M. Clegg, S. Diekmann, N. C. Seeman, E. von Kitzing, and P. Hagerman). *European Journal of Biochemistry*, 230, 1-2.
- 19 Stewart, A. (ed.) (1995) Genetic nomenclature guide — including information on genomic databases. *Trends in Genetics*, 11(3), supp!. A summary of the most important rules and guidelines for the genetic

**Appendix B**

- nomenclature of 15 favoured research organisms used by geneticists and developmental biologists.
- 20 IUPAC (1995). Glossary of class names of organic compounds and reactive intermediates based on structure (IUPAC recommendations 1995) (ed. G. P. Moss, P. A. S. Smith, and D. Tavernier). *Pure and Applied Chemistry*, 67, 1307-1375.  
 A glossary of terms used to denote classes of (mostly organic) compounds, substituent groups, and reactive intermediates, in contrast to individual compounds. The terms have been selected both from IUPAC or *IUB/IUBMB* nomenclature publications and from the chemical literature.  
 URL: [http://www.chern.qrnw.ac.uk/  
iupac/class1](http://www.chern.qrnw.ac.uk/iupac/class1)
- 21 IUPAC and IFCC (1996). Glossary of terms in quantities and units in clinical chemistry (IUPAC-IFCC recommendations 1996) (ed. H. P. Lehmann, X. Fuentes-Arderiu, and L. F. Bertello). *Pure and Applied Chemistry*, 68, 957-1000.  
 A glossary containing terms considered of particular interest to the practising clinical chemist. Definitions taken from a variety of published sources have been provided in a consistent terminology.
- 22 JCBN (1996). Nomenclature of carbohydrates (recommendations 1996) (ed. A. D. McNaught). *Pure and Applied Chemistry*, 68, 1919-2008.  
 An expansion of and replacement for the document entitled 'Tentative rules for carbohydrate nomenclature - part I, 1969' (reprinted in item 4 at pp. 127-148). It also replaces in essence several other sets of recommendations (also reprinted in item 4) covering various specialized areas of carbohydrate terminology.  
 URL: [http://www.chern.qrnw.ac.uk/  
iupac/2carb1](http://www.chern.qrnw.ac.uk/iupac/2carb1)
- 23 IUPAC (1996). Basic terminology of stereochemistry (IUPAC recommendations 1996) (ed. G. P. Moss). *Pure and Applied Chemistry*, 68, 2193-2222.  
 A glossary of the more important, and most widely used, stereochemical terms. It extends the list of those defined in Section E (stereochemistry) of item 1 (reprinted in item 4 at pp. 1-18), and includes some terms from inorganic, macromolecular, and physical organic chemistry, as well as some misleading terms (with guidance on correct usage or acceptable alternatives). Mention is made of many of the symbols used in stereochemical nomenclature.  
 URL: [http://www.chern.qrnw.ac.uk/  
iupac/stereol](http://www.chern.qrnw.ac.uk/iupac/stereol)
- 24 IUPAC (1996). Glossary of terms used in photochemistry (IUPAC recommendations 1996) (ed. J. W. Verhoeven). *Pure and Applied Chemistry*, 68, 2223-2286.  
 A revised and enhanced version of a glossary first published in 1988.
- 25 Clark, B. F. C. and 13 others (1996) Prokaryotic and eukaryotic translation factors - ad hoc nomenclature subcommittee report. *Biochemie*, 78, 1119-1122.  
 Proposals for updating and extending to prokaryotic factors the document entitled 'Nomenclature of initiation, elongation and termination factors for translation in eukaryotes - recommendations 1988' (reprinted in item 4 at pp. 90-92). NC-IUBMB has not formally adopted the report (although published under the name of IUBMB), but it has recommended (in item 30) that the proposals should be followed.
- 26 JCBN (1997). Nomenclature of glycolipids (recommendations 1997) (ed. M. A. Chester). *Pure and Applied Chemistry*, 69, 2475-2487.  
 A replacement for the section on glycolipids of the document entitled 'The nomenclature of lipids - recommendations 1976' (reprinted in item 4 at pp. 180-190).  
 URL: [http://www.chern.qrnw.ac.uk/  
iupac/rnisc/glylp.htrnl](http://www.chern.qrnw.ac.uk/iupac/rnisc/glylp.htrnl)
- 27 IUPAC, IUBMB, and IUPAB (1998). Recommendations for the presentation of NMR structures of proteins and nucleic acids (recommendations 1998) (ed. J. L. Markley, A. Bax, Y. Arata, C. W. Hilbers, R. Kaptein, B. D. Sykes, P. E. Wright, and K. Wiithrich). *Pure and Applied Chemistry*, 70, 117-142. Correction: *ibidem*, 1998, 70, Errata pp. (or part 6, i).
- 28 IUPAC (1998). Glossary of terms used in medical chemistry (IUPAC recommendations 1998) (ed. C. G. Wermuth, C. R. Ganellin, P. Lindberg, and L. A. Mitscher). *Pure and Applied Chemistry*, 70, 1129-1143.  
 A glossary compiled from a number of sources with the aim of establishing international definition standards in a subject where rapid changes are occurring. Concise definitions in a consistent terminology are provided for about 100 commonly used terms.  
 URL: [http://www.chern.qrnw.ac.uk/  
iupac/rnedchernl](http://www.chern.qrnw.ac.uk/iupac/rnedchernl)

**Newsletters**

The biochemical nomenclature committees (JCBN and NC-IUB or NC-IUBMB) have together published newsletters in various journals of biochemistry from time to time since 1980. These are designed to inform scientists about the work of the committees, to call attention to features of recommendations that are recently published or are in press, to report on current nomenclature problems under study, and to make recommendations not meriting publication as separate documents.

A schedule of all the published newsletters is included in the publication list available via the World Wide Web and noted at item 33; this schedule enumerates all the appearances in print of each of the newsletters (or of excerpts therefrom) and states their partial contents, with links to the websites of any directly accessible relevant recommendations. The two most recent newsletters are listed below; WWW versions of

## Appendix B

their full texts are available. Excerpts from previous newsletters are included in item 4.

- 29 JCBN and NC-IUBMB (1997). Newsletter 1996. *European Journal of Biochemistry*, **247**, 733-739; and elsewhere.

Topics covered include: vitamin A, retinoids, and retinoate analogues; absorbance and attenuation; glycosaminoglycans and proteoglycans; biochemical equations, catalytic antibodies; nomenclature of proteins and of receptors; and terminology in immunology. *See also* items 35 and 36.

URL: [http://www.chem.qmw.ac.uk/  
iupac/newsletter/1996/](http://www.chem.qmw.ac.uk/iupac/newsletter/1996/)

- 30 JCBN and NC-IUBMB (1999). Newsletter 1999. *European Journal of Biochemistry*, **264**, 607-609 and elsewhere.

Topics covered include: symbols for selenocysteine; IUBMB-Nicholson metabolic maps; nomenclature recommendations on the World Wide Web; databases for ribosomal proteins and for gene families; and the recommendation regarding translation factors noted under item 25.

URL: [http://www.chem.qmw.ac.uk/  
iupac/newsletterj1999/](http://www.chem.qmw.ac.uk/iupac/newsletterj1999/)

## Listings

- 31 Lists of separately published current recommendations on specific topics of biochemical interest issued by JCBN, NC-IUB, NC-IUBMB, or certain other international committees are included in the information or instructions provided to authors by a number of journals of biochemistry (e.g. *Archives of Biochemistry and Biophysics*, *Biochemical Journal*, *European Journal of Biochemistry*, *Journal of Biological Chemistry*) and presented from time to time in the first volume or part of their printed versions issued for a calendar year or posted on their websites. *See also* item 33.

32 A list of all JCBN, NC-IUB, and NC-IUBMB recommendations currently accessible through the World Wide Web, with their URLs and links to WWW versions of their full texts, is provided at the Biochemical Nomenclature Committees home page, together with general information concerning the committees. Included may be newly approved recommendations in advance of the printed versions.

URL: [http://www.chem.qmw.ac.uk/  
iubmb/nomenclature/](http://www.chem.qmw.ac.uk/iubmb/nomenclature/)  
or [http://www.chem.qmw.ac.uk/  
iupac/jcbn/](http://www.chem.qmw.ac.uk/iupac/jcbn/)

Similar information is presented in item 30

- 33 A complete list of all JCBN, NC-IUB, and NC-IUBMB publications, enumerating all their appearances in print and including any in translation, is available via the World Wide Web, with links to the websites of those documents directly accessible.

URL: [http://www.chem.qmw.ac.uk/  
iubrn/bibliog/jcbn.htrn1](http://www.chem.qmw.ac.uk/iubrn/bibliog/jcbn.htrn1)

- 34 A list of current IUPAC publications on nomenclature and symbolism is included in the instructions to authors provided in the first part issued for a calendar year of certain of the journals published by the Royal Society of Chemistry. The 1999 list includes the main contents of item 4, the section or chapter headings for items 1, 2, 3, and 9, and a subject-by-subject catalogue, complete to mid-1998, of separately published current recommendations on specific chemical topics.

URL: [http://www.rsc.org/is/journals/  
authrefs/jappdx.htrn](http://www.rsc.org/is/journals/authrefs/jappdx.htrn)

- 35 A list of approved documents on the nomenclature of immunology is included in item 29 at p. 737.

- 36 Lists of other nomenclature and reference publications of interest to biochemists are given in item 4 at pp. 341-347 and in item 29 at p. 738.

# **Appendix C**

## **Organizations that are helpful to biochemists and molecular biologists**

Much of the information in this Appendix was collated from sources on the World Wide Web (WWW) in December 1996. The information presented here can be checked or updated by reference either to the ICSU home page:

<http://www.icsu.org>

or the site maintained at the University of Waterloo Electronic Library Scholarly Societies Project:

<http://www.lib.uwaterloo.ca/society/>

### **International unions**

The International Council For Science (ICSU) is a non-governmental organization, founded in 1931 to bring together natural scientists in international scientific endeavour. It comprises 94 multidisciplinary National Scientific Members (scientific research councils or science academies) and 23 international, single-discipline Scientific Unions to provide a wide spectrum of scientific expertise enabling members to address major international, interdisciplinary issues which none could handle alone. ICSU also has 30 Scientific Associates.

The International Council for Science

51 Boulevard de Montmorency

F-75016 Paris

France

Telephone: +33 1 45 25 03 29

Telefax: +33 1 42 88 94 31

E-mail: [secretariat@icsu.org](mailto:secretariat@icsu.org)

WWWURL: <http://www.icsu.org>

The unions concerned with biochemistry and molecular biology which are members of ICSU are:

International Union of Biochemistry and Molecular Biology (IUBMB)

The IUBMB unites biochemists and molecular biologists in 63 countries which are members of the Union. Each country

has either an Adhering Body or Associate Adhering Body in the Union which is represented as a biochemical society, as a national research council or as an academy of sciences.

You may reach the IUBMB and learn more about the activities by contacting your Adhering Body or the General Secretary:

Dr Frank Vella  
Department of Biochemistry  
University of Saskatchewan  
18 Leyden Crescent  
Saskatoon  
Saskatchewan  
Canada S7J 2S4

Telephone: +1 306 374 1304

WWW URL: <http://bmbsgill.leeds.ac.uk/iupab>

## Appendix C

International Union of Pure and Applied Chemistry (IUPAC)  
 Founded in 1919, the International Union of Pure and Applied Chemistry (IUPAC) is a voluntary, non-governmental, non-profit association of National Adhering Organizations representing the chemists, from both industry and academia, of 40 countries. In addition, IUPAC has links with 14 Observer Countries, 30 regional and international Associated Organizations, which are concerned with chemistry and its application, and approximately 160 Company Associates from 24 countries.

IUPAC Secretariat

International Union of Biological Sciences (IUBS)  
 The International Union of Biological Sciences (IUBS) was created in 1919, and held its first General Assembly that same year. Its objectives are: to promote the study of biological sciences, to facilitate and coordinate research and other scientific activities that require international cooperation, to ensure the discussion and dissemination of international conferences, and to assist in the publication of their reports. The Executive Committee of IUBS can be contacted at:

IUBS  
 51 Boulevard de Montmorency  
 F-75016 Paris  
 France  
 Telephone: +33 145 25 00 09  
 Telefax: +33 145252029  
 E-mail: [iubs@paris7.jussieu.fr](mailto:iubs@paris7.jussieu.fr)  
 WWWURL: <http://www.iesu.org/membership/SUM/iubs.html>

International Union of Crystallography (IUCr)  
 The IUCr is a scientific union adhering to ICSU. Its objectives are to promote international cooperation in crystallography and to contribute to all aspects of crystallography, to promote international publication of crystallographic research, to facilitate standardization of methods, units, nomenclatures and symbols, and to form a focus for the relations of crystallography to other sciences.

The Executive Secretary of the IUCr may be contacted at:

International Union of Crystallography  
 2 Abbey Square  
 Chester CH1 2HU  
 United Kingdom  
 Telephone: +44 1244345431

Telefax: +441244344843

 WWW URL: <http://www.iuer.ae.uk/>

International Brain Research Organization (IBRO)  
 The International Brain Research Organization (IBRO) was founded in 1960 in response to the growing demand from scientists in many countries and different disciplines for the creation of a central organization for the better mobilization and utilization of the world's scientific resources for research on the brain. The general objectives and goals of IBRO are: to foster throughout the world fundamental scientific research contributing to an understanding of the brain, normal and abnormal; to promote international collaboration and worldwide education in brain research; and to work through and with existing organizations to help in reaching their own particular objectives and to solicit their aid in the objectives of IBRO. The Executive Committee can be contacted at:

IBRO  
 51 Boulevard de Montmorency  
 F-75016 Paris  
 France  
 Telephone: +33 146479292,  
 Telefax: +33145206006  
 E-mail: [ibro@pratique.fr](mailto:ibro@pratique.fr)  
 WWWURL: <http://www.icsu.org/membership/SUM/IBRO.html>

International Union of Immunological Societies (IUIS)  
 The International Union of Immunological Societies (IUIS) was established in May 1969. Its objectives are to organize international cooperation in immunology and to promote communication between the various branches of immunology and allied subjects encourage within each scientifically independent territory cooperation between the societies that represent the interests of immunology and contribute to the advancement of immunology in all its aspects. The IUIS can be contacted *c/o*:

Keith James (Secretary General of IUIS)

International Union of Physiological Sciences (IUPS)  
 The objectives of IUPS are to encourage the advancement of the physiological sciences, to facilitate the dissemination of knowledge in the field of physiological sciences, to foster and encourage research in the field of physiological sciences, to promote the International Congresses of Physiological Sciences, to promote such other meetings as may be useful for

the advancement of the physiological sciences, and to promote such other measures as will contribute to the development of physiological sciences in developing countries. The IUPS Secretary General can be reached at:

LGN, Batiment CERVI  
Hôpital de la Pitié-Salpêtrière  
83 Boulevard de l'Hôpital  
P-75013 Paris  
France

Telephone: +33142177537

International Union of Pharmacology (IUPHAR)  
Founded in 1959 as a section of the International Union of Physiological Sciences, 'The International Union of Pharmacology', IUPHAR, has been independent since 1966. The Union is a voluntary, non-governmental, non-profit association of national organizations presently representing the pharmacologists of 47 member countries and three regional associations. IUPHAR is a member of the International Council of Scientific Unions and participates in the work of its scientific committees. It receives international recognition particularly by the United Nations Educational and Scientific Organization. IUPHAR can be contacted *clo*:

Paul M. Vanhoutte, Secretary General, IUPHAR  
Vice-President Research  
Direction de la Recherche et du Développement

## Federations of biochemists and molecular biologists

In addition to the Unions there are four regional organizations for biochemists.

The Federation of European Biochemical Societies (FEBS) which now has 32 constituent societies.  
(For address see *The Biochemical Society* below.)

WWW URL: <http://www.febs.unibe.ch/>

The Pan American Association of Biochemists and Molecular Biologists (PABMB).  
(For address see *American Society for Biochemistry and Molecular Biology* below.)

Federation of Asian and Oceanian Biochemists and Molecular Biologists (FAOBMB) which now has 18 biochemistry and molecular biology societies associated.

(For address see *The Japanese Biochemical Society* below.)

The Federation of African Societies of Biochemistry and Molecular Biology (FASBMB)  
The Chairman  
Department of Biochemistry  
University of Nairobi  
PO Box 30197  
Nairobi  
Kenya

International Federation of Clinical Chemists (IFCC) which is loosely linked to IUPAC.

Human Genome Organisation (HUGO)  
One Park Square West  
London NW1 4LJ  
United Kingdom

**Appendix C****Other Regional Organizations**

The European Molecular Biology Organization  
 Postfach 1022.40  
 Meyerhofstrasse 1  
 69117 Heidelberg  
 Germany

European Federation of Biotechnology  
 For information contact one of the following:

Society of Chemical Industry  
 14 Belgrave Square  
 London SWIX 8PS  
 United Kingdom

DECHEMA

 59 Portland Place  
 London WIN 3AJ  
 United Kingdom

E-mail: [genadmin@biochemistry.org](mailto:genadmin@biochemistry.org).

The Japanese Biochemical Society  
 Ishikawa Building-3f  
 25-16, Hongo 5-Chome  
 Bunkyo-ku  
 Tokyo  
 Japan

# Appendix D

## The Internet

J. H. Parish and N. A. Maughan

Department of Biochemistry and Molecular Biology, University of Leeds, Leeds LS2 9JT, UK

### Contents

709	Introduction	
709	Glossary	Commonly used Internet terms
711	Getting started	
711	URLs of use in biochemistry	

### Introduction

This appendix is in three sections: first we present a glossary of terms commonly used in discussions of the Internet; secondly we consider a worked example of how to find a biochemical fact using the Internet's search facilities; finally there is a list of biochemically interesting and/or useful sites. The reader is strongly advised to become familiar with the Internet and to note that it is expanding very rapidly: we do not guarantee that all the sites will remain available for the currency of this Dictionary. Additionally more sites will undoubtedly go on line and the reader should rely on search engines rather than the specific sites that are mentioned here.

### Glossary

Some of this glossary is based on N. A. Maughan and J. H. Parish (1995). The Information Superhighway and Biochemistry. *Biochemical Education* 23, 184-189, © 1995 International Union of Biochemistry and Molecular Biology. Parts of the text are reproduced here with permission.

**anonymous** FTP FTP access to a site where files, etc., can be accessed. The login name for such a site is 'anonymous' (or 'ftp') and the required password is the user's e-mail address.

**applet** a little application; this term is used to describe a module written, usually, in Java.

**Archie** a database listing filenames of files in FTP servers throughout the world. It can be used to locate a particular public domain file if the exact filename is known.

**archive** see software archive.

**archive format** one of a variety of file types in which collections of computer files are put together for storage and retrieval. One of the most common is TAR (tape archive, so called because it was originally designed for this); other examples include BOO and ZOO files (for PCs); certain other archive formats are **compressed files**.

**ASCII** abbr. for American Standard Code for Infonnation Inter-change; a standard set of characters readable by all computers.

**bionet** names of newsgroups of interest to biochemists start with the text 'bionet'; examples include the newsgroups bionet.plants and bionet.molbio.yeast. *Distinguish from BioNet*.

**SioNet** an educational software consortium whose URL is <http://www.leeds.ac.uk/bionet.htm1>. *Distinguish from bionet*.

**bookmark** a URL stored in a browser file, usually to allow quick access to a frequently used WWW site without the need to type in the URL.

**browser** a piece of local software that allows access to WWW pages; an example is Netscape.

**cgi** abbr. for Common Gateway Interface: a programming language similar to C used for producing programs, etc., in HTML.

**compressed file** a computer file (or a collection of these) in archive format that has been compressed by an appropriate algorithm, such as that of Lempel-Zif. In UNIX, such files are indicated by the extensions .Z, .gz, or .sh. For PCs they are usually indicated by the extension .zip. Certain compressed files may be programs that compress themselves. Others require a decompression utility such as uncompress, gunzipe (UNIX), and PKUNZIP and WINZIP (PCs). A good **software** archive will include notes (typically in a file called README or OOREADME) on decompression utilities that are required and copies of any decompression software required for compressed files in their own archive.

**DNS** abbr. for Domain Name Server: a computer, transparent to the average end-user, that parses IP addresses and establishes the necessary connection between the appropriate nodes.

**domain** part of an IP address; in the example given in that entry, 'leeds.ac.uk' is a domain.

**e-mail** abbr. for electronic mail.

**e-mail address** an address for e-mail of the form <name>@<address> where the <address> is an IP address in its named format, e.g. [howard@bmbus1.leeds.ac.uk](mailto:howard@bmbus1.leeds.ac.uk) or [j.h.parish@leeds.ac.uk](mailto:j.h.parish@leeds.ac.uk). Another example is [president@whitehouse.gov](mailto:president@whitehouse.gov). Note that e-mail addresses and IP addresses are case-insensitive.

## Appendix D

**ethernet** low-level protocols and associated hardware (cabling) for computer communications.

**ethernet address** *an alternative name for* machine address.

**FTP** *abbr. for* file transfer protocol: similar to Telnet in that it requires a user name and password but is only capable of transferring files. FTP has limited help facilities (obtained by typing in ?): it uses UNIX conventions for changing directories etc. The most important consideration is to tell the FTP program whether the file transfer is to be binary or ASCII (i.e. text).

**Gopher** a menu-based alternative to using WWW for finding out what sites contain files you might wish to receive.

**home page** 1 the first page loaded by a WWW browser such as Netscape when it starts up. 2 the main WWW site for a particular person or group, often a contents list with links to connected sites.

**http** *abbr. for* HyperText transfer protocol; also used as a suffix for computer files that are written in HTML etc.

**HTML** *abbr. for* HyperText Mark-up Language: an interpreted computer language used for producing HyperText.

**HyperText** a form of marked text used for certain computer applications.

**Internet** a large global network of computers that arose from a United States military network (ARPANET) that started in 1969. ARPANET was built to be reliable in that if one part of the network was damaged by enemy action, messages between computers would automatically be re-routed. The in-built reliability between sites makes this type of network popular with all users: any computer on the Internet has the capacity to communicate with any other computer on the Internet. The methods and protocols for communicating on the Internet were finalized in 1985 and programs that use the Internet continue to be developed.

**IP** *abbr. for* Internet protocol (*see* protocol).

**IP address** a unique address for an Internet computer. It is a software address: although actually a binary number it is usually represented in 'dotted decimal' notation, e.g. 129.11.110.24. Associated with this (for the vast majority of sites) is a 'named' version of this, in the case cited above it is **bmbus1.leeds.ac.uk**. The conventions for such named addresses are fairly straightforward. The last two letters (uk in that case) indicate the country: other examples include **ca** (Canada), **in** (India), **de** (Germany), and **si** (Slovenia). The exception is the USA: as IP is American, the default is the USA. The '**.ac**' in the case above means 'academic'; in the UK this field can also be **.gOV** (government), **.co** (or, rarely, **.com**; commercial), or **.org** (organization). A similar convention is used in many countries, e.g. in the USA, **.gOV** (government), **.com** (commercial), **.edu** (education), **.mil** (military). Some countries (e.g. Germany) do not usually have this field at all.

**Java** an object-oriented computer language designed for producing WWW pages etc. At the time of writing this glossary, Java is not universally used for this purpose as it has to be interpreted in software and is relatively slow. However, the importance of Java is set to increase as specialized processors designed for running Java programs become available and common. Unlike many computer neologisms, Java is not an acronym but rather a reference to Java coffee, which is popular with the original authors of the language.

**link** a connection between one WWW site and another; the presence of a link is indicated by underlined and/or coloured text; clicking on this text automatically instructs the browser to open the relevant WWWpage.

**machine address** *or* ethernet address a binary number unique to a computer (more exactly its network hardware) that is used by DNS, etc. It should be transparent to the average end-user. The number is usually represented as colon-delimited hexadecimal numbers, e.g. the hardware associated with **bmbus1.leeds.ac.uk** (*see* IP address) has the machine address 00:00:f8:20:5f:3a.

**Netscape** a popular (and highly effective) browser available for a variety of personal computers, workstations, and graphics terminals.

**newsgroup** an electronic bulletin board on the Internet, where anyone can post a message. These messages can be read by anyone else with access to the Internet and readers can post replies to messages. The distinction between electronic mail and newsgroups is that the former is a method of sending private messages to individuals

whereas the latter is a means of posting messages in a public arena. Newsgroups therefore provide a flexible and convenient method for exchanging ideas and opinions and getting answers to technical queries. Newsgroups are arranged by subject and the number of newsgroups currently on the Internet is in the thousands. There are several newsgroups devoted to various aspects of biochemistry and therefore some care must be taken to post queries to the most appropriate newsgroup.

**news reader** a program to read and reply to newsgroup messages.

Most multi-user systems will have a news reader installed on them. Several news readers are available for PCs and Macintosh machines. **node** a point in a computer network where different communication lines connect; it may be a computer or a simpler electronic device, depending on the size and complexity of the network.

**protocol** a set of rules governing the way that data are exchanged between computers, for example, determining the format of messages.

**search engines** Internet sites that have facilities for searching for text. Depending on the way in which they work they are variously referred to as Web crawlers, robots, etc. Three good examples are:

<http://www.yahoo.com>

<http://www.altavista.com>

<http://www.search.com>

**software archive** a site usually accessed by anonymous FTP, from which public-domain software can be downloaded. Some of the software is binary, i.e. is designed to be loaded directly into a local computer; some is code written in a high-level language (such as C or C++) and needs to be compiled locally. Typically software for PCs (Windows or Windows95) and Macintosh computers is of the former type and more generic code and software for UNIX systems is of the latter.

**SRS** *abbr. for* Sequence Retrieval System: a system for molecular biologists that contains links to the major sequence and 3-D structure databases etc. Examples are listed under 'Molecular biology research tools' below.

**system administrator** a person you should get in touch with if you are setting up an internet node for the first time.

**Telnet** a method of logging into a computer on the Internet from another Internet computer (which could be in the same room or across the world). Telnet is typically used to access remote computers which have facilities on them not available locally. For example, a researcher may want to query a library catalogue or access a database containing information on protein sequences.

**URL** *abbr. for* uniform resource locator: a method for identifying WWW sites, which is 'uniform', i.e. independent of any specific protocol. URLs have a characteristic convention of starting <type>:// address. FTP and Gopher sites start 'ftp://' and 'gopher://' respectively. WWW sites start 'http://'. Here is a fairly typical URL:

<http://www.leeds.ac.uk/>

Note that the www. field is optional and is not found at all sites. The URL can be extended by adding a level down and/or an actual page reference as, following that example,

<http://www.leeds.ac.uk/bmb/bmb.html>

In that example 'bmb' is the name of a Department (Biochemistry and Molecular Biology) and 'bmb.html' is an example of a home page.

**uniform resource locator** *see* URL.

**Usenet** collectively, the newsgroups on the Internet.

**WAIS** *abbr. for* wide area information system: a system for the retrieval of documents etc. that supports a directory of servers and is useful for certain free text searches.

**W3** *abbr. for* World Wide Web (*see* WWW).

**World Wide Web** *see* WWW.

**WWW** *or* **W3** *abbr. for* World Wide Web; a network of pages on the Internet. The pages combine formatted text and graphics. The characteristic feature of the WWW is the way in which the pages are cross-referenced using links. The pages are distributed: they can be on local machines or in another country.

## Getting started

The list of URLs given below may seem somewhat daunting. A useful first step in getting acquainted with the Internet is to carry out a MEDLINE search. To do this, follow the steps below.

1. Using your browser, type in the URL, <http://www3.ncbi.nlm.nih.gov/Entrez/> (NOTE: the capital E of Entrez is important). This will take you to a very valuable US government site that offers a range of information.
2. In the list of databases, under 'Search WWW Entrez', click on Search the molecular biology subset of MEDLINE. A screen appears in which there is a white box which invites you to 'Enter Term'. Place your cursor in this box, and type in a term for which you would like references. For example you could type in 'citrate synthase'. Then click on the grey box that says 'Accept'. If you do this, a screen appears that contains a grey box telling you that (at the time of writing) there are 620 documents. In fact it says 'Retrieve 620 documents'.
3. Below it there is a smaller white box that allows you to limit the number of documents to be passed to you. The default on this is 50 documents - you can alter it as you wish, but remember that transfer of a large number of documents may take a very long time.
4. When you have decided how many of the documents you wish to transfer, click on 'Retrieve 620 documents' (the number in the grey box remains the same, but only 50, or such number as you have typed in the white box, will be transferred).
5. A list of citations, starting with the most recent, appears on the screen. Below each citation, a list of options will be found. One of the most useful of these is Abstract format. If you click on this, an abstract of the document (available in most, but not all cases) will appear.

## URLs of use in biochemistry

Users are advised that pages are subject to change without notice. If you are unable to find a particular page try altering the search criteria.

### Search engines (general)

<http://www.yahoo.com/>

A comprehensive search engine that is easy to use but requires some guessing as to what categories should be searched. Other search engines can be accessed via Yahoo.

<http://www.altavista.com/>

A comprehensive search engine that is a good starting point if you do not know what subcategory to start with but which produces large numbers of URLs if the key word(s) are not specified carefully. Its Advanced Search option allows the use of Boolean operators such as AND and OR and the user can dictate the date of the items searched and the order in which the search results are displayed.

<http://http.demon.net/external/cusi.html>

Similar to Yahoo, worth using in Europe in the afternoon

when North American Internet activity can slow down transatlantic access to Yahoo.

<http://www.lycos.com/>

A popular if idiosyncratic browser for the WWW; not always suitable for scientific enquiries.

<http://www.search.com/>

A set of links to AltaVista and Magellan (a comparable site); it also provides direct search facilities of its own.

<http://netscape.com/home/internet-search.html>

The URL that is accessed if Netscape users choose 'Net Search' from their Netscape window. It allows searching and provides access to AltaVista, Magellan, Yahoo, Lycos, etc.

<http://www.wais.com/>

A starting point for WAIS servers.

### Molecular biology and bioinformatics search engines

A very useful starting point is Pedro's list: it is available in copied (mirrored) sites in several continents as follows:

USA: [http://www.public.iastate.edu/~pedro/research\\_tools.html](http://www.public.iastate.edu/~pedro/research_tools.html)

Europe: <http://www.biophys.uni-duesseldorf.de/bionet/research-tools.html>  
[http://www.fmi.ch/biology/research\\_tools.html](http://www.fmi.ch/biology/research_tools.html)

Asia: [http://www.peri.co.jp/Pedro/research\\_tools.html](http://www.peri.co.jp/Pedro/research_tools.html)

Pedro's list provides links to databases, software and analysis tools and is incorporated into a search engine at <http://www.ebi.ac.uk/htbin/bwurld.pl>

Some other useful general starting points:

<http://www.molbiol.ox.ac.uk>

<http://info.er.usgs.gov/network/science/biology/index.html>

<http://www.bioinf.leeds.ac.uk/bioinformatics.html>

<http://www.hgmp.mrc.ac.uk/Bioinformatics>

<http://www.bio.cam.ac.uk>

<http://www.abc.hu/biosites.html>

<http://golgi.harvard.edu/biopages.html>

[http://www.ebi.ac.uk/general/other\\_bioservers.html](http://www.ebi.ac.uk/general/other_bioservers.html)

[http://rldb.rz\\_berlin.mpg.de./links/biolinks.html](http://rldb.rz_berlin.mpg.de./links/biolinks.html)

### Maps and models

Several sites that are excellent for teaching (including self-education):

<http://www.genome.ad.jp/>

(this is also a very extensive site for genome links)

<http://www.imb-jena.de/IMAGE.html>  
(for 3-D structures)

<http://www.biochemgen.ucsd.edu/>  
(human metabolic disorders)

<http://www2.shef.ac.uk/chemistry/web-elements/web-elements-home.html>

## Appendix D

(periodic table of chemical elements)	REBASE (restriction enzymes)
<a href="http://cst.lanl.gov/julie/imagemap/periodic.periodic.html">http://cst.lanl.gov/julie/imagemap/ periodic.periodic.html</a>	<a href="http://www.gdb.org/Dan/rebase/rebase.html">http://www.gdb.org/Dan/rebase/rebase.html</a>

### Introduction

Ten years from the dawn of the field of bioinformatics, we are beginning to harvest the copious fruits of the various genome projects. In spite of early flood warnings, the resulting torrent of sequence information has all but broken our databanks. The endeavour to cope with, and to rationalize, these vast quantities of data has required cooperation on a global scale. Today, there are hundreds of bio-databanks around the world, many of which are now linked together over the Internet via the World Wide Web (WWW). The WWW is now the vehicle of choice for disseminating biological information, and the resources discussed in the following pages can be pursued further using the Web addresses given in Table 3.

The first step, then, in facilitating access to biological information is to assemble it into central, shareable resources, i.e. databases. There are many different database types, de-

pending on the nature of information being stored and the manner of its storage. For example, two of the themes that dominate bioinformatics research are the acquisition and storage of protein primary and tertiary structures. But the level of complexity involved in archiving a three-dimensional structure is clearly very much higher than that required to store linear amino-acid sequences. Separate disciplines have therefore evolved to manage, or curate, these different database types and to analyse the information they contain. The computational investigation of primary structures (which will henceforth be referred to as sequences) and of tertiary structures (henceforth referred to simply as structures) is known as protein sequence and protein structure analysis respectively (sequence analysis in this context is thus not to be confused with sequence determination).

In the course of this discussion, we will encounter primary,

## Appendix E

secondary, composite, and other, specialist databases. Such resources store different levels of information in completely different formats, leading to a variety of communication problems. However, the advent of user-friendly Web browsers has addressed many of these difficulties, and emerging network technologies are providing exciting new tools with which to brave the information revolution.

The need to harness the sea of biological information is still acute. There are currently more than half a million sequences in public and private databases around the world. This is to be contrasted with the number of known protein structures, now around 5000. This represents a vast information deficit. But, locked up in protein sequences is a huge amount of structural, functional, and evolutionary information. The goal, then, is to try to unearth this information and convert it into biochemical knowledge.

The ultimate challenge, that of predicting protein structure from the linear amino-acid sequence, is unlikely to be realized for decades to come. We do not yet understand enough about the rules that govern protein folding, nor do we have sufficient structures in our databases to make prediction from sequence feasible in the short term. The state of the art, in terms of both sequence and structure analysis, is thus currently at the level of pattern recognition. For protein structures, fold-recognition algorithms (which rely on building reference libraries of protein-fold templates) are only about 50-60% reliable. Such approaches will improve as the database of known structures expands. For protein sequence analysis, the reliability of family/function recognition (which relies on building compendia of protein sequence descriptors) is much higher, but varies considerably with the type of analysis method employed. The difficulty is in being able to distinguish between the mathematical significance of a result returned by a database search algorithm and its biological significance.

The principle of sequence analysis hinges on the observation that sequences belonging to families have accumulated mutations, presumably within an unknown archetype, and that divergent drift is characteristic of the family. Such homologous relationships can be identified with ease where levels of sequence identity remain high, but when these drop to below 50% it becomes increasingly difficult to establish relationships reliably. Analyses can be pursued with decreasing certainty towards the 'Twilight Zone' (the 0-25% identity range), where results are no longer statistically significant. Within the Twilight Zone, alignments may appear plausible to the eye, but cannot be supported by statistical methods. Although sequences may diverge to such an extent that little or no similarity remains at the sequence level, their structures are more likely to be preserved. Such relationships can no longer be detected by sequence-based methods, but fall into the realm of fold recognition.

The following pages aim to provide a guide to the terms used (and abused) in the fields of protein sequence and structure analysis. A list of WWW addresses is given to allow readers to obtain the most up-to-date information about the various databases and resources discussed.

## Sequence analysis

Identifying conserved motifs within sequences can provide insights into protein structure and function, and allow us to establish means of classification. The goal is to rationalize the data in the primary sources, by assigning sequences to families. The essence of those families is distilled into potent sequence descriptors that are housed in secondary databases, which then facilitate the diagnosis of future query sequences used to search the database. It is important to establish secondary databases because the primary sources are growing at such a rate that it is becoming increasingly difficult to resolve distant relationships from background noise.

The underlying tool of sequence analysis methods is multiple sequence alignment. Application of those methods involves the derivation of some kind of representation, or abstraction, of conserved alignment elements, which may be diagnostic of structure or function. A bewildering array of terms is used to describe the different types of data representation employed by the various approaches: e.g., motifs, segments, patterns, regular expressions, rules, profiles, signatures, fingerprints, features, domains, and blocks. Several of these have fairly well-defined meanings, but difficulties arise when they are used interchangeably. Some basic definitions of these, and other, concepts are outlined below.

### Family, superfamily, clan

It should be relatively straightforward to understand the terms family and superfamily, which usually imply shared functional characteristics and an obvious sequence relationship. Nevertheless, there is still debate regarding when and how properly to use them. The G-protein-coupled receptors (GPCRs) provide a useful illustrative example. The adrenoceptors, muscarinic receptors, opioid receptors, opsins, etc., are distinct protein families with characteristic pharmacological and signalling profiles: for example, they may be separated on the basis of the ligands they bind, their tissue distribution, the second-messenger systems to which they couple, or their amino-acid sequences. In most cases, the families may be divided into receptor subtypes, depending on their selectivity for particular agonists and antagonists, which specificities are reflected in slight changes in their primary structures. All of these receptor families share the same structural framework, which is thought to consist of seven transmembrane (7TM) helices. They thus belong to a superfamily (which for historical reasons has been termed rhodopsin-like) that is characterized by a unique 7TM signature. This can be readily identified by sequence analysis approaches.

The rhodopsin-like GPCR superfamily, then, can be identified by its characteristic transmembrane sequence signature, and its individual family members resolved from it on the basis of characteristic changes, primarily in the loop regions that lie between the transmembrane helices. At least five other GPCR families are now known, all of which appear to contain 7TM domains, but share no discernible sequence similarity with the rhodopsin-like superfamily. The term clan has been coined to describe such a group of families, for which there are indications of an evolutionary relationship, but between which there is no statistically significant similarity of sequence.

It is important to define these terms with care, because of the underlying evolutionary implications. The shared sequence similarities within families and superfamilies suggest divergence from a single common ancestor. By contrast, the relationship between clan members is unclear: it may be the result of divergence from a remote ancestor, or it may have arisen through independent convergence to a common function and architecture.

## Homology

Protein sequences are said to be homologous if they are related by divergence from a common ancestor. This very simple definition is confounded and abused in the literature. Homology is not a measure of similarity – it is an absolute statement that sequences have a divergent rather than a convergent relationship. Thus phrases that quantify homology (e.g., 'the sequences show 50% homology', or 'sequences are 70% homologous', or 'have a high degree of homology') are, strictly, meaningless and should be avoided.

## Motifs

When building a multiple sequence alignment, as more divergent sequences are added, insertions are often required to bring equivalent parts of adjacent sequences into the correct juxtaposition. At the end of such a process, islands of conservation may be observed appearing within a sea of mutational changes, as shown in Figure 1. These conserved regions, which are often quite short (typically 10-20 amino acids in length), tend to denote the structural or functional core of the protein. Their conserved nature allows them to be used to diagnose family membership via a range of sequence analysis techniques. They are most frequently termed motifs. Synonymous terms are block, segment, and feature.

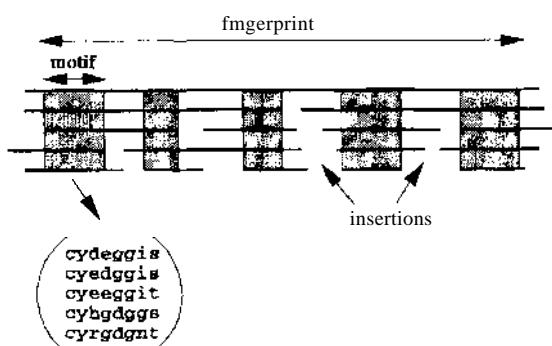

Figure 1. Conserved motifs in a multiple sequence alignment, representing the core structural and key functional sites of the aligned protein family. The broken horizontal parallel bars denote the sequence alignment; the shaded boxes show the locations of the motifs, groups of motifs forming characteristic fingerprints; the excerpt indicates typical residue frequency information contained within a motif, which provides the basis for database searching.

## Patterns

For database searching, the sequence data within an individual motif can be reduced to a single consensus expression. That expression discards all but the most significant residue information, concentrating on the most highly conserved posi-

Alignment	Expression
GAVDFIALCDRYF GPIDFVCFCERFY GRVEFLNRCDRYY	G-X- [IV] - [DE] -F- [IVL] -X- {PG} -C- [DE] -R- [FY] 2

Figure 2. Generation of a regular expression from a multiple sequence alignment. The single-letter amino acid code is used: X denotes any residue; square brackets group together the allowed residues at a given position; curly brackets group together the disallowed residues at a position.

tions. The expression shown in Figure 2 tells us that positions 1, 5, 9, and 11 are completely conserved; positions 3, 4, 10, 12, and 13 allow one of two possible residues (whatever is specified within square brackets is allowed at that position); positions 2 and 7 can be anything (X); and position 8 can be anything except proline or glycine (whatever is specified within curly brackets is *not* allowed at that position). Such expressions are used to trawl sequence databases for *identical* matches; their use is relatively limited because they tolerate no similarity. In other words, a sequence that is 99% similar is regarded as a mismatch – thus, for example, a sequence consistent with the expression in Figure 2, but with leucine in place of the allowed isoleucine or valine at position 3, would not be matched, in spite of showing only a single, conservative substitution. The result of searching a database with such an expression is therefore either an exact match, or no match at all; the outcome is either 'on' or 'off', and may hence be referred to as a binary event. Expressions of this type are most frequently termed patterns. Synonymous terms are regular expression and signature.

## Rules

Regular expression patterns are used to greatest diagnostic effect when, within a given sequence alignment, a highly conserved motif (typically 10-20 residues in length) is found to characterize that specific protein family (this might be a core piece of the protein architecture, or it might carry critical functional residues). Often, however, it is possible to identify much shorter, generic patterns within sequence alignments. These tend to be diagnostic of specific functional sites: e.g., sugar attachment sites, phosphorylation, hydroxylation, myristylation, sulfation sites, etc. These patterns, which are often only three or four residues long, do not provide good discrimination, but can give a guide as to whether a certain type of site *might* exist in a sequence. They are most frequently termed rules. Synonymous terms are pattern and regular expression.

## Fingerprints

Patterns have very limited diagnostic power because they require target sequences to match the expression exactly. Thus, as we have seen, a sequence that fits a pattern at all but one position will be rejected as a mismatch. To address this problem, it is possible to build more powerful discriminators.

Within a sequence alignment, it is usual to find not one, but several motifs that characterize the aligned family (see Figure 1). Diagnostically, it makes sense to use all the conserved regions to build a family signature, so that in a database search there is a higher chance of identifying a distant relative, whether or not all parts of the signature are matched.

## Appendix E

In an approach of this sort, the motifs are treated independently. The sequence information they contain is converted into scoring tables that are populated only by the observed residue frequencies at each motif position. The scoring system is thus considered to be unweighted, in the sense that no additional scores (e.g., from mutation or substitution matrices) are used to enhance discriminating power. However, diagnostic performance is enhanced by iterative database scanning. The motifs therefore grow, and become more mature, with each database pass, as more sequences are matched and added to the scoring tables. Full potency is gained from the mutual context provided by motif neighbours, which allows sequence identification even when some parts of the signature are absent. Thus, for example, a sequence that matches only four of seven motifs may still be diagnosed as a true match if the motifs are matched in the correct order in the sequence, and the distances between them are consistent with that expected of true neighbouring motifs. Groups of aligned, ungapped, unweighted segments of this type are most frequently termed fingerprints; they are also called signatures.

### Blocks

As mentioned above, the constituent motifs of a fingerprint are unweighted (i.e. the scoring system uses only observed residue frequencies), which sometimes leads to relatively poor diagnostic performance. However, it is possible to build more powerful representations of motifs by applying different weighting schemes. In one approach, sequence segments within a motif are clustered to reduce multiple contributions to residue frequencies from groups of closely related sequences. Each cluster is then treated as a single segment, each of which is assigned a score that gives a measure of its relatedness; the most distant segment is given a weight of 100. Most protein families will be defined by several such clustered, weighted motifs. For a given query sequence, as with a fingerprint, the more motifs matched, the greater the confidence that the sequence belongs to that family. Aligned, ungapped, weighted segments of this type are most frequently termed blocks (synonymous terms are motif, segment, and feature).

### Profiles

By contrast with the use of patterns, blocks, and fingerprints, an alternative approach is to distil the sequence information within *complete* alignments into scoring tables. Such tables define which residues are allowed at given positions, which positions are highly conserved and which degenerate, and which positions, or regions, can tolerate insertions. The scoring system is intricate, and may include evolutionary weights and results from structural studies, as well as data implicit in the alignment. In addition, variable penalties are specified to weight against insertions and deletions occurring in core secondary structure elements. Such tables are used to search databases for similar matches, their inherent complexity rendering them very potent discriminators. They are most frequently termed profiles. Weight matrix and position-specific scoring table are synonymous terms.

## Structure analysis

The terms 'domain' and 'module' are not to be confused with the jargon of protein sequence analysis. These terms have specific definitions in the context of protein structure (although they are often used imprecisely and cause confusion). It is beyond the scope of this discussion to consider structure analysis in detail, but in order to draw the distinction from the terms used in sequence analysis, the concepts of domains and modules are outlined below.

### Domains

Domains are compact, local, semi-independent folding units that need not be formed from contiguous regions of an amino-acid sequence: they may be discrete entities, joined only by a flexible linking region of polypeptide chain; they may have extensive interfaces, sharing many close contacts, and they may exchange chains with domain neighbours. In the simplest genetic terms, domains may be considered to have arisen via gene fusion and gene duplication events. Multifunctional enzymes, for example, are most readily understood in terms of gene fusion: the dehydrogenases are believed to have arisen from the fusion of a gene coding for a dinucleotide-binding domain with a series of genes, each coding for different catalytic domains. By contrast, the structural domains of chymotrypsin (anti-parallel beta-barrels with identical topology), are thought to have arisen by gene duplication, the interface between the domains providing the catalytic crevice.

In light of the complexity of protein architecture, these examples are somewhat simplistic. The rationalization and classification of protein folds is an arcane discipline, which has led to the development of a variety of domain and fold databases. Currently, amongst the most well-known of these are the scop (Structure Classification Of Proteins) resource, the CATH protein structure classification database, and the ProDom protein domain database. All of these databases are accessible via the WWW, and readers are referred to their Web addresses (see Table 3) for further information.

### Modules

Modules are autonomous folding units, and as such can be thought of as a subset of protein domains. They are contiguous in sequence and are frequently used as building blocks to confer a variety of complex functions on the parent protein. In genetic terms, the spread of modules cannot be explained by simple gene duplication and fusion events, but is largely thought to be the result of genetic shuffling mechanisms. It is useful to make a distinction between extracellular modules (e.g. the fibronectin 3, immunoglobulin, and EGF modules) and intracellular modules (e.g. Src homology 2 and 3 (*see SH* domain), and pleckstrin homology): their cellular location is seldom interchangeable, and their methods of propagation differ. It is argued that extracellular modules are encoded by exons that are flanked by introns, and that these exons can be shuffled, while being protected by their intron buffers. This model does not hold for bacteria, which have no introns, suggesting that other methods of propagation exist. There is also no observed correlation with intron borders for intracellular modules, suggesting either a different shuffling mechanism, or that intracellular modules arose much earlier. For

further information, please refer to the WWW address given in Table 3.

## Applications of sequence analysis methods: examples

The examples below indicate how functional sites, domains, modules, and families may be encoded by different sequence analysis approaches. (Different methods encode sequence alignment information in different ways - e.g. frequency tables, weight matrices, profiles, etc.) In each case, a regular expression is given (as indicated by the accession number and code retrieved from PROSITE 13.0), and corresponding references to blocks, fingerprints, and profiles are provided where such information exists. The full current lists of patterns, fingerprints, and profiles are available from the WWW addresses given in Table 3.

### Functional sites

Functional sites usually contain only two or three key residues, which can be encoded by regular expression rules. Rules are too short to be diagnostically reliable, and can only give a guide as to whether a particular attachment site, glycosylation site, splice site, etc., might be present. A 'hit' with a rule should therefore be supported by biochemical evidence.

#### N-glycosylation site (PS00001 ASN\_GLYCOSYLATION)8

N-{P}-{ST}-{P}

Possible N-glycosylation sites may be located with the rule shown above. Proline residues are disallowed at positions 2 and 4, as their presence at these points may hinder correct folding of the sequence and inhibit glycosylation. There is no true family, per se, defined by this functional site; consequently, equivalent blocks, profiles and fingerprints have not been derived.

#### Protein kinase C phosphorylation site (PS00005

PKC\_PHOSPHO\_SITE)8

[ST]-X-[RK]

Possible protein kinase C phosphorylation sites may be located with the rule shown above. The enzyme exhibits a preference for phosphorylation of serine or threonine residues found in close proximity to C-terminal basic residues. Additional N- or C-terminal basic residues enhance phosphorylation kinetics. As with the glycosylation site, there is no true family per se, and equivalent blocks, profiles, and fingerprints have not been derived.

#### Protein splicing signature (PS00881 PROTEIN\_SPICING)8,12,13

[LIVA]-[LIVMY]-[VAT]-H-N-[STC]

Possible inteins may be located with the pattern shown above. Inteins, or protein introns, are parts of protein sequences that are post-translationally excised, their flanking regions (exteins) being spliced together to yield an additional protein product. This process is believed to be self-catalysed, apparently initiating at the C-terminal splice junction, where a conserved asparagine residue mediates the nucleophilic attack of the peptide bond between it and its neighbouring residue.

Maximum number of observed repeats: 2. This pattern, which encodes residues close to the asparagine involved in the

nucleophilic attack, is a poor discriminator for inteins, finding three times more false positive sequences than true positives. More powerful descriptors are found in the BLOCKS and PRINTS databases, with accession numbers BL00881 and PR00379 respectively.

### Domains and modules

Protein domains and modules may be encoded by patterns, blocks, profiles or fingerprints. With the growing numbers of sequences available in databases, deriving effective discriminators for modules has become problematic. Module sequences are often highly divergent and tend not to contain conserved functional residues (module function may vary depending on biological context). Structurally important residues may be hard to detect at the sequence level, and even the number of cysteines, which may stabilize folds by forming disulfide bridges, may vary in a protein family. For this reason, some modules can only be effectively encoded by profiles.

#### Apple module (PS00495 APPLE)8,12,13

C-X(3)-[LIVMFY]-X(5)-[LIVMFY]-X(3)-[DENQ]-  
[LIVMFY]-X(10)-C-X(3)-C-T-X(4)-C-X-  
[LIVMFY]-F-X-[FY]-X(13,14)-C-X-[LIVMFY]-[RK]-  
X-[ST]-X(14,15)-S-G-X-[ST]-[LIVMFY]-X(2)-C

The apple module, shown schematically in Figure 3, is a 90-residue domain stabilized by three disulfide bonds. Multiple tandem repeats of the domain are found in the N termini of the related plasma serine proteases plasma kallikrein and coagulation factor XI (*see* blood coagulation).

The pattern spans the complete apple module. Maximum number of observed module repeats: 4. Alternative descriptors: BLOCKS accession number BL00495; PRINTS accession number PR00005.

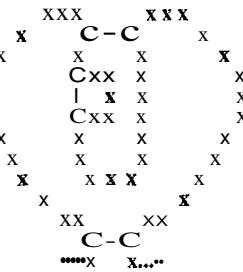

Figure 3. Schematic representation of the apple domain showing the locations of the disulfide linkages. The single-letter amino acid code is used: X denotes any residue.

#### Cyclic nucleotide-binding domain (PS00888 CNMP\_BINDING\_1)8,12,13

[LIVM]-[VIC]-X(2)-G-[DENQTA]-X-[GA]-X(2)-  
[LIVMFY](4)-X(2)-G

Proteins that bind cyclic nucleotides (cAMP or cGMP) share a structural domain of around 120 residues. The domain is constructed from three alpha-helices and a distinctive eight-stranded, anti-parallel beta-barrel. Six invariant residues characterize the domain, three of which are glycines thought to be

## Appendix E

essential for maintenance of the structural integrity of the barrel.

This pattern spans beta-strands 2 and 3, and contains the first two conserved glycines. Maximum number of observed domain repeats: 2. Alternative descriptors: BLOCKS accession number BL00888; PRINTS accession number PROO103.

DEAD box (PS00039 DEAD\_ATP\_HELICASE)8,13

[LIVMF](2)-D-E-A-D-[RKENJ-X-[LIVM-FYGSTNj]

A number of eukaryotic and prokaryotic proteins involved in ATP-dependent nucleic-acid unwinding have been characterized on the basis of structural similarity. All share a number of conserved motifs, one of which (the so-called 'DEAD box') represents a special version of the B motif of ATP-binding proteins.

This pattern spans the DEAD-box motif. Alternative descriptor: BLOCKS accession number BL00039.

DAG/PE-binding domain (PS00479 DAG\_PE\_BINDING\_DOMAIN)<sup>8,12,13</sup>

H-X-[LIVMFYW]-X(10,11)-C-X(2)-C-X(3)-[LIVMF]-X(2,7)-[SAGC]-[LIVMFYW]-X-C-X(2)-C-X(4)-H-X(2)-C-X(6,7)-C

The N-terminal region of protein kinase C binds phorbol esters (PEs) and diacylglycerol (DAG) in a phospholipid-dependent manner. DAG is an important second messenger; PEs, which are analogues of DAG, are potent tumour promoters that cause several physiological changes when administered to cells and tissues. The DAG/PE-binding domain is characterized by a 50-residue cysteine-rich region, which binds two zinc ions. The metal-ion ligands are thought to be provided by six conserved cysteines and two histidines.

This pattern spans the complete DAG/PE domain. Maximum number of observed domain repeats: 2. Alternative descriptors: BLOCKS accession number BL00479; PRINTS accession number PR00008.

Kringle module (PS00021 KRINGLE)8,12,13

[FY]-C-R-N-P-[DNR]

Kringle modules are autonomous structural units found throughout the blood clotting and fibrinolytic proteins. They are believed to play roles in binding mediators (e.g., membranes, other proteins or phospholipids) and in regulating proteolytic activity. Kringles (so-called because cartoon representations of their primary structures resemble Danish pastries of this name) are characterized by a triple loop, three-disulfide-bridge structure, whose conformation is defined by a number of hydrogen bonds and small pieces of antiparallel beta-sheet.

The pattern encodes a well-conserved hexapeptide towards the centre of the kringle domain. Maximum number of observed module repeats: 38. Alternative descriptors: BLOCKS accession number BL00021; PRINTS accession number PROOOI8.

P-type 'trefoil' module (PS00025 P\_TREFOIL)8,13

R-X(2)-C-X-[FYPSTj-X(3,4)-[STj-X(3)-C-X(4)-C-C-[FYWH]

Figure 4. Schematic representation of disulfide linkages that form the P-domain. The single-letter amino acid code is used: x denotes any residue; Φ indicates the presence of large hydrophobic residues; @ marks the location of the pattern.

The P-type 'trefoil' module (or P-domain) is a 45-residue cysteine-rich region, the six cysteines of which form disulfide bridges in the order 1-5, 2-4, 3-6, as illustrated schematically in Figure 4. The domain has been found in a variety of extracellular eukaryotic proteins.

The pattern encodes the central four cysteine residues. Maximum number of observed module repeats: 6. Alternative descriptor: BLOCKS accession number BL00025.

WW module (PS01159WW\_DOMAIN\_I)8,12,13

W-X(9,11)-[VFYJ-[FYW]-X(6,7)-[GSTNE]-[GSTQCR]-[FYW]-X(2)-P

WW modules are conserved 35–40 residue regions found in a number of disparate proteins. The domain is characterized by two conserved tryptophan residues and a conserved proline (hence its alternative name, WWP). Among the proteins known to contain WW domains is **dystrophin**, the product encoded by the gene responsible for Duchenne muscular dystrophy. The domain appears to bind proteins that contain characteristic proline motifs ([AP]-P-P-[AP]-Y), and, to an extent, resembles SH3 domains. It is often associated with other domains that typify proteins involved in signal transduction.

This pattern spans the full WW domain. Maximum number of observed module repeats: 4. Alternative descriptors: BLOCKS accession number BL01159; PRINTS accession number PR00403; PROSITE profile accession number PS50020.

Zinc finger (C<sub>2</sub>H<sub>2</sub>type) domain (PS00028 ZNCJINGER\_C2H2)8,12,13

C-X(2,4)-C-X(3)-[LIVMFYWC]-X(8)-H-X(3,5)-H

Zinc fingers are small, self-folding units in which zinc is a crucial structural component. The finger contains a repeated 28-residue sequence, including two conserved cysteine and two conserved histidine residues in a C-X(2)-C-X(12)-H-X(3)-H type motif. The 12 residues separating the second cysteine and the first histidine are largely polar and basic, implicating this

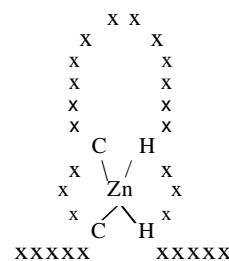

Figure 5. Schematic representation of zinc coordination by the C<sub>2</sub>H<sub>2</sub>-type zinc finger. The single-letter amino acid code is used: x denotes any residue.

region in particular in nucleic-acid binding. A single atom of zinc is bound in a tetrahedral array to yield a finger-like projection (shown schematically in Figure 5), which interacts with nucleotides in the major groove of the nucleic acid - the zinc binds to the conserved cysteine and histidine residues. Fingers have been found to bind to about five base pairs of nucleic acid containing short runs of guanine residues. They are found in all transcription factors, and also in proteins such as RNA and DNA polymerases. The ability to bind to both RNA and DNA suggests versatility not demonstrated by the helix-turn-helix motif: the zinc finger may thus represent the original nucleic-acid binding protein.

The pattern encodes the cysteine and histidine ligands. Maximum number of observed finger repeats: 37. Alternative descriptors: BLOCKS accession number BL00028; PRINTS accession number PROO048.

### Protein families

Protein families may be effectively encoded by patterns, blocks, profiles, or fingerprints. Some typical examples are given below.

**Short-chain alcohol dehydrogenases (PS00061)**  
ADH\_SHORT)8,12,13

[LIVSPADK]-X(2)-Y-[PSTAGNCYJ-[STAGNQ-CIVM]-[STAGq-K-{PC}-[SAGFR]-[LIVMTAGD]-X(2)-[LIVMFYWJ-X(3)-[LIVMFWGAPTH]-[GSAC-QRHM]

Primary sequence comparisons indicate an evolutionary relationship between many dehydrogenases. Most dehydrogenases possess at least two domains, the first binding the coenzyme (often NAD), and the second binding the substrate. This latter domain determines the substrate specificity and contains amino acids involved in catalysis. Little sequence similarity has been found in the coenzyme-binding domain, although there is a large degree of structural similarity. It is thus postulated that the dehydrogenase structure has arisen through gene fusion of a common ancestral coenzyme nucleotide sequence with various substrate-specific domains. A number of short conserved regions characterize the alcohol dehydrogenases, one of which includes two perfectly conserved residues: a tyrosine and a lysine. In glucose dehydrogenase, the tyrosine has been shown to be important for catalytic activity and/or for subunit binding.

The pattern encodes the functionally important tyrosine and lysine residues. Maximum number of observed repeats: 2. Alternative descriptors: BLOCKS accession number BL00061; PRINTS accession number PROOO80.

**Lipocalin signature (PS00213 L1POCALIN)**8,12,13

[DENG]-X-[DENQGSTARK]-X(O,2)-[DENQARK]-[LIVFYJ-{CP}-G-{C}-W-[FYWLRH]-X-[LIVMTA]

The lipocalins are primarily a family of extracellular ligand-binding proteins that display high specificity for small hydrophobic molecules. Their functions include transport of nutrients, control of cell regulation, pheromone transport, cryptic coloration, and the enzymatic synthesis of prostaglandins. The structure shows a novel, eight-stranded, anti-parallel beta-barrel fold. Sequence similarity is low, and appears to be restricted to conserved disulfides and three mo-

tifs, which form a juxtaposed cluster that may act as a common cell-surface receptor site. The antiparallel beta-barrel fold is similarly exploited by the fatty-acid-binding proteins, which also bind small hydrophobic molecules. Similarity at the sequence level is less obvious, being confined to a single short N-terminal motif.

This pattern encodes the N-terminal motif that characterizes both the lipocalins and fatty-acid-binding proteins. More powerful descriptors: BLOCKS accession number BL00213; PRINTS accession number PROO 179.

**G-protein-coupled receptors (PS00237 G\_PROTEIN\_RECECTOR)**8,12,13

[GSTALIVMFYWq-[GSTANCPDE]-{EDPKRH}-X(2)-[LIVMNQGA]-X(2)-[LIVMFT]-[GSTANq-[LIVMFYWSTAq-[DENH]-R-[FYWCSD]-X(2)-[LIVM]

G-protein-coupled receptors (GPCRs) constitute a vast protein family encompassing a wide range of functions (including various autocrine, paracrine, and endocrine processes). They show considerable diversity at the sequence level, on the basis of which they can be separated into distinct families. These families belong to a clan, within which there are indications of an evolutionary relationship, but between members of which there is no statistically significant similarity in sequence. The currently known clan members include the rhodopsin-like GPCRs, the secretin-like GPCRs, the cAMP receptors, the fungal pheromone mating factor receptors, and the metabotropic glutamate receptor family.

The rhodopsin-like GPCRs themselves represent a widespread protein family that includes hormone, neurotransmitter, and light receptors, all of which transduce extracellular signals through interaction with guanine nucleotide-binding (G) proteins. Although their activating ligands vary widely in structure and character, the amino-acid sequences of the receptors are very similar and are believed to adopt a common structural framework comprising seven transmembrane helices.

This pattern encodes part of the third transmembrane domain, which contains a completely conserved arginine residue that is implicated in binding the G-protein. More powerful descriptors: BLOCKS accession number BL00237; PRINTS accession number PR00237.

### Primary databases

Nucleic acid and protein sequences are stored in primary databases. The principal primary resources are (for proteins) PIR, SWISS-PROT, mips, PSD-KYOTO, PRF, and NRL-3D and (for nucleic acids) EMBL, GenBank, and DDBJ. There are, of course, many others.

The proliferation of primary databases causes problems: do they all have the same format? Which is the most accurate? Which is the most up-to-date? Which is the most comprehensive? Which should we use?

SWISS-PROT is often regarded as the 'best', at least in terms of the quality of its annotations. But its sequence data are taken from PIR, compared with which it is neither as comprehensive, nor as up-to-date. NRL-3D is derived from the Brookhaven protein structure databank, so contains only se-

## Appendix E

quences for which three-dimensional coordinates have been made available - it is therefore only small, and highly redundant, yet in view of the link it provides to structure, it is nevertheless a valuable resource. In the past, choosing which database to use was largely a matter of which was available locally. Nowadays, the problem is more likely to be a question of finding the right WWW page to allow you to perform the relevant search. In practice, to ensure the most comprehensive search, it is best to search several sources.

### Cooperative projects

Maintaining databases is a laborious, time-consuming process. To relieve some of the inherent burdens, a number of groups have cooperated to share data: for protein sequences, PIR, mips, and PSD-KYOTO join forces as PIR-International; for nucleic-acid sequences, EMBL, GenBank, and DDBJ pool their resources.

### Composite databases

Cooperative projects help with data distribution, but do not address the problem of multiple database formats. One approach to tackling proliferating primary databases is to compile a composite resource. Here, data from a variety of different sources are merged, rendering searches extremely efficient, the more so if redundancies between contributing sources are eliminated. But the situation is complicated by the fact that there are now several composites available (see Table 1), each of which uses different data sources, has a different format, and uses different redundancy criteria.

**Table 1.** Examples of composite protein sequence databases

Database	Data sources
nrdb	PDB, PIR, SWISS-PROT, GenPept, GenPept updates
Entrez	PDB, PIR, SWISS-PROT, PRF
mipsX	PIR, mips, patchX, PSD-KYOTO
OWL	SWISS-PROT, PIR, GenBank, NRL-3D

Of the available composite databases, the nrdb, Entrez, and mipsX resources are in fact non-identical. Only OWL is truly non-redundant, in the sense that strict redundancy criteria are applied to the amalgamation of the primary sources (i.e., both identical and trivially different sequences are eliminated). OWL is therefore relatively small and hence efficient in database searching. But it is not as up-to-date as, for example, nrdb. So again, the user is faced with the choice of which is best to use. In practice, the ease of use of the Web makes it possible to search them all.

### Secondary databases

Secondary databases contain information derived from the primary sources. There are numerous secondary, or 'value-added', databases available, all of which have different formats, use different analysis methods, and house different types of information, and most of which use different data sources (although SWISS-PROT is emerging as something like a standard) - see Table 2.

As with the primary sources, the proliferation of secondary databases causes problems: Which is the most accurate? Which is the most up-to-date? Which is the most comprehensive? Which should we use?

PROSITE is the most widely used resource. It houses a comprehensive array of patterns, rules and profiles, encoding a variety of functional sites, domains and families. In most cases, it provides good annotations and links to other biological databases, yet diagnostically it is probably the least reliable. The profile library is still small, but profiles provide much better discrimination than can patterns. Similarly, the BLOCKS database is a more powerful resource than PROSITE, but it provides no additional annotation, and, because it is derived from families identified in PROSITE, it offers no further family coverage. The PRINTS fingerprint database does provide family signatures not seen in PROSITE and offers more powerful discrimination, yet it is not as comprehensive. The situation is similar for its BLOCKS-format counterpart (strictly a tertiary database, as it is derived from secondary data), which provides even more potent discriminators.

**Table 2.** Examples of secondary databases

Database	Data source	Information stored
PROSITE	SWISS-PROT	patterns, rules, profiles
Profiles	SWISS-PROT	weight matrices
BLOCKS	SWISS-PROT, PROSITE	clustered, weighted motifs
PRINTS	OWL	unweighted motifs
BLOCKS-format-PRINTS	PRINTS	clustered, weighted motifs
ProDom	SWISS-PROT	domain alignments
SBASE	SWISS-PROT	annotated domain sequences
Pfam*	SWISS-PROT	annotated alignments
PIMA	Entrez	marked-up alignments

\*Pfam is bases on probabilistic Hidden Markov Model.

The ProDom, SBASE, Pfam, and PIMA databases effectively contain marked-up domain sequences and alignments, derived from largely automated processes, rather than the descriptors housed in these other resources. They provide no supporting documentation and, diagnostically, are often unreliable. Nevertheless, in a comprehensive search protocol, it is wise to include as many secondary databases as possible, as no single resource can yet guarantee a diagnosis.

### Information networks

Progress in bioinformatics would not have been possible without the international computer network, the Internet. The 'universe of network-accessible information' has been dubbed the World Wide Web, an 'embodiment of human knowledge'. Participating groups make information available on servers, all of which have unique addresses, referred to as Uniform Resource Locators, or URLs. Armed with a URL and a suitable WWW browser (e.g., Netscape, Mosaic, or Lynx), users may visit any site in the world and use the tools and data made available by those institutions or organizations. The URLs of some of the resources discussed above are given in Table 3.

**Table 3.** World Wide Web addresses of various bioinformatics resources

## Restriction enzymes and Methylases

**Richard J. Roberts\* and Dana Macelis**

New England Biolabs, 32 Tozer Road, Beverly, MA 01915, USA

Tel: (508) 927-3382

Fax: (508) 921-1527

E-mail: roberts@neb.com

\* To whom correspondence should be addressed

The restriction enzyme database, REBASE, is a collection of information about restriction enzymes and methylases (1). Recently, homing endonucleases (2) have also been included in REBASE. Among the 2825 restriction enzymes now known, there are 18 fully characterized Type I specificities, 210 different Type II specificities and 4 different Type III specificities. Tables 1-3 contain a listing of all prototype restriction enzymes (Types I, II, and III), together with their commercially available isoschizomers and neoschizomers. Table 4 contains a listing of the 23 homing endonucleases for which recognition sequences are available. REBASE currently stores 3959 published references, which include abstracts, and 464 unpublished observations.

REBASE is updated daily. Each month, a set of REBASE data files are released publicly and distributed to the scientific community, at no charge, via e-mail. They can also be retrieved by anonymous ftp ([www.neb.com](http://www.neb.com), in pub/rebase), WAIS ([www.neb.com](http://www.neb.com), port 210) or through the World Wide Web (<http://www.neb.com/rebase>). These data files are ASCII text files, many of which are designed specifically for use with a variety of software packages such as GCG, IGSuite, GENEPROM, Staden, DNA Strider, Pro-Cite, PC/Gene, SEQAIIDII, GENETYX, DNASIS, CAD Gene, and Reference Manager. Other data files include a complete set of references, including abstracts, to papers on restriction

enzymes and methylases; a list of all commercial suppliers of restriction enzymes and methylases, complete with contact information and a listing of enzymes they currently sell. New data files are constantly being added and each release of REBASE includes a monthly newsletter indicating that the files at the WWW and ftp sites have been updated, and listing new enzymes, newly available formats, enzyme name changes, etc. To join the mailing list or for more information, contact either author (e-mail: [macelis@neb.com](mailto:macelis@neb.com); [roberts@neb.com](mailto:roberts@neb.com); telephone (508) 927-3382; fax (508) 921-1527).

In forming Tables 1-3, all endonucleases cleaving DNA at a specific sequence have been considered to be restriction enzymes, although in most cases there is no direct genetic evidence for the presence of a restriction-modification system. The endonucleases are named in accordance with the proposal of Smith and Nathans (3).

1. Recognition sequences use the standard abbreviations (*European Journal of Biochemistry* 150, 1-5 11985)) to represent ambiguity.

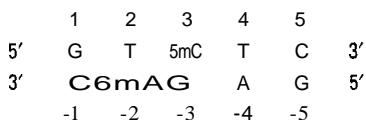

R=A or G	B=not A (C or G or T)
y=C or T	0=not C(A or G or T)
M=A or C	H=not G(A or C or T)
K=G or T	V=not T (A or C or G)
S=G or C	N=A or C or G or T
W=A or T	

Recognition sequences are written from 5' to 3', only one strand being given, and the point of cleavage is indicated by an arrow (↑). When no arrow appears, the precise cleavage site has not been determined. For enzymes such as *BeiVI*, which cleaves away from its recognition sequence, the sites of cleavage are indicated in parentheses. Thus GTATCC (6/5) indicates cleavage as shown below:

5'-GTATCCNNNNNNi-3'  
3'-CATAGGNNNNNNi-5'

In all cases the recognition sequences are oriented so that the cleavage sites lie on their 3'-side.

2. The site of methylation by the cognate methylase when known is indicated as follows. The first number shows the base within the recognition sequence that is modified. A negative number indicates the complementary strand, numbered from the 5' base of that strand. The number in parentheses indicates the specific methylation involved. (6) =N<sup>6</sup>-methyladenosine; (5) =5-methylcytosine; (4) =N<sup>4</sup>-methylcytosine. Thus for *Alw261* the designation 3(5), -4(6) signifies the following pattern of methylation:

3. Commercial sources of restriction enzymes are abbreviated as follows:

A, Amersham Life Sciences-USB (10/96); B, Life Technologies Inc., Gibco-BRI (10/96); C, Minitech Molecular Biology Products (10/96); O, Angewandte Gentechnologie Systeme 110/96); E, Strata gene (10/96); F, Fermentas MBIIIO/96); G, Appligene On cor (10/96); H, American Allied Biochemical, Inc. (10/96); I, SibEnzyme Ltd (10/96); J, Nippon Gene Co., Ltd (10/96); K, Takara Shuzo Co. Ltd (10/96); L, NIBI Gene Sciences Ltd (10/96); M, Boehringer-Mannheim (11/96); N, New England Biolabs (11/96); O, Toyobo Biochemicals (10/96); P, Pharmacia Biotech Inc. (10/96); R, CHIMERx (5/96); S, Promega Corporation (10/96); T, Sigma (10/96); U, Advanced Biotechnologies Ltd (10/96). The date in parentheses indicates the most recent update.

4. Enzymes that cut on both sides of their recognition sequence, such as *Bael*, *BegI*, *Bsp241*, *CjeI* and *CjePI*, have 4 cleavage sites each instead of 2. For example, *Bsp241* cleaves as indicated:

This is described in Table 2 and some REBASE reports as *Bsp241* (8/13)GACNNNNNTGG(12/7). Thus the recognition site is excised in a fragment, 32 base pairs long, with 5-base 3'-extensions at each end.

5. *DpnI* requires the presence of 6-methyladenosine within the recognition sequence GmATC.  
 6. *EeoRl* isoschizomers fall into two classes based upon their sensitivity to methylation. *EeoRll* will not cleave when the second cytosine in the recognition sequence is methylated to 5-methylcytosine whereas *MvaI* will cleave such a sequence. Isoschizomers of *EeoRll* that are like *MvaI* are indicated by t.  
 7. *MboI* isoschizomers fall into two classes based upon their sensitivity to methylation. *MbaI* will not cleave when the recognition sequence contains 6-methyladenosine whereas *Sau3AI* will not cleave when its recognition sequence contains 5-methylcytosine. Isoschizomers of *MbaI* that are like *Sau3AI* are indicated by t.  
 8. *TaqII* differs from other restriction enzymes in recognizing two distinct sequences: GACCG and CACCC.

1. The cleavage sites, where known, are indicated by ↑ on the strand presented and by \_ on the complementary strand.

2. The commercial sources are M: Boehringer-Mannheim (11/96); N: New England BioLabs (11/96); R: Promega Corporation (10/96).

# Appendix G

## Sequence-rule priorities of some common ligands in molecular entities

The names of some common ligands are listed alphabetically below, the numbers preceding them indicating the relative priorities assigned to the ligands under the **sequence** rule. A higher number denotes greater preference; for example, a hydroxy group (numbered 57) takes precedence over an amino group (numbered 43). It should be noted that any change to the structure of a listed ligand may alter the order of preference. Where a ligand consists of or contains a heavy or radioactive isotope of hydrogen, the relative priorities are tritium> deuterium> protium. Racemates with a single chiral centre are labelled (*RS*); extensions of the sequence rule are used in the *EIZ*, *pro-Rlpro-S*, *pro-Elpro-Z*, and *RelSi* nomenclature systems.

64 acetoxy	28 3,5-dinitrophenyl	70 methylthio (CH <sub>3</sub> S-)
36 acetyl	59 ethoxy	II neopentyl
48 acetylamino	40 ethoxycarbonyl	56 nitro
21 acetylenyl	3 ethyl	27 m-nitrophenyl
10 allyl	46 ethylamino	33 o-nitrophenyl
43 amino	68 fluoro	24 p-nitrophenyl
44 ammonio (+H <sub>3</sub> N-)	35 formyl	55 nitroso
37 benzoyl	63 formyloxy	6 pentyl
49 benzoylamino	62 glycosyloxy	61 phenoxy
65 benzoyloxy	7 hexyl	22 phenyl
13 benzyl	I hydrogen	47 phenylamino
60 benzyloxy	57 hydroxy	54 phenylazo
41 benzyloxycarbonyl	76 iodo	18 propenyl
50 benzyloxycarbonylamino	9 isobutyl	4 propyl
75 bromo	8 isopentyl	29 1-propynyl
42 <i>tert</i> -butoxycarbonyl	20 isopropenyl	12 2-propynyl
5 butyl	14 isopropyl	73 sulfo (HO <sub>3</sub> S-)
16 <i>sec</i> -butyl	69 mercapto (HS-)	25 m-tolyl
19 <i>tert</i> -butyl	58 methoxy	30 o-tolyl
38 carboxy	39 methoxycarbonyl	23 p-tolyl
74 chloro	2 methyl	53 trimethylammonio
17 cyclohexyl	45 methylamino	32 trityl
52 diethylamino	71 methylsulfinyl	15 vinyl
51 dimethylamino	66 methylsulfinyloxy	31 2,6-xylyl
34 2,4-dinitrophenyl	72 methylsulfonyl	26 3,5-xylyl
	67 methylsulfonyloxy	

# Appendix H

## Species names

Below is a list of genera/species cited frequently in this Dictionary, together with their common names, where applicable. The asterisked names have their own entries in the Dictionary.

- \**Agrobacterium*
- Amanita* a genus of toadstools; *A. muscaria* is fly agaric,
- A. phalloides* the 'death-cap' (deadly agaric)
- \**Arabidopsis thaliana*
- \**Aspergillus*
- \**Bacillus*
- Bos taurus* cattle
- Brassica* a genus of cruciferous plants; *B. napus* is the swede, *B. oleracea* includes the cabbage, cauliflower, etc.
- Caenorhabditis elegans* a nematode
- Candida* a genus of yeasts
- Canis familiaris* the dog
- Chlamydomonas reinhardtii* a unicellular green alga
- \**Clostridium*
- Corynebacterium* a genus of **coryneform** (def. 2) bacteria
- \**Dictyostelium discoideum*
- Digitalis* the foxglove genus
- \**Drosophila*
- \**Escherichia coli*
- Euglena* a unicellular, flagellate alga belonging to the Euglenophyta
- Gallus gallus* the domestic fowl
- Haemophilus influenzae* an aerobic, nonmotile Gram-negative rod
- Halobacterium halobium* a halophilic archaeabacterium
- Klebsiella* a genus of Gram-negative rod non-motile bacteria
- Lactobacillus* a genus of **lactic-acid bacteria**
- Lycopersicon esculentum* the tomato
- Mus musculus* the mouse
- \**Mycobacterium*
- \**Neurospora*
- Nocardia* a genus of rod or filamentous Gram-positive nonmotile bacteria
- \**Paramecium*
- Penicillium* mould
- Pisum sativum* the garden pea
- \**Plasmodium*
- Pseudomonas* a genus of Gram-negative rod-shaped motile bacteria
- Rattus norvegicus* the rat
- \**Rhizobium*
- \**Saccharomyces*
- \**Salmonella*
- \**Schizosaccharomyces pombe*
- Shigella* a genus of nonmotile Gram-negative rod **coliform** bacteria
- \**Staphylococcus*
- \**Streptococcus*
- \**Streptomyces*
- Sus scrofa* the pig
- \**Tetrahymena*
- Thermus aquaticus* a thermophilic archaeabacterium
- Trypanosoma* a genus of parasitic protozoans;  
see **trypanosome**
- \**Xenopus laevis*
- Zea mays* maize (corn)
